2. Add the original message flow and the copy of the message flow to your BAR file; see "Adding files to a broker archive" on page 3223.
3. Open the BAR file. The resources in your broker archive are listed on the **Manage** page.
4. On the **Manage** page, you can now edit the configurable properties for both message flows. For more information, see "Editing configurable properties" on page 3227.

Results

Tip: The names that are assigned in the BAR file are also used on the command line; for example, if you run the **mqsilist** command on the execution group, or if you run the **mqsichangetrace** command for a message flow.

What to do next

Next:

Deploy the BAR file by following the instructions in "Deploying a broker archive file" on page 3235. Both message flows are deployed to the execution group and use the values for the configurable properties that you set in the BAR file.

Use the Broker Archive editor to create and manage broker archive (BAR) files.

Configuring a message flow at deployment time with user-defined properties

Use user-defined properties (UDPs) to configure message flows at deployment and run time, without modifying program code. You can give a UDP an initial value when you declare it in your program, or when you use the Message Flow editor to create or modify a message flow.

Before you begin

Before you start:

For an overview of user-defined properties, see "User-defined properties" on page 1147.

For an example of how to code a UDP statement, see "DECLARE statement" on page 5117.

About this task

In ESQL, you can define UDPs at the module or schema level. After a UDP has been defined in the Message Flow editor, you can modify the value before you deploy it.

To configure UDPs, complete the following steps.

Procedure

1. Open the broker archive (BAR) file. The contents of the BAR file are shown in the **Manage** page of the Broker Archive editor. On this page, you can expand a flow to show the individual nodes that it contains.
2. Click the message flow in which you are interested (not the `.cmf` compiled message flow file). The UDPs that are defined in that flow are displayed with their values in the **Properties** view.
3. If the value of the UDP is unsuitable for your current environment or task, change it to an appropriate value. The value of the UDP is set at the flow level, and is the same for all eligible nodes that are contained in the flow. If a subflow includes a UDP that has the same name as a UDP in the main flow, the value of the UDP in the subflow is not changed.
4. Save your BAR file.

Results

Next:

Deploy the message flow by following the instructions in "Deploying a broker archive file" on page 3235.

Related concepts:

Use the CMP API to query, discover, and set message flow user-defined properties dynamically at run time. You can use the CMP API to set properties with a data type of character.

"Deploying a broker archive file" on page 3235
After you have created and populated a broker archive (BAR) file, deploy the file to an execution group on a broker, so that the file contents can be used in the broker.

Related reference:

"DECLARE statement" on page 5117
Use the DECLARE statement to define a variable, the data type of the variable and, optionally, its initial value.

"Broker Archive editor" on page 6794
Use the Broker Archive editor to create and manage broker archive (BAR) files.

"Message Flow editor" on page 6810
The Message Flow editor is the default editor provided by the Broker Application Development perspective for defining a graphical representation of a message flow in the WebSphere Message Broker Toolkit, and for setting properties for individual message flow nodes.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

Refreshing the contents of a broker archive

Refresh the contents of a broker archive (BAR) file by rebuilding it in the Broker Archive editor. Alternatively, remove resources from your broker archive and, having made the required changes, add them back again.

Before you begin

Before you start:

This topic assumes that you have created a BAR file and added files to it. For more information, see “Creating a broker archive” on page 3222 and “Adding files to a broker archive” on page 3223.

About this task

You are likely to change resources that you have already added to your BAR file. BAR files that need to be refreshed are shown with an "out-of-sync" icon in the Broker Development view. (When any changes are made to deployable files in the workspace that have previously been built in the broker archive, the BAR file is considered to be inconsistent. The BAR file is also inconsistent if any changes are made to the project to which the files belong.)

To refresh the contents of a BAR file before you deploy it, complete the following steps.

Procedure

1. Open the BAR file. The contents of the BAR file are shown on the **Manage** page of the Broker Archive editor.
2. To refresh all the resources in the BAR file on the **Manage** page, click **Rebuild existing broker arcive entries** .

   A dialog box opens, showing progress. When the operation is complete, click **Details** to see information about what was refreshed, what was not, and why. If the refresh process is successful, you see the same information that is placed in the user log by each of the resource compilers.

   Alternatively, you can refresh the archive contents by right-clicking a BAR file in the Broker Development view and selecting **Build Broker Archive**. The broker archive is rebuilt in the background.

   You can view the user and service logs on the User Log and Service Log pages of the Broker Archive editor. Clear the contents of logs by clicking **Remove** ( ).
3. Optional: To view details about the build of an individual deployable resource on the **Manage** page, right-click the deployable resource and click **Details**.

   The Properties view opens and the Details tab is displayed. The Details tab shows the following details about the deployable resource:

   - The workspace resource, with references to the linked workspace resources (for example, `.msgflow` `.mset`, `.xml`, and `.xslt` files).
   - The status of the last compilation, which shows the user log entry for the last compilation. You can copy text, but you cannot modify it.

What to do next

Next:

Deploy the BAR file by following the instructions in “Deploying a broker archive file” on page 3235.

Deploying resources

Deploy message flow applications to execution groups by sending a broker archive (BAR) file to a broker, which unpacks and stores the contents ready for when your message flows are started.

Before you begin

Before you start:

Complete the following steps:

- Create and start a broker. You must also start a WebSphere MQ listener for the associated queue manager.
- In the WebSphere Message Broker Toolkit, you must connect to a broker, and create an execution group.
- Create a BAR file that contains the resources that you want to deploy; see “Packaging resources” on page 3221.

About this task

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See “Restrictions that apply in each operation mode” on page 3657.

If you are working with a single message flow, and want to deploy and test it quickly, you can deploy just that flow. Drag the message flow onto the execution group to which you want to deploy it. A BAR file is generated automatically, and

deployed to the broker. You can then run and test the message flow, change the flow, and deploy it again with a minimum of steps involved.

In most cases, you are working with one or more message flows, one or more message sets, and other objects that you want to deploy with the message flows. In these cases, you can deploy these resources together by packaging them in a BAR file yourself, and deploying just that file. For instructions about how to deploy a BAR file, see "Deploying a broker archive file."

If you are deploying a message flow that uses WebSphere Adapters, see "Deploying a message flow that uses WebSphere Adapters" on page 3240. To deploy by using the WebSphere Message Broker Explorer, see "Importing a broker archive file to the WebSphere Message Broker Explorer" on page 3242.

If your message flows include user-defined nodes, you must also distribute the compiled C or Java code for each node to every broker that uses those message flows. For more details, see "Developing user-defined extensions" on page 2970.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Deploying a broker archive file

After you have created and populated a broker archive (BAR) file, deploy the file to an execution group on a broker, so that the file contents can be used in the broker.

Before you begin

Before you start:

This topic assumes that you have created a BAR file. For more information, see "Creating a broker archive" on page 3222.

About this task

Choose one of the following methods to deploy a BAR file:

- "Using the WebSphere Message Broker Toolkit"
- "Using the WebSphere Message Broker Explorer" on page 3237
- "Using the **mqsideploy** command" on page 3238
- "Using the CMP API" on page 3238

If you change a BAR file, and want to propagate those changes to one or more brokers, you can redeploy the updated BAR file by following the instructions in "Redeploying a BAR file" on page 3239.

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657.

Using the WebSphere Message Broker Toolkit

About this task

To deploy a BAR file by using the WebSphere Message Broker Toolkit, complete the following steps. You can deploy to only one execution group at a time.

Procedure

1. Optional: Typically, an incremental BAR file deployment is performed. To perform a complete BAR file deployment, right-click the target execution group in the Brokers view and click **Delete** > **All Flows and Resources**. Wait for the operation to complete before continuing.

   Do not click **Delete** > **All Flows and Resources** if you want to refresh one or more of the child processes with the contents of the BAR file. For an explanation of the difference between a complete and an incremental BAR file deployment, see "Message flow application deployment" on page 3213.
2. Deploy a BAR file or message flow to an execution group by using one of the following methods:
   - Drag a message flow or BAR file onto your target execution group, shown in the Brokers view.
   - Right-click the BAR file, and click **Deploy**. The Deploy dialog box opens, listing the execution groups to which the WebSphere Message Broker Toolkit is connected.

     Select an execution group, and click **OK**.
   - Right-click the execution group, and click **Deploy**. The Resources dialog box opens. You can choose to deploy resources from the workspace, or BAR files from the file system.
     - Specify the type of resource to deploy by selecting the appropriate radio button. The available resources for that category are listed.
     - Select the resource that you want to deploy.
     - Click **OK**.
3. If you have not saved the BAR file since you last edited it, you are asked whether you want to save the file before deploying. If you click **Cancel**, the BAR file is not saved and deployment does not take place.

Results

The BAR file is transferred to the broker, which deploys the file contents (for example, message flows and message sets) to the execution group. In the Brokers view, the deployed resources are added to the appropriate execution group.

Using the WebSphere Message Broker Explorer

Before you begin

Before you start:

Import a BAR file into the WebSphere Message Broker Explorer by following the instructions in "Importing a broker archive file to the WebSphere Message Broker Explorer" on page 3242.

About this task

To deploy a BAR file by using the WebSphere Message Broker Explorer, complete the following steps.

Procedure

1. Expand the Broker Resources folder and select the folder that contains your BAR files.
2. Optional: Typically, an incremental BAR file deployment is performed. To perform a complete BAR file deployment, right-click the target execution group in the Brokers view and click **Delete** > **All Flows and Resources**. Wait for the operation to complete before continuing.

   Do not **Delete** > **All Flows and Resources** if you want to refresh one or more of the child processes with the contents of the BAR file. For an explanation of the difference between a complete and an incremental BAR file deployment, see "Message flow application deployment" on page 3213.
3. Deploy the BAR file to an execution group by using one of the following methods:
   - Drag the file onto your target execution group in the Navigator view. You can drag a BAR file from either your WebSphere Message Broker Explorer workspace, or from your file system.
   - Right-click the BAR file and click **Deploy file**. A dialog box opens, listing the execution groups to which the WebSphere Message Broker Explorer is connected.

     Select an execution group, then click **OK**.

   If you use the **Deploy file** method, you can select (and deploy to) multiple execution groups at a time.
4. If you have not saved the BAR file since you last edited it, you are asked whether you want to save the file before deploying. If you click **Cancel**, the BAR file is not saved and deployment does not take place.

Results

The BAR file is transferred to the broker, which deploys the file contents (for example, message flows and message sets) to the execution group. Expand the broker in the Navigator view to see the assigned message flows and message sets added to the appropriate execution group.

Using the mqsideploy command
About this task

To deploy a BAR file by using the **mqsideploy** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.
2. Enter the appropriate command for your operating system and configuration, by using the following examples as a guide.

   On distributed systems:

   ```
   mqsideploy -i ipAddress -p port -q qmgr -e egroup -a barfile
   ```

   The command performs an incremental deployment. Add the **–m** parameter to perform a complete BAR file deployment.

   The **-i** (IP address), **-p** (port), and **-q** (queue manager) parameters represent the connection details for the queue manager that is associated with the broker. If you have created the broker on the computer on which you run this command, you can specify the broker name instead.

   You must also specify the **-e** (execution group name), and **-a** (BAR file name) parameters.

   On z/OS:

   ```
   /f MQ01BRK,dp e=egroup a=barfile
   ```

   The command performs an incremental deployment. Add the **m**=yes parameter to perform a complete BAR file deployment.

   In the example, *MQ01BRK* is the name of the broker. You must also specify the names of the execution group and the BAR file (the **e=** and **a=** parameters).

Results

The command reports when responses are received from the broker. If the command completes successfully, it returns 0 (zero).

Using the CMP API
About this task

To deploy by using the CMP API, use the deploy method of the ExecutionGroupProxy class.

The following code shows how an application can perform an incremental deployment:

```
import com.ibm.broker.config.proxy.*;
public class DeployBAR {

  public static void main(String[] args) {
    BrokerConnectionParameters bcp =
       new MQBrokerConnectionParameters("localhost", 2414, "MB7QMGR");
    try {
      BrokerProxy b = BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy eg = b.getExecutionGroupByName("default");
      DeployResult dr = eg.deploy("MyBAR.bar", true, 30000);
      System.out.println("Result = "+dr.getCompletionCode());
```

```
    } catch (Exception e) {
      e.printStackTrace();
    }
  }
}
```

By default, the deploy method performs an incremental deployment. To perform a complete deployment, use a variant of the method that includes a `false` value for the Boolean isIncremental parameter. For example, e.deploy("deploy.bar",false,0). Set this parameter to `true` to request an incremental deployment.

Redeploying a BAR file

About this task

You might change a BAR file and want to propagate those changes to one or more brokers. If so, you can redeploy the updated BAR file to one or more execution groups by using one of the deployment methods described previously. You do not have to stop the message flows that you deployed previously; all resources in the execution group or groups that are in the redeployed BAR file are replaced and new resources are applied.

If your updates to the BAR file include the deletion of resources, a redeployment does not result in their deletion from the broker. For example, assume that your BAR file contains message flows F1, F2, and F3. Update the file by removing F2 and adding message flow F4. If you redeploy the BAR file, all four flows are available in the execution group when the redeployment has completed. F1 and F3 are replaced by the contents of the redeployed BAR file.

To clear previously deployed resources from the execution group before you redeploy (for example, if you are deleting resources), use one of the methods described previously.

- To use the WebSphere Message Broker Toolkit, follow the instructions for a complete deployment, making sure that you select **Delete** > **All Flows and Resources** before deploying.
- To use the WebSphere Message Broker Explorer, follow the instructions for a complete deployment, making sure that you select **Delete All Flows and Resources** before deploying.
- To use the **mqsideploy** command, follow the instructions, making sure that you add the **-m** parameter to perform a complete BAR file deployment.
- To use the CMP API, follow the instructions for a complete deployment.

If your message flows are not transactional, stop the message flows before you redeploy to be sure that all the applications complete cleanly and are in a known and consistent state. You can stop individual message flows, execution groups, or brokers.

If your message flows are transactional, the processing logic that handles commitment or rollback ensures that resource integrity and consistency are maintained.

What to do next

Next:

Check the results of the redeployment by following the instructions in “Checking the results of deployment” on page 3243.

Administration API for WebSphere Message Broker (CMP API)

Deploying a message flow that uses WebSphere Adapters

Deploy the resources that are generated when you run the Adapter Connection wizard by adding them to a broker archive (BAR) file.

Before you begin

Before you start:

- Read "WebSphere Adapters nodes" on page 1914.
- Complete the steps in "Preparing the environment for WebSphere Adapters nodes" on page 717
- Complete the steps in "Connecting to an EIS by using the Adapter Connection wizard" on page 2037.

About this task

To deploy the message flow successfully, you must deploy the WebSphere Adapters component, either on its own or in the same BAR file as your message flow. If the WebSphere Adapters component is not available, deployment of the message flow fails. The following list includes the file extensions of the resources that you deploy:

- `.msgflow` (the message flow)
- `.inadapter` (the inbound WebSphere Adapters component)

- `.outadapter` (the outbound WebSphere Adapters component)
- `.xsdzip` (the message set)
- `.libzip` (the library)

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657.

Procedure

1. For details of the steps that you must complete before you can deploy a message flow, see "Deploying resources" on page 3234.
2. Add the message flow to the BAR file. (For a description of how to add files to a BAR file, see "Adding files to a broker archive" on page 3223.) When you add a message flow that contains one or more WebSphere Adapters nodes to a BAR file, a dialog box opens so that you can identify the following resources:
   - One or more WebSphere Adapters components to be used by the WebSphere Adapters nodes
   - One or more message sets that contain an XSD for the business objects that are used by the WebSphere Adapters nodes
3. When you have added the message flow, WebSphere Adapters components, and message set, deploy the BAR file.

Related concepts:

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

Importing a broker archive file to the WebSphere Message Broker Explorer

Before you can deploy broker resources to your brokers by using the WebSphere Message Broker Explorer, you must first import a broker archive file into a Broker Archive Folder.

Before you begin

You must have a broker archive file created and available before you can import it into the WebSphere Message Broker Explorer.

About this task

To import a broker archive file:

Procedure

1. Open the WebSphere Message Broker Explorer.
2. You can import a broker archive file into an existing Broker Archive Folder, or create a new one. To create a new Broker Archive Folder:
   a. Right-click Broker Archive Files, and click **New** > **Broker Archive Folder**. The Broker Archive Folder wizard is displayed.
   b. Enter a Broker Archive Folder name, and click **Finish**.

   A new Broker Archive Folder is created with the name you specified in the Broker Archive Folder wizard.
3. Right-click your Broker Archive Folder, and select **Import Broker Resources**. The **Import** wizard is displayed.
4. Click **Browse** next to the **From directory** field to select the directory containing your broker archive.
5. Select the broker archive files that you want to import.
6. Click **Browse** next to the **Info folder** field to select your Broker Archive Folder.
7. Click **Finish**. The selected broker archive files are imported into the selected Broker Archive Folder.

Results

You can now deploy your broker archive to your broker. A copy of the imported broker archive file is created, and placed in the WebSphere Message Broker Explorer workspace. If you change the broker archive file outside of the WebSphere Message Broker Explorer the changes are not made to the imported broker archive file. The default location on Windows for the WebSphere Message Broker Explorer workspace is `C:\Documents and Settings\<userid>\Application Data\IBM\MQ Explorer\<server project>\`. Any subsequent changes you make to the broker archive file within the WebSphere Message Broker Explorer are made to the version in the WebSphere Message Broker Explorer workspace.

Use the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer to create execution groups on your broker.

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Checking the results of deployment

After you have made a deployment, check that the operation has completed successfully.

About this task

You can check the results of a deployment in the following ways:

- "Using the WebSphere Message Broker Toolkit"
- "Using the WebSphere Message Broker Explorer" on page 3244
- Using the **mqsideploy** command
- Using the CMP API

Also, check the system log on the target system where the broker was deployed to make sure that the broker has not reported any errors.

Using the WebSphere Message Broker Toolkit

About this task

Follow these steps to check a deployment using the WebSphere Message Broker Toolkit:

Procedure

1. In the Broker Application Development perspective, open the Deployment Log view:
   a. Click **Window** > **Show View** > **Other**.
   b. In the Show View window expand **Broker Runtime**, and click **Deployment Log**.
2. View the messages relating to each deployment in the Deployment Log view.

Results

The Deployment Log is only updated after a deployment has been completely processed by the broker. If a deployment fails, the reasons for the failure are shown here.

Using the WebSphere Message Broker Explorer

About this task

Follow these steps to check a deployment using the WebSphere Message Broker Explorer:

Procedure

1. Select the broker with which you want to work in the Navigator view.
2. View the messages in the Administration Log view.

Results

The Administration Log shows all recent configuration change attempts made to the broker and, where possible, the user that requested it.

Using the `mqsideploy` command

About this task

If you use the **mqsideploy** command to deploy, the command displays the results of the deployment. It also returns a numeric completion code value to indicate the outcome. If the deployment completes successfully, the command returns 0. For details of other values that you might see returned, see "**mqsideploy** command" on page 3872.

Using the CMP API

About this task

Code your application to test the results of the deploy actions that it takes. You can use code like the following snippet:

```
DeployResult dr = eg.deploy("MyBAR.bar", true, 30000);
System.out.println("Overall result = "+dr.getCompletionCode());

// Display log messages
Enumeration logEntries = dr.getLogEntries();
while (logEntries.hasMoreElements()) {
  LogEntry le = (LogEntry)logEntries.nextElement();
  System.out.println("General message: " + le.getDetail());
}
```

The deploy method blocks other processes until the broker has responded to the deployment request. When the method returns, the `DeployResult` object represents the outcome of the deployment at the time when the method returned; the object is not updated by the CMP API.

If the deployment message could not be sent to the broker, a `ConfigManagerProxyLoggedException` exception is thrown at the time of the deployment. If the broker receives the deployment message, log messages for the overall deployment are displayed, followed by completion codes specific to each

broker that is affected by the deployment. The completion code, shown in the following table, is one of the static instances from the `CompletionCodeType` class.

Completion code	Description
pending	The deployment is held in a batch and is not sent until you call BrokerProxy.sendUpdates().
submitted	The deploy message was sent to the broker, but no response was received before the timeout period expired.
success	The broker has successfully completed the deployment.
failure	The broker has generated one or more errors during deployment. You can call the getLogEntries() method of the `DeployResult` class to get more information about the deployment failure. This method returns an enumeration of available `LogEntry` objects.

Renaming objects that are deployed to execution groups

You cannot rename an object while it is still deployed to an execution group. You must change it in the broker archive, then redeploy the broker archive (BAR) file.

About this task

To rename a deployed object, complete the following steps.

Procedure

1. Remove the object from the execution group. For more details, see "Removing a deployed object from an execution group."
2. Rename the object.
3. Refresh the contents of the broker archive. For more details, see "Refreshing the contents of a broker archive" on page 3233.
4. Redploy the BAR file. For more details, see "Deploying a broker archive file" on page 3235.

Related concepts:

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

Related tasks:

"Deploying resources" on page 3234
Deploy message flow applications to execution groups by sending a broker archive (BAR) file to a broker, which unpacks and stores the contents ready for when your message flows are started.

"Removing a deployed object from an execution group"
You might want to remove deployed objects from an execution group if, for example, you want to rename them.

"Refreshing the contents of a broker archive" on page 3233
Refresh the contents of a broker archive (BAR) file by rebuilding it in the Broker Archive editor. Alternatively, remove resources from your broker archive and, having made the required changes, add them back again.

"Deploying a broker archive file" on page 3235
After you have created and populated a broker archive (BAR) file, deploy the file to an execution group on a broker, so that the file contents can be used in the broker.

Use the advice given here to help you to resolve common problems that can arise when you deploy message flows or message sets.

Removing a deployed object from an execution group

You might want to remove deployed objects from an execution group if, for example, you want to rename them.

Before you begin

Before you start:

Stop all message flows in the execution group. For more details, see "Stopping an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 944.

About this task

You can remove deployed objects from an execution group in the following ways:

- "Using the WebSphere Message Broker Explorer"
- "Using the **mqsideploy** command"
- "Using the CMP API" on page 3248

Using the WebSphere Message Broker Toolkit

About this task

To remove an object from an execution group by using the WebSphere Message Broker Toolkit, complete the following steps.

Procedure

1. In the Brokers view, right-click the object that you want to remove.
2. Click **Delete**, then **OK** to confirm.

Results

The request is sent to the broker, and a synchronous response is sent back.

Using the WebSphere Message Broker Explorer

About this task

To remove an object from an execution group by using the WebSphere Message Broker Explorer, complete the following steps.

Procedure

1. In the Navigator view, expand the broker and execution group with which you want to work.
2. Right-click the object that you want to remove.
3. Click **Delete**, then **OK** to confirm.

Results

The request is sent to the broker, and a synchronous response is sent back.

Using the `mqsideploy` command

About this task

To remove an object from an execution group by using the **mqsideploy** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.
2. Enter the appropriate command for your operating system and configuration, using the following examples as a guide.

   On distributed systems:

   ```
   mqsideploy -i ipAddress -p port -q qmgr –e egroup
              –d file1.cmf:file2.cmf:file3.dictionary:file4.xml
   ```

   The **-i** (IP address), **-p** (port), and **-q** (queue manager) parameters represent the connection details for the queue manager associated with the broker. If you have created the broker on the computer on which you run this command, you can specify the broker name instead.

   On z/OS:

   ```
   /f MQ01BRK1,dp e=egroup d=file1.cmf:file2.cmf:file3.dictionary:file4.xml
   ```

   where *MQ01BRK1* is the name of the broker.

   The **-d** parameter (**d=** on z/OS) is a colon-separated list of files that you want to remove from the named execution group. When you run the command, the deployed objects (`file1.cmf, file2.cmf, file3.dictionary, file4.xml`) are removed from the specified execution group.

   Optionally, specify the **-m** parameter (**m=** on z/OS) to clear the contents of the execution group. This option tells the execution group to completely clear all existing data before the new BAR file is deployed.

Results

The command reports when responses are received from the broker. If the command completes successfully, it returns zero (0).

Using the CMP API

About this task

To remove deployed objects from an execution group, get a handle to the relevant `ExecutionGroupProxy` object, then run the deleteDeployedObjectsByName method. Use the following code as an example.

```
import com.ibm.broker.config.proxy.*;

public class DeleteDeployedObjects {
  public static void main(String[] args) {
    BrokerConnectionParameters bcp =
            new MQBrokerConnectionParameters
                      ("localhost", 1414, "QM1");
    try {
      BrokerProxy b =
            BrokerProxy.getInstance(bcp);
      ExecutionGroupProxy e =
            b.getExecutionGroupByName("default");
      e.deleteDeployedObjectsByName(
            new String[] { "file1.cmf",
                           "file2.cmf",
                           "file3.dictionary",
                           "file4.xml" }, 0);
    }
    catch (ConfigManagerProxyException e) {
```

```
      e.printStackTrace();
    }
  }
}
```

What to do next

Next:

If you have removed one or more message flows, you can now remove the resource files that are associated with those message flows; for example, JAR files.

Considering performance in the broker environment

When you design your broker environment, and the resources associated with the brokers, decisions that you make can affect the performance of your brokers and applications.

About this task

Message flows

A message flow includes an input node that receives a message from an application over a particular protocol; for example, WebSphere MQ. The message must be parsed by the input node, although some parsers support partial parsing which might reduce processing, because only the parts of the message that are referenced are parsed. Other processing in a message flow that might affect performance are the amount, efficiency, and complexity of ESQL, access to databases, and how many message tree copies are made.

You must consider how you split your business logic; how much work should the application do, and how much should the message flow do? Every interaction between an application and a message flow involves I/O and message parsing, and therefore adds to processing time. Design your message flows, and design or restructure you applications, to minimize these interactions.

For more information about these factors, see "Optimizing message flow response times" on page 3264.

Messages and message models

The type, format, and size of the messages that are processed can have a significant effect on the performance of a message flow. For example, if you process persistent messages, they have to be stored for safekeeping.

You might need to process messages with a well-defined structure; if so, you can create MRM models for your messages. If you do not plan to interrogate the structure, you can work with undefined messages, such as BLOB messages.

If you are working in XML, be aware that it can be verbose, and therefore produce large messages, but XML message content is easier to understand than other formats, such as CWF. Field size and order might be important; these factors can be included in your MRM model.

For more information about these factors, see “Optimizing message flow response times” on page 3264 and Performance considerations for regular expressions in TDS messages.

Broker configuration

You can create and configure one or more brokers, on one or more computers, and for each broker you can create multiple execution groups, and multiple message flows. Your configuration decisions can influence message flow performance, and how efficiently messages can be processed.

For more information about these factors, see “Tuning the broker” on page 3254, “Optimizing message flow throughput” on page 587.

All these factors are examined in more detail in the Designing for Performance SupportPac (IP04).

For a description of common performance scenarios, review “Resolving problems with performance” on page 3504.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

Setting the JVM heap size

When you start an execution group, it creates a Java virtual machine (JVM) for executing a Java user-defined node.

About this task

You can pass parameters to the JVM to set the minimum and maximum heap sizes; the default maximum heap size is 256 MB. To give more capacity to a message flow that is going to process large messages, reduce the minimum JVM heap size to allow the main memory heap to occupy more address space.

Increase the maximum heap size only if you use Java intensively with, for example, user-defined nodes.

Use caution when you set the maximum heap size, because the Java Runtime Environment takes the values for its initial, maximum, and current heap sizes to calculate how frequently it drives garbage collection. A large maximum heap size

drives garbage collection less frequently. If garbage collection is driven less frequently, the heap size associated with the execution group continues to grow.

Use the information on JVM parameter values on the **mqsichangeproperties** command to set the heap size that you require.

Related concepts:

"JVM heap sizing" on page 3269
The Java virtual machine (JVM) heap is an independent memory allocation that can reduce the capacity of the main memory heap.

"Stack storage" on page 3268
Depending on the design of your message flow, you might need to increase the stack size.

Select the objects and properties associated with the Java Virtual Machine (JVM) that you want to change.

Increasing the stack size on Windows, Linux, and UNIX systems

Increase the stack size on Windows, Linux, and UNIX systems by setting the **MQSI_THREAD_STACK_SIZE** environment variable to an appropriate value.

About this task

When you restart brokers that are running on the system, they use the new value.

The value, in bytes, of **MQSI_THREAD_STACK_SIZE** that you set is used for every thread that is created in a DataFlowEngine process. If the execution group has many message flows assigned to it, and you set a large value for **MQSI_THREAD_STACK_SIZE**, the DataFlowEngine process needs a large amount of storage for the stacks.

Set this environment variable to at least 48 KB. The default values are:

Linux and UNIX
1 MB

AIX 2 MB

z/OS 50 KB

Windows
Determined by the operating system.

Related concepts:

"Stack storage" on page 3268
Depending on the design of your message flow, you might need to increase the stack size.

Related tasks:

"Increasing the stack size on z/OS"
Change the stack size on z/OS by altering or adding the Language Environment (LE) **_CEE_RUNOPTS** environment variable. This can be done for all execution groups defined to a broker, or a specific execution group.

Increasing the stack size on z/OS

Change the stack size on z/OS by altering or adding the Language Environment (LE) **_CEE_RUNOPTS** environment variable. This can be done for all execution groups defined to a broker, or a specific execution group.

Before you begin

Broker components on z/OS are compiled using the XPLINKage (extra performance linkage), which adds optimization to the runtime code. However, if the initial stack size is not large enough, stack extents are used. The initial stack size is 1 MB, and 1 MB is used in each extent. Ensure that you choose a large enough downward stack size because the performance of XPLINK can be adversely affected when stack extents are used.

To determine suitable stack sizes, you can use the Language Environment Report Storage tool.

To use this tool, use the **RPTSTG** option with the **_CEE_RUNOPTS** environment variable to test a message flow. Set this option in the component profile (`BIPBPROF` for a broker) during the development and test of message flows that are intended for production; for example:

```
export _CEE_RUNOPTS=RPTSTG\(ON\)
```

You can then override the default values for the stack sizes on z/OS by altering or adding the **_CEE_RUNOPTS** environment variable.

You can do this for all execution groups defined to a broker, or a specific execution group.

About this task

To update the component profile, take the following steps:

Procedure

1. Stop the broker.
2. Make the necessary changes to the profile.
3. Submit `BIPGEN` to re-create the `ENVFILE` and any execution group specific `ENVFILE`s.
4. Restart the broker.

Results

To update the stack sizes for a specific execution group in a broker, take the following steps:

1. Stop the broker.
2. Make the necessary changes to the execution group specific profile.
3. Submit `BIPGEN` to re-create the broker `ENVFILE` and any execution group specific `ENVFILE`s.

4. Restart the broker.

Example

The following example shows how you can change the default stack value of 1 MB to 2 MB:

```
export _CEE_RUNOPTS=THREADSTACK64\(ON,2M,1M,128M\)
```

What to do next

When you use the **RPTSTG** option, it increases the time that an application takes to run, so use it as an aid to the development of message flows only, and not in your final production environment. When you have determined the correct stack sizes needed, remove this option from the **_CEE_RUNOPTS** environment variable.

XPLINK stacks grow downward in virtual storage while the standard linkage grows upward. To avoid affecting performance by switching between downward stack space and upward stack space during run time, compile user-defined extensions using the XPLINK option where possible. If your message flow uses user-defined extensions that have been compiled with the standard linkage convention, set a suitable value for the upward stack size.

Related concepts:

"Stack storage" on page 3268
Depending on the design of your message flow, you might need to increase the stack size.

Related tasks:

"Increasing the stack size on Windows, Linux, and UNIX systems" on page 3255
Increase the stack size on Windows, Linux, and UNIX systems by setting the **MQSI_THREAD_STACK_SIZE** environment variable to an appropriate value.

Tuning the HEAP settings on z/OS

HEAP controls the allocation of the initial heap, controls allocations of additional heap increments, and specifies how that storage is managed.

About this task

WebSphere Message Broker requests an initial heap storage allocation and subsequent heap increments, the sizes of which depend on the type of process. For example, the DFE process requests an initial heap storage allocation of 40 Mb, with subsequent heap increments of 5 Mb. RPTOPTS can be used to generate a report of the runtime options in effect for each process.

- KEEP, which is the default value, specifies that storage allocated to HEAP increments is not released when the last segment of the allocated storage is freed.
- FREE specifies that storage allocated to HEAP increments is released when the last segment of the allocated storage is freed.

For performance reasons, WebSphere Message Broker takes the default, KEEP. For most message processing scenarios, when storage allocations are less than 5 Mb, it is more efficient to reuse storage that has been freed within the heap increment. With KEEP, the 5 Mb heap increment remains allocated, even if all of the storage segments have been released.

If storage requests frequently exceed 5 Mb, these requests are allocated directly on the heap. When the object is freed, the allocation remains on the heap, and is reused for subsequent storage requests whose size is less than, or equal to, the size of the heap allocation. Over time, the heap allocation is used for different-sized objects, and this can lead to fragmentation, which in turn can result in high storage usage. In these circumstances, consider setting the HEAP runtime environment variable for the Language Environment to use the FREE parameter.

To set HEAP for all execution groups in a broker, change or add the Language Environment _CEE_RUNOPTS environment variable in the component profile (BIPBPROF):

1. Stop the broker.
2. Make the necessary changes to the profile.
3. Submit BIPGEN to re-create the ENVFILE and any execution group specific ENVFILEs.
4. Restart the broker.

To set HEAP for a specific execution group, change or add the Language Environment _CEE_RUNOPTS environment variable in the execution group specific profile (renamed BIPEPROF):

1. Stop the broker.
2. Make the necessary changes to the execution group specific profile.
3. Submit BIPGEN to re-create the broker ENVFILE and any execution group specific ENVFILEs.
4. Restart the broker.

For example, you can change the default values of KEEP to FREE in the following line:

```
_CEE_RUNOPTS=HEAP64(40M,5M,FREE,9M,32K,KEEP,4096,4096,FREE)
```

Setting configuration timeout values

Change timeout values that affect configuration tasks in the broker.

Before you begin

Before you start:

Read "Packaging and deployment overview" on page 3210 to understand the conditions under which these timeout values apply.

About this task

The broker receives configuration requests from the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, and CMP API applications. You can also change its configuration by running several commands, for example, **mqsideploy**.

Several factors affect the time that a broker takes to apply and respond to these requests. These factors include the load on the computer on which the broker is running, network delays between components, and the work that execution groups are performing at the time the request is received. The number of message flows in an execution group, and their complexity, and large message sets, might also affect the time taken.

You can change the length of time that a broker can take to perform these actions by using two parameters that you can set on the **mqsicreatebroker** and **mqsichangebroker** commands. The combined default value for these parameters is approximately 6 minutes (360 seconds).

During development and test of message flows and broker configurations, experiment with the values that you set for these timeout parameters to determine appropriate values for your resources.

- **-g** *ConfigurationChangeTimeout*

  This value defines the maximum time (in seconds) that is allowed for a user configuration request to be processed, and defaults to 5 minutes (300 seconds). The value is affected by the system load (including processor use), and by the load of each execution group. If the request is not completed in this time, the broker generates warning message BIP2066, but continues to implement the change. The broker records further diagnosis information in the system and event logs.

- **-k** *InternalConfigurationTimeout*

  This value defines the maximum time (in seconds) that is allowed for an internal configuration change to be processed and defaults to 1 minute (60 seconds). For example, it defines the length of time that the broker can take to start an execution group before a response is required.

  The broker starts an internal process to start an execution group and to make all the message flows active. Part of this initialization is performed serially (one execution group at a time), therefore if the change affects more than one execution group, the time required increases. If an execution group exceeds this timeout value, the broker generates a warning message BIP2080. However, the initialization continues and the execution group is started. The broker records further diagnosis information in the system and event logs.

The sum of the values of *ConfigurationChangeTimeout* and the *InternalConfigurationTimeout* parameters represents the maximum length of time that a broker can take to process a deployed configuration message before it generates a negative response. Check that typical configurations complete successfully within the time that you have specified, to minimize warning messages.

Look for success messages in the Administration log in the WebSphere Message Broker Explorer, or Deployment Log in the WebSphere Message Broker Toolkit. When success messages are displayed the deployment has completed. If you start a deployment and record how long it takes for the success messages to appear, you can use this time interval as the basis for setting these timeout values.

If the broker is on a production system, increase the values for both *ConfigurationChangeTimeout* and *InternalConfigurationTimeout* parameters to allow for application messages that are currently being processed by message flows to be completed before the configuration change is applied. Also consider increasing the value if you have merged message flows into fewer execution groups that you are using for testing.

If the broker is on a development or test system, you might want to reduce timeout lengths (in particular, the value of the *ConfigurationChangeTimeout* parameter) to improve perceived response times, and to force a response from a broker that is not showing expected behavior. However, reducing the timeout values decreases the probability of deploying a configuration change successfully.

During broker startup, the *InternalConfigurationTimeout* parameter is automatically extended based on the number of execution groups which a broker contains. At this time, the timeout period reported in the BIP2080 warning message may not match the value configured for the *InternalConfigurationTimeout* parameter.

Message flow performance

Understand the factors that control and influence the performance of your message flows.

About this task

- "Optimizing message flow throughput" on page 587
- "Optimizing message flow response times" on page 3264
- "System resources for message flow development" on page 3267

Optimizing message flow throughput

Each message flow that you design must provide a complete set of processing for messages received from a certain source. This design might result in very complex message flows that include large numbers of nodes that can cause a performance overhead, and might create potential bottlenecks. You can increase the number of message flows that process your messages to provide the opportunity for parallel processing and therefore improved throughput.

About this task

The mode that your broker is working in can affect the number of message flows that you can use; see "Restrictions that apply in each operation mode" on page 3657.

You can also consider the way in which the actions taken by the message flow are committed, and the order in which messages are processed.

Consider the following options for optimizing message flow throughput:

Multiple threads processing messages in a single message flow

When you deploy a message flow, the broker automatically starts an instance of the message flow for each input node that it contains. This behavior is the default. However, if you have a message flow that handles a very large number of messages, the input source (for example, a WebSphere MQ queue) might become a bottleneck.

You can update the `Additional Instances` property of the deployed message flow in the BAR file: the broker starts additional copies of the message flow on separate threads, providing parallel processing. This option is the most efficient way of handling this situation, if you are not concerned about the order in which messages are processed.

If the message flow receives messages from a WebSphere MQ queue, you can influence the order in which messages are processed by setting the `Order Mode` property of the MQInput node:

- If you set `Order Mode` to By User ID, the node ensures that messages from a specific user (identified by the UserIdentifier field in the MQMD) are processed in guaranteed order. A second message from one user is not processed by an instance of the message flow if a previous message from this user is currently being processed by another instance of the message flow.
- If you set `Order Mode` to By Queue Order, the node processes one message at a time to preserve the order in which the messages are read from the queue. Therefore, this node behaves as though you have set the `Additional Instances` property of the message flow to zero.
- If you set `Order Mode` to `User Defined`, you can order messages by any message element, by setting an XPath or ESQL expression in the Order field location property. The node ensures that messages with the same value in the order field message element are processed in guaranteed order. A second message with the same value in the order field message element is not processed by an instance of the message flow if a previous message with the same value is currently being processed by another instance of the message flow.

  If the field is missing, an exception is raised, and the message is rolled back. NULL and empty values are processed separately, in parallel.

  If you set `Order Mode` to By User ID or `User Defined`, and the message flow uses transformation nodes, it is advisable to set the `Parse Timing` to Immediate.

For publish/subscribe applications that communicate with the broker over any supported protocol, messages for a particular topic are published by brokers in the same order as they are received from publishers (subject to reordering based on message priority, if applicable). Therefore each

subscriber receives messages from a particular broker, on a particular topic, from a particular publisher, in the order that they are published by that publisher.

However, it is possible for messages, occasionally, to be delivered out of order. This situation can happen, for example, if a link in the network fails and subsequent messages are routed by another link.

If you need to ensure the order in which messages are received, you can use either the **SeqNum** (sequence number) or **PubTime** (publish time stamp) parameter on the **Publish** command for each published message, to calculate the order of publishing.

For more information about the techniques recommended for all MQI and AMI users, see the *Application Programming Reference* and *Application Programming Guide* sections in the WebSphere MQ Version 7 Information Center online for programs written to the MQI, and the *WebSphere MQ Application Messaging Interface* book for programs written to the AMI.

The *WebSphere MQ Application Messaging Interface* book is available from the WebSphere MQ Library web page (listed under Version 5.3), or from SupportPac MA0F on the WebSphere MQ SupportPacs web page.

See also the *Publish/Subscribe User's Guide* section in the WebSphere MQ Version 7 Information Center online.

The broker does not provide message ordering for messages received across WebSphere MQ Web Services Transport.

Multiple copies of the message flow in a broker
You can also deploy several copies of the same message flow to different execution groups in the same broker. This option has similar effects to increasing the number of processing threads in a single message flow, although typically provides less noticeable gains.

This option also removes the ability to determine the order in which the messages are processed, because, if there is more than one copy of the message flow active in the broker, each copy can be processing a message at the same time, from the same queue. The time taken to process a message might vary, and multiple message flows accessing the same queue might therefore read messages from the input source in a random order. The order of messages produced by the message flows might not correspond to the order of the original messages.

Ensure that the applications that receive message from these message flows can tolerate out-of-order messages. Additionally, ensure that the input nodes in these message flows are suitable for deployment to different processes.

Copies of the message flow in multiple brokers
You can deploy several copies of the same message flow to different brokers. This option requires changes to your configuration, because you must ensure that applications that supply messages to the message flow can put their messages to the right input queue or port. You can often make these changes when you deploy the message flow by setting the message flow's configurable properties.

The scope of the message flow
You might find that, in some circumstances, you can split a single message flow into several different flows to reduce the scope of work that each message flow performs. If you do split your message flow, be aware that it

is not possible to run the separate message flows in the same unit of work, and if transactional aspects to your message flow exist (for example, the updating of multiple databases), this option does not provide a suitable solution.

The following two examples show when you might want to split a message flow:

1. In a message flow that uses a RouteToLabel node, the input queue has become a bottleneck. You can use another copy of the message flow in a second execution group, but this option is not appropriate if you want all of the messages to be handled in the order in which they are shown on the queue. You can consider splitting out each branch of the message flow that starts with a Label node by providing an input queue and input node for each branch. This option might be appropriate, because when the message is routed by the RouteToLabel node to the relevant Label node, it has some level of independence from all other messages.

   You might also need to provide another input queue and input node to complete any common processing that the Label node branches connect to when unique processing has been done.
2. If you have a message flow that processes very large messages that take a considerable time to process, you might be able to:
   a. Create other copies of the message flow that use a different input queue (you can set this option up in the message flow itself, or you can update this property when you deploy the message flow).
   b. Set up WebSphere MQ queue aliases to redirect messages from some applications to the alternative queue and message flow.

   You can also create a new message flow that replicates the function of the original message flow, but only processes large messages that are immediately passed on to it by the original message flow, that you modified to check the input message size and redirect the large messages.

The frequency of commits

If a message flow receives input messages on a WebSphere MQ queue, you can improve its throughput for some message flow scenarios by modifying its default properties after you have added it to a BAR file. (These options are not available if the input messages are received by other input nodes; commits in those message flows are performed for each message.)

The following properties control the frequency with which the message flow commits transactions:

- `Commit Count`. This property represents the number of messages processed from the input queue before an MQCMIT is issued.
- `Commit Interval`. This property represents the time interval that elapses before an MQCMIT is started.

Optimizing message flow response times

You can use different solutions to improve message flow response times.

Before you begin

Before you start:

Read the following concept topic:

- "Message flow nodes" on page 1024

About this task

When you design a message flow, the flexibility and functional capabilities of the built-in nodes often mean that there are several ways to achieve the processing and results that you require. You might find that different solutions deliver different levels of performance and, if performance is an important consideration for you, take it into account when designing your message flow

Your applications can perceive performance in either of these ways:

- The response time indicates how quickly each message is processed by the message flow. The response time is particularly influenced by how you design your message flows. Response time is discussed in this topic.
- The throughput indicates how many messages of particular sizes can be processed by a message flow in a specified time. The throughput is mainly affected by configuration and system resource factors, and is discussed in "Optimizing message flow throughput" on page 587, with other domain configuration information.

Several aspects influence message flow response times. However, as you create and modify your message flow design to arrive at the best results for your specific business requirements, also consider the eventual complexity of the message flow. The most efficient message flows are not necessarily the easiest to understand and maintain; experiment with the solutions available to arrive at the best balance for your needs.

Several factors influence message flow response times:

The number of nodes that you include in the message flow

Every node increases the amount of processing required in the broker, therefore, consider the content of the message flow carefully, including the use of subflows.

Use as few nodes as possible in a message flow; every node that you include in the message flow increases the amount of processing required in the broker. The number of nodes in a single flow has an upper limit, which is governed by system resources, particularly the stack size. For more information about stack sizes, see "System resources for message flow development" on page 3267.

How the message flow routes and processes messages

In some situations, you might find that the built-in nodes, and perhaps other nodes that are available in your system, provide more than one way of providing the same function. Choose the simplest configuration. For example, to define some specific processing based on the value of a field in each message, you might design a message flow that has a sequence of Filter nodes to handle each case. If appropriate, you can group messages through the Filter node to reduce the number of nodes through which each message type has to pass before being processed.

For example, you might have a message flow that handles eight different messages (Invoice, Despatch Note, and so on). You can include a Filter node to identify each type of message and route it according to its type. You can optimize the performance of this technique by testing for the most frequent message types in the earliest Filter nodes. However, the eighth message type must always pass through eight Filter nodes.

If you can group the message types (for example, if the message type is numeric, and you can test for all types greater than four and not greater than four), you can reduce the number of Filter nodes required. The first Filter node tests for greater than four, and passes the message on to two further Filter nodes (attached to the True and False terminals) that test for less than two and less than six. An additional four Filter nodes can then test for one or two, three or four, and so on. Although the number of Filter nodes required is the same, the number of nodes through which each message passes is reduced.

You might find that using a RouteToLabel node with a set of Label nodes provides a better alternative to a sequence of Filter nodes. Each message passes through a smaller number of nodes, improving throughput. However, you must also consider that using a RouteToLabel node necessitates the use of a Compute node: the increase in the amount of processing required in the broker that is caused by the node might outweigh the advantages. If you are dealing with a limited number of message types, a small number of Filter nodes is more efficient.

The following sample demonstrates how you can use the RouteToLabel and Label nodes instead of using multiple Filter nodes in the XML_PassengerQuery message flow.

- Airline Reservations

The following sample demonstrates how you can store routing information in a database table in an in-memory cache in the message flow.

- Message Routing

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

If your message flow includes loops
Avoid loops of repeating nodes, which can be very inefficient and can cause performance and stack problems. You might find that a Compute node with multiple PROPAGATE statements avoids the need to loop around a series of nodes.

The efficiency of the ESQL
Check all the ESQL code that you have created for your message flow nodes. As you develop and test a node, you might maintain statements that are not required when you have finalized your message processing. You might also find that something you have coded as two statements can be coded as one. Taking the time to review and check your ESQL code might provide simplification and performance improvements.

If you have imported message flows from a previous release, check your ESQL statements against the ESQL available in Version 6.1 to see if you can use new functions or statements to improve its efficiency.

The use of persistent and transactional messages
Persistent messages are saved to disk during message flow processing. You can avoid this situation by specifying that messages are non-persistent on input, output, or both. If your message flow is handling only non-persistent messages, check the configuration of the nodes and the message flow itself; if your messages are non-persistent, transactional support might be unnecessary. The default configuration of some nodes enforces transactionality; if you update these properties and redeploy the message flow, response times might improve.

Message size
A larger message takes longer to process. If you can split large messages into smaller units of information, you might be able to improve the speed at which they are handled by the message flow. The following sample demonstrates how to minimize the virtual storage requirements for the message flow to improve a message flow's performance when processing potentially large messages.

- Large Messaging

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Message format
Although WebSphere Message Broker supports multiple message formats, and provides facilities that you can use to transform from one format to another, this transformation increases the amount of processing required in the broker. Make sure that you do not perform any unnecessary conversions or transformations.

You can find more information about improving the performance of a message flow in a developerWorks article (developerWorks article on message flow performance).

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

System resources for message flow development

Configure your message flows to make the best use of computer resources, especially if you will process large messages.

As well as designing your message flow to optimize throughput, you must ensure that particular areas of storage are efficiently used so that your system does not suffer from capacity issues, and that processes do not end because of lack of resources.

Consider the following storage issues when developing your message flows:

- "Stack storage" on page 3268
- "JVM heap sizing" on page 3269
- "Configuring the storage of events for aggregation nodes" on page 753
- "Configuring the storage of events for Collector nodes" on page 755

Related reference:

"Message flows" on page 4015
Use the reference information in this section to develop your message flows and related resources.

Stack storage:

Depending on the design of your message flow, you might need to increase the stack size.

When a message flow thread starts, it requires storage to perform the instructions that are defined by the message flow nodes. This storage comes from the execution group's heap and stack size. The default stack size that is allocated to a message flow thread depends on the operating system that is used:

Windows On Windows, each message flow thread is allocated 1 MB of stack space.

Linux On Linux, each message flow thread is allocated 1 MB of stack space.

UNIX On UNIX, each message flow thread is allocated 1 MB of stack space.

AIX On AIX, each message flow thread is allocated 2 MB of stack space.

z/OS On z/OS, each message flow thread is allocated 512 KB of downward stack space and 50 KB of upward stack space.

In a message flow, a node typically uses 2 KB of the stack space. A typical message flow can therefore include 250 nodes on z/OS, 500 nodes on UNIX systems and 500 nodes on Windows. This amount can be higher or lower depending on the type of nodes used and the processing that they perform.

In WebSphere Message Broker, any processing that involves nested or recursive processing can cause extensive usage of the stack. For example, in the following situations you might need to increase the stack size:

- When a message flow is processing a message that contains a large number of repetitions or complex nesting.
- When a message flow is executing ESQL that calls the same procedure or function recursively, or when an operator (for example, the concatenation operator) is used repeatedly in an ESQL statement.

You can increase the stack size to improve performance. For details, see:

- "Increasing the stack size on Windows, Linux, and UNIX systems" on page 3255
- "Increasing the stack size on z/OS" on page 3256

Use the reference information in this section to develop your message flows and related resources.

JVM heap sizing:

The Java virtual machine (JVM) heap is an independent memory allocation that can reduce the capacity of the main memory heap.

Every execution group creates its own JVM. The execution group uses the JVM to execute the internal administration threads that require Java. This usage is typically minimal. The primary use of the JVM is for the message flow nodes that include the IBM primitives, user defined extensions, and Java routines that are called from ESQL. You cannot control how much of the JVM heap the IBM primitives use, but you can affect usage of the JVM heap in the Java that is implemented in the following resources:

- A Java user-defined extension node
- A JavaCompute node
- A Java routine that is called from ESQL

From WebSphere Message Broker onwards, the JVM is created with a minimum of 32 MB of space, and a maximum of 256 MB, allocated and reserved for its use. As with any JVM, you can pass parameters in to set the minimum and maximum heap sizes. Note that on 32-bit platforms, the JVM reserves heap space based on the maximum heap size.

You might need to increase the maximum heap size allocated if you plan to run large messages through the Java primitive nodes listed above.

To give more capacity to a message flow that is going to process large messages, reduce the minimum JVM heap size to allow the main memory heap to occupy more address space. For details of how to reduce the minimum JVM heap size, see "Setting the JVM heap size" on page 3254.

Related concepts:

"Stack storage" on page 3268
Depending on the design of your message flow, you might need to increase the stack size.

Configuring the storage of events for aggregation nodes:

You can use an Aggregation configurable service to control the storage of events for AggregateControl and AggregateReply nodes.

About this task

By default, the storage queues used by all aggregation nodes are:

- SYSTEM.BROKER.AGGR.CONTROL

- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST
- SYSTEM.BROKER.AGGR.UNKNOWN
- SYSTEM.BROKER.AGGR.TIMEOUT

However, you can control the queues that are used by different aggregation nodes by creating alternative queues containing a *QueuePrefix*, and using an Aggregation configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry time of an aggregation:

Procedure

1. Create the storage queues to be used by the aggregation nodes. The following queues are required:
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.CONTROL
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REPLY
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REQUEST
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.UNKNOWN
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create an Aggregation configurable service. You can create a configurable service to be used with either a specific aggregation or with all aggregations in an execution group.
   a. If the configurable service is to be used with a specific aggregation, ensure that the name of the configurable service is the same as the name that you specify in the `Aggregate name` property on the AggregateControl and AggregateReply nodes. If the configurable service is to be used with all aggregations in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Timeout** property to control the expiry time of an aggregation.

   For example, create a configurable service called `myAggregation`, which specifies queues prefixed with SYSTEM.BROKER.AGGR.SET1 and a timeout of 60 seconds:

   ```
   mqsicreateconfigurableservice MYBROKER -c Aggregation -o myAggregation
   -n queuePrefix,timeoutSeconds -v SET1,60
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Aggregation configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see "Configurable services properties" on page 3766
3. In the AggregateControl and AggregateReply nodes:

a. Ensure that the name of the Aggregation configurable service is the same as the name specified in the `Aggregate name` property on the **Basic** tab; for example, `myAggregation`. If no Aggregation configurable service exists with the same name as the `Aggregate name` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.

b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for Collector nodes:

You can use a Collector configurable service to control the storage of events for Collector nodes.

About this task

By default, the storage queues used by all Collector nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Resequence node.

However, you can control the queues that are used by different Collector nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Collector configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry for the collection:

Procedure

1. Create the storage queues to be used by the Collector node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Collector configurable service. You can create a configurable service to be used with either a specific collection or with all collections in an execution group.
   a. If you are creating a configurable service to be used with a specific collection, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Collector node. If you are creating a configurable service to be used with all collections in the execution group, ensure that the configurable service has the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.

c. Optional: Set the **Collection expiry** property.

For example, create a Collector configurable service called `myCollectorService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, and with a collection expiry of 60 seconds:

```
mqsicreateconfigurableservice MYBROKER -c Collector -o myCollectorService
-n queuePrefix,collectionExpirySeconds -v SET1,60
```

You can use the **mqsideleteconfigurableservice** command to delete the Collector configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.

For more information, see "Configurable services properties" on page 3766

3. In the Collector node:
   a. If the configurable service is to be used for a specific collection, specify the name of the configurable service in the `Configurable service` property on the **Advanced** tab; for example, `myCollectorService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for Resequence nodes:

You can use a Resequence configurable service to control the storage of events for Resequence nodes.

About this task

By default, the storage queues used by all Resequence nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Collector node.

However, you can control the queues that are used by different Resequence nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Resequence configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the timeout and the start and end of the sequence:

Procedure

1. Create the storage queues to be used by the Resequence node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Resequence configurable service. You can create a configurable service to be used with either a specific sequence or with all sequences in an execution group.

a. If you are creating a configurable service to be used with a specific sequence, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Resequence node. If you are creating a configurable service to be used with all sequences in the execution group, ensure that the configurable service has the same name as the execution group.

b. Set the **Queue prefix** property to the required value.

c. Optional: Set the **Missing message timeout**, **Start of sequence**, and **End of sequence** properties.

For example, create a Resequence configurable service called `myResequenceService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, with a missing message timeout of 60 seconds, and which waits five seconds before determining the start and end numbers in a sequence:

```
mqsicreateconfigurableservice MYBROKER -c Resequence -o myResequenceService
-n queuePrefix,missingMessageTimeoutSeconds,startSequenceSeconds,endSequenceSeconds -v SET1,60
```

You can use the **mqsideleteconfigurableservice** command to delete the Resequence configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see "Configurable services properties" on page 3766

3. In the Resequence node:

a. If the configurable service is to be used for a specific sequence, specify the name of the configurable service on the **Advanced** tab; for example, `myResequenceService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.

b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for timeout nodes:

You can use a Timer configurable service to control the storage of events for TimeoutNotification and TimeoutControl nodes.

About this task

By default, the storage queue used by all timeout nodes is the SYSTEM.BROKER.TIMEOUT.QUEUE.

However, you can control the queues that are used by different timeout nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Timer configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queue that is used to store event states:

Procedure

1. Create the storage queue to be used by the timeout nodes. The following queue is required:
   - SYSTEM.BROKER.TIMEOUT.*QueuePrefix*.QUEUE

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queue, WebSphere Message Broker creates the queue when the node is deployed; this queue is based on the default queue. If the queue cannot be created, the message flow is not deployed.

2. Use the **mqsicreateconfigurableservice** command to create a Timer configurable service. You can create a configurable service to be used with either specific timeout requests or with all timeout requests in an execution group.
   a. If the configurable service is to be used with specific timeout requests, create the configurable service with the same name as the `Unique identifier` property on the TimeoutNotification and TimeoutControl nodes. If the configurable service is to be used with all timeout requests in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.

   For example, create a Timer configurable service that uses a queue prefixed with SYSTEM.BROKER.TIMEOUT.SET1:

   ```
   mqsicreateconfigurableservice MB7BROKER -c Timer -o myTimer
   -n queuePrefix -v SET1
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Timer configurable service. However, the storage queue is not deleted automatically when the configurable service is deleted, so you must delete it separately.For more information, see "Configurable services properties" on page 3766.
3. In the TimeoutNotification and TimeoutControl nodes:
   a. Ensure that the name of the Timer configurable service is the same as the name specified in the `Unique Identifier` property on the **Basic** tab; for example, `myTimer`. If there is no Timer configurable service with the same name as the `Unique Identifier`, and if there is a configurable service with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Tuning the SAP adapter for scalability and performance

You can configure the number of listeners on the adapter and the number of additional instances on the message flow to prevent delays when processing synchronous calls from SAP.

Before you begin

Before you start:

- Ensure that you have created and saved a message flow that contains one or more SAP nodes; for more information, see "Developing message flows that use WebSphere Adapters" on page 2033.
- Read the concept topic "SAP adapter scalability and performance" on page 1949.

About this task

The following steps describe how to tune the SAP adapter for scalability and performance.

Procedure

1. Deploy the BAR file, as described in "Deploying a message flow that uses WebSphere Adapters" on page 3240.
2. Start user trace, as described in "Starting user trace" on page 3197.
3. Start to collect accounting and statistics data, as described in "Starting to collect message flow accounting and statistics data" on page 3288.
4. Run the SAP programs at a typical load.
5. Check user trace for message BIP3461. This message tells you the highest number of listeners that are waiting for message flow threads at any one time. In an ideal situation, this number should be as low as possible. To reduce the number of listeners that are waiting for message flow threads, increase the number of instances on the SAPInput node, or the message flow that contains it.
6. Inspect the accounting and statistics data for the message flow.

Related concepts:

"SAP adapter scalability and performance" on page 1949
You can improve performance by configuring the number of listeners on the adapter and the number of additional instances on the message flow to prevent delays when processing synchronous calls from SAP.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

Monitoring message flow performance

You can configure your message flow to collect statistics about the operation and behavior of your message flows. Use this information to assess the performance of your message flows.

Before you begin

Before you start:

Read the concept topic about message flow accounting and statistics data.

About this task

The following topics describe the tasks that you can complete to control collection of message flow accounting and statistics data by using the command line:

- "Starting to collect message flow accounting and statistics data" on page 3288
- "Stopping message flow accounting and statistics data collection" on page 3293
- "Viewing message flow accounting and statistics data collection parameters" on page 3294
- "Modifying message flow accounting and statistics data collection parameters" on page 3296
- "Resetting message flow accounting and statistics archive data" on page 3297

The following topics describe the tasks that you can complete to control collection of message flow accounting and statistics data by using the WebSphere Message Broker Explorer:

- "Starting accounting and statistics data collection in the WebSphere Message Broker Explorer" on page 3299
- "Viewing message flow accounting and statistics data" on page 3300
- "Filtering message flow accounting and statistics data" on page 3302
- "Stopping accounting and statistics data collection in the WebSphere Message Broker Explorer" on page 3304

The topics listed here show examples of how to issue the accounting and statistics commands. The examples for z/OS are shown for SDSF; if you are using another interface, you must modify the example shown according to the requirements of that interface. For details of other z/OS options, see "Issuing commands to the z/OS console" on page 3980.

Related concepts:

"Message flow accounting and statistics data" on page 3281

"Issuing commands to the z/OS console" on page 3980
You operate the broker using the z/OS START, STOP, and MODIFY commands.

Message flow accounting and statistics data

Message flow accounting and statistics data is the information that can be collected by a broker to record performance and operating details of message flow execution.

Message flow accounting and statistics data records dynamic information about the runtime behavior of a message flow. For example, it indicates how many messages are processed and how large those messages are, as well as processor usage and elapsed processing times. The broker collects the data and records it in a specified location when one of a number of events occurs (for example, when a snapshot interval expires or when the execution group you are recording information about stops).

The broker takes information about statistics and accounting from the operating system. On some operating systems, such as Windows, Linux, and UNIX, rounding can occur because the system calls that are used to determine the processor times are not sufficiently granular. This rounding might affect the accuracy of the data.

The following restrictions apply to data collection:

- Data relating to the size of messages is not collected for WebSphere Adapters nodes (for example, the SAPInput node), the FileInput node, the JMSInput node, or any user-defined input node that does not create a message tree from a bit stream.

Collecting message flow accounting and statistics data is optional; by default it is switched off. To use this facility, request it on a message flow or execution group basis. The settings for accounting and statistics data collection are reset to the defaults when an execution group is redeployed. Previous settings for message flows in an execution group are not passed on to the new message flows deployed to that execution group. Data collection is started and stopped dynamically when you issue the **mqsichangeflowstats** command or when you click **Statistics** > **Start Statistics** on the message flow in the WebSphere Message Broker Explorer; you do not need to change the broker or the message flow, or redeploy the message flow, to request statistics collection.

You can activate data collection on both your production and test systems. If you collect the default level of statistics (message flow), the effect on broker performance is minimal. However, collecting more data than the default message flow statistics can generate high volumes of report data that might affect performance slightly.

When you plan data collection, consider the following points:

- Collection options
- Accounting origin
- Output formats

You can find more information about how to use accounting and statistics data to improve the performance of a message flow in this developerWorks article on message flow performance.

Related concepts:

Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

Message flow accounting and statistics collection options:

The options that you specify for message flow accounting and statistics collection determine what information is collected. You can request two types of data collection: Snapshot data and archive data.

- Snapshot data is collected for an interval of approximately 20 seconds. The exact length of the interval depends on system loading and the level of current broker activity. You cannot modify the length of time for which snapshot data is collected. At the end of this interval, the recorded statistics are written to the output destination and the interval is restarted.
- Archive data is collected for an interval that you have set for the broker on the **mqsicreatebroker** or **mqsichangebroker** command. You can specify an interval of between 1 and 43200 minutes, the default value is 60 minutes. At the end of this interval, the recorded statistics are written to the output destination and the interval is restarted.

  An interval is prematurely expired and restarted when any of the following events occur:
  - The message flow is redeployed.
  - The set of statistics data to be collected is modified.
  - The broker is shut down.

  This preserves the integrity of the data already collected when that event occurs.

  z/OS On z/OS, you can set the command parameter to 0, which means that the interval is controlled by an external timer mechanism. This support is provided by the Event Notification Facility (ENF), which you can use instead of the broker command parameter if you want to coordinate the expiration of this timer with other system events.

You can request snapshot data collection, archive data collection, or both. You can activate snapshot data collection while archive data collection is active. The data recorded in both reports is the same, but is collected for different intervals. If you

activate both snapshot and archive data collection, be careful not to combine information from the two different reports, because you might count information twice.

View statistics data as it is generated, using the Broker Statistics view in the WebSphere Message Broker Explorer.

You can use the statistics generated for the following purposes:

- You can record the load that applications, trading partners, or other users put on the broker. This allows you to record the relative use that different users make of the broker, and perhaps to charge them accordingly. For example, you could levy a nominal charge on every message that is processed by a broker, or by a specific message flow.

  Archive data provides the information that you need for a use assessment of this kind.
- You can assess the execution of a message flow to determine why it, or a node within it, is not performing as you expect.

  Snapshot data is appropriate for performance assessment.
- You can determine the route that messages are taking through a message flow. For example, you might find that an error path is taken more frequently than you expect and you can use the statistics to understand when the messages are routed to this error path.

  Check the information provided by snapshot data for routing information; if this is insufficient for your needs, use archive data.

Message flow accounting and statistics accounting origin:

Accounting and statistics data can be accumulated and reported with reference to an identifier associated with a message in a message flow. This identifier is the accounting origin, which provides a method of producing individual accounting and statistics data for multiple accounting origins that generate input to message flows. The accounting origin can be a fixed value, or it can be dynamically set according to your criteria.

For example, if your broker hosts a set of message flows associated with a particular client in a single execution group, you can set a specific value for the accounting origin for all these flows. You can then analyze the output provided to assess the use that the client or department makes of the broker, and charge them accordingly.

If you want to track the behavior of a particular message flow, you can set a unique accounting origin for this message flow, and analyze its activity over a specified period.

To make use of the accounting origin, you must perform the following tasks:

- Activate data collection, specifying the correct parameter to request basic support (the default is none, or no support). For details, see "**mqsichangeflowstats** command" on page 3744.
- Configure each message flow for which you want a specific origin to include ESQL statements that set the unique value that is to be associated with the data collected. Data for message flows for which a specific value has not been set are identified with the value `Anonymous`.

  The ESQL statements can be coded in a Compute, Database, or Filter node.

  You can configure the message flow either to set a fixed value, or to determine a dynamic value, and can therefore create a very flexible method of recording sets of data that are specific to particular messages or circumstances. For more information, refer to "Setting message flow accounting and statistics accounting origin" on page 3290.

You can complete these tasks in either order; if you configure the message flow before starting data collection, the broker ignores the setting. If you start data collection, specifying accounting origin support, before configuring the message flow, all data is collected with the Accounting Origin set to `Anonymous`. The broker acknowledges the origin when you redeploy the message flow. You can also modify data collection that has already started to request accounting origin support from the time that you issue the command. In both cases, data that has already been collected is written out and collection is restarted.

When data has been collected, you can review information for one or more specific origins. For example, if you select XML publication messages as your output format, you can start an application that subscribes to the origin in which you are interested.

"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

Output formats for message flow accounting and statistics data:

When you collect message flow statistics, you can choose the output destination for the data.

Select one of the following destinations:
- User trace
- XML publication
- SMF

Statistics data is written to the specified output location in the following circumstances:
- When the archive data interval expires.
- When the snapshot interval expires.
- When the broker shuts down. Any data that has been collected by the broker, but has not yet been written to the specified output destination, is written during shutdown. It might therefore represent data for an incomplete interval.
- When any part of the broker configuration is redeployed. Redeployed configuration data might contain an updated configuration that is not consistent with the existing record structure (for example, a message flow might include an additional node, or an execution group might include a new message flow). Therefore the current data, which might represent an incomplete interval, is written to the output destination. Data collection continues for the redeployed configuration until you change data collection parameters or stop data collection.
- When data collection parameters are modified. If you update the parameters that you have set for data collection, all data that is collected for the message flow (or message flows) is written to the output destination to retain data integrity. Statistics collection is restarted according to the new parameters.
- When an error occurs that terminates data collection. You must restart data collection yourself in this case.

User trace

You can specify that the data that is collected is written to the user trace log. The data is written even when trace is switched off. The default output destination for accounting and statistics data is the user trace log. The data is written to one of the following locations:

Windows **Windows**

If you set the work path by using the **-w** parameter of the **mqsicreatebroker** command, the location is `workpath\log`.

If you have not specified the broker work path, the location is:

- On Windows:`%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\log`, where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:
  - On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\common\log`
  - On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\common\log`

  The value might be different on your computer.

Linux UNIX **Linux and UNIX**

`/var/mqsi/common/log`

z/OS **z/OS**

`/component_filesystem/log`

XML publication

You can specify that the data that is collected is published. The publication message is created in XML format and is available to subscribers registered in the broker network that subscribe to the correct topic.

The topic on which the data is published has the following structure:

`$SYS/Broker/`*`brokerName`*`/StatisticsAccounting/`*`recordType`*`/`*`executionGroupLabel`*`/`*`messageFlowLabel`*

The variables correspond to the following values:

brokerName
The name of the broker for which statistics are collected.

recordType
Set to `SnapShot` or `Archive`, depending on the type of data to which you are subscribing. Alternatively, use # to register for both snapshot and archive data if it is being produced. This value is case sensitive and must be entered as `SnapShot`.

executionGroupLabel
The name of the execution group for which statistics are collected.

messageFlowLabel
The label on the message flow for which statistics are collected.

Subscribers can include filter expressions to limit the publications that they receive. For example, they can choose to see only snapshot data, or to see data that is collected for a single broker. Subscribers can specify wild cards (+ and #) to receive publications that refer to multiple resources.

The following examples show the topic with which a subscriber registers to receive different sorts of data:

- Register the following topic for the subscriber to receive data for all message flows running on *BrokerA*:

  $SYS/Broker/*BrokerA*/StatisticsAccounting/#

- Register the following topic for the subscriber to receive only archive statistics that relate to a message flow *Flow1* running on execution group *Execution* on broker *BrokerA*:

  $SYS/Broker/*BrokerA*/StatisticsAccounting/Archive/*Execution*/*Flow1*

- Register the following topic for the subscriber to receive both snapshot and archive data for message flow *Flow1* running on execution group *Execution* on broker *BrokerA*

  $SYS/Broker/*BrokerA*/StatisticsAccouting/#/*Execution*/*Flow1*

For help with registering your subscriber, see Message display, test and performance utilities SupportPac (IH03).

SMF

On z/OS, you can specify that the data collected is written to SMF. Accounting and statistics data uses SMF type 117 records. SMF supports the collection of data from multiple subsystems, and you might therefore be able to synchronize the information that is recorded from different sources.

To interpret the information that is recorded, use any utility program that processes SMF records.

Starting to collect message flow accounting and statistics data

You can start collecting message flow accounting and statistics data for an active broker at any time. You can specify what type of statistics you want to collect, and where to send the data.

Before you begin

Before you start:

- Ensure that you have created a message flow; for more information, see "Creating a message flow" on page 1431.
- Ensure that you have deployed a broker archive (BAR) file; for more information, see "Deploying a broker archive file" on page 3235.
- Read the concept topic, "Message flow accounting and statistics collection options" on page 3282.

About this task

Select the granularity of the data that you want to be collected by specifying the appropriate parameters on the **mqsichangeflowstats** command. You must request statistics collection on a broker basis. If you want to collect information for more than one broker, you must issue the corresponding number of commands.

To start collecting message flow accounting and statistics data:

Procedure

1. Identify the broker for which you want to collect statistics .
2. Decide the resource for which you want to collect statistics. You can collect statistics for a specific execution group, or for all execution groups for the specified broker.
   - If you indicate a specific execution group, you can request that data is recorded for a specific message flow or all message flows in that group.
   - If you specify all execution groups, you must specify all message flows.
3. Decide if you want to collect thread-related statistics.
4. Decide if you want to collect node-related statistics. If you do, you can also collect information about terminals for the nodes.
5. Decide if you want to associate data collection with a particular accounting origin. This option is valid for snapshot and archive data, and for message flows and execution groups. However, when active, you must set its origin value in each message flow to which it refers. If you do not configure the participating message flows to set the appropriate origin identifier, the data collected for that message flow is collected with the origin set to `Anonymous`.

   For more information, see "Setting message flow accounting and statistics accounting origin" on page 3290.
6. Decide the target destination:
   - User trace log (the default setting). The output data can be processed using **mqsireadlog** and **mqsiformatlog**.
   - XML format publication message. If you chose this target destination, register the following topic for the subscriber:

`$SYS/Broker/`*`brokerName`*`/StatisticsAccounting/`*`recordType`*`/`*`executionGroupLabel`*`/`*`messageFlowLabel`*

     Where *brokerName*, *executionGroupLabel*, and *messageFlowLabel* represent the broker, execution group, and message flow on which you want to receive data. *recordType* is the type of data collection on which you want to receive publications (snapshot, archive, or the number sign (#) to receive both

snapshot and archive). The value that you specify for record type is case sensitive; therefore, if you choose to receive snapshot data, set the record type to `SnapShot`.

- z/OS SMF (on z/OS only)

7. Decide the type of data collection that you want:
   - Snapshot
   - Archive

   You can collect snapshot and archive data at the same time, but you have to configure them separately.
8. Issue the **mqsichangeflowstats** command with the appropriate parameters to reflect the decisions that you have made.

   For example, to turn on snapshot data for all message flows in the default execution group for BrokerA, and include node data with the basic message flow statistics, use the following command:

   ```
   mqsichangeflowstats BrokerA -s -e default -j -c active -n basic
   ```

   z/OS Using SDSF on z/OS, enter:

   ```
   /F BrokerA,cs s=yes,e=default,j=yes,c=active,n=basic
   ```

   For more examples, see "**mqsichangeflowstats** command" on page 3744.

Results

When the command completes successfully, data collection for the specified resources is started:

- If you have requested snapshot data, information is collected for approximately 20 seconds, and the results are written to the specified output.
- If you have requested archive data, information is collected for the interval defined for the broker (on the **mqsicreatebroker** or **mqsichangebroker** command, or by the external timer facility ENF). The results are written to the specified output, the interval is reset, and data collection starts again.

What to do next

You can collect message flow accounting and statistics data in various output formats.

Setting message flow accounting and statistics accounting origin:

When you request accounting origin support for collecting message flow accounting and statistics data on the **mqsichangeflowstats** command, you must also configure your message flows to provide the correct identification values that indicate what the data is associated with.

Before you begin

Before you start:

- Ensure that you have created a message flow; for more information, see "Creating a message flow" on page 1431.

- Read the concept topic, “Message flow accounting and statistics accounting origin” on page 3284

About this task

Accounting and statistics data is associated with an accounting origin. For more information, see “Message flow accounting and statistics data” on page 3281 and “Message flow accounting and statistics accounting origin” on page 3284.

You can set a different value for every message flow for which data collection is active, or the same value for a group of message flows (for example, those in a single execution group, or associated with a particular client, department, or application suite).

The accounting origin setting is not used until you deploy the message flow or flows to the brokers on which they are to run. You can activate data collection, or modify it to request accounting origin support, before or after you deploy the message flow. You do not have to stop collecting data when you deploy a message flow that changes accounting origin.

To configure a message flow to specify a particular accounting origin, complete the following steps.

Procedure

1. Open the message flow with which you want to work.
2. Click **Selection** above the palette of nodes.
3. Right-click a Compute, Database, or Filter node in the editor view, then click **Open ESQL**. The associated ESQL file is opened in the editor view, and your cursor is positioned at the start of the correct module. You can include the required ESQL in any of these nodes, so decide which node in each message flow is the most appropriate for this action.

   To take advantage of the accounting origin support, include one of these nodes in each message flow for which you want a specific origin set. If you have not configured one of these three nodes in the message flow, you must add one at a suitable point (for example, immediately following the input node) and connect it to other nodes in the flow.
4. Update the ESQL in the node module to set an accounting origin. The broker uses the origin identifier that is set in the Environment tree. You must set a value in the field with correlation name `Environment.Broker.Accounting.Origin`. This field is not created automatically in the Environment tree when the message is first received in the broker. The field is created only when you set it in an ESQL module that is associated with a node in the message flow.

   If you do not set a value in the message flow, the default value `Anonymous` is used for all output. If you set a value in more than one place in the message flow, the value that you set immediately before the message flow terminates is used in the output data.

   The code that you must add has the following form:

   ```
   SET Environment.Broker.Accounting.Origin = "value";
   ```

   You can set the identifier to a fixed value (as shown previously), or you can determine its value based on a dynamic value that is known only at run time. The value must be character data, and can be a maximum of 32 bytes. For example, you might set its value to the contents of a particular field in the

message that is being processed (if you are coding ESQL for a Compute node, you must use correlation name InputBody in place of Body in the following example):

```
IF Body.DepartmentName <> NULL THEN
   SET Environment.Broker.Accounting.Origin = Body.DepartmentName;
END IF;
```

5. Save the ESQL module, and check that you have not introduced any errors.
6. Save the message flow, and check again for errors.

Results

You are now ready to deploy the updated message flow; for more information, see "Deploying resources" on page 3234. Accounting and statistics data records that are collected after the message flow has been deployed includes the origin identifier that you have set.

Stopping message flow accounting and statistics data collection

You can stop collecting data for message flow accounting and statistics at any time. You do not have to stop the message flow, execution group, or broker to make this change, nor do you have to redeploy the message flow.

Before you begin

Before you start:

- Start to collect message flow accounting and statistics data
- Read the concept topic about message flow accounting and statistics data

About this task

You can stop collecting data for message flow accounting and statistics at any time. You do not have to stop the message flow, execution group, or broker to make this change, nor do you have to redeploy the message flow.

You can modify the parameters that are currently in force for collecting message flow accounting and statistics data without stopping data collection. See "Modifying message flow accounting and statistics data collection parameters" on page 3296 for further details.

To stop collecting data:

Procedure

1. Check the resources for which you want to stop collecting data.

   You do not have to stop all active data collection. You can stop a subset of data collection. For example, if you started collecting statistics for all message flows in a particular execution group, you can stop doing so for a specific message flow in that execution group. Data collection for all other message flows in that execution group continues.

2. Issue the **mqsichangeflowstats** command with the appropriate parameters to stop collecting data for some or all resources.

   For example, to switch off snapshot data for all message flows in all execution groups for BrokerA, enter:

   ```
   mqsichangeflowstats BrokerA -s -g -j -c inactive
   ```

   z/OS Using SDSF on z/OS, enter:

   ```
   /F BrokerA,cs s=yes g=yes j=yes c=inactive
   ```

   Refer to the "**mqsichangeflowstats** command" on page 3744 for further examples.

Results

When the command completes successfully, data collection for the specified resources is stopped. Any outstanding data that has been collected is written to the output destination when you issue this command, to ensure the integrity of data collection.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Viewing message flow accounting and statistics data collection parameters

You can review and check the parameters that are currently in effect for message flow accounting and statistics data collection by using the **mqsireportflowstats** command.

Before you begin

Before you start:

- Start to collect message flow accounting and statistics data
- Read the concept topic about message flow accounting and statistics data

About this task

To view message flow accounting and statistics data collection parameters:

Procedure

Issue the **mqsireportflowstats** command with the appropriate parameters to view the parameters that are currently being used by the broker to control archive data collection or snapshot data collection.
You can view the parameters in force for a broker, an execution group, or an

individual message flow.
For example, to view parameters for snapshot data for all message flows in all execution groups for BrokerA, enter:

```
mqsireportflowstats BrokerA -s -g -j
```

z/OS Using SDSF on z/OS, enter:

```
/F BrokerA,rs s=yes,g=yes,j=yes
```

Refer to the "**mqsireportflowstats** command" on page 3929 for further examples.

Results

The command displays the current status, for example:

```
BIP8187I: Statistics Snapshot settings for flow MyFlow1 in execution
group default - On?: inactive,
ThreadDataLevel: basic, NodeDataLevel:  basic,
OutputFormat: usertrace, AccountingOrigin: basic
```

What to do next

Next:

You can now modify the data collection parameters.

Modifying message flow accounting and statistics data collection parameters

You can modify the parameters that you have set for message flow accounting and statistics data collection. For example, you can start collecting data for a new message flow that you have deployed to an execution group for which you are already collecting data. You can modify parameters while data collection is active; you do not have to stop data collection and restart it.

Before you begin

Before you start:
- Start to collect message flow accounting and statistics data
- Read the concept topic about message flow accounting and statistics data

About this task

To modify message flow accounting and statistics parameters:

Procedure

1. Decide which data collection parameters you want to change. You can modify the parameters that are in force for a broker, an execution group, or an individual message flow.
2. Issue the **mqsichangeflowstats** command with the appropriate parameters to modify the parameters that are currently being used by the broker to control archive data collection or snapshot data collection.

   For example, to modify parameters to extend snapshot data collection to a new message flow MFlow2 in execution group EG2 for BrokerA, enter:

   ```
   mqsichangeflowstats BrokerA -s -e EG2 -f MFlow2 -c active
   ```

   z/OS Using SDSF on z/OS, enter:

   ```
   /F BrokerA,cs s=yes,e=EG2,f=MFlow2,c=active
   ```

   If you want to specify an accounting origin for archive data for a particular message flow in an execution group, enter:

   ```
   mqsichangeflowstats BrokerA -a -e EG4 -f MFlowX -b basic
   ```

   z/OS Using SDSF on z/OS, enter:

   ```
   /F BrokerA,cs a=yes,e=EG4,f=MFlowX,b=basic
   ```

   Refer to the "**mqsichangeflowstats** command" on page 3744 for further examples.

Results

When the command completes successfully, the new parameters that you have specified for data collection are in force. These parameters remain in force until you stop data collection or make further modifications.

Related concepts:

Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

Resetting message flow accounting and statistics archive data

You can reset message flow accounting and statistics archive data to purge any accounting and statistics data not yet reported for that collecting interval. This removes unwanted data. You can request this at any time; you do not have to stop data collection and restart it to perform reset. You cannot reset snapshot data.

Before you begin

Before you start:
- Start to collect message flow accounting and statistics data
- Read the concept topic about message flow accounting and statistics data

About this task

To reset message flow accounting and statistics archive data:

Procedure

1. Identify the broker, and optionally the execution group, for which you want to reset archive data. You cannot reset archive data on a message flow basis.
2. Issue the **mqsichangeflowstats** command with the appropriate parameters to reset archive data.

   For example, to reset archive data for BrokerA, enter:

   ```
   mqsichangeflowstats BrokerA -a -g -j -r
   ```

   z/OS Using SDSF on z/OS, enter:

```
/F BrokerA,cs a=yes,g=yes,j=yes,r=yes
```

Results

When this command completes, all accounting and statistics data accumulated so far for this interval are purged and will not be included in the reports. Data collection is restarted from this point. All archive data for all flows (indicated by `-j` or `j=yes`) in all execution groups (indicated by `-g` or `g=yes`) is reset.

This command has a minimal effect on snapshot data because the accumulation interval is much shorter than for archive data. It does not effect the settings for archive or snapshot data collection that are currently in force. When the command has completed, data collection resumes according to the current settings.

You can change any other options that are currently in effect when you reset archive data, for example accounting origin settings or output type.

Starting accounting and statistics data collection in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to start collecting snapshot accounting and statistics data for your brokers, execution groups, and message flows. You can then view the accounting and statistics data in the Broker Statistics and Broker Statistics Graph views.

Before you begin

Before you start:

- Ensure that you have created a message flow; for more information, see "Creating a message flow" on page 1431.
- Ensure that you have deployed a broker archive (BAR) file; for more information, see "Deploying a broker archive file" on page 3235.
- Read the concept topic, "Message flow accounting and statistics data" on page 3281.

About this task

Use the snapshot accounting and statistics data displayed in the Broker Statistics and Broker Statistics Graph views to monitor the performance and resource usage of your broker or execution group at the message flow, node, or terminal level.

You can start collecting accounting and statistics data for an active broker at any time. You can start collecting accounting and statistics data for multiple brokers at the same time.

To start collecting snapshot message flow accounting and statistics data by using the WebSphere Message Broker Explorer:

Procedure

1. In the WebSphere MQ Explorer - Navigator view, expand the Brokers folder.
2. Right-click the execution group or message flow for which you want to collect statistics.
   - If you selected an execution group, click **Statistics All Flows** > **Start Statistics**.
   - If you selected a message flow click **Statistics** > **Start Statistics**.

   A message is sent to the broker to start collecting accounting and statistics data for the selected resource.
3. Click **Window** > **Show View** > **Broker Statistics** to open the Broker Statistics and Broker Statistics Graph view. These two views are displayed together. If you close one of the views, the other view is also closed.

Results

Accounting and statistics data for the selected broker, execution group, or message flow is displayed in the Broker Statistics and Broker Statistics Graph views. It can take up to 30 seconds for accounting and statistics data to be received from the broker and displayed in the Broker Statistics Graph view. The message `Waiting for Data` is displayed in the title bar is displayed until accounting and statistics data is received from the selected broker, execution group, or message flow. When data is received from the broker, it is displayed in numeric form in the Broker Statistics view, and a visual representation of this data is shown in the Broker Statistics Graph view. Select individual or multiple items in the Broker Statistics

view to change the information displayed in the Broker Statistics Graph view.

What to do next

Next:

To examine the current data in the two views, click **Pause** in the Broker Statistics Graph view to prevent the current data from being overwritten with new data. Click **Play** to resume displaying more accounting and statistics data. You can change the visual representation of the data by clicking **Linear**, **Logarithmic**, and **Stacked**.

You can also select the metrics that are displayed in the graph view; for more information, see "Filtering message flow accounting and statistics data" on page 3302.

Viewing message flow accounting and statistics data

You can use the Broker Statistics and Broker Statistics Graph views in the WebSphere Message Broker Explorer to view snapshot accounting and statistics data as it is produced by the broker.

Before you begin

Before you start:

- "Starting accounting and statistics data collection in the WebSphere Message Broker Explorer" on page 3299
- Read the concept topic about message flow accounting and statistics data

About this task

Use the accounting and statistics data displayed in the Broker Statistics and Broker Statistics Graph views to monitor the performance and resource usage of your broker or execution group at the message flow, node or terminal level. The WebSphere Message Broker Explorer displays snapshot accounting and statistics data.

When you open the Broker Statistics and Broker Statistics Graph views, the WebSphere Message Broker Explorer connects to all the brokers that you have in your workspace and attempts to collect statistics data from the brokers. The message `Waiting for Data` is displayed in the title bar is displayed until accounting and statistics data are received from the selected broker, execution group or message flow. When data is received from the broker it is displayed in numeric form in the Broker Statistics view, and a visual representation of this data is shown in the Broker Statistics Graph view.

To view message flow accounting and statistics data using the WebSphere Message Broker Explorer:

Procedure

1. Click **Window** > **Show View** > **Broker Statistics** to open the Broker Statistics and Broker Statistics Graph view. These two views are displayed together. If you close one of the views, the other view is also be closed.
2. In the **WebSphere MQ Explorer - Navigator** view select the broker, execution group or message flow for which you want to view accounting and statistics data.

Results

Accounting and statistics data for the selected broker, execution group, or message flow is displayed in the Broker Statistics and Broker Statistics Graph views. It can take up to thirty seconds for accounting and statistics data to be received from the broker and displayed in the Broker Statistics Graph view. Select individual or multiple items in the Broker Statistics view to change the information displayed in the Broker Statistics Graph view.

What to do next

If you want to examine the current data in the two views, click the **Pause** button in the Broker Statistics Graph view to prevent the current data from being overwritten with new data. Click the **Play** button to resume displaying new accounting and statistics data. You can change the visual representation of the data by clicking on the **Linear**, **Logarithmic**, and **Stacked** buttons.

You can also select the metrics that are displayed in the graph view, see “Filtering message flow accounting and statistics data” on page 3302.

Filtering message flow accounting and statistics data

You can select the metrics for the snapshot accounting and statistics data that are displayed in the Broker Statistics and Broker Statistics Graph views in the WebSphere Message Broker Explorer.

Before you begin

Before you start:

- Read the concept topic about message flow accounting and statistics data
- "Starting accounting and statistics data collection in the WebSphere Message Broker Explorer" on page 3299
- "Viewing message flow accounting and statistics data" on page 3300

About this task

When you open the Broker Statistics and Broker Statistics Graph views, the WebSphere Message Broker Explorer connects to all the brokers that you have in your workspace and attempts to collect snapshot statistics data from the brokers. The message `Waiting for Data` is displayed in the title bar until accounting and statistics data are received from the selected broker, execution group, or message flow.

When data is received from the broker, it is displayed in numeric form in the Broker Statistics view, and a visual representation of this data is shown in the Broker Statistics Graph view. When accounting and data statistics data has started to be collected and displayed for your broker, execution group, or message flow, you can select the metrics that are displayed in the Broker Statistics and Broker Statistics Graph views.

The metrics that you can select depend on whether you are viewing the accounting and statistics data from a broker, an execution group, or a message flow. To view a list of the metrics that you can filter on, see "Metrics for accounting and statistics data in the WebSphere Message Broker Explorer" on page 6744.

To filter the message flow accounting and statistics data in the Broker Statistics and Broker Statistics Graph views:

Procedure

1. Click **Window** > **Show View** > **Broker Statistics** to open the Broker Statistics and Broker Statistics Graph view.
2. In the **WebSphere MQ Explorer - Navigator** view, select the broker, execution group, or message flow for which you want to view accounting and statistics data.
3. Click the **Filter** button in the Broker Statistics Graph view. The Select metrics to graph window is displayed.
4. Select the metrics that you want to display from the list in the Broker Statistics and Broker Statistics Graph view. Clear all the metrics that you do not want to display in the Broker Statistics and Broker Statistics Graph view.
5. Click **OK**.

Results

The selected metrics are displayed in the Broker Statistics and Broker Statistics Graph views. Data for additional metrics that you have selected are displayed the next time the statistics data is refreshed.

Stopping accounting and statistics data collection in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to stop collecting accounting and statistics data for your brokers, execution groups, and message flows.

About this task

You can stop collecting data for message flow accounting and statistics at any time. You do not have to stop the message flow, execution group, or broker to make this change, nor do you have to redeploy the message flow. You do not have to stop all active data collection. You can stop a subset of data collection. For example, if you started collecting statistics for all message flows in a particular execution group, you can stop doing so for a specific message flow in that execution group. Data collection for all other message flows in that execution group continues.

To stop collecting message flow accounting and statistics data:

Procedure

1. In the WebSphere MQ Explorer - Navigator view, expand the Brokers folder.
2. Right-click the execution group or message flow for which you want to stop collecting statistics.
   - If you selected an execution group, click **Statistics All Flows** > **Stop Statistics**.
   - If you selected a message flow click **Statistics** > **Stop Statistics**.

Results

A message is sent to the broker to stop collecting accounting and statistics data for the selected resource.

Use the **mqsireportresourcestats** command to display current statistics gathering options for resources in the broker.

Resource statistics

Resource statistics are collected by a broker to record performance and operating details of resources that are used by execution groups.

As a system administrator, you can use the resource statistics to ensure that your systems are using the available resources in the most efficient manner. By monitoring systems and analyzing statistical trends, you can keep system resource usage within boundaries that you consider acceptable, and help to pre-empt situations where system resources are overstretched and might become unavailable. Analysis of the data returned potentially requires specialist skills and knowledge of each resource type.

If you detect that system resources are under pressure, you can examine the statistics collected by the broker to assess whether the cause of the concern is the use of those resources by processes in WebSphere Message Broker.

You must activate statistics collection; by default, collection is not active. If you activate statistics, you might experience a minor degradation in operating performance of the broker or brokers for which you are collecting data. You can collect data on one or more execution groups, as well as all execution groups on a broker, so that you can limit the statistics gathering activity if appropriate.

Resource statistics complement the accounting and statistics data that you can collect on message flows, which are also available in the WebSphere Message Broker Explorer; for details, see "Monitoring message flow performance" on page 3279.

To start, stop, or check the status of resource statistics collection, use one or more of the following options:

- The WebSphere Message Broker Explorer
- The **mqsichangeresourcestats** and **mqsireportresourcestats** commands
- A CMP application

To view the output that is generated by statistics collection, use one or more of the following options:

- The WebSphere Message Broker Explorer; numeric data and graphs are displayed for each execution group for which you have activated statistics collection.

- An application that subscribes to a publication, in the form of an XML message, that is published by the broker every 20 seconds. The message contains the data collected for each execution group for which you have activated statistics collection.

  The topic for each message has the following structure:

  `$SYS/Broker/`*`broker_name`*`/ResourceStatistics/`*`execution_group_name`*

  You can set up subscriptions for a specific execution group on a specific broker. For example:

  `$SYS/Broker/MB7BROKER/ResourceStatistics/default`

  You can also use wildcards in the subscriptions to broaden the scope of what is returned. For example, to subscribe to reports for all execution groups on all brokers, use the following values:

  `$SYS/Broker/+/ResourceStatistics/#`

For details of all the statistics that are reported for each resource manager, and the publication content, see "Resource statistics data" on page 6745.

Starting resource statistics collection

Use the **mqsichangeresourcestats** command to start collecting resource statistics.

Before you begin

Before you start:

- Ensure that you have created a message flow; for more information, see "Creating a message flow" on page 1431.

- Ensure that you have deployed a broker archive (BAR) file; for more information, see "Deploying a broker archive file" on page 3235.
- Read the concept topic, "Resource statistics" on page 3306.

About this task

Use resource statistics data to monitor the performance and resource usage of your execution groups. You can start collecting data for active execution groups at any time.

If you prefer, you can start collecting resource statistics by using the WebSphere Message Broker Explorer; see "Starting resource statistics collection in the WebSphere Message Broker Explorer" on page 3310.

To start resource statistics collection:

Procedure

1. If your broker is running on Linux, UNIX, or Windows systems, set up the correct command environment. For details of how to complete this task, see "Setting up a command environment" on page 213.
2. Decide whether you want to collect statistics for a specific execution group, or for all execution groups on the broker.
3. Run the **mqsichangeresourcestats** command with the appropriate parameters.

   For example, to start collecting resource statistics for the default execution group for BrokerA, enter the following command:

   ```
   mqsichangeresourcestats BrokerA -c active -e default
   ```

   For further examples, see "**mqsichangeresourcestats** command" on page 3819.

Related concepts:

Stopping resource statistics collection

Use the **mqsichangeresourcestats** command to stop collecting resource statistics.

Before you begin

Before you start:

- Read the concept topic about resource statistics.
- Start execution group resource statistics collection.

About this task

You can stop collecting data for an active execution group at any time.

If you prefer, you can stop collecting resource statistics by using the WebSphere Message Broker Explorer; see "Stopping resource statistics collection in the WebSphere Message Broker Explorer" on page 3312.

To stop resource statistics collection:

Procedure

1. If your broker is running on Linux, UNIX, or Windows systems, set up the correct command environment. For details of how to complete this task, see "Setting up a command environment" on page 213.
2. Decide whether you want to stop collection for a specific execution group, or for all execution groups on the broker. The way in which you started collection is not important; you can stop collection for one execution group, even if you started it for all execution groups. You can also stop collection for all execution groups, even if you started only one, or each one separately.
3. Run the **mqsichangeresourcestats** command with the appropriate parameters.

   For example, to stop collecting resource statistics for the default execution group for BrokerA, enter:

   ```
   mqsichangeresourcestats BrokerA -c inactive -e default
   ```

   See the "**mqsichangeresourcestats** command" on page 3819 for further examples.

Related concepts:

"Resource statistics" on page 3306
Resource statistics are collected by a broker to record performance and operating details of resources that are used by execution groups.

Viewing status of resource statistics collection

Use the **mqsireportresourcestats** command to view the status of resource statistics collection.

Before you begin

Before you start:

- Read the concept topic about resource statistics.

About this task

The command indicates whether resource statistics collection is active or inactive for each execution group that you have specified on the command.

If you prefer, you can view resource statistics collection status by using the WebSphere Message Broker Explorer; see "Viewing the status of resource statistics collection in the WebSphere Message Broker Explorer" on page 3317.

To view resource statistics collection status:

Procedure

1. If your broker is running on Linux, UNIX, or Windows systems, set up the correct command environment. For details of how to complete this task, see "Setting up a command environment" on page 213.
2. Decide whether you want to view status for a specific execution group, or for all execution groups on the broker.
3. Run the **mqsireportresourcestats** command with the appropriate parameters.

   For example, to view status for the default execution group on BrokerA, enter:

   ```
   mqsireportresourcestats BrokerA -e default
   ```

   See the "**mqsireportresourcestats** command" on page 3944 for further examples.

Starting resource statistics collection in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to start collecting resource statistics data for your execution groups. You can then view the data in the Broker Resources and Broker Resources Graph views.

Before you begin

Before you start:

- Ensure that you have created a message flow; for more information, see "Creating a message flow" on page 1431.
- Ensure that you have deployed a broker archive (BAR) file; for more information, see "Deploying a broker archive file" on page 3235.
- Read the concept topic, "Resource statistics" on page 3306.

About this task

Use the resource statistics data to monitor the performance and resource usage in your execution groups. You can start collecting data for active execution groups at any time.

If you prefer, you can start resource statistics collection by using the **mqsichangeresourcestats** command; for more information, see "Starting resource statistics collection" on page 3307.

To start resource statistics collection in the WebSphere Message Broker Explorer, complete the following steps.

Procedure

1. In the WebSphere MQ Explorer - Navigator view, expand the Brokers folder, then expand the folder of the broker with which you are working.
2. Right-click the execution group for which you want to collect statistics. If you want statistics for several execution groups on this broker, select more than one by using standard operating system interfaces. For example, on Windows systems, hold down the **Ctrl** key and select each execution group before you right-click to open the menu.
3. Click **Statistics** > **Start Resource Statistics**. A message is sent to the broker to start collecting data for the selected execution groups. The property Resource Statistics Active is updated in the properties view of each affected execution group to indicate that data collection is now active.

   A warning message is displayed in the execution group properties window to warn you that performance might be affected by your action.
4. To view statistics, click **Window** > **Show View** > **Resource Statistics** to open the Broker Resources and Broker Resources Graph views. If you are displaying statistics for this execution group for the first time, the views might be empty until the first data is received. Update messages are sent every 20 seconds, and the views refresh automatically.

   The Broker Resources and Broker Resources Graph views are displayed together. If you close one of the views, the other view is also closed.

Stopping resource statistics collection in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to stop collecting resource statistics data for your execution groups.

Before you begin

Before you start:
- Read the concept topic about resource statistics.
- Start resource statistics collection

About this task

You can stop collecting data for active execution groups at any time.

If you prefer, you can stop collecting resource statistics by using the **mqsichangeresourcestats** command; see "Stopping resource statistics collection" on page 3308.

To stop collecting resource statistics in the WebSphere Message Broker Explorer:

Procedure

1. In the **WebSphere MQ Explorer - Navigator** view, expand the Brokers folder.
2. Right-click the broker or execution group for which you want to stop statistics collection. If you want to stop statistics collection for several execution groups, you can select more than one by using standard operating system interfaces; for example, on Windows systems, hold down the Ctrl key and select each execution group before you right-click to open the menu.
3. Click **Statistics** > **Stop Resource Statistics**. A message is sent to the broker to stop collecting resource data for the selected execution groups. The status of data collection is updated in the properties view for each affected execution group.

Results

If you click **Window** > **Show View** > **Resource Statistics** to open the Broker Resources and Broker Resources Graph views when statistics collection is not active, the data that is displayed represents the last update message received by the WebSphere Message Broker Explorer. If you have never started statistics collection for this execution group, the views are displayed but contain no data.

Viewing resource statistics data in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to view resource statistics data for your execution groups in the Broker Resources and Broker Resources Graph views.

Before you begin

Before you start:

- Read the concept topic, "Resource statistics" on page 3306.
- Start resource statistics collection: "Starting resource statistics collection in the WebSphere Message Broker Explorer" on page 3310

About this task

You can also view resource statistics collection by subscribing to the topic on which statistics are published. For further details, see "Subscribing to statistics reports" on page 3317.

To view resource statistics in the WebSphere Message Broker Explorer, complete the following steps.

Procedure

1. In the **WebSphere MQ Explorer - Navigator** view, expand the Brokers folder.
2. To open the Resource Statistics and Resource Statistics Graph views, click **Window** > **Show View** > **Resource Statistics**. These two views are displayed together. If you close one of the views, the other view is also closed.
3. Use the information in these views to review the use of resources for which statistics are available.

   The following examples demonstrate the types of question that can be answered by collecting resource statistics. This list is not exhaustive, and does include all resource types. For a full list of resource types, and the type of information that is collected for each one, see "Resource statistics data" on page 6745

   JVM statistics

   How much memory is the JVM using?

Many tools that are specific to an operating system give you the total memory that is used by the execution group, but they do not show you how that memory is divided between Java processing and other processing in the execution group. By looking at the field `CommittedMemoryInMB`, you can see how much memory is currently allocated to the JVM. Then look at the field `MaxMemoryInMB` to see the maximum amount of memory that can be allocated.

How often is garbage collection done? Is it affecting the performance of the execution group?

To see how often the JVM is doing garbage collection, check the `CumulativeNumberOfGCCollections` field to see if the rate of collections is increasing. Garbage collection is a normal process, and is therefore expected to some degree. However, excessive garbage collection can affect performance.

To see if current garbage collection is excessive, monitor the `CumulativeGCTimeInSeconds` value. If this value is increasing by more than 2 seconds in each 20-second statistics interval, try increasing the JVM maximum heap size for your execution group by using the **mqsichangeproperties** command. You might also want to inspect all the Java user-defined nodes and JavaCompute nodes that are included in your deployed message flows, to ensure that they do not create and delete many objects that could be reused; frequent deletions can contribute to excessive garbage collection.

Do I need to change the minimum or maximum heap sizes?

- If the `CumulativeGCTimeInSeconds` value is increasing by more than 2 seconds in each 20 second statistics interval, increase the maximum heap size to reduce this increase.
- If the `UsedMemoryInMB` value is never close to the `InitialMemoryInMB` value, you might have allocated more memory for the heap than is required. Therefore, reduce the JVM minimum heap size value for the execution group to a value that is closer to the `UsedMemoryInMB` value.

Change these values gradually, and check the results to find the optimum settings for your environment.

Parsers

Are message parsers using more memory than expected?

A message flow parses input messages and can create many output messages. These messages may have large bit streams or large message trees. The parsers created to perform this message processing might consume a large amount of memory. Use the Parsers statistics to determine if message flow parsers are using more memory than expected. If so, consider deploying such flows into separate execution groups or improving ESQL or Java plugin API processing to efficiently handle large messages or transformations.

Is message parsing or writing failing frequently for a particular message flow?

If a message flow receives or attempts to write an invalid message, it is likely that this will be rejected by a parser. Use the message parsers statistics to see if a message flow is rejecting a large amount of input or output messages compared with successful processing.

Outbound sockets

Are the nodes reusing outbound sockets?

Creating outbound sockets can be an expensive operation, and the number of sockets available on a computer is a finite resource. Therefore, increasing socket reuse can enhance performance. If the workload is continuous and consistent, the `TotalSockets` value indicates an initial period of activity, which then reduces when the execution group starts to reuse sockets.

A steady increase in the `TotalSockets` value over time is expected because sockets are closed after a period of inactivity, or when they have been used many times.

If the `TotalSockets` value increases significantly over time, this trend might indicate that outbound sockets are not being reused.

If your message flows include HTTPRequest nodes, check that you have set the keepalive property Enable HTTP/1.1 keepalive.

Check also whether the endpoint that is called uses keepalive sockets.

Which endpoints are most used?

The values `TotalMessages` indicates how busy each endpoint is. The value in the summary record tells you how much activity occurred across the whole execution group.

How large are sent and received messages?

The values of the `SentMessageSize_*` and `ReceivedMessageSize_*` fields give a profile of the message sizes flowing to and from each endpoint.

JDBC connection pools

Do I need to change the size of the connection pool?

If the statistics show that the count of callers waiting for connections is high, and the wait time is increasing, consider increasing the size of the pool using the `MaxConnectionPoolSize` property for the JDBCProvider configurable service.

Alternatively, try reducing the number of additional instances configured for the message flow.

TCPIPClientNodes

Are the nodes reusing outbound sockets?

Creating outbound sockets can be an expensive operation, and the number of sockets available on a computer is a finite resource. Therefore, increasing socket reuse can enhance performance. If the workload is continuous and consistent, the

`TotalSockets` value indicates an initial period of activity, which then reduces when the execution group starts to reuse sockets.

A steady increase in the `TotalSockets` value over time is expected because sockets are closed after a period of inactivity, or when they have been used many times.

If the `TotalSockets` value increases significantly over time, this trend might indicate that outbound sockets are not being reused.

If your message flows include HTTPRequest nodes, check that you have set the keepalive property Enable HTTP/1.1 keepalive.

Check also whether the endpoint that is called uses keepalive sockets.

How the does the information that I see in WebSphere Message Broker Explorer relate to my TCP/IP flows?

An entry is displayed for each configurable service, not for each flow.

Viewing the status of resource statistics collection in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to view the status of resource statistics collection in the Broker Resources view.

Before you begin

Before you start:
- Read the concept topic about resource statistics.

About this task

If you prefer, you can view resource statistics collection status by using the **mqsireportresourcestats** command; see "Viewing status of resource statistics collection" on page 3309.

To view the status of resource statistics collection in the WebSphere Message Broker Explorer:

Procedure

1. In the **WebSphere MQ Explorer - Navigator** view, expand the Brokers folder.
2. Click the execution group for which you want to view statistics collection status. You can view status for only one execution group at a time.

   In the **WebSphere MQ Explorer - Content** view, the **Resource Statistics Active** field indicates whether statistics collection is active. If the field contains the value `None`, statistics collection is inactive. If collection is active, the field contains the value `CICS`, `CORBA`, `FTEAgent`, `JVM`, `Parsers`, `Security`, `Sockets` or `JDBC Connection Pooling`.

Subscribing to statistics reports

You can subscribe to topics that return statistics about the operation of your message flows and resource managers.

About this task

Message flow performance

If you enable message flow accounting and statistics collection for a broker, you can subscribe to the messages that the broker publishes on the following topic:

`$SYS/Broker/`*`brokerName`*`/StatisticsAccounting/`*`recordType`*`/`*`executionGroupLabel`*`/`*`messageFlowLabel`*

where *broker_name* is the name of the broker, *recordType* is the type of record (SnapShot or Archive), *executionGroupLabel* is the name of the execution group that you created on that broker, and *messageFlowLabel* is the name of the message flow that you deployed to the execution group.

These messages contain statistics reports and are published at a regular interval, which you control by setting the statsInterval property of the broker. Each publication is a JMS BytesMessage that contains the statistics report in XML format.

Resource performance

If you enable resource statistics collection for one or more execution groups on a broker, you can subscribe to the messages that the broker publishes at 20-second intervals on the following topic:

`$SYS/Broker/`*`brokerName`*`/ResourceStatistics/`*`executionGroupLabel`*

For more information about how to interpret the resource statistics that are included in the publication, see "Viewing resource statistics data in the WebSphere Message Broker Explorer" on page 3313.

Using wildcards in subscriptions

Procedure

You can use wild cards when you subscribe to statistics reports. For example, to receive message flow statistics reports for all brokers and all execution groups, subscribe to the following topic:

```
$SYS/Broker/+/StatisticsAccounting/#
```

To receive execution group resource statistics reports for all brokers and all execution groups, subscribe to the following topic:

```
$SYS/Broker/+/ResourceStatistics/+
```

For further details about how you can use wildcards, see "Special characters in topics" on page 6395.

Results

Subscribers receive statistics reports only from those brokers that are enabled to produce statistics.

Business-level monitoring

You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

Before you begin

Before you start:

Before starting to configure monitoring, read the following information.

1. Understand the basic concepts; see "Monitoring basics" on page 3320.
2. Decide what type of monitoring you intend to do; see "Monitoring scenarios" on page 3323.
3. Decide whether to use monitoring properties, or a monitoring profile; see "Deciding how to configure monitoring events for message flows" on page 3325.

About this task

An event is a message that a message flow publishes when something interesting happens. The message contains information about the source of the event, the time of the event, and the reason for the event. The event can include the message bit stream, and can also include selected elements from the message body. These fields can be used to correlate messages that belong to the same transaction, or to convey business data to a monitoring application.

To receive monitoring events, you must take the following steps:

1. Configure event sources on the flow, either by monitoring properties or a monitoring profile.
2. Ensure that the event sources are enabled; use the **mqsireportflowmonitoring** command to report settings. Use the monitoring properties for the node, or the **mqsichangeflowmonitoring** `-i` command to enable event sources, if appropriate.
3. Activate monitoring for the flow; use the **mqsichangeflowmonitoring** `-c` command.
4. Subscribe to the topic for the flow:

   `$SYS/Broker/`*`brokerName`*`/Monitoring/`*`executionGroupName`*`/`*`flowName`*

Related concepts:

"**mqsichangeflowmonitoring** command" on page 3738
Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

Monitoring basics

Message flows can be configured to emit events. The events can be read and used by other applications for transaction monitoring, transaction auditing, and business process monitoring.

Monitoring Events

A monitoring event is an XML document that conforms to the monitoring event schema. Each event contains the following information:

- Source of the event
- Name of the event
- Sequence number and creation time
- Correlation ID for events emitted by the same transaction or unit of work

Additionally, a monitoring event can contain the following items:

- Application data extracted from the message
- Part or all of the message bit stream

See "The monitoring event" on page 6774 for more details

Event Sources

A message flow can emit two kinds of events:

Transaction events
Transaction events are emitted only from input nodes.

Terminal events
Terminal events are emitted from any terminal of any node, including input nodes.

An individual message flow can choose to emit transaction events, terminal events, or both kinds of event. You can configure, enable, and disable, both types of events in either of the following ways:

- Using the monitoring properties of the message flow.
- Using a monitoring profile configurable service.

The use of a monitoring profile configurable service overrides the monitoring properties of a message flow.

An event source address identifies an event source in a message flow.

Because terminal events can be emitted from any node in a message flow, they can be used as an alternative to dedicated event-emitting nodes or subflows such as that supplied in SupportPac IA9V.

Event sources emit events only if monitoring is activated for the message flow.

Terminal events

Any terminal in a message flow can be an event source. If the event source is active, it emits an event each time a message passes through the terminal, subject to the evaluation of the eventFilter expression; see "Event output options."

Transaction events

Each input node in a message flow contains three events sources, in addition to terminal events.

Event source	Event source address	Description
Transaction start	*Nodename*.transaction.Start	The event is emitted when the message is read from the transport.
Transaction end	*Nodename*.transaction.End	The event is emitted when WebSphere Message Broker has completed all processing of the message.
Transaction rollback	*Nodename*.transaction.Rollback	The event is emitted instead of transaction end if the message flow throws an exception which is not caught and processed within the message flow.

Events are emitted subject to the evaluation of the eventFilter expression; see "Event output options."

If a message flow handles its own exceptions, a transaction end event, rather than a transaction rollback event, is issued, because the flow has taken control of the error and terminated normally. In this case, if you need to distinguish errors, you can configure terminal events at appropriate nodes in the flow.

Event output options

When you configure an event source, you can define a filter to control whether the event is emitted. You can tailor event emission to your business requirements, by

filtering out events that do not match a set of rules. For example, you might decide to emit events only for transactions above a minimum amount.

```
$Body/StockTrade/Details/Value > 10000
```

This can reduce the number of events emitted, and reduce the workload on your monitoring application.

Events are published to a topic, where they can be read by multiple subscribers. The topic name is of the form:

```
$SYS/Broker/brokerName/Monitoring/executionGroupName/flowName
```

The hierarchical structure allows subscribers to filter the events which they receive. One subscriber can receive events from all message flows in the broker, while another receives only the events from a single execution group.

You decide whether events participate in transactions when you configure a monitoring event source. In general:

- If you want an event to be emitted only if the message flow transaction commits, configure the event source to coordinate the events with the message flow transaction.
- If you want an event to be emitted regardless of whether the message flow transaction commits or rolls back, configure the event source to emit events out of sync point. Such events are available immediately.
- If you want a group of events to be emitted together regardless of whether the message flow transaction commits or rolls back, configure the event source to emit events in a second, independent, unit of work.

Default monitoring configuration

If monitoring is activated for a message flow, and neither monitoring properties nor a monitoring profile configurable service have been configured for the flow, the default behavior is for transaction events to be emitted from each input node of the message flow. The events contain the bit stream of the input message.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"The monitoring event" on page 6774
You can configure WebSphere Message Broker to emit a monitoring event (an XML document) when something interesting happens. Events are typically emitted to support transaction monitoring, transaction auditing, and business process monitoring. The event XML conforms to the monitoring event schema `WMBEvent.xsd`.

Monitoring scenarios

Events can be used to support transaction monitoring, transaction auditing and business process monitoring.

Transaction monitoring and auditing

The events published by WebSphere Message Broker can be written to a transaction repository, creating an audit trail of the transactions that are processed by a broker. A transaction repository can be used for monitoring, auditing and replay of transactions. Bitstream data can be included so that failed transactions can be resubmitted. You can perform the following tasks to set up transaction monitoring and auditing.

Configure events for your transactions
In most cases bitstream information is not sufficient to allow querying of the logged transactions. Key fields and other correlation data can be extracted from the message payload and placed into the `wmb:applicationData/wmb:simpleContent` or `wmb:applicationData/wmb:complexContent` element of the event. The logging application or message flow can extract these fields and log them with the message bit stream.

Subscribe to the event topic and write events to a repository
You can create a message flow, or any WebSphere MQ application, that subscribes to the event topic and writes events to a relational database. The details of the database schema depend on the requirements of your organization, for example the number of key fields and transaction IDs.

Business process monitoring

The events published by a broker can be monitored by WebSphere Business Monitor. Important fields in the message payload can be added to the events emitted by your message flows, allowing them to be monitored. You can use the following items to help you use WebSphere Business Monitor to monitor your message flows:

Message Driven bean
The events must be submitted to the CEI repository in order for WebSphere Business Monitor to monitor them. A message driven bean is supplied for this purpose. The message driven bean, which runs in

WebSphere Application Server, subscribes to the event topic and writes events that match its subscription to the CEI repository as Common Base Event events.

WebSphere Business Monitor Model
WebSphere Message Broker includes an example monitor model for use with WebSphere Business Monitor. This model demonstrates how to monitor transaction events and terminal events, including events that capture data from the input message and output message. Modify the model to match your actual events and message formats.

The following sample provides a Message Driven Bean and a WebSphere Business Monitor Model to help you use WebSphere Business Monitor to monitor events in your message flows:

- WebSphere Business Monitor

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

message flows.

Deciding how to configure monitoring events for message flows

Decide whether to use monitoring properties, or a monitoring profile configurable service, to customize the events produced by a message flow.

If you want to customize events when you are designing the message flow, use monitoring properties. If you want to customize events after a message flow has been deployed, but without redeploying, use a monitoring profile. This topic gives information about both methods.

Using monitoring properties to configure events

Using the WebSphere Message Broker Toolkit Message Flow Editor, you can configure event sources on most nodes in a message flow. A node that supports the configuration of event sources has a Monitoring tab on its Properties view; use this tab to add events and to set their properties. When you deploy the message flow in a broker archive file, the monitoring properties are included as part of the message flow.

Key facts about monitoring properties:

- Use monitoring properties when you want to configure events at message flow design time.
- Monitoring properties apply only to the message flow in question. You can share monitoring properties between message flows only by creating reusable subflows.
- Monitoring properties are deployed in a BAR file as part of the message flow.
- You use the **mqsichangeflowmonitoring** command to activate the message flow to emit monitoring events.
- You can use the **mqsichangeflowmonitoring** command to enable or disable individual event sources in a message flow.
- To change any other properties of an event, you alter the monitoring properties in the flow, then redeploy the BAR file.

To configure monitoring events using monitoring properties, see this information: "Configuring monitoring event sources using monitoring properties" on page 3327.

Tip: Use the **mqsireportflowmonitoring** command to report a list of the names of the event sources for a message flow. You can then use these event source names in a **mqsichangeflowmonitoring** command to enable or disable individual event sources from the command line.

Using a monitoring profile to configure events

Using operational commands, you can create a monitoring profile configurable service directly on the broker, and associate it with one or more message flows.

Key facts about monitoring profiles:

- Use a monitoring profile when you want to configure events for a message flow that has already been deployed and for which no events have been configured.

- Use a monitoring profile to override the monitoring properties of a message flow that has already been deployed, as an alternative to redeploying the BAR file. The monitoring profile completely replaces all monitoring properties.
- A single monitoring profile can be applied to many message flows, provided that the message flows contain the same event sources.
- Monitoring profiles are created directly on the broker using the **mqsicreateconfigurableservice** command and the **mqsichangeproperties** command. They are not deployed in a BAR file.
- You use the **mqsichangeflowmonitoring** command to associate the monitoring profile with a message flow.
- You use the **mqsichangeflowmonitoring** command to activate the message flow to emit monitoring events.
- You can use the **mqsichangeflowmonitoring** command to enable or disable individual event sources in a message flow.

To configure monitoring events using monitoring properties, see this information:

"Configuring monitoring event sources using a monitoring profile" on page 762

Tip: Use the **mqsireportflowmonitoring** command to report a list of event sources for a message flow. You can then use the names of these event source in a subsequent **mqsichangeflowmonitoring** command to enable and disable individual event sources from the command line.

Tip: Use the **mqsireportflowmonitoring** command to report the monitoring profile for a message flow. You can edit the profile, to add or change event sources, then update it using the **mqsichangeproperties** command.

Tip: Use the **mqsireportflowmonitoring** command to create the equivalent monitoring profile for a message flow for which monitoring properties are configured. You can edit the profile, then use it to create a new monitoring profile configurable service using the **mqsicreateconfigurableservice** and **mqsichangeproperties** commands. You can then associate the new profile with the original flow using the **mqsichangeflowmonitoring** command. You can use this technique to override the monitoring properties for a message flow, without having to edit the flow and redeploy the BAR file.

Configuring monitoring event sources using monitoring properties

In the Message flow Editor, use the Monitoring tab on the properties of a node to add one or more monitoring events.

Before you begin

Before you start:

Read the following topics:

- "Business-level monitoring" on page 3319
- "Monitoring basics" on page 3320

You must have a message flow that contains a node to which you want to add a monitoring event.

You can use XPath 1.0 expressions to configure a monitoring event. Some XPath expressions, listed in "XPath expressions that are not suitable for the export monitoring information option" on page 6782, are not suitable for use with the export monitoring information option ("Creating a monitor model for WebSphere Business Monitor V7" on page 3341).

Creating events

About this task

An event source is a point in a message flow from which a monitoring event can be emitted. Each event source has a set of properties that control the contents of the monitoring events that it emits.

Procedure

1. Display the properties for the node.
2. Select the Monitoring tab.
3. Click **Add**.

   The Add entry window is displayed.
4. Complete the **Event Source** field.

   The field has a drop-down list of all events that can be defined for this node. The event source information is used to populate the attributes of the `wmb:eventPointData/wmb:messageFlowData/wmb:node` element of the event. When you have selected the event source, the corresponding value for `Event Source Address` is displayed as a read-only property.

Tip: If you later decide to enable or disable events using the **mqsichangeflowmonitoring** command, you must specify a value for `Event Source Address`, not `Event Name`.

5. Complete the **Event Name** details; select either **Literal** or **Data location**.

   Every monitoring event has a name that is placed in the `wmb:eventPointData/wmb:eventIdentity/@wmb:eventName` attribute of the event. The default names are shown in the following table:

Event source	Default event name	Example
Transaction start	*nodeLabel*.TransactionStart	MQInput.TransactionStart
Transaction end	*nodeLabel*.TransactionEnd	MQInput.TransactionEnd
Transaction rollback	*nodeLabel*.TransactionRollback	MQInput.TransactionRollback
Terminal	*nodeLabel.terminal_label*.Terminal	MQInput.OutTerminal

   You can override the default in these ways:

   - By specifying an alternative literal string.
   - By specifying an XPath query; the query extracts the event name from a field in the input message. Click **Edit** to use the XPath Expression Builder.

   You cannot use monitoring properties to configure transaction events on the following nodes:

   "Collector node" on page 4333

   "Resequence node" on page 4651

   Use a monitoring profile instead; see "Configuring monitoring event sources using a monitoring profile" on page 762.

6. Optional: Complete the Event Filter section by providing an XPath expression to control whether the event is emitted. Take one of the following steps:

   - Type in the expression (for example, `$Body/StockTrade/Details/Value > 10000`); or
   - Click **Edit** to launch XPath Expression Builder.

   The expression must evaluate to true or false, and can reference fields in the message tree, or elsewhere in the message assembly. The default value is `true()`, which means that the event is always produced.

   Using this facility, you can tailor event emissions to your business requirements, by filtering out events that do not match a set of rules. This can reduce the number of events emitted, and reduce the workload on your monitoring application.

7. Optional: Complete the **Event Payload** section if the event is to contain selected data fields extracted from the message. Click **Add** to launch the Add Data Location dialog box. Take one of the following steps:

   - Type in the location (for example, `$LocalEnvironment/File/Name`); or
   - Click **Edit** to launch XPath Expression Builder.

   You can extract one or more fields from the message data and include it with the event. The fields can be simple or complex. Simple content is contained in the `wmb:applicationData/wmb:simpleContent` field of the event; complex data is contained in the `wmb:applicationData/wmb:complexContent` field.

   This facility is commonly used for communicating significant business data in a business event. If the event contains the input bit stream, this facility can also be used to extract key fields, allowing another application to provide an audit trail or to resubmit failed messages.

8. Optional: Select the **Include bitstream data in payload** field if the event is to capture message bitstream data.

   Content
   Select from `Headers`, `Body`, `All`.

   Encoding
   Select from `base64`, `HexBinary` and `CData` (the original text, without encoding).

9. Optional: Select the Correlation tab, to complete details for event correlation.
10. Complete the **Event Correlation** details; for information about correlation, see "Correlation and monitoring events" on page 6778.

Every monitoring event must contain at least one correlation attribute, and can contain up to three. If you do not specify any correlation information, the first event source in the message flow allocates a unique identifier that all later event sources in the same transaction will use.

a. Optional: Complete the **Local transaction correlator** details.

   Automatic
   The local correlator used by the most recent event for this invocation of the message flow will be used. If no local correlator exists yet, a new unique value will be generated.

   Specify location of correlator
   Enter a value, or click Edit to launch the XPath Expression Builder. The local correlator will be read from the specified location in the message tree. Ensure that the specified location contains a correlator value unique to this invocation of the message flow.

b. Optional: Complete the **Parent transaction correlator** details to extract a correlation field from the parent transaction.

   Automatic
   The parent correlator used by the most recent event for this invocation of the message flow will be used. If no parent correlator exists yet, no parent correlator will be used.

   Specify location of correlator
   Enter a value, or click Edit to launch the XPath Expression Builder. The parent correlator will be read from the specified location in the message tree. Ensure that the specified location contains a suitable value for the parent correlator.

c. Optional: Complete the **Global transaction correlator** details to extract a correlation field from a global transaction.

   Automatic
   The global correlator used by the most recent event for this invocation of the message flow will be used. If no global correlator exists yet, no global correlator will be used.

   Specify location of correlator
   Enter a value, or click Edit to launch the XPath Expression Builder. The global correlator will be read from the specified location in the message tree. Ensure that the specified location contains a suitable value for the global correlator.

11. Optional: Choose whether the emission of monitoring events by a message flow is coordinated with the message flow transaction, or is in an independent unit of work, or is not in a unit of work.

Click the Transaction tab and select the appropriate option for **Event Unit of Work**.

Message flow
The event, and all other events with this setting, are emitted only if the message flow commits its unit of work successfully.

If the transaction start event is specified to be included in the message flow unit of work, but the message processing fails and this unit of work is not published, the transaction start event will be included in an independent unit of work. This ensures that your monitoring application receives a pair of events (start and rollback), rather than receiving a rollback event in isolation.

Independent
The event is emitted in a second unit of work, independent of the main unit of work. The event, and all other events with this setting are emitted whether or not the main unit of work commits successfully.

An independent transaction can be started only if the main transaction has been either committed or rolled back. If the **Commit count** property of the flow is greater than one, ("Configurable message flow properties" on page 4020), or the **Commit by message group** property is set ("Receiving messages in a WebSphere MQ message group" on page 1554), the events targeted for the independent transaction are instead emitted out of sync point, and a message is output stating that this has been done.

None The event is emitted out of sync point (not in any unit of work.) The event is emitted when the message passes through the event source, and is available for reading immediately.

Not all these options are available on all event types. The defaults and allowed values are shown in the following table:

Event source	Allowed values	Default
Transaction start	Message flow Independent None	Message flow
Transaction end	Message flow None	Message flow
Transaction rollback	Independent None	Independent
Terminal	Message flow Independent None	Message flow

12. Click **Finish**.

    The **Events** table in the Monitoring tab of the Properties view for the node is updated with details of the event that you just added; the event is enabled.
13. Optional: Disable the event.
14. Save the message flow.

Deploying monitoring properties

Procedure

1. When you have added all events to the flow, add the message flow to the broker archive (BAR) file and deploy the BAR file.

Monitoring is inactive for the flow; deploying the BAR file does not activate it.

2. Activate monitoring for the flow by using the **mqsichangeflowmonitoring -c** command.

Updating monitoring properties

About this task

The monitoring properties for a node show all monitoring events that are defined for that node. Edit the monitoring properties of a node to do these tasks:

- Enable or disable a monitoring event.
- Add, delete, or change the monitoring events for the node.

Procedure

1. Right-click the node and select **Properties**.
2. Select the Monitoring tab.

   The monitoring events that you have previously defined are displayed.
3. Select or clear the **Enabled** check box for each event as appropriate.
   - To disable an event, clear the check box.
   - To enable an event, select the check box.
4. To add an event, click **Add**.
5. To delete an event, select the event, then click **Delete**.
6. To edit an event, select the event, then click **Edit**.

   The Add Event is displayed. For a description of options on this window, see "Creating events" on page 3327.
7. Save the message flow.

A monitoring application uses correlation attributes to identify events that belong to the same business transaction.

Configuring monitoring event sources using a monitoring profile

You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

Before you begin

Before you start:

Read the following topics:

- "Business-level monitoring" on page 3319
- "Monitoring basics" on page 3320

You must have a message flow that contains a node to which you want to add a monitoring event.

You can use XPath 1.0 expressions to configure a monitoring event.

Creating a monitoring profile

About this task

First create a monitoring profile XML file. This is a file that lists the event sources in the message flow that will emit events, and defines the properties of each event.

Procedure

Follow the guidance at "Monitoring profile" on page 6768 to create your monitoring profile XML file.

Applying a monitoring profile

About this task

When you have created a monitoring profile XML file, follow these steps to apply it.

Procedure

1. Use the **mqsicreateconfigurableservice** command to create a configurable service for the monitoring profile. In the following command example, replace *myBroker* with the name of your broker, and *myMonitoringProfile* with the name of your monitoring profile.

   ```
   mqsicreateconfigurableservice myBroker -c MonitoringProfiles
        -o myMonitoringProfile
   ```

2. Use the **mqsichangeproperties** command to associate your monitoring profile XML file with the configurable service. In the following command example, replace *myBroker* with the name of your broker, *myMonitoringProfile* with the name of your monitoring profile, and *myMonitoringProfile.xml* with the name of the monitoring profile XML file.

```
mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
     -n profileProperties -p myMonitoringProfile.xml
```

Set the `useParserNameInMonitoringPayload` property to TRUE to force the `wmb:applicationData/wmb:complexContent/wmb:elementName` attribute to hold the name of the input node parser, if present. See "MonitoringProfiles configurable service" on page 3781 for details.

```
mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
     -n useParserNameInMonitoringPayload -v TRUE
```

3. Use the **mqsichangeflowmonitoring** command to apply a monitoring profile configurable service to one or more message flows.
   - Apply a monitoring profile to a single message flow *messageflow1* in execution group *EG1*:

     ```
     mqsichangeflowmonitoring myBroker -e EG1
          -f messageflow1 -m myMonitoringProfile
     ```

   - Apply a monitoring profile to all message flows in all execution groups:

     ```
     mqsichangeflowmonitoring myBroker -g -j -m myMonitoringProfile
     ```

   Monitoring for the flow is inactive; applying the monitoring profile does not activate it.
4. Alternatively, use the broker archive editor to apply a monitoring profile configurable service to one or more message flows, by setting message flow property **Monitoring Profile Name**.
   a. In the WebSphere Message Broker Toolkit, switch to the Broker Application Development perspective.
   b. In the Broker Development view, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
   c. Click the **Manage and Configure** tab.
   d. Click the message flow on which you want to set the monitoring profile configurable service. The properties that you can configure for the message flow are displayed in the **Properties** view.
   e. In the **Monitoring Profile Name** field, enter the name of a monitoring profile.
   f. Save the BAR file.
   g. Deploy the BAR file.

   Monitoring for the flow is inactive; deploying the BAR file does not activate it.
5. Activate monitoring for the flow using the `mqsichangeflowmonitoring -c` command.
   - Activate monitoring for a single message flow *messageflow1* in execution group *EG1*:

     ```
     mqsichangeflowmonitoring myBroker -e EG1
          -f messageflow1 -c active
     ```

   - Activate monitoring for all message flows in all execution groups:

     ```
     mqsichangeflowmonitoring myBroker -g -j -c active
     ```

Updating a monitoring profile

Procedure

1. Follow the guidance at "Monitoring profile" on page 6768 to update your monitoring profile XML file.
2. Use the **mqsichangeproperties** command to update the configurable service to use the new XML file. For example:

   ```
   mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
        -n profileProperties -p myMonitoringProfile.xml
   ```

"Example XPath expressions for event filtering" on page 6781
Use numeric, string, or Boolean expressions when configuring an event source, to determine whether the event is emitted.

Activating monitoring

Use the **mqsichangeflowmonitoring** command to activate monitoring after you have configured monitoring event sources.

Before you begin

Before you start: You must have configured monitoring event sources by using either monitoring properties or a monitoring profile; see these topics:

"Configuring monitoring event sources using monitoring properties" on page 3327

"Configuring monitoring event sources using a monitoring profile" on page 762

About this task

The use of a monitoring profile configurable service overrides the monitoring properties of a message flow.

If monitoring is activated for a message flow, and neither monitoring properties nor a monitoring profile configurable service have been configured for the flow, the default behavior is for transaction events to be emitted from each input node of the message flow. The events contain the bit stream of the input message.

Activating monitoring from the command line

About this task

Use the `-c active` parameter. You can activate monitoring for all message flows in all execution groups, or specify the execution groups and message flows for which monitoring is to be activated.

Procedure

- To activate monitoring for all message flows in all execution groups on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c active -g -j
  ```

  To activate monitoring for all message flows in all execution groups on z/OS: z/OS

  ```
  F MI10BRK,cm c=active,g=yes,j=yes
  ```

- To activate monitoring for all message flows in the default execution group on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c active -e default -j
  ```

  To activate monitoring for all message flows in the default execution group on z/OS: z/OS

  ```
  F MI10BRK,cm c=active,g=default,j=yes
  ```

- To activate monitoring for the myFlow message flow in the default execution group on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c active -e default -f myFlow
  ```

  To activate monitoring for the myFlow message flow in the default execution group on z/OS: z/OS

  ```
  F MI10BRK,cm c=active,g=default,f=myFlow
  ```

Deactivating monitoring from the command line

About this task

Use the `-c inactive` parameter. You can deactivate monitoring for all message flows in all execution groups, or specify the execution groups and message flows for which monitoring is to be activated.

Procedure

- To deactivate monitoring for all message flows in all execution groups on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c inactive -g -j
  ```

To deactivate monitoring for all message flows in all execution groups on z/OS: z/OS

```
F MI10BRK,cm c=inactive,g=yes,j=yes
```

- To deactivate monitoring for all message flows in the default execution group on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c inactive -e default -j
  ```

  To deactivate monitoring for all message flows in the default execution group on z/OS: z/OS

  ```
  F MI10BRK,cm c=inactive,g=default,j=yes
  ```

- To deactivate monitoring for the myFlow message flow in the default execution group on Linux, UNIX, and Windows: Linux UNIX Windows

  ```
  mqsichangeflowmonitoring myBroker -c inactive -e default -f myFlow
  ```

  To deactivate monitoring for the myFlow message flow in the default execution group on z/OS: z/OS

  ```
  F MI10BRK,cm c=inactive,g=default,f=myFlow
  ```

Related tasks:

"Configuring monitoring event sources using monitoring properties" on page 3327
In the Message flow Editor, use the Monitoring tab on the properties of a node to add one or more monitoring events.

"Configuring monitoring event sources using a monitoring profile" on page 762
You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

Related reference:

"**mqsichangeflowmonitoring** command" on page 3738
Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

Enabling and disabling event sources

When events have been configured for a message flow and deployed to the broker, you can enable and disable individual events. You can do this from the command line, without having to redeploy the message flow, or you can do this from the Message Flow Editor, in which case you must redeploy.

Enabling and disabling events from the command line

Before you begin

Before you start: You must have previously configured events using either Message Flow Editor monitoring properties, or a monitoring profile configurable service.

Procedure

Use the **mqsichangeflowmonitoring** to enable and disable event sources. For example:

```
mqsichangeflowmonitoring WBRK_BROKER
     -e default
     -f myMessageFlow
     -s "SOAP Input1.terminal.out,MQOutput1.terminal.in"
     -i enable
```

```
mqsichangeflowmonitoring WBRK_BROKER
     -e default
     -f myMessageFlow
     -s "SOAP Input1.terminal.catch"
     -i disabled
```

You can enable or disable multiple events at once; the change of state takes place immediately.
If you configured events using monitoring properties, the change persists if the message flow is restarted, but is lost if the message flow is redeployed. To make the change permanent, you must also update the monitoring properties.

Tip: When specifying values for the -s parameter, use the **Event source address** property of the event, not the **Event name** property.

Tip: To find the list of configured event sources for a message flow, you can use the mqsireportflowmonitoring command. For example:

```
mqsireportflowmonitoring WBRK_BROKER
      –e default
      –f myMessageFlow
      –n
```

Tip: If you configured events using monitoring properties, you can see a list of the configured event sources in the Message Flow Editor:

1. Open the message flow using the Message Flow Editor.
2. Click the canvas.
3. Select the Monitoring tab in the Properties view.

The monitoring events that you have previously defined are displayed.

Enabling and disabling events from the Message Flow Editor

Before you begin

Before you start: You must have previously configured events using the Message Flow Editor monitoring properties.

About this task

Use the Message Flow Editor to enable and disable event sources.

Procedure

1. Open the message flow using the editor.
2. Click the canvas.
3. Select the Monitoring tab in the Properties view. The monitoring events that you have previously defined are displayed.
4. Select or clear the **Enabled** check box for each event as appropriate.
   - To disable an event, clear the check box.
   - To enable an event, select the check box.
   - To disable all events, click **Uncheck All**.
5. Save the message flow.
6. Rebuild and redeploy the BAR file.

Creating a monitoring model for use by WebSphere Business Monitor

Enable WebSphere Business Monitor to monitor WebSphere Message Broker events.

Before you begin

Before you start: You must have configured monitoring for a message flow; see "Deciding how to configure monitoring events for message flows" on page 3325.

About this task

IBM WebSphere Business Monitor is business activity monitoring software that provides a real-time view of your business processes and operations. It contains personalized business dashboards that calculate and display key performance indicators (KPIs) and metrics derived from business processes, business activity data, and business events from a wide range of information sources, including WebSphere Message Broker message flows. This gives you immediate insight into your business operations so that you can mitigate problems or take immediate advantage of opportunities, resulting in cost savings and increased revenues.

The following WebSphere Business Monitor sample shows you how to generate events from a message flow, create a corresponding monitor model, and use that model in WebSphere Business Monitor to view KPIs from the events:

- WebSphere Business Monitor

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The steps that you take depend on the version of WebSphere Business Monitor that you are using:

"Creating a monitor model for WebSphere Business Monitor V6.2" on page 3339

"Creating a monitor model for WebSphere Business Monitor V7" on page 3341

Related tasks:

"Generating XML Schemas" on page 2963
You can generate either a single XML Schema from a message definition file, or multiple XML Schemas from a message set.

"Business-level monitoring" on page 3319
You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

Creating a monitor model for WebSphere Business Monitor V6.2

Export monitoring information from WebSphere Message Broker to create a monitoring model for WebSphere Business Monitor V6.2

About this task

In WebSphere Message Broker

Procedure

1. If an event contains complex data extracted from a message, supply details of the structure of the data to WebSphere Business Monitor:
   a. Ensure that the complex data is modeled as a complex type in a message definition file within a message set in the WebSphere Message Broker Toolkit.
   b. In the Application Development perspective, right-click the message set folder and click **Generate XML Schemas** to create a `.zip` file of XML schemas from the definitions in the message set.
   c. Extract the file containing the XML schemas on the computer where you will be using the Monitoring Model Editor.
2. Export the `WMBEvent.xsd` file from an existing message set (or create a message set, then export it from there):
   a. In the Application Development perspective, right-click the message set and click **New** > **Message Definition File From** > **IBM Supplied Message**.
   b. In the window that is displayed, scroll down and click **Message Broker Monitoring Event**.
   c. Click **Finish**.
   d. Right-click the message set again, and click **Generate** > **XML Schemas**.
   e. In the window that is displayed, click **Export to an external directory**, then enter or browse to a directory.
   f. Click **Finish**. A compressed file containing the `WMBEvent.xsd` file is created in the directory that you specified.

   The `WMBEvent.xsd` file gives WebSphere Business Monitor details of the structure of the WebSphere Message Broker event.

What to do next

In WebSphere Business Monitor V6.2

This section outlines the steps you need to take in WebSphere Business Monitor. See the documentation for WebSphere Business Monitor for full and up-to-date details.

1. In the WebSphere Business Monitor development toolkit, create a Monitor Model.

   Import the WMBEvent.xsd schema and any schemas describing complex data that were exported from WebSphere Message Broker, then create a monitor

model. You see errors, because the model is currently empty. You also see a key, which you can rename, for example to LocalTransactionID.

2. Create WebSphere Business Monitor inbound events.

   A *monitoring context definition* is the term used by WebSphere Business Monitor to describe all the data that should be collected about an entity (such as a transaction or business process). Each runtime instance (referred to as a monitoring context instance) collects information from inbound events and stores this information in fields that represent the business measures that a monitoring context collects: metrics, counters, and stopwatches.

   You need to define an inbound event to describe each event source defined in your message flow that contains information that you want to monitor. For example, if your message flow has Transaction start, Transaction end and Transaction rollback event sources, define an inbound event for each of these event sources.

   You typically define inbound events for these three event sources because they contain information that tells WebSphere Business Monitor when the start and end of the monitoring context instance occurs. You also define inbound events to describe any event sources downstream in the flow that contain data that you want to monitor, for example in the In terminal of the MQOutput node.Creating inbound events typically involves the following actions:

   a. Define event parts within the inbound event.

      Event parts are XML Schema definition (XSD) types that provide information about the structure of part of an event. For a WebSphere Message Broker event, define event parts to describe the different parts of the event that you want to monitor data from. For a description of the event structure, see "The monitoring event" on page 6774.

      As a minimum, define an event part for the event described by type wmb:event. To monitor data about the source of the event (information about the message flow name, broker name), also define an event part for the eventPointData section described by type wmb:eventPointData. You might also want to define event parts to describe message payload data from the applicationData section of the event.

   b. Define a correlation expression.

      You typically correlate events on fields from the eventCorrelation section in the WebSphere Message Broker event. For example, you could correlate events using the localTransactionId field from the WebSphere Message Broker event.

      You must also define whether the event should create a monitoring context; create this for a Transaction start event.

   c. Optional: Define a filter condition.

      Set a filter condition. For example you might want to filter events for a specific broker, execution group, or message flow.

   d. Optional: Define the event sequence path.

      Select a field in the inbound event that can be used to set the order in which the inbound events are processed. For example, you could use creationTime from the WebSphere Message Broker event.

   e. Complete the key.

      The key uniquely identifies a monitoring context instance. You can select any value for the key; for a WebSphere Message Broker event a typical value is the localTransactionId field from the WebSphere Message Broker event.

3. Define the metrics.

Having defined inbound events you can now define your metrics. Metrics hold data from the event in a monitoring context.

You might want to define metrics that hold event source data from the eventPointData section of the WebSphere Message Broker event, for example broker name or message flow name. You can also define metrics that hold event sequencing information, for example TimeStarted and TimeEnded metrics, which hold the creationTime for Transaction start and Transaction end or Transaction rollback events.

In addition, metrics can be defined to hold application data from the WebSphere Message Broker event.

Creating a monitor model for WebSphere Business Monitor V7

Export monitoring information from WebSphere Message Broker to create a monitoring model for WebSphere Business Monitor V7

Before you begin

Before you start:

For earlier versions, see "Creating a monitor model for WebSphere Business Monitor V6.2" on page 3339.

The monitoring information needed to create a monitor model can only be exported from WebSphere Message Broker when the following conditions are met:

- The flow is not empty.
- The flow has no error markers against it in the Problems view.

Consider these points before exporting a message flow:

- WebSphere Business Monitor must be able to identify the start and end of a monitoring context. Always define transaction events (`transaction.Start`, `transaction.End`, and `transaction.Rollback`) on message flows that are monitored by WebSphere Business Monitor.
- The WebSphere Business Monitor toolkit does not support local elements with anonymous types. The export monitoring information option therefore does not generate an event part for event payload XPath queries which resolve to an element of this type. You see a warning message in the report log *flowProjectName*`_batchgen_report.txt`.
- The WebSphere Business Monitor toolkit does not support creating metrics of type `xs:anyType`. If an XPath expression in your event payload resolves to an element of type `xs:anyType`, the export monitoring information option creates an event part of this type, but you cannot create a metric of this type in the WebSphere Business Monitor toolkit. Create an event part with a supported type; see *Defining Event Parts* in the WebSphere Business Monitor information center.
- If you include unmodeled data, the export monitoring information option cannot type the data. It assigns a type of `string` to the data.
- The option to export monitoring information does not support XPath queries that contain wildcards.

Tip: If you want to separately identify `transaction.Start` and `transaction.End` events that are issued following message flow error handling, create an event source on the Failure terminal of the Input node.

About this task

Use the subsequent WebSphere Message Broker procedure to create a .zip file that contains the following monitoring information about the message flow:

All monitoring information that is defined in the message flow files.

The WMBEvent.xsd file, which is the schema for the emitted event.

All `.xsd` files in the message sets that are referenced by the selected flows.

In WebSphere Message Broker

Procedure

1. In the WebSphere Message Broker Toolkit, right-click the message flow or message flow project, and click **Export**. The Export wizard starts.
2. Click **Business Monitoring** > **Application monitoring information**, then click **Next**.
3. Select the flows from which you want to export monitoring information, and specify a file name.
4. Optional: Specify that an existing file should be overwritten without warning.
5. Optional: If working set filtering is enabled, select the **Apply working set filtering to artifact selection(s) on this page** check box.
6. Click **Finish**. A .zip file that contains the application monitoring information is saved.

   A report of the export is written to file *flowProjectName*`_batchgen.report.txt` in the log directory of the message flow project.

What to do next

In WebSphere Business Monitor V7

In the WebSphere Business Monitor development toolkit, import the `.zip` file that you exported from WebSphere Message Broker. The Generate Monitor Model wizard starts. As you work through the wizard, you can select some or all of the following templates, depending on the event sources in your message flow:

- **Average Transaction Duration** This template is available if you have created `transaction.Start`, `transaction.End`, and `transaction.Rollback` event sources. If you select this template, a metric and stopwatch are created for you in the monitor model showing the Average Transaction Duration, and a key performance indicator (KPI) is created using the data from this stopwatch.
- **Number of Failed Transactions** This template is available if you have created `transaction.Rollback` event sources. If you select this template, metrics are created for you in the monitor model showing the number of failed transactions and the failed transaction time (this has a default value of 1 January 9999 01:00:00.) A measure and dimension are also created for use in creating multidimensional reports. See *Defining Dimensions* in the WebSphere Business Monitor information center.
- **Message Flow Correlation** This template provides information about the broker (such as broker name, execution group name, parentTransactionID, globalTransactionID). You can display this information in a Business Space Dashboard with other metrics and key performance indicators. Because these metrics are used in the correlation expression for the inbound events defined, select this template only if the events for a specified monitoring context are from the same execution group.

See the documentation for WebSphere Business Monitor for full and up-to-date details.

"XPath expressions that are not suitable for the export monitoring information option" on page 6782
Some XPath expressions produce a warning on the Monitoring tab.

Reporting monitoring settings

Use the **mqsireportflowmonitoring** command to report monitoring settings for a flow.

About this task

The following examples show how to report monitoring options for a broker called BROKER1, execution group default, and message flow PurchaseOrder.

Report configured events for a message flow

Procedure

Issue the following command on Linux, Unix, or Windows:

Linux UNIX Windows

```
mqsireportflowmonitoring BROKER1 -e default -f PurchaseOrder -n
```

Issue the following command on z/OS: z/OS

```
F MI10BRK,rm BROKER1,e='default',f='PurchaseOrder,n='yes''
```

Report all possible events for a message flow

Procedure

Issue the following command on Linux, Unix, or Windows:

Linux UNIX Windows

```
mqsireportflowmonitoring BROKER1 -e default -f PurchaseOrder -a
```

Issue the following command on z/OS: z/OS

```
F MI10BRK,rm e='default',f='PurchaseOrder,a='yes'
```

Report specified events for a message flow

Procedure

Issue the following command on Linux, Unix, or Windows:

Linux UNIX Windows

```
mqsireportflowmonitoring BROKER1 -e default -f PurchaseOrder
     -s "MQInput1.transaction.Start,MQOutput1.terminal.catch"
```

Issue the following command on z/OS: z/OS

```
F MI10BRK,rm e='default',f='PurchaseOrder',
     s="MQInput1.transaction.Start,MQOutput1.terminal.catch"
```

Tip: When specifying values for the -s parameter, use the **Event source address** property of the event, not the **Event name** property.

Export a message flow's monitoring profile

About this task

Use the following command to export a profile to file `myMonProf.xml`

Procedure

Issue the following command on Linux, Unix, or Windows:

Linux UNIX Windows

```
mqsireportflowmonitoring BROKER1 -e default -f PurchaseOrder -x -p myMonProf.xml
```

Issue the following command on z/OS: z/OS

```
F MI10BRK,rm e='default',f='PurchaseOrder',x='yes',p='myMonProf.xml'
```

If monitoring for a message flow is configured using monitoring properties, rather than a monitoring profile configurable service, the command creates and returns the equivalent monitoring profile XML file.

Tip: This is an alternative to using an XML editor to create a monitoring profile XML file.

Chapter 13. Troubleshooting and support

If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

About this task

This section contains information about the various techniques that you can use to diagnose problems with WebSphere Message Broker.

Procedure

- "Making initial checks" on page 3347
- "Dealing with problems" on page 3363
- "Using logs" on page 3526
- "Using trace" on page 3533
- "Using dumps and abend files" on page 3558
- "Recovering after failure" on page 3574
- "Contacting your IBM Support Center" on page 3563

What to do next

You can also read the general troubleshooting guidance in the following topics:

- "Troubleshooting overview"
- "Searching knowledge bases" on page 3569
- "Getting product fixes" on page 3570
- "Contacting IBM Software Support" on page 3571
- "IBM Support Assistant Data Collector" on page 3565

If a WebSphere Message Broker component or command has returned an error, and you want further information about a message written to the screen or the log, you can browse for details of the message in Diagnostic messages; the lists of messages grouped in numeric order.

For information that is specific to debugging message flow applications, see Chapter 10, "Testing and debugging message flow applications," on page 3143.

"Troubleshooting" on page 6864
Use the reference information in this section to help you diagnose errors in WebSphere Message Broker.

Troubleshooting overview

Troubleshooting is the process of finding and eliminating the cause of a problem. Whenever you have a problem with your IBM software, the troubleshooting process begins as soon as you ask yourself "what happened?"

A basic troubleshooting strategy at a high level involves:

1. "Recording the symptoms of the problem" on page 3346

2. “Re-creating the problem”
3. “Eliminating possible causes”

Recording the symptoms of the problem

Depending on the type of problem that you have, whether it be with your application, your server, or your tools, you might receive a message that indicates that something is wrong. Always record the error message that you see. As simple as this sounds, error messages sometimes contain codes that might make more sense as you investigate your problem further. You might also receive multiple error messages that look similar but have subtle differences. By recording the details of each one, you can learn more about where your problem exists.

Sources of error messages:

- Problems view
- Local error log
- Eclipse log
- User trace
- Service trace
- Error dialog boxes
- **mqsiexplain** command

Re-creating the problem

Think back to what steps you were doing that led to the problem. Try those steps again to see if you can easily re-create the problem. If you have a consistently repeatable test case, it is easier to determine what solutions are necessary.

- How did you first notice the problem?
- Did you do anything different that made you notice the problem?
- Is the process that is causing the problem a new procedure, or has it worked successfully before?
- If this process worked before, what has changed? (The change can refer to any type of change that is made to the system, ranging from adding new hardware or software, to reconfiguring existing software.)
- What was the first symptom of the problem that you witnessed? Were there other symptoms occurring around the same time?
- Does the same problem occur elsewhere? Is only one machine experiencing the problem or are multiple machines experiencing the same problem?
- What messages are being generated that could indicate what the problem is?

You can find more information about these types of question in “Making initial checks” on page 3347.

Eliminating possible causes

Narrow the scope of your problem by eliminating components that are not causing the problem. By using a process of elimination, you can simplify your problem and avoid wasting time in areas that are not responsible. Consult the information in this product and other available resources to help you with your elimination process.

- Has anyone else experienced this problem? See: “Searching knowledge bases” on page 3569.
- Is there a fix you can download? See: “Getting product fixes” on page 3570.

Making initial checks

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

About this task

This section contains a list of questions to consider. As you go through the list, make a note of anything that might be relevant to the problem. Even if your observations do not suggest a cause straight away, they might be useful later if you have to carry out a systematic problem determination exercise.

Procedure

- "Has WebSphere Message Broker run successfully before?"
- "Did you log off Windows while WebSphere Message Broker components were active?" on page 3349
- "Are the Linux and UNIX environment variables set correctly?" on page 3350
- "Are there any error messages or return codes that explain the problem?" on page 3350
- "Can you reproduce the problem?" on page 3352
- "Has the message flow run successfully before?" on page 3353
- "Have you made any changes since the last successful run?" on page 3355

Has WebSphere Message Broker run successfully before?

If you have successfully run a WebSphere Message Broker component, determine whether your problem is caused by incorrect installation and setup, or a different cause. If it has *not* run successfully before, work through the information to determine what is preventing successful operation.

About this task

Complete the following steps:

Procedure

1. **Check your setup**

   WebSphere Message Broker might not be set up correctly.

   Linux UNIX On Linux and UNIX operating systems, check that you have set up the command environment correctly; see "Setting up a command environment" on page 213 for more information.

2. **Verify the installation**

   Check "Verifying your WebSphere Message Broker installation" on page 290 for information about how you can verify a basic configuration on your system. This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or

the WebSphere Message Broker Explorer. On Linux on x86 and Windows, you can use the Default Configuration wizard and the Samples Preparation wizard to help you with basic configuration and verification.

For more detailed configuration information, refer to Chapter 7, “Configuring brokers for test and production environments,” on page 579.

Related tasks:

Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

Did you log off Windows while WebSphere Message Broker components were active?

How to avoid problems caused by logging off while components are active.

About this task

Windows On Windows, logging off when a WebSphere Message Broker component (a broker) is active can cause a problem.

You might see messages, including BIP2070, BIP2642, BIP1102, and BIP1103, in the Windows Event log.

When you log off, any queue manager that supports the WebSphere Message Broker component is stopped unless it is defined to run as a Windows service. The component runs Windows services and remains active, but it finds that the queue manager and queue manager objects that are associated with it are no longer available.

Procedure

To avoid this problem, set the queue manager that is used by the broker to run as a Windows service, so that logging off Windows from does not cause this problem.

After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

Related reference:

"Environment variables after installation" on page 3642
On distributed systems, ensure that your environment is set up correctly.

Are there any error messages or return codes that explain the problem?

You can find details of error messages and return codes in several places.

Procedure

- **BIP messages and reason codes**

WebSphere Message Broker error messages have the prefix BIP. If you receive any messages with this prefix (for example, in the UNIX, Linux, or z/OS syslog), you can search for them in the information center for an explanation.You can also view the full content of a BIP message by using the **mqsiexplain** command. For more information, see "**mqsiexplain** command" on page 3879.

Windows In the Windows Event log, references to BIP messages are identified by the source name "WebSphere Broker v6000", where v6000 can be replaced by a number representing the exact service level of your installation, for example 6001.

WebSphere Message Broker messages that have a mixture of identifiers such as BIPmsgs, BIPv700, BIPv610, BIPv500, WMQIv210, MQSIv202, and MQSIv201 indicate a mixed installation, which does not work properly.

- **Other messages**

  For messages with a different prefix, such as AMQ or CSQ for WebSphere MQ, or SQL for DB2, see the appropriate messages and codes documentation for a suggested course of action to help resolve the problem.

  Messages that are associated with the startup of WebSphere Message Broker, or were issued while the system was running before the error occurred, might indicate a system problem that prevented your application from running successfully.

  A large or complex WebSphere Message Broker broker environment might require some additional configuration of the environment beyond what is recommended in "Installing complementary products" on page 300. The need for such configuration changes is typically indicated by warning or error messages that are logged by the various components, including WebSphere MQ, the databases, and the operating system. These messages are normally accompanied by a suggested user response.

Can you see all of your files and folders?

How to show all files in Windows Explorer:

About this task

If you are using Windows Explorer to view your files and you cannot see all of your files and folders, such as the broker workpath directory, this is because

Windows Explorer, by default, hides some files and folders.

Procedure

1. Click **Tools** > **Folder options**. The Folder Options dialog box opens.
2. Click the **View** tab and select **Show hidden files and folders**.

Related tasks:

Chapter 13, "Troubleshooting and support," on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

"Making initial checks" on page 3347
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

"Changing the location of the work path" on page 1011
The work path directory is the location where a component stores internal data, such as installation logs, component details, and trace output. The shared-classes directory is also located in the work path directory and is used for deployed Java code. If the work path directory does not have enough capacity, redirect the directory to another file system that has enough capacity.

Can you reproduce the problem?

If you can reproduce the problem, consider the conditions under which you can do so.

Procedure

- **Is the problem caused by a particular message flow?** If so, use the debugging facility of the WebSphere Message Broker Toolkit and user tracing to identify the problem.
- **Is the problem caused by a command?** On distributed operating systems, you issue commands at the system command line.

  z/OS On z/OS, you can issue commands from the console, the syslog, or by submitting a batch job. You enter customization commands from an OMVS session. Console commands that you enter from the console or syslog might be converted to uppercase, depending on the system configuration. This conversion can cause some commands, such as **mqsichangetrace**, to fail, especially if these commands contain parameters that must be lowercase. An error message indicating that the execution group is not available might be caused by the execution group name being in the wrong case. The same thing can happen on message flows.
- **Does a problem command work if it is entered by another user ID?**

  If the command works when it is entered by another user ID, check the environment of each user. Paths, especially shared library paths, might be different. On Windows, UNIX systems, and Linux verify that all users have set up their command environment correctly; refer to sample profile for more information.

  Windows On Windows, the environment for the broker is determined by the system settings, not by a particular user's variables. However, the user's variables affect non-broker commands.

UNIX On LinuxUNIX systems, only the service ID that is specified when the broker was created can start a broker.

Windows On Windows, any authorized user can start a broker.

Related concepts:

"Flow debugger overview" on page 3158
Use the flow debugger in the WebSphere Message Broker Toolkit to track messages through your message flows.

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

Has the message flow run successfully before?

Sometimes a problem appears in a message flow that has previously run successfully.

About this task

To identify the cause of the problem, answer the following questions:

Procedure

- **Have you made any changes to the message flow since it last ran successfully?**

  If so, it is likely that the error exists somewhere in the new or modified part of the flow. Examine the changes and see if you can find an obvious reason for the problem.

- **Have you used all the functions of the message flow before?**

  Did the problem occur when you used part of the message flow that had never been invoked before? If so, it is likely that the error exists in that part. Try to find out what the message flow was doing when it failed by using user tracing, trace nodes, and the WebSphere Message Broker Toolkit debugger function.

  If you have run a message flow successfully on many previous occasions, check the current queue status and the files that were being processed when the error occurred. It is possible that they contain some unusual data value that invokes a rarely-used path in the message flow.
- **Does the message flow check all return codes?**

  Has your system been changed, perhaps in a minor way, but your message flow does not check the return codes it receives as a result of the change? For example:

  – Does your message flow assume that the queues that it accesses can be shared? If a queue has been redefined as exclusive, can your message flow deal with return codes indicating that it can no longer access that queue?

  – Have any security profiles been changed? A message flow could fail because of a security violation.
- **Does the message flow expect particular message formats?**

  If a message with an unexpected message format has been put onto a queue (for example, a message from a queue manager on a different operating system) it might require data conversion or a different form of processing. Also, check whether you have changed any of the message formats that are used.
- **Does the message flow run on other WebSphere Message Broker systems?**

  Is there something different about the way that your system is set up that is causing the problem? For example, have the queues been defined with the same maximum message length or priority? Are there differences in the databases used, or their setup?
- **Are you using any user-defined extensions?**

  There might be translation or compilation problems with loadable implementation library (LIL) files. Before you look at the code, examine the output from the translator, the compiler or assembler, and the linkage editor, to see if any errors have been reported. Fix any errors to make the user-defined extension work.

  If the documentation shows that each of these steps was completed without error, consider the coding logic of the message flow, message set, or user-defined extension. Do the symptoms of the problem indicate which function is failing and, therefore, which piece of code is in error? See “User-defined extensions overview” on page 2971 for more information.
- **Can you see errors from WebSphere Message Broker or external resources, such as databases?**

  Your message flow might be losing errors because of incorrect use of the failure terminals on built-in nodes. If you use the failure terminals, make sure that you handle errors adequately. See “Handling errors in message flows” on page 2823 for more information about failure terminals.

Related concepts:

“Trace” on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your

problem.

If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

"Making initial checks" on page 3347
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

"Resolving problems when developing message flows" on page 3395
Use the advice given here to help you to resolve common problems that can arise when developing message flows.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

Related reference:

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

Have you made any changes since the last successful run?

Have you changed WebSphere Message Broker, any related software, or any hardware?

About this task

When you are considering changes that might have been made recently, think not only about WebSphere Message Broker, but also about the other programs with which it interfaces, the hardware, device drivers, and any new applications.

Procedure

- **Have you changed your initialization procedure?**

  On z/OS, have you changed any data sets or library definitions? Has the operating system been initialized with different parameters? Check for error messages generated during initialization.

- **Has the profile of the user who is running the commands on Linux or UNIX systems been changed?**

  If so, this might mean that the user no longer has access to the required objects and commands.

- **Has any of the software on your system been upgraded to a later release?**

  Check that the upgrade completed successfully, and whether the new software is compatible with WebSphere Message Broker (check the product readme.html file).

- **Do your message flows deal with the errors and return codes that they might get as a result of any changes that you have made?**

Check that your message flow can handle all possible error situations.

The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

Is there a problem with descriptive text for a command?

On Linux and UNIX systems, be careful when including special characters (backslash (\) and double quotation mark (") characters) in descriptive text for some commands.

About this task

If you use either of these characters in descriptive text, precede them with the escape character backslash (\) ; that is, enter \\ or \" if you want \ or " in your text.

Is there a problem with a database?

If you have database problems, complete a set of initial checks to identify errors.

Procedure

- Check that the database is started.
- Check that you have correctly completed ODBC configuration:

– Linux UNIX On Linux and UNIX systems, check that you have created a copy of the sample ODBC configuration file (`odbc.ini`), and have modified them for your environment, and that you have not added any extra unsupported parameters.

– Windows On Windows systems, click **Start** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)** to configure the connections you require.

Detailed instructions for setting up ODBC connections on distributed systems are provided in "Enabling ODBC connections to the databases" on page 668.

- Use the "**mqsicvp** command" on page 3857 to help you with ODBC database diagnostics.
- Check that you have correctly completed JDBC configuration. Detailed instructions for setting up JDBC connections are provided in "Enabling JDBC connections to the databases" on page 683.
- Check the number of database connections that are in use on DB2 for AIX. If you use local mode connections, a maximum of 10 is supported.
- If messages that indicate that `imbdfdb2v6.lil` failed to load, check that you have installed a supported database. Details of database managers and versions are given in "Supported databases" on page 3591.

Use the **mqsicvp** command to perform verification tests on a broker, or to verify ODBC connections.

Is there a problem with the network?

WebSphere Message Broker uses WebSphere MQ for inter-component communication. If components are on separate queue managers, they are connected by message channels.

About this task

There can be communication problems between any of these:

Procedure

- Brokers
- The WebSphere Message Broker Explorer
- The WebSphere Message Broker Toolkit

What to do next

If any two components are on different queue managers, make sure that the channels between them are working. Use the WebSphere MQ **display chstatus** command to see if messages are flowing.

Use the **ping** command to check that the remote computers are connected to the network, or if you suspect that the problem might be with the network itself. For example, use the command **ping** *brokername*, where *brokername* is a computer name. If you get a reply, the computer is connected. If you don't get a reply, ask your network administrator to investigate the problem. Further evidence of network problems might be messages building up on the transmission queues.

“Securing WebSphere MQ resources” on page 1559
Secure the WebSphere MQ resources that your broker configuration requires.

Have you recently changed a password?

Check that you have updated passwords correctly.

About this task

If you have changed the operating system password for one of the following user IDs, the broker or the deployed message flows might have access problems:

- The ID that you have specified for the broker's **serviceUserId** on Windows
- The ID that you have specified for access to a database

If these problems occur, complete one or more of the following steps:

Procedure

- Change the properties of the broker to reflect the password change. Use the **mqsichangebroker** command to change the appropriate parameters.
- Run the **mqsisetdbparms** command to redefine the correct values for the user ID and password.
- Ensure that your passwords do not contain reserved keywords. For example, "IBM" is a reserved keyword in DB2.

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Have you applied any service updates?

Check what service updates you have applied to your software.

About this task

If you have applied an APAR or a PTF to WebSphere MQ for z/OS, or a fix pack or interim fix has been applied to a distributed operating system, check that no error message was produced. If the installation was successful, check with the IBM Support Center for any known error with the service update.

Procedure

- If a service update has been applied to any other product, consider the effect that it might have on WebSphere Message Broker.

- Ensure that you have followed any instructions in the service update that affect your system. For example, you might need to redefine a resource, or stop and restart a component.
- If you are not sure whether a service update has been applied to your system, search for and view the release notes stored in the product installation directory. These notes include the service level and details of the maintenance that you have applied.

Do you have a component that is running slowly?

If a particular component, or the system in general, is running slowly, you can take some actions to improve the performance.

About this task

Consider the following actions:

Procedure

- Check whether tracing is on. You might have started WebSphere Message Broker user tracing or service tracing, ODBC tracing, WebSphere MQ tracing, or native database tracing. If one or more of these traces are active, turn them off.
- Clear out all old abend files from your errors directory. If you do not clear the directory of unwanted files, you might find that your system performance degrades because significant space is used up.
- On Windows, use the workpath **-w** parameter of the **mqsicreatebroker** command to create the errors directory in a hard disk partition that does not contain WebSphere Message Broker or Windows.
- Increase your system memory.

Additional checks for z/OS users

Problem determination for z/OS users.

About this task

On WebSphere Message Broker for z/OS, you might find that:

- The console has unexpected messages; look for an explanation by searching for the message number in the information center, or referring to other relevant messages and codes documentation.
- RRS is not started; issue the command **D A,RRS**.
- The queue manager is not available; issue the WebSphere MQ command **DISPLAY THREAD(*)**.
- DB2 is not working; issue the DB2 command **DISPLAY THREAD**.

The cause of your problem on z/OS could be in any of the following areas. Check each of these, starting with whichever seems the most likely, based on the nature of your problem.

Procedure

- The queue manager address space
- A queue manager in your queue-sharing group
- The channel initiator address space
- Batch or TSO address space
- The z/OS system (including ARM, RRS, or the Coupling Facility)
- The network (including APPC or TCP/IP)
- Another system, for example a queue manager on another operating system or a WebSphere MQ client
- The external security manager product, for example RACF or ACF2
- DB2

What to do next

Understanding interactions between the runtime components

There are two runtime components: the broker and the execution group. These components communicate with each other by exchanging command requests inside WebSphere MQ messages to perform actions, such as deploying a message flow.

After completion of the command request, responses are sent back to the originating component, indicating whether the request was successful.

On WebSphere Message Broker for z/OS, you see extra information messages issued by z/OS runtime components that allow you and IBM Service personnel to determine the interactions between the various runtime components, including the Configuration Manager, broker and execution group.

When the broker receives command requests the broker issues a message that identifies the command request. When this request completes, a message is issued that indicates whether the command is successful. Each command request that the broker receives results in at least one matching command request being sent to an execution group, and a corresponding message being issued. Every response from an execution group that results from these command requests result in a message being issued. These messages can be turned on and off and are to be used by the IBM Service team.

When an execution group receives command requests from the broker, the execution group issues information messages that identify the command request. For actions that are contained within a command request, an information message is issued that identifies the action to be performed and the resource upon which the action is to take effect. When the request completes, the execution group issues a message that indicates that the message has been processed.

Loading IBM and user-defined nodes and parsers

When an execution group starts, it loads all available IBM and user-defined nodes and parsers. For each library that is loaded, two messages are issued. One is issued before the library is loaded and one is issued after the library has been loaded.

If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

Resolving problems when running commands

Use the advice given here to help you to resolve common problems that can arise when you run commands.

Backing up or restoring the broker returns error BIP1253 or BIP1262

Procedure

- **Scenario:** An error message is generated when you back up or restore a broker:
  - The following message is returned when you run the **mqsibackupbroker** command:

    `BIP1253E Failed to backup the broker 'broker_name' (error 'error_code')`
  - The following message is returned when you run the **mqsirestorebroker** command:

    `BIP1262E Could not delete the existing configuration of broker 'broker_name'.`
- **Explanation:** Both backup and restore commands require read/write access to the files that contain broker configuration data. Access has failed and the command cannot complete its operation successfully.
- **Solution:** Typically, you might see one of these errors if you are running the backup or restore command against an active broker, and a conflict of access has occurred. If your broker is active, use the **mqsistop** command to stop the broker, and try the operation again.

  You might also see one of these errors if the directory to which the command is writing, or from which it is reading, is temporarily inaccessible because of communications or authorization problems. Check that your user ID has access to the directory that you specified in the command.

ReportEvent() error message is issued on Windows when you attempt to run a command

Procedure

- **Scenario:** A ReportEvent () message is generated whenever you attempt to run any `mqsi*` command, The ReportEvent () message is followed by the result of the command itself.
- **Explanation:** The Windows Application Log has become full.
- **Solution:** Clear the Windows Application Log from the Event Viewer.

You want to run a command that uses SSL to administer a remote broker over a secured channel.

Procedure

- **Scenario:** You want to run an `mqsi*` command using SSL to administer a remote broker over a secured channel. Note, that you can do this only for `mqsi*` commands that have the -n `.broker` option.
- **Solution:** In order to connect to a broker using SSL, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. For example:

  ```
  export IBM_JAVA_OPTIONS=-Djavax.net.ssl.keyStorePassword=MYKEYSTOREPASSWORD
    -Djavax.net.ssl.trustStorePassword=MYTRUSTSTOREPASSWORD
  ```

  In the same environment, you must then run the command using the -n option to specify a `.broker` file that describes the connection you want to establish.

  You can export `.broker` files by using the export option in the WebSphere Message Broker Explorer. To do this, right-click on the secured broker you want to export a `.broker` file for, and select **Export *.broker**.

A time-out error is issued when you attempt to run a command on AIX when Stack Execution Disable (SED) is enabled

Procedure

- **Scenario:** You want to run an `mqsi*` command on AIX with Stack Execution Disable enabled, but the command times out even if the **-w** option is set to 360.
- **Explanation:** `mqsi*` commands attempt to create a JVM with Java Native Interface (JNI) calls. Because of Stack Execution Disable, the JVM creation fails. For more information about Stack Execution Disable, see AIX Stack Execution Disable.
- **Solution:** Use the **sedmgr** command to create exemption records from Stack Execution Disable. For example, for **mqsilist**:

  ```
  sedmgr c exempt /opt/mqsi/7.0/bin/mqsilist
  ```

  The following commands might be affected by this issue:

  - **biphttplistener**
  - **bipbroker**
  - **bipservice**
  - **mqsideploy**
  - **mqsilist**
  - **mqsimode**
  - **mqsireloadsecurity**
  - **mqsireportresourcestats**
  - **mqsiwebuseradmin**

Use the **mqsirestorebroker** command to restore the broker configuration from a backup file.

Resolving problems when running samples

Use the advice given here to help you to resolve common problems that can arise when you run or remove samples.

About this task

Use the following instructions to diagnose the problem.

1. Use WebSphere MQ Explorer to determine which queue the input message is on:
   a. Start WebSphere MQ Explorer.
   b. Expand the folders to display the broker queue manager, MB7QMGR.
   c. Click the Queues folder in the queue manager to display its queues.
   d. Check the Current depth column to identify the queue that is holding the input message. If several messages are stored on one queue, right-click the queue, then click **Browse Messages** to determine if the message that you are interested in is on the queue.
2. Use the following table to identify the problem, and a suggested solution to overcome it. If the sample that you are running does not use a database, ignore the database-related problems listed in the table.
3. If the table did not help you solve the problem, return to the WebSphere Message Broker Toolkit and check the Problems view for error messages. Use this information to solve the problem.
4. If you created the sample yourself, you must check that all the objects in the sample have been named and configured correctly.

Problem	Reason	Suggested solution
The input message stays on the IN queue.	The broker, the queue manager, the listener, or the message flow itself has stopped.	Check that all the components are running and that the listener for the queue manager is listening on the port for the queue manager. Start any components that are not running.
	An unidentifiable message already on the IN queue cannot be processed by the message flow.	In WebSphere MQ Explorer, right-click the IN queue, then click **All tasks** > **Clear Messages**.
The input message goes to the FAIL queue.	The MQInput node cannot identify which parser it must use to parse the message.	If you are using the Enqueue facility in the workbench or the RfhUtil tool that is supplied in SupportPac IH03, you must type all the necessary message header information in the fields in the tool. If you are using the `mqsiput.exe` tool, you must add the header information to the message file itself.

Problem	Reason	Suggested solution
The input message goes to the SYSTEM.DEAD.LETTER.QUEUE	The queue on which the input message was supposed to be put does not exist.	Ensure that you have created all the queues required for the sample.
You cannot find the input message on any queue.	You have not refreshed the display in WebSphere MQ Explorer, or you have refreshed only some of the queues.	To refresh all the queues in WebSphere MQ Explorer, right-click the Queues folder, then click **Refresh**. All the queues in the folder are refreshed.
	The input message was passed to a terminal that was not connected to another node, and the message was discarded.	Ensure that all the nodes are connected to each other as required by the sample.

When using a DB2 database, the input message goes to the FAIL queue or the Event Log contains a message saying that the database was not found, or both.	DB2 is not running.	In a DB2 Command Window, enter the following command:
		`db2 start`
		
		If DB2 is already running, you receive the following message:
		`The database manager is already active.`

	The message flow is trying to access a database table that is not in the default schema. The name of the default schema is determined by, and is the same as, the user name that is used to access the database. If the table is not in the default schema, and no other schema is specified in the ESQL for the message flow, the message flow looks for the table in the default schema.	In a DB2 Command Window, enter the following commands:
		`DB2 "CONNECT TO database user` *`username`*`"`
		`DB2 "CREATE VIEW` *`tablename`*
		`  AS SELECT * FROM` *`tableschema.tablename`*`"`
		
		where:
		• *username* is the user name of the broker
		• *tableschema* is the schema that contains the table that the message flow is accessing
		• *tablename* is the table that the message flow is accessing

You receive the following error messages when you try to remove a DB2 database on Windows:
 	
`BIP9830I: Deleting the DB2 Database` *`Your_database_name`*`.`
 	
`BIP9835E: The DB2 batch command failed with the error code SQLSTATE=57019. The database could not be created/deleted. The error code SQLSTATE=57019 was returned from the DB2 batch command.`
	If you use the DB2 Control Center to perform a query, a connection is opened to the database. This connection stays open until the DB2 Control Center is closed, when the connection is ended.	Close the DB2 Control Center application. To try to remove the sample again, click **Yes**.

Problem	Reason	Suggested solution
You run a web services sample by using the prebuilt Test Client scenario and it hangs, then times out.	The problem occurs when you have a SOAPInput node that is being called by a SOAPRequest node. The default port that web services use is 7800, and the SOAPRequest nodes are set up to use this port. However, if this port is already in use, for example, by another sample, the port number is automatically incremented by one. Therefore, the default port must also be changed to match.	Issue the following **mqsireportproperties** command on one line, to check which port your provider execution group is using: `mqsireportproperties MB7BROKER -e sampleExecutionGroup -o HTTPConnector -n port` where *sampleExecutionGroup* is the appropriate execution group for the sample that is being run. To verify that the port that the SOAPRequest node is using is the correct port to call the provider flow, change the port of the SOAPRequest nodes to the port that the provider execution group is using by completing the following steps: 1. Open the message flow located in the message set project. 2. (Perform this step for all of your SOAPRequest nodes). Open the **HTTP Transport** tab in the Properties view. If the port is not correct, change the port in the `Web service URL` property to the correct port for your web services provider or TCP/IP Monitor. 3. Save the message flow. 4. Rebuild and redeploy the broker archive (BAR) file. If you have set up a TCP/IP Monitor, you have already checked which port the web services provider is using, but you must still configure the consumer to send the messages to your TCP/IP Monitor, then rebuild and redeploy the BAR file. Alternatively, you can remove one of the samples that is using the same port, so that only one sample is deployed at a time.
In some samples, the format of the XML output in the Test Client might be displayed in a different format to the format that is shown in the documentation.	In all cases the output data is identical, it is the format that is different.	You can change the format of the output by selecting either **View as Source** or **View as XML Structure** from the menu in the Test Client.

Resolving problems when creating resources

Use the advice given here to help you to resolve common problems that can occur when you create resources.

About this task

Look for the problem that you have encountered, and follow the guidance provided to recover from the error.

Problems when creating a broker:

- “Message BIP8081 is issued when creating a broker”
- “You cannot create files when creating a broker on AIX”
- “The JCL BIPGEN fails when you create a component on z/OS” on page 3370
- “Your DataFlowEngine ends with an abend when you create a broker on HP-UX using Oracle” on page 3370

Problems when creating other resources:

- “Error message BIP2624 is issued when creating an execution group” on page 3370
- “The Default Configuration wizard fails with invalid argument specified” on page 3371

Message BIP8081 is issued when creating a broker

Procedure

- **Scenario:** Message BIP8081E is displayed when you are creating a broker, the inserted message does not format correctly, and the broker is not created.
- **Explanation:** This problem occurs because you are not a member of the correct group.
- **Solution:** Read the explanation of message BIP8081, and ask your WebSphere Message Broker administrator to give your user ID access to the mqbrkrs group.

You cannot create files when creating a broker on AIX

Procedure

- **Scenario:** When you run the **mqsicreatebroker** command on WebSphere Message Broker for AIX, the following message is displayed:

  ```
  BIP8135E Unable to create files. Operating System return code 1
  ```

- **Explanation:** The user ID that you create for WebSphere Message Broker testing must have a primary group of mqbrkrs. The following example shows an AIX SMIT panel listing the **Change / Show Characteristics of a User**:

```
                Change / Show Characteristics of a User

Type or select values in entry fields.
Press Enter AFTER making all desired changes.
[TOP]                                [Entry Fields]
* User NAME                          peterc
  User ID                            [202]                    #
  ADMINISTRATIVE USER?               false                    +
  Primary GROUP                      [mqbrkrs]                +
  Group SET                          [mqbrkrs,mqm,system,sys> +
```

The JCL BIPGEN fails when you create a component on z/OS

Procedure

- **Scenario:** The BIPGEN job fails when you are copying the broker profile BIPBPROF from the PDSE to the file system.
- **Explanation:** The file system might lack the required space, the component profile might not exist, or you might not have the appropriate authority.
- **Solution:** Make the following checks:
  - The file system has sufficient space. You can check how much space is used and how much is free in a file system using the OMVS command **df -P /pathname**. 100 MB is 3 276 800 512 byte sectors.
  - The profile file exists in the PDSE.
  - Your user ID has the appropriate authority to write to the file system.

Your DataFlowEngine ends with an abend when you create a broker on HP-UX using Oracle

Procedure

- **Scenario:** Your message flow (DataFlowEngine or DFE) ends with an abend when you create a broker on HP-UX using Oracle.
- **Explanation:** This problem occurs when you have installed DB2and Oracle on the same computer.
- **Solution:** Remove the DB2 LIL files that are used by WebSphere Message Broker. For example, issue the following commands:

```
mv install dir/lib/imbdfdb2v6.lil install dir/lib/imbdfdb2v6.blank
mv install dir/lib/imbdfdb2.lil install dir/lib/imbdfdb2.blank
```

Error message BIP2624 is issued when creating an execution group

Procedure

- **Scenario:** When you create an execution group, you get several BIP2624 messages (MQRC=2012 (MQRC_ENVIRONMENT_ERROR)), and no WebSphere MQ messages are processed.
- **Explanation:** You have created the broker to run as a WebSphere MQ trusted application (that is, the broker runs in the same process as the WebSphere MQ queue manager), but the user ID that you specified does not have the required authority.
- **Solution:** If you request the trusted application option on the **mqsicreatebroker** command by specifying the **-t** parameter, perform the appropriate steps for your operating system:

  Windows **Windows**

  Using the **-i** parameter on the **mqsicreatebroker** command, specify a service user ID that is a member of WebSphere MQ group mqm.

Linux UNIX **Linux and UNIX systems**

Specify the user ID mqm on the **-i** parameter on the **mqsicreatebroker** command.

The Default Configuration wizard fails with invalid argument specified

Procedure

- **Scenario:** On a Windows system, the Default Configuration wizard fails. The Default Configuration wizard log contains the following error message:

  ```
  Invalid argument John Smith specified. Argument specified should be well formed.
  Correct and reissue the command.
  ```

- **Explanation:** You have entered a user name that contains one or more spaces. The Default Configuration does not support the use of user names that contain spaces, because the space character can cause problems in communications with other operating systems.
- **Solution:** Use an alternative user name that does not contain any spaces in the Default Configuration wizard.

Resolving problems that occur when you start resources

Use the advice given here to help you to resolve common problems that can occur when you start resources.

About this task

Procedure

Resolving problems when starting a broker

Use the advice given here to help you to resolve common problems that can arise when you start a broker.

About this task

When you start a broker by using the **mqsistart** command, the **mqsicvp** command is run automatically to check that the broker environment is set up correctly (for example, the installed level of Java is supported). On Linux and UNIX, the **mqsicvp** command also verifies that the ODBC environment (if specified) is configured correctly. For more information, see "**mqsicvp** command" on page 3857.

For advice about specific problems that can occur when you start a broker, see the following section.

The broker fails to start because there is not enough space in the Java TMPDIR directory or access permissions for the Java TMPDIR directory are inadequate: Procedure

- **Scenario:** The broker fails to start and either an error message indicates that insufficient space is available or a BIP4512 exception indicates a java.lang.NoClassDefFoundError in the stack trace.
- **Explanation:** This error has two possible causes:
  - The broker uses Java JAR files. When the broker starts, the Java runtime environment extracts the JAR files into a temporary directory, Java TMPDIR. On Linux, UNIX, and z/OS computers, the TMPDIR directory is typically `/tmp`; on Windows computers, it is `c:\temp`. If this directory is not large enough to hold the JAR files, the broker does not start.
  - If the program is packaged as a PAR file, the user must have access to the system temporary directory and adequate space must be available in the temporary directory.
- **Solution:** Use one of the following methods to specify the location of this temporary JAR directory:
  - Use the environment variable `TMPDIR`.
  - Set the system property `java.io.tmpdir`.

  Allow at least 50 MB of space per execution group in this directory for WebSphere Message Broker components. You might need more space if you

deploy large user-defined nodes or other JARs to the broker. You should ensure that all the dependencies of the compute node class are deployed to the broker.

Diagnostic message ICH408I is issued on z/OS when your broker fails to start: About this task

Two scenarios are described here. Choose the appropriate one.

Procedure

- **Scenario 1:** The following diagnostic message is written to the SDSF SYSLOG on z/OS when your broker fails to start:

```
ICH408I USER(MA10USR ) GROUP(TSOUSER ) NAME(OTHER, A N (ANO) 484
  /argo/MA10BRK/ENVFILE
-                                        --TIMINGS (MINS.)--
 ----PAGING COUNTS---
-JOBNAME  STEPNAME PROCSTEP    RC   EXCP    CPU    SRB  CLOCK   SERV  PG
   PAGE   SWAP    VIO SWAPS
  CL(DIRSRCH ) FID(01D7D3E2E3F1F9002D08000000000003)
  INSUFFICIENT AUTHORITY TO LOOKUP
  ACCESS INTENT(--X)  ACCESS ALLOWED(OTHER ---)
```

- **Explanation:** The started task ID, under which the broker runs, must be in a RACF or z/OS UNIX System Services (USS) group that has rwx permissions on the broker directory. For example, consider a broker that is created under directory `/argo/MA00BRK`. It runs under started task ID MA00USR. Issuing the **`ls -al`** command from the root directory `/` to find the permission bit settings on `/argo` returns:

```
drwxrwx---  5 BPXROOT  ARGOUSR      8192 Jul 30  13:57  argo
```

  If you issue the **`id MA00USR`** command to find the group membership of started task ID MA00USR you see:

```
uid=14938(MA00USR) gid=5(TSOUSER) groups=229(ARGOUSR)
```

  These results show that the started task ID MA00USR potentially has rwx permissions on subdirectories to `/argo`, because these permissions are set for both the user and the group that is associated with MA00USR. If the permissions are not set correctly, you see the type of diagnostic message shown in the scenario.

- **Solution:** Make sure that the started task ID, under which the broker runs, is in a RACF or USS group that has rwx permissions on the broker directory.

- **Scenario 2:** The following diagnostic message is written to the SDSF SYSLOG on z/OS when your broker fails to start:

```
ICH408I USER(MA10USR ) GROUP(WMQIBRKS  ) NAME(MA10USR
  CSFRNG CL(CSFSERV )
  INSUFFICIENT ACCESS AUTHORITY
  FROM ** (G)
  ACCESS INTENT(READ   )  ACCESS ALLOWED(NONE   )
```

- **Explanation:** During the broker start up process, Java accesses a secure random number generator. Consequently, the broker started task ID needs access to the CSFRNG resource in the CSFSERV class.
- **Solution:** Make sure that the started task ID that the broker runs under has access to the CSFRNG resource in the CSFSERV class.

Abend code 047 is issued with a diagnostic message:

Procedure

- **Scenario:** On z/OS, your broker generates abend code 047 when you try to start it, and the following diagnostic message is written to the SDSF SYSLOG:

```
IEA995I SYMPTOM DUMP OUTPUT 463
SYSTEM COMPLETION CODE=047
 TIME=10.53.47  SEQ=00419  CPU=0000  ASID=008E
 PSW AT TIME OF ERROR  078D0000   98D09E52  ILC 2  INTC 6B
   ACTIVE LOAD MODULE           ADDRESS=18D08828  OFFSET=0000162A
   NAME=SPECIALNAME
        61819987 968995A2 A3618499 89A58599 */argoinst/driver*
        F1F46D82 96858261 A4A29961 93979761 *14_boeb/usr/lpp/*
        A6949889 61828995 61828997 89948189 *wmqi/bin/bipimai*
        95                                  *n               *
   DATA AT PSW  18D09E4C - 58109948  0A6B5820  B8E95020
   GPR  0-3  00000000  0000003C  00000000  00000000
   GPR  4-7  18D10300  18D115F0  00000013  00000004
   GPR  8-11 18D111CF  18D101D0  18D0BBBE  18D0ABBF
   GPR 12-15 98D09BC0  18D101D0  98D09E22  00000000
 END OF SYMPTOM DUMP
```

- **Explanation:** System completion code 047 means that an unauthorized program issued a restricted Supervisor Call (SVC) instruction. The diagnostic message also indicates that the program in error was bipimain.
- **Solution:** When you install WebSphere Message Broker, issue the command **extattr +a bipimain** from the `bin` directory of the installation path to give APF authorization to program `bipimain`.

Error message BIP2228 is issued when you try to start a second broker on Linux or UNIX:
Procedure

- **Scenario:** Error message BIP2228, which mentions `semctl` in the syslog, is displayed when you try to start a second broker on Linux or UNIX.
- **Explanation:** This error typically indicates a permissions problem with a semaphore used by WebSphere Message Broker. A semaphore is created when the first broker starts after a reboot (or after an initial installation), and only members of the primary group of the semaphore creator can access this semaphore. This problem is a consequence of the UNIX System V IPC primitives that are used by WebSphere Message Broker.

  The BIP2228 message is logged by any broker that is started by a user who is not a member of the primary group of the semaphore creator. The broker tries to access the semaphore, but fails with a permissions-related error. The broker then terminates with the BIP2228 message.
- **Solution:** Avoid this problem by ensuring that all user IDs used to start WebSphere Message Broker have the same primary group. If this action is impractical, ensure that all user IDs are members of primary groups of all other user IDs. Contact your IBM Support Center for further assistance.

MQIsdp client connection is refused by the broker:
Procedure

- **Scenario:** When a new MQIsdp client tries to connect to the broker, its connection is refused.
- **Explanation:** MQIsdp Client ID fields must be unique. If a client sends a CONN packet that contains the same Client ID as a currently connected client, the behavior is undefined.
- **Solution:** Ensure that Client IDs are unique.

Error messages BIP2604 and BIP2624 are issued when you start a broker or a new message flow:
Procedure

- **Scenario:** The following messages are written to the USS syslog on z/OS when your execution group, or a newly deployed or started message flow, fails to start:

```
(PMQ1BRK.default)[8]BIP2624E: Unable to connect to queue manager 'PMQ5':
        MQCC=2; MQRC=2025; message flow node 'ComIbmMQConnectionManager'
(PMQ1BRK.default)[8]BIP2604E: Node failed to open WebsphereMQ queue
       'INPUT1' owned by queue manager 'PMQ5': completion code 2; reason code 2025
```

- **Explanation:** The WebSphere MQ return code of 2025 indicates that the maximum number of concurrent connections has been exceeded. On z/OS, a typical cause of this problem is the setting for IDBACK in the WebSphere MQ CSQ6SYSP macro.
- **Solution:** See the *z/OS System Setup Guide* section of the WebSphere MQ Version 7 Information Center online for information about setting the IDBACK variable.

When you start the broker through the DataFlowEngine, it cycles continually:
Procedure

- **Scenario:** When you start the broker through the DataFlowEngine, it continually cycles, starts and stops, and errors BIP2801 and BIP2110 appear in the log:

```
Unable to load implementation file '/opt/IBM/DistHu b/v2/lib/libdhbNBIO.so',
rc=The file access permissions do not allow the specified action.
Message broker internal program error.
```

- **Explanation:** The permissions on `/opt/IBM` have a value of 700, meaning that the broker service user ID cannot read the disthub files.
- **Solution:** Set the permissions on `/opt/IBM` to 755, which is rwxr-xr-x.

You have changed your logon password and cannot start your broker on Windows:
Procedure

- **Scenario:** You have changed your logon password on Windows, and when you start the broker, you see the following error message:

```
BIP8026E: It was not possible to start the component.
The component could not be started using the service user ID that was supplied when
the component was created. Ensure that the service user ID and password are still
valid. Ensure that the service user ID has permission to access all of the products
directories, specifically the 'bin' and 'log' directories.  Check for system
messages (on Windows this would be the application event log).
```

- **Solution:** Change properties of your broker by completing the following steps:
  1. Change your broker by using the command:

```
mqsichangebroker brokername -i ServiceUserID -a ServicePassword
```

     For example, to change your logon password to `user1pwd` for user ID `user1` on the broker called `WBRK_BROKER`, use the following command:

```
mqsichangebroker WBRK_BROKER -i user1 -a user1pwd
```

  2. Restart your broker.

Broker on Windows platform fails to start with message BIP2818 and an abend:
Procedure

- **Scenario:** You have more than one broker defined on a single Windows computer, and your brokers use different service user IDs. You can start brokers that share a common service user ID, but if you try to run a broker with a different service user ID at the same time you see BIP2818 message in Event

Viewer saying “Failed to create semaphore”. An abend file is also created (message BIP2110). The abend shows function CreateMutexW and err no 17.

- **Explanation:** On Windows computers, brokers that run on the same computer must all use the same service user ID.
- **Solution:** Revise your broker configuration so that all brokers on a single Windows computer run with the same service user ID.

The Java installation is at an incorrect level:
Procedure

- **Scenario:** You issue the command to start a broker, but the broker does not start and the system log includes message BIP8892, for example:

```
Verification failed. The installed Java level 1.3.2 does not
   meet the required Java level 1.5.
```

- **Explanation:** The command performs a check on the level of the Java product installed on the computer to ensure that the Java product is at the required level. The check has failed, therefore the broker is not started.
- **Solution:**
  - On distributed systems, you must use the JVM that is supplied with the broker; no other Java product is supported. Check that you have run **mqsiprofile**, or (on Windows only) that you issued the **mqsistart** command from the correct command console.

    If you ran the profile command, check the settings of the environment variables in **mqsiprofile**; MQSI_JREPATH, PATH, and the appropriate library path environment variables for your operating system. Change these settings to point to the integrated JVM, and ensure that no other Java installation is in the path.
  - On z/OS, install the correct level of Java that is reported in this message, update the broker profile BIPBPROF and submit BIPGEN to refresh the component ENVFILE.

Authorization errors are reported on z/OS:
Procedure

- **Scenario:** You issue the command to start a broker, but the component does not start and the JOBLOG includes message BIP8903, for example:

```
Verification failed. The APF Authorization check failed
   for file '/usr/lpp/mqsi/bin/mqsireadlog'.
WebSphere Message Broker requires that only bipimain is APF Authorized
   for successful operation. File '/usr/lpp/mqsi/bin/mqsireadlog'
   fails that requirement.
If the file indicated in the message is bipimain, use the USS command
   extattr to ensure that it is APF Authorized.
If the file indicated in the message is not bipimain, use the USS
   command extattr to ensure that it is not APF Authorized.
For more information, search the information center for "APF attributes".
```

- **Explanation:** When you start a broker, a series of checks is made to ensure that the broker environment is set up correctly. One or more of the checks for the broker identified in the message has failed, therefore the broker is not started. The errors shown here indicate that the authorizations for some files are incorrect and incompatible with broker operation.

  The broker requires that a single file, `bipimain`, is APF authorized, but the checks indicate that the authorization for file `mqsireadlog` is incorrect.
- **Solution:** The file `bipimain` must be APF authorized, and all other files must not have that authorization. Make the required changes to authorization for the files that are identified in the error messages and try the operation again.

Error message BIP8875 is issued when you start a broker:
Procedure

- **Scenario:** You issue the **mqsistart** command to start a broker, but the broker does not start and the system log shows message BIP8875, for example:

```
The component verification for MB7BROKER has finished,
but one or more checks failed.
```

- **Explanation:** The command performs a series of checks to ensure that the broker environment, WebSphere MQ queues, and Java are correct and accessible. One or more of the checks for the broker identified in the message has failed, therefore the broker is not started.
- **Solution:** Look in the system log, or in the Application log in the Event Viewer on Windows. Additional messages have been written before this message to indicate which checks have failed. All the checks are performed every time you issue **mqsistart**, therefore all errors are included in the log. Some messages are also returned when you run the command from the command line.

  Investigate the one or more errors that have been reported and check return codes and additional details. Look at the complete message content to check for typical causes of the error, and follow the advice given for the messages that you see in the log. View the complete message text in the Diagnostic Messages reference topics.

  For example, you might see one or more of the following messages:

  – BIP8875W: The component verification for '*component_name*' has finished, but one or more checks failed.
  – BIP8877W: The environment verification for component '*component_name*' has finished, but one or more checks failed.
  – BIP8883W: The WebSphere MQ verification for component '*component_name*' has finished, but one or more checks failed.
  – BIP8885E: Verification failed. Failed to connect to queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8887E: Verification failed for queue '*queue_name*' on queue manager '*queue_manager_name*' while issuing '*operation*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8888E: Verification failed. Failed to disconnect from queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
  – BIP8892E: Verification failed. The installed Java level '*level_installed*' does not meet the required Java level '*level_supported*'.
  – BIP8893E: Verification failed for environment variable '*variable_name*'. Unable to access file '*file_name*' with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*.
  – BIP8895E: Verification failed. Environment variable '*variable_name*' is incorrect or missing.
  – BIP8896E: Verification failed. Unable to access the registry with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*
  – BIP8897E: Verification failed. Environment variable '*variable_name*' does not match the component name '*component_name*'.
  – BIP8903E: Verification failed. The APF Authorization check failed for file '*file_name*'.
  – BIP8904E: Verification failed. Failed to start file '*file_name*' with return code '*return_code*' and errno '*error_number*'.

If you cannot resolve the problems that are reported, and you receive a message such as BIP8893 that includes additional information, include these items in the information that you provide when you contact IBM Service.

Warning messages BIP8288-BIP8297 are shown in the syslog when you start a broker:
Procedure

- **Scenario:** Warning messages BIP8288-BIP8297 are shown in the syslog when you start a broker on Linux and UNIX systems.
- **Explanation:** One or more problems were detected with the ODBC environment on Linux and UNIX systems.

  When you start a broker by using the **mqsistart** command, the **mqsicvp** command is run automatically to check that the broker environment is set up correctly. On Linux and UNIX systems, this command also verifies that the ODBC environment is configured correctly. If the ODBCINI environment variable is set, the **mqsicvp** command writes warning messages to the syslog in the following situation:
  – If the file to which the ODBCINI environment variable points does not exist, or the broker does not have access to read it or write to it

  If the environment variable ODBCUOINI is set, the **mqsicvp** command writes warning messages to the syslog in the following situations:
  – If the file that is referenced by the ODBCUOINI environment variable does not exist, or the broker does not have access to read or write to the file
  – If ODBCSYSINI is not set
  – If the directory that is referenced by the ODBCSYSINI environment variable does not contain a file called `odbcinst.ini`, or the broker does not have access to read or write to this file
  – If the IE02_PATH environment variable is not set
- **Solution:** Examine the warning messages in the syslog. To view more information, run the **mqsicvp** command from the command line.

Broker startup on z/OS is very slow:
Procedure

- **Scenario:** The broker startup on z/OS takes many minutes, with an extended time taken in loading the `imbjplug2` .lil file.
- **Explanation:** When WebSphere Message Broker is run in a shared file system sysplex environment, the LPAR that the broker started in does not necessarily own the file system mount points that the broker uses. In this scenario all file accesses have to pass through the coupling facility, which adversely affects performance. During startup the broker accesses and reads many files, and loads many Java class files. All these file operations are slowed, causing longer startup times.
- **Solution:** For optimal startup performance, mount the directories that the broker accesses in the LPAR in which the broker is started. In particular, mount the WebSphere Message Broker installation directories locally. Mounting file systems lists the directories that WebSphere Message Broker on z/OS needs on the file system at run time; mount them locally for optimal performance.

Error messages AMQ7626 and BIP8048 are displayed when you try to start a broker:
Procedure

- **Explanation:** You see these messages when using a broker on a queue manager that is configured for global coordination with Oracle.

- **Solution:** Start the queue manager manually with the **-si** flag before starting the broker.

Resources terminate during startup:
Procedure

- Windows **Scenario:** The following error message is displayed when you start a broker on Windows:

  ```
  ServiceName - DLL initialization failure Initialization of the
  dynamic link library c:\windows\system32\user32.dll failed.
  The process is terminating abnormally.
  ```

- **Explanation:** This error is issued by Windows when it fails to start a service because it has insufficient storage.
- **Solution:** This error is an operating system problem. Information about how to recover from this problem is available in the Microsoft Developer Network (MSDN). You can access MSDN on the Web at `http://msdn.microsoft.com`.

Resources hang at startup on Windows:
Procedure

- Windows **Scenario:** You try to start the broker on Windows, but nothing happens in the Event log to show that a connection has started.
- **Explanation:** This problem is typically caused by processes having only one thread. To see if this is the cause, check the Windows Task Manager. If either of the processes `bipconfigmgr.exe` or `dataflowengine.exe` has started, check the number of threads owned by the process. If the process has only one thread, you are likely to encounter this problem.
- **Solution:**
  1. Shut down the broker using the **mqsistop** command and end the process from within the Task Manager.
  2. From the Windows **Start** button, click **Settings** > **Control Panel**
  3. Double-click **Administrative Tools**
  4. Double-click **Services** to open the Services window. From the list of available services, locate and right-click the broker resource you are attempting to start (the service name begins with `IBM WebSphere Message Broker component`). Click **Properties** from the menu.
  5. Make a note of the **This Account** setting. Contact the system administrator to obtain the password associated with **This Account**, because these settings are lost when you change values.
  6. Select **System Account** as the **Log On As** option, and select **Allow Service to Interact with Desktop.** These selections allow you to see any hidden dialog messages. Click **OK** to accept the changes.
  7. Restart the resource that is failing and report any subsequent error messages and dialog box messages to your IBM Service Representative.

8. When your IBM Service Representative has resolved this problem for you, make sure that you restore the **This Account**, **Password**, and **Confirm Password** entries to the values that you used when you created the broker.

Error message BIP8048 is issued when you start a component:
Procedure

- **Scenario:** Error message BIP8048 is issued when you start a component.
- **Explanation:** This message indicates that WebSphere MQ is not responding as expected when it tries to start the queue manager. This problem might be because the **strmqm** executable file is not present on UNIX or Linux systems, or the **amqmdain** executable file is not present on Windows, or permissions are incorrect.
- **Solution:** Check that your WebSphere MQ installation is fully functional:
  - On Windows, start the "IBM MQSeries" service.
  - On UNIX or Linux, issue the **strmqm** command to start the queue manager that is associated with this component.

  If the check fails, your WebSphere MQ installation is incomplete. This error occurs typically because you have previously installed WebSphere Application Server, which installs an embedded WebSphere MQ component that does not support WebSphere Message Broker.

  Uninstall WebSphere Application Server, then install the full WebSphere MQ product that is provided with WebSphere Message Broker.

You experience problems with the default configuration:
Procedure

- **Scenario:** You have run the Default Configuration wizard but there are problems with the default configuration.
- **Solution:** Use the Default Configuration wizard to remove the default configuration.

  If the Default Configuration wizard does not remove the default configuration completely, a wizard failure window opens with instructions on where to find the log. Take the following steps:

  1. Follow any advice that is given in the Default Configuration wizard log and try each step again.
  2. If retrying fails, restart the computer and run the Default Configuration wizard again.
  3. If the wizard still does not remove the default configuration, remove each component manually by performing the following actions in the order shown:
     a. Issue the following commands to find out which components are installed:
        - **mqsilist** (lists the brokers)
        - **dspmq** (lists WebSphere MQ components: the queue manager)
     b. In the WebSphere Message Broker Toolkit, delete the connection file `LocalDomain.broker` from the project LocalProject.
     c. In the WebSphere Message Broker Toolkit, delete the project LocalProject.
     d. Stop the default broker by issuing the command:
        ```
        mqsistop MB7BROKER
        ```
     e. Delete the default broker by issuing the command:
        ```
        mqsideletebroker MB7BROKER -w
        ```

The **-w** parameter deletes all files related to this broker from the associated work path.

f. If you need to remove the queue manager manually, issue the following commands:

```
endmqlsr -w -m MB7QMGR
endmqm -i MB7QMGR
dltmqm MB7QMGR
```

4. If you still experience problems after removing the default configuration manually, contact your IBM Support Center.

A "Not Found" error is issued when you click a link to a specific sample:
Procedure

- **Scenario:** You see a "Not Found" error when you click a link to a specific sample, indicating that a URL is invalid.
- **Explanation:** You can view sample applications only when you use the information center that is integrated with the WebSphere Message Broker Toolkit. If you are viewing a stand-alone or online information center, you cannot access these resources.
- **Solution:** If you want to access samples, ensure that you are viewing the information center from within the WebSphere Message Broker Toolkit.

The Quick Tour is displayed as a blank window:
Procedure

- **Scenario:** The Quick Tour is displayed as a blank window.
- **Explanation:** The Quick Tour requires Adobe Flash Player (was Macromedia Flash Player) Version 7, and is displayed as a blank window if the Adobe Flash Player plug-in is not installed or is at the wrong level on the default browser.
- **Solution:** Download the Adobe Flash Player by using one of the following methods:
  - Follow the link at the bottom of the Quick Tour page.
  - Select the specific Adobe Flash Player for your operating system and browser from the Adobe Flash Player download page.

Error message BIP0832 is issued on startup:
Procedure

- **Scenario:** The following error message is displayed on startup:

  ```
  BIP0832E: A class java.io.FileNotFoundException exception occurred which
  reported the following message: [filepath] (The process cannot access the
  file because it is being used by another process). Resolve the reason of
  error and try again.
  ```

- **Explanation:** An invalid WebSphere MQ Java Client trace output file has been specified on the Enqueue preferences screen.
- **Solution:**
  1. Open the Enqueue preferences screen by clicking **Windows** > **Preferences**, then clicking **Enqueue** on the left.
  2. In the **To file** field, specify a valid output file (one that is not read-only or already in use).

Your execution groups restart repeatedly:
Procedure

- **Scenario:** Your execution groups restart repeatedly. The system log might show an error, such as BIP2060.

- **Explanation:** The problem might be caused by:
  - The broker environment variables incorrectly defined
  - Incorrect Loadable Implementation Library directory permissions
  - Incorrect database permissions
  - Invalid user-written LILs
- **Solution:** Check:
  - Environment variables as described in "Environment variables after installation" on page 3642
  - File and directory permissions as described in "Checking the permission of the installation directory" on page 606
  - Group memberships as described in "Execution groups" on page 53 and "Creating an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 937

You cannot tell whether startup is complete on z/OS:
Procedure

- **Scenario:** You cannot tell whether startup has completed on your z/OS system.
- **Solution:** To determine if startup is complete:
  1. Check the messages in the system log. The following example shows a system log entry for a startup of a broker with one execution group:

```
S STU3053
$HASP100 STU3053  ON STCINRDR
IEF695I START STU3053  WITH JOBNAME STU3053  IS ASSIGNED TO USER STU3
 , GROUP STCGROUP
$HASP373 STU3053  STARTED
+(broker53) 0 BIP9141W: The component was started.
+(broker53) 0 BIP2001I: The WebSphere Business Integration Message Broker
service has started
 process ID 33554919.
+(broker53.default) 0 BIP2201I: Execution Group started: process '67109
442
 196'; thread '0'; additional information 'broker53', '76eb7f2d-e800-00
 00-0080-974c271866d2', 'default', 'true', 'Q4A3', 'false', 'ARG5D651',
  'ARGO53', '********', 'false', 'f9c27f2d-e800-0000-0080-974c271866d2'
 , '/local/argo/driver/drv3', '/local/argo/tgrp53/broker53'.
+(broker53.default) 0 BIP9137I: A work manager has been registered by R
443
 RMS registration services, work manager name is BIP.STU30532.006710919
 6.IBM.UA  .
```

  2. Display the address spaces. The following example shows the display of a broker with one execution group:

```
D OMVS,U=STU3
BPXO040I 18.49.59 DISPLAY OMVS 446
OMVS     000E ACTIVE          OMVS=(68,05)
USER     JOBNAME  ASID        PID       PPID STATE   START     CT_SECS
STU3     STU30531 0069   33554696   33554919 HR    18.49.15      2.217
  LATCHWAITPID=         0 CMD=bipbroker broker53
STU3     STU30532 03FD   67109196   67109222 HR    18.49.23     19.816
  LATCHWAITPID=         0 CMD=DataFlowEngine broker53 76eb7f2d-e800-00
STU3     STU3053  0036   33554768   83886483 HRI   18.49.08       .653
  LATCHWAITPID=         0 CMD=bipservice Q4A3BRK AUTO
STU3     STU30532 03FD   67109222   33554696 1W    18.49.23     19.816
  LATCHWAITPID=         0 CMD=bipimain DataFlowEngine broker53 76eb7f2
STU3     STU3053  0036   83886483          1 1WI   18.49.08       .653
  LATCHWAITPID=         0 CMD=/local/argo/driver/drv3/bin/bipimain bip
STU3     STU30531 0069   33554919   33554768 1W    18.49.15      2.217
  LATCHWAITPID=         0 CMD=bipimain bipbroker broker53
```

Results

The infrastructure main program bipimain is the first process in every address space. It starts bipservice, bipbroker, or DataFlowEngine as the second process in the same address space. For each execution group, an additional address space is started. In this example, only one execution group is available.

Abend code 0C1 is issued when you try to start the DataFlowEngine on z/OS: Procedure

- **Scenario:** The first two WebSphere Message Broker address spaces start successfully, but the third address space (the DataFlowEngine) fails to start. The result is an 0C1 abend.
- **Explanation:** The DataFlowEngine address space is generated by the admin agent. If the region size is too small, either because an insufficient region size was specified in the procedure, or because the region size was overridden by the z/OS IEFUSI exit, the DataFlowEngine address space might fail to start, and fails with an 0C1 abend.
- **Solution:**
  1. Use the IPCS command on the dump (move the dump from the file system to a traditional MVS data set if required):

     ```
     verbx vsmdata,'noglobal,jobname(vcp0brk2)'
     ```

     where *vcp0brk2* is the name of the failing job.
  2. Find the string `'VSM LOCAL DATA AREA AT ADDRESS '`. The field ELIM gives the available region size and must be greater than `0C800000`. If the field SMFEL is not `ffffffff`, the IEFUSI exit has changed the allowable region size. This value must also be greater than 0C80000.
  3. If you have an IEFUSI exit, check that the exit does not limit the broker address spaces. For example, a commonly used field is OUCBSUBN. This field can be STC or OMVS for the broker, and indicates how the address space was started.

Error message BIP2604 with return code `MQRC_CONNTAG_IN_USE` is issued during the start of a message flow on z/OS: Procedure

- **Scenario:** Error message BIP2604 is issued with return code `MQRC_CONNTAG_IN_USE` during the start of a message flow on z/OS:

  ```
  BIP2604E: Node failed to open WebSphere MQ queue [queue name]
  owned by queue manager [queue manager name]
  ```

  This message is output every 30 minutes.
- **Explanation:** On z/OS, WebSphere MQ supports serialized access to shared resources, such as shared queues, through the use of a connection tag (serialization token) when an application connects to a queue manager that participates in a queue sharing group.

  In this case, a message flow node fails to connect to the indicated WebSphere Message Broker queue manager that is associated with the input queue, because the serialization token that it passed is already in use within the queue sharing group.

  This message is for information only. It indicates that serialization is occurring when two or more message flow input nodes try to connect to a queue manager to get messages from a shared queue.

- **Solution:** Check whether another instance of the message flow, or a flow using the same serialization token, is already running. If so, no further action is needed. Otherwise contact your IBM Support Center.

After creating or changing a configurable service, you restart your broker but your message flow does not start, and message BIP2275 is issued in the system log or Windows Event Viewer:
Procedure

- **Scenario:** After creating or changing a configurable service, you restart your broker but your message flow does not start, and message BIP2275 is issued in the system log or Windows Event Viewer, indicating that an error occurred while loading the message flow from the persistent store.
- **Explanation:** When you change or create the configurable service, the connection properties are not fully validated at that point; the broker does not attempt to use them to make a connection. For inbound adapters, the connection is made only when the broker is restarted. Therefore, the properties that you set on the configurable service might be invalid.
- **Solution:** Look at the messages following the BIP2275 message to determine if the message flow failed to start because of invalid connection properties. For example, in SAP you would see message BIP3414 with a reason such as:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE'
```

  followed by a BIP3450 message with an adapter error message such as:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE
```

  This error was detected by the adapter. The following message describes the diagnostic information that is provided by the adapter:

```
Connect to SAP gateway failed
Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
  SYSNR=00
```

```
LOCATION CPIC (TCP/IP) on local host
ERROR partner not reached (host invalidhost.test.co, service 3300)
TIME Fri Nov 28 15:27:32 2008
RELEASE 640
COMPONENT NI (network interface)
VERSION 37
RC -10
MODULE nixxi_r.cpp
LINE 8728
DETAIL NiPConnect2
SYSTEM CALL SiPeekPendConn
ERRNO 10061
ERRNO TE
```

This message suggests that the **applicationServerHost** and **gatewayHost** properties are incorrect. When you have determined which properties are incorrect, use the **mqsichangeproperties** command to correct the properties, or use the **mqsideleteconfigurableservice** command to revert to the properties that were deployed in the adapter. Restart the broker.

A device allocation error is issued:
Procedure

- **Scenario:** A device allocation error is issued.
- **Explanation:** A likely cause of this problem is that you do not have the correct permissions set on the component file system for the started task ID.
- **Solution:** Check the system log; if the problem is caused by having incorrect permissions set for the started task ID, you often see an RACF authorization failure message, as shown in the following example.

```
ICH408I USER(TASKID1 ) GROUP(TSOUSER ) NAME(FRED (FRED) 959
 /argo/MA11BRK/ENVFILE
 CL(DIRSRCH ) FID(01D7C7E2E3F0F8000F16000000000003)
 INSUFFICIENT AUTHORITY TO LOOKUP
 ACCESS INTENT(--X)  ACCESS ALLOWED(OTHER ---)
IEE132I START COMMAND DEVICE ALLOCATION ERROR
IEA989I SLIP TRAP ID=X33E MATCHED.  JOBNAME=*UNAVAIL, ASID=00A8.
D J,BPXAS
IEE115I 11.13.04 2001.212 ACTIVITY 601
```

In this example, the started task ID does not have access to the file system component. The ICH408I message shows:

- The file that the task is trying to access
- The user ID that is trying to access the file
- The permissions that the ID is expecting to have (`INTENT` in the message)
- The permissions that the ID actually has (`ALLOWED` in the message)

You can use this information to correct the permissions, then reissue, in this example, the start broker request. This type of message is produced if the user who is issuing the command (which might be to start the broker, or to submit JCL to start one of the utility jobs) does not have the correct file system permissions for the file system component. Use the ICH408I information to rectify the problem.

Another possible reason for authorization failures is inconsistencies in the RACF definitions for a user ID in the MVS image and the OMVS segment. Also check with your system administrator that the RACF ID that is used on MVS has a corresponding OMVS image created.

Windows Vista and Windows Server 2008 fail to recognize WebSphere Message Broker digital signatures: "Unknown Publisher":

Procedure

- **Scenario:** User A installs WebSphere Message Broker, and can run all programs (`mqsi*.exe`, `bip*.exe`, including the command console launcher). User B is created and given appropriate privileges. When User B runs an executable file such as the command console launcher, a window opens and reports that the executable file is from an unidentified publisher.
- **Explanation:** The operating system has not installed the appropriate digital certificates for User B.
- **Solution:** User B must manually install the certificates:
  1. In Windows Explorer, navigate to the `bin` directory for the WebSphere Message Broker installation; for example, on 32-bit systems, `C:\Program Files\IBM\MQSI\7.0\bin`
  2. Right-click any .exe file to open the Properties window.
  3. Click the Digital Signatures tab.
  4. Select the appropriate certificate from the list, then click **Details**. The Digital Signature Details window is displayed.
  5. Click **View Certificate**. The Certificate window is displayed.
  6. Click **Install Certificate** and complete the steps in the wizard. (Click **Next**, **Next**, **Finish**, then click **OK**.)
  7. Close the Certificate window. You return to the Digital Signature Details.
  8. Select the countersignature from the list, then click the **Details** button. A new Digital Signature Details window is displayed. You can repeat the preceding steps to install other certificates.

The create command fails, and error message BIP8022 is issued:
Procedure

- **Scenario:** Error message BIP8022 is displayed when you use the **`mqsicreatebroker`** command on Windows, even if the supplied user name and password are correct.
- **Explanation:** The Microsoft component "Shared File and Printer Services" is required.
- **Solution:** Correct this error by installing the "Share File and Printer for Microsoft network" service on the Windows system.

Your execution group restarts repeatedly with a JVM Startup failure:
Procedure

- **Scenario:** When you start the DataFlowEngine it continually starts and stops, displaying errors BIP2116E and BIP7409S in the log:

  ```
  BIP2116E: Message broker internal error: diagnostic information 'Fatal Error; exception thrown bef
  BIP7409S: The broker was unable to create a JVM. The return code indicates that an unrecognized op
  ```

- **Explanation:** When you start an execution group, it creates a Java virtual machine (JVM) for executing Java user-defined nodes, and its creation failed due to an incorrect JVM option.
- **Solution:** Correct the JVM option by completing the following steps:
  1. Stop the broker.

     ```
     mqsistop brokerName
     ```

  2. Check the jvmSystemProperty value of the failing execution group.

     ```
     mqsireportproperties brokerName -e egName -o ComIbmJVMManager -n
     jvmSystemProperty -f
     ```

  3. If the jvmSystemProperty has an invalid option, correct or reset its value.

```
mqsichangeproperties brokerName -e egName -o ComIbmJVMManager -n
jvmSystemProperty -v "" -f
```

4. Start the broker.

```
mqsistart brokerName
```

Resolving problems that occur when migrating or importing resources

Use the advice given here to help you to resolve common problems that can occur when you import or migrate resources.

About this task

Migration information is regularly updated on the WebSphere Message Broker support web page with the latest details available. Click **Troubleshoot**, then look for a document with a title like "Problems and solutions when migrating".

Procedure

- "Resolving problems when migrating or importing message flows and message sets" on page 3390
  - "Message flows that refer to a migrated user-defined node have connection errors" on page 3390
  - "After migration, message flows cannot locate a user-defined node" on page 3390
  - "A message flow fails with exception BIP5027" on page 3390

- "Resolving problems when migrating or importing other resources" on page 3391
  - "The **mqsimigratecomponents** command fails with database error BIP2322" on page 3391
  - "The **File** > **Import** menu provides only the option to import a compressed file inside an existing project" on page 3391

Related tasks:

Chapter 3, "Migrating and upgrading," on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Related reference:

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Resolving problems when migrating or importing message flows and message sets

Use the advice given here to help you to resolve common problems that can occur when you import or migrate message flows and message sets.

Message flows that refer to a migrated user-defined node have connection errors:
Procedure

- **Scenario:** After migration, all message flows that refer to a migrated user-defined node have errors indicating that connections cannot be made.
- **Explanation:** One possible cause is that the original user-defined node had space characters as part of one or more terminal names. The spaces are wrongly rendered as 'X20'.
- **Solution:** Edit the user-defined node `.msgnode` file, which is available in the same project as the flows that you have migrated. Correct any terminal names that are at fault. Ensure that the names are exactly as the broker node implementation expects.

After migration, message flows cannot locate a user-defined node:
Procedure

- **Scenario:** After migration, message flows cannot locate a user-defined node.
- **Explanation:** One possible cause is that the flows do not have the correct reference internally to a user-defined node.
- **Solution:** Select the **Locate subflow** menu for the node that cannot be located. Using the Browse dialog box, locate the user-defined node (which is in the same project as migrated flows). The message flow now links to the user-defined node correctly and the task list entry is removed when you save the flow.

A message flow fails with exception BIP5027:
Procedure

- **Scenario:** You have migrated a message flow from Version 6.0 to Version 7.0. When you deploy and run the message flow on a Version 7.0 broker, it generates message BIP5027 and throws an exception.
- **Explanation:** You have set the Validate property on one or more nodes in the message flow. In Version 6.0, the XMLNSC parser ignores the Validate property setting, but in Version 7.0, it honors the setting. Because you set this property to Content or Content And Value, the parser tries to validate the message against

the message set defined by the Message Set property on the node. The validation fails, and the message flow generates an exception.

- **Solution:** Set the Validate property of the node to None and redeploy the relevant BAR file.

  For more information about changes in behavior after migration, see "Reviewing technical changes in Version 7.0" on page 205.

Resolving problems when migrating or importing other resources

Use the advice given here to help you to resolve common problems that can arise when you import or migrate resources other than message flows.

About this task

- "The **mqsimigratecomponents** command fails with database error BIP2322"
- "The **File** > **Import** menu provides only the option to import a compressed file inside an existing project"
- "COBOL compiler errors when importing a copybook" on page 3392

The mqsimigratecomponents command fails with database error BIP2322:
About this task

Procedure

- **Scenario:** The **mqsimigratecomponents** command fails with database error BIP2322: `The 'CREATE TABLE' command is not allowed within a multi-statement transaction in the 'BROKER1' database.`
- **Explanation:** If you are using the **mqsimigratecomponents** command to migrate a broker that uses a Sybase database, you must modify the database to enable the Data Definition Language (DDL) that the command uses.
- **Solution:** Take the following steps:
  1. Log on to ISQL using a system administrator account.
  2. Run the following series of commands:

```
1> use master
2> go
1> sp_dboption "BROKER1","ddl in tran",TRUE
2> go
Database option 'ddl in tran' turned ON for database 'BROKER1'.
Run the CHECKPOINT command in the database that was changed.
(return status = 0)
1> use BROKER1
2> go
1> checkpoint
2> go
```

     where *BROKER1* is the name of the Sybase broker database.

The File > Import menu provides only the option to import a compressed file inside an existing project:
Procedure

- **Scenario:** You have a compressed file that contains message set projects and message flow projects. When you click **File** > **Import**, you have only the option to import the compressed file inside an existing project, but you want to re-create the message set projects and message flow projects.

- **Solution:** When you export and import files, do not export or import the root directory, which is created for you because of the project file. When you export your message flow and message set projects:
  1. Click **Create only selected directories**.
  2. Clear the project root folder.
  3. Select the files and subdirectories as required. The project root folder is selected, but is displayed as gray.

  Then, when you import the compressed file:
  1. Clear the root (/) folder.
  2. Select the files and subfolders as required. The project root folder is selected, but is displayed as gray.

COBOL compiler errors when importing a copybook:
Procedure

- **Scenario:** The report file that is generated by the import contains COBOL compiler errors. For example, you try to import the following copybook:

  ```
  01 AIRLINE-REQUEST.
  ....05 CUSTOMER.
  ........10 NAME.............PIC X(45).
  ....05 ADDRESS.
  ........10 STREET.............PIC X(30).
  ........10 CITY.................PIC X(25).
  ........10 STATE...............PIC X(20).
  ........10 ZIP-CODE.........PIC X(5).
  ....05 FLIGHT-NO.............PIC X(6).
  ....05 TRAN-DATE............PIC X(10).
  ....05 COST.....................PIC X(7).
  ....05 CC-NO..................PIC X(20).
  ....05 RESPONSE.
  ........10 STATUS.............PIC X(100).
  ........10 DETAILS............PIC X(100).
  ```

  The report file contains errors:

  ```
  Line No : 4 IGYDS1089-S "ADDRESS" was invalid. Scanning was resumed at the next area "A" item, lev
  Line No : 14 IGYDS1089-S "STATUS" was invalid. Scanning was resumed at the next area "A" item, lev
  ```

- **Explanation:** The errors are caused by the copybook containing field names that are COBOL reserved keywords.
- **Solution:** Change the name of the fields in question, so that they are not COBOL reserved keywords, and retry the import.

Related tasks:

"Resolving problems when migrating or importing message flows and message sets" on page 3390
Use the advice given here to help you to resolve common problems that can occur when you import or migrate message flows and message sets.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Resolving problems when stopping resources

Use the advice given here to help you to resolve problems when you stop resources.

About this task

Procedure

- "You cannot stop the broker"
- "You cannot stop the broker queue manager"
- "The execution group ends abnormally"

You cannot stop the broker

Procedure

- **Scenario:** You run the **mqsistop** command to stop the broker, but the system freezes, and does not stop any of the execution groups.
- **Explanation:** One possible cause is that a message flow is being debugged and it is currently stopped at a breakpoint. WebSphere Message Broker regards this as a message in flight situation, and refuses to stop the broker through the normal command.
- **Solution:** Click **Stop debugging** in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. After that operation has completed, the broker stops.

  If you cannot stop the debug session, end all execution group processes that are associated with that broker to allow the broker to stop. Your messages are backed out. Click **Stop debugging** after the broker restarts.

You cannot stop the broker queue manager

Procedure

- **Scenario:** You are trying to use the WebSphere MQ **endmqm** command to stop a broker queue manager on a distributed system, but it does not stop.
- **Explanation:** In certain circumstances, attempting to stop a broker queue manager does not cause the queue manager to stop. This situation can occur if you have configured any message flows with multiple threads (you have set the message flow property Additional Instances to a number greater than zero).
- **Solution:** If you want to stop the broker's queue manager, stop the broker by running the **mqsistop** command and specifying the **-q** parameter. (The **-q** parameter is not available on z/OS.) This command runs the WebSphere MQ **endmqm** command on your behalf in a controlled fashion that shuts down the broker and the queue manager cleanly.

The execution group ends abnormally

About this task

Procedure

- **Scenario:** Your execution group processes end abnormally.
- **Explanation:** When execution group processes end abnormally, they are restarted automatically by the `bipbroker` process. If an execution group process fails, it is restarted three times during each five-minute interval. The first five-minute interval begins when the execution group is first started. RetryInterval defaults to 5

  Remove the execution group from the broker configuration, deploy the broker configuration, then later add the execution group, and redeploy the broker configuration. The row is re-created and RetryInterval is set to its default value of 5.
- **Solution:** To change the default value:

  1. Stop the broker.

2. Change the value of the RetryInterval in the database table.
3. Restart the broker.

Related tasks:

"Starting and stopping a broker" on page 921
Run the appropriate command to start or stop a broker.

"Stopping a WebSphere MQ queue manager when you stop a broker" on page 929
If you are preparing to stop a broker, you can stop the broker's WebSphere MQ queue manager at the same time.

Use the **mqsistop** command to stop the specified component.

Resolving problems when deleting resources

Use the advice given here to help you to resolve problems when you delete resources.

About this task

You cannot delete a project from your workspace

Procedure

- **Scenario:** You cannot delete a project from your workspace. You get error messages indicating that the containing directory cannot be deleted, or the project file is missing.
- **Explanation:** If you attempt to delete a project, and the directory that contains the project is in use, or you have any files that are contained within the project that have been opened by programs other than the WebSphere Message Broker Toolkit, some of the resources in the project are not deleted, but others, including the project file, might be deleted.
- **Solution:** Before you delete a project, make sure that other applications do not have the files open, and that you do not have an open command prompt located in the directory. To recover from this problem, manually delete any remaining files and directories from your workspace directory, then click **Delete** from the project in the WebSphere Message Broker Toolkit.

Related tasks:

"Deleting a broker" on page 930
Delete a broker using the command line on the system where the broker component is installed.

"Deleting a message flow project" on page 1427
A message flow project is the container in which you create and maintain all the resources associated with one or more message flows. These resources are created as files, and are displayed in the project in the Broker Development view. If you do not want to retain a message flow project, you can delete it.

Related reference:

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

Resolving problems when developing message flows

Use the advice given here to help you to resolve common problems that can arise when developing message flows.

About this task

Resolving appearance problems when developing message flows

This topic contains advice for dealing with some common appearance problems that can arise when developing message flows:

The task list does not update when you make corrections to your files: Procedure

- **Scenario:** The task list does not update any modifications that you make to an ESQL or mapping file. You have made corrections to the files, and while there are no error flags in the file or file icon, the error remains as a task list item.
- **Solution:** To work around this problem, set the following environment variable:

```
JITC_COMPILEOPT=SKIP{org/eclipse/ui/views/tasklist/TaskListContentProvider}
{resourceChanged}
```

You rename a flow that contains errors, but the task list entries remain: Procedure

- **Scenario:** When you rename a message flow in the WebSphere Message Broker Toolkit for which there are error icons (red crosses) displayed on nodes and connections, those error icons are removed when changes are made. However, the task list entries remain.
- **Solution:** Refresh the Message Flow editor by closing and reopening it.

Terminals on a subflow get out of sync as changes are made:

Procedure

- **Scenario:** You have a message flow that contains subflow nodes. The name or number of terminals on the subflow gets out of sync when changes are made on the subflow itself. The same problem can happen with promoted properties.
- **Solution:** Refresh the Message Flow editor by closing and reopening it. Close the Message Flow editor that contains subflows while the subflows are being changed.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Resolving problems when you use CORBA nodes

Advice for dealing with common problems that can arise when you develop message flows that contain CORBA nodes.

Before you begin

WebSphere Message Broker does not currently support all CORBA operations and types. Ensure that you are passing in a valid IDL file that contains supported operations and types. For a full list of what is supported, see "CORBA support" on page 2149. To ensure that the IDL file is valid, run it through an IDL parser.

About this task

- "Error message BIP4891 is issued when you include a CORBARequest node in a message flow"
- "A CORBA IDL file drop error is issued when you are using an IDL file that contains includes" on page 3397
- "Error message BIP4910 is issued during deployment when you are using an IDL file that contains includes" on page 3397

Error message BIP4891 is issued when you include a CORBARequest node in a message flow:

Procedure

- **Scenario:** You have created a message flow that contains a CORBARequest node, but error message BIP4891 is issued, indicating that the node did not receive a valid body.
- **Explanation:** This error message indicates that the CORBARequest node is trying to call an operation but cannot find the required input parameters in the incoming tree. WebSphere Message Broker uses the DataObject parser to read and write message from CORBA applications. If you use an input node to pass XML into the CORBARequest node, ensure that it uses the DataObject domain.
- **Solution:** Ensure that the incoming message has the correct structure. If you are using an input node to pass XML into the CORBARequest node, set the `Message domain` property on the **Input Message Parsing** tab of the input node to `DataObject`.

A CORBA IDL file drop error is issued when you are using an IDL file that contains includes:
Procedure

- **Scenario:** You have dragged a CORBA IDL file onto the canvas but a CORBA IDL file drop error is issued.
- **Explanation:** If you have imported an IDL file that contains includes, you must drag the top-level IDL file onto the canvas so that the CORBARequest node has all the relevant information. Similarly, when setting properties on the CORBARequest node, if you have imported an IDL file that contains includes, you must select the top-level IDL file in the `IDL file` property.
- **Solution:** Drag the top-level IDL file onto the canvas, or set the `IDL file` property on the CORBARequest node to the top-level IDL file.

Error message BIP4910 is issued during deployment when you are using an IDL file that contains includes:
Procedure

- **Scenario:** You are deploying a message flow that contains a CORBARequest node, but error message BIP4910 is issued.
- **Explanation:** This error is issued when you have imported an IDL file that contains includes, but not all the included IDL files have been added to the BAR file. For example, you might have dragged only the message flow onto the execution group. If you have imported an IDL file that contains includes, you must ensure that all the included IDL files are added to the BAR file so that all the relevant information is available to the message flow.
- **Solution:** When you deploy a message flow that contains a CORBARequest node and an IDL file that contains includes, ensure that all included IDL files are added to the BAR file.

  If you are dragging a message flow that uses a multifile IDL file onto an execution group in the Broker Development perspective, included IDL files are not deployed. To deploy message flows that use multifile IDL files, you must create a BAR file.

Resolving problems when you use Email nodes

Advice for dealing with common problems that can arise when you develop message flows that contain Email nodes.

About this task

- "A negative email size displays in the local environment"
- "A parsing error displays when you reparse an email attachment as XML" on page 3399
- "Removing unwanted null characters from an email" on page 3399

A negative email size displays in the local environment:
Procedure

- **Scenario:** The EmailInput node receives an email from an email server that supports Post Office Protocol 3 (POP3) but the size of the email, including any attachments, might display a negative value in the `Root.EmailInputHeader.Size` Multipurpose Internet Mail Extensions (MIME) logical tree.
- **Explanation:** The email server provider that supports POP3 uses the **`TOP`** command to fetch the headers for the email message and the **`LIST`** command to determine the size of the entire message. The server then subtracts the two values to determine the size of the message body. If the server reports the size of the entire message incorrectly, you might see a negative number in the local environment Size field.
- **Solution:** You can use a Compute node to calculate the size of the email message and the size of any attachments. The following example ESQL can be used to calculate the size of the email content and attachments for a multipart MIME document. In this example, the result is stored in the LocalEnvironment:

```
DECLARE CURSOR REFERENCE TO InputRoot.MIME.Parts;
      DECLARE I INTEGER 0;

      FOR SOURCE AS CURSOR.Part[] DO
         SET I = I + LENGTH( SOURCE.Data.BLOB.BLOB);
      END FOR;

      SET OutputLocalEnvironment.Variables.EmailSize = I;
```

  For more information about messages that belong to the MIME domain, see "Manipulating messages in the MIME domain" on page 2612.

A parsing error displays when you reparse an email attachment as XML:
Procedure

- **Scenario:** Your message flow retrieves emails from an email server by using an EmailInput node. The email contains an XML document attachment that you want to reparse. However, when you try to reparse the attachment you receive parsing errors from WebSphere Message Broker reporting that you have an invalid XML character.
- **Explanation:** Some email servers might insert carriage return (CR) and line feed (LF) characters at the end of an email. Typically you would want to keep these characters, but in this scenario you must remove them so that you can reparse your XML data.
- **Solution:** Use the following ESQL in a Compute node to remove the CR and LF characters:

```
DECLARE NEWEMAIL BLOB TRIM( TRAILING X'0d0a' FROM InputRoot.
MIME.Data.BLOB.BLOB );
```

Removing unwanted null characters from an email:
Procedure

- **Scenario:** Your email attachment contains unwanted null characters that you would like to remove.
- **Explanation:** Your email attachment might contain null characters that you would like to remove; for example, you intend to reparse the data in the attachment.
- **Solution:** Use the following ESQL in a Compute node to remove the null characters:

```
DECLARE NEWEMAIL BLOB TRIM( TRAILING X'00' FROM InputRoot.MIME.
Data.BLOB.BLOB)
```

Related concepts:

Use the EmailInput node to retrieve an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

Resolving ESQL problems when developing message flows

This topic contains advice for dealing with some common ESQL problems that can arise when developing message flows:

A `Routine not defined` error message is issued in ESQL when you move a routine:
Procedure

- **Scenario:** A `Routine not defined` error message is displayed in ESQL when you move a routine from one schema to another.
- **Explanation:** If a routine that was referenced by code in one schema is moved to another schema, where it is still visible, a false error is generated stating that the routine cannot be resolved.
- **Solution:** Clean the project by clicking **Project** > **Clean**.

The product fails to respond when you paste ESQL statements from Adobe Reader:
Procedure

- **Scenario:** When you copy and paste certain ESQL statements from Adobe Reader into the ESQL editor, WebSphere Message Broker stops responding.
- **Explanation:** This problem occurs when you paste text directly from Adobe Reader into either the ESQL editor or the Java editor.
- **Solution:** To work around this problem, either enter the text manually, or copy and paste it to a text editor (such as Notepad), then perform another copy and paste action from there.

You do not know how message flows handle the code page of ESQL files:
Procedure

- **Scenario:** You do not know how message flows handle the code page of ESQL files.
- **Solution:** The code page of an ESQL file is the code page of the WebSphere Message Broker Toolkit on which the file is created. You must deploy a message flow using an ESQL file on a WebSphere Message Broker Toolkit with the same code page setting as the ESQL file. When multiple ESQL files are involved in a single compiled message flow (`.cmf`) file, all these ESQL files must be in the same code page.

  See "Editor preferences and localized settings" on page 6793 for more information.

You do not know the naming restrictions for ESQL procedures and functions:
Procedure

- **Scenario:** You do not know the restrictions for choosing names for ESQL modules or schema scope ESQL and mapping procedures and functions.
- **Solution:** Module and schema scope procedures and functions cannot have names starting with `IBM_WBIMB_` because `IBM_` is reserved for IBM use, and `IBM_WBIMB_` is reserved for WebSphere Message Broker.

Error message BIP5431 is issued and the broker fails:
Procedure

- **Scenario:** Error message BIP5431 is displayed and the broker fails.
- **Explanation:** When setting output message properties, you have specified an incorrect physical format name for the message format.

- **Solution:** The name that you specify for the physical layer must match the name that you have defined for it. The default physical layer names are `Binary1`, `XML1` and `Text1`.

You are unable to call Java from ESQL:
Procedure

- **Scenario:** Your Java class files are not being found.
- **Explanation:** When creating the class files, you have not placed them in the correct location within the system CLASSPATH.
- **Solution:** See the "CREATE PROCEDURE statement" on page 5103 for further information.

Error message BIP3203 is issued: Format expression is not a valid FORMAT expression for converting expression to type:
Procedure

- **Scenario:** Your format expression contains an unrecognized character for the conversion.
- **Explanation:** Your format expression for a numeric conversion was used to convert to or from a *DATE*, *TIME*, *TIMESTAMP*, *GMTTIME* or *GMTTIMESTAMP* variable. Another possible explanation is that your format expression for a DateTime conversion was used to convert to or from an *INTEGER*, *DECIMAL* or *FLOAT* variable.
- **Solution:** Replace the format expression with one from the applicable types. For more information about valid data types and expressions, see the "ESQL reference" on page 5019 topic.

Error message BIP3204 is issued: Input expression does not match FORMAT expression. Parsing failed to match:
Procedure

- **Scenario:** You have used an input string that does not match the format expression.
- **Explanation:** Your format expression contains data that does not match the current element of the format expression.
- **Solution:** Either rewrite the format expression to match the input data, or modify the input data to match the format expression. For more information about valid data types and expressions, see the "ESQL reference" on page 5019 topic.

The CAST function does not provide the expected DST offset for non-GMT time zones:
Procedure

- **Scenario:** You are using the CAST function to convert a string to a TIME variable, in a broker that is running in a time zone other than GMT. The daylight saving time (DST) offset is not correctly calculated.
- **Explanation:** If no time zone is associated with the time string passed to CAST, it is converted to GMT time. If no date is supplied, the current system date is assumed.
- **Solution:** Specify the correct time zone and date. See "Formatting and parsing dateTimes as strings" on page 5253 for more information.

Error message BIP3205 is issued: The use of a FORMAT expression is not allowed when converting:

Procedure

- **Scenario:** You have used a format expression when it is not applicable, for example when converting from decimal to integer.
- **Explanation:** The use of format expressions is limited to casting between datetime and string values or numeric and string values. Your format expression cannot be applied in this case.
- **Solution:** Either remove the FORMAT clause, or change the parameters. For more information about valid data types and expressions, see the "ESQL reference" on page 5019 topic.

Problems when developing message flows with file nodes

Use the advice given here to help you to resolve some common problems that can arise when you develop message flows that contain file nodes.

About this task

- "A file node flow stops processing files and error message BIP3331 or BIP3332 is issued" on page 3403

- "During processing of a large file, error message BIP2106 is issued or the broker stops because of insufficient memory"
- "Missing or duplicate messages after recovery from failure in a flow attached to a FileInput node" on page 3404
- "No file is created in the output directory after FileOutput node processing" on page 3405
- "Output file name overrides have not been applied" on page 3406

A file node flow stops processing files and error message BIP3331 or BIP3332 is issued:
Procedure

- **Scenario:** Files in the specified input directory are not being processed. Error message BIP3331 or BIP3332 is issued.
- **Explanation:** The error messages explain that the FileInput node encountered an exception and could not continue file processing. This problem can be caused when the FileInput node cannot move files from its input directory to the archive or backout directory because of file system permissions or another file in the target directory preventing the file to be transferred. In this situation, the node is unable to process input files without losing data so processing stops. Two messages are issued; the first is either BIP3331 or BIP3332 which specifies a second message which describes the cause of the problem in more detail.
- **Solution:** If the first error message issued is BIP3331, stop the flow and resolve the problem. The FileInput node is unable to complete successful processing of the file.
  1. Stop the flow.
  2. Find the error message referenced in the BIP3331. This second error message identifies the problem and the files and directories causing it.
  3. Ensure the broker has the required access to these files and directories.
  4. You might need to move, delete or rename files in the archive or transit directories.
  5. Check whether the input file causing the problem has been successfully processed (except for being moved to the archive or backout directory). If it has been successfully processed, remove it from the input directory.
  6. Restart the flow.

  If the first error message issued is BIP3332, you do not need to stop the flow because the FileInput node has detected the problem before starting file processing. Find the error message referenced in the BIP3332 message. This second error message identifies the problem and the files and directories causing it.

During processing of a large file, error message BIP2106 is issued or the broker stops because of insufficient memory:
Procedure

- **Scenario:** Large input files cause the broker to issue messages, or stop, because insufficient memory is available.
- **Explanation:** The FileInput node can process very large files. Subsequent processing in the flow attached to its Out terminal might require more memory than is available to the broker.
- **Solution:** In most cases, the FileInput node imposes a limit of 100 MB on the records propagated to the attached flow. If your application needs to access large amounts of data, you might need to increase its available memory and reduce the number of available instances. See "Resolving problems with performance" on page 3504

on page 3500 for more information. If your application needs to process messages larger than 100 MB, you can override the FileInput node record size limit by taking the following actions:

– Before starting the broker, set the environment variable MQSI_FILENODES_MAXIMUM_RECORD_LENGTH to the required limit as an integer number of bytes, for example:

```
SET MQSI_FILENODES_MAXIMUM_RECORD_LENGTH=268435456
```

– When the broker first initializes a FileInput node, it will use the environment variable value instead of the default value of 100 MB. Subsequent changes to the environment variable value will not affect the broker limit until the broker is restarted.

– If the `Record detection` property is set to `Whole File`, the limit applies to the file size. If the `Record detection` property is set to `Fixed Length` or `Delimited`, the limit applies to the record size. The FileOutput node is not affected by changes to this limit.

–

Note: Increasing the FileInput node record size limit might require additional broker resources, particularly memory. You must thoroughly test and evaluate your broker's performance when processing these files. The number of factors that are involved in handling large messages make it impossible to provide specific broker memory requirements.

You can also reduce the memory required to process the file's contents in the following ways:

– If you are processing a whole file as a single BLOB, split it into smaller messages by specifying on the **Records and Elements** tab of the FileInput node's properties:

  - A value of `Fixed Length` in the `Record detection` property
  - A large value in the `Length` property, for example 1000000.

– If you are writing the file's contents to a single output file, specify `Record is Unmodified Data` in the FileOutput node's `Record definition` property; this reassembles the records in an output file of the same size as the input file. Wire the FileInput node's End of Data terminal to the FileOutput node's Finish File terminal. Configure the flow to have no additional instances to ensure that the output records arrive in sequence.

– If you are processing large records using the techniques shown in the Large Messaging sample, ensure that you do not cause the execution group to access the whole record. Avoid specifying a value of `$Body` in the `Pattern` property of a Trace node.

– If you have specified a value of `Parsed Record Sequence` in the FileInput node's `Record definition` property, the broker does not limit the size of the record. If subsequent nodes in the message flow try to access an entire large record, the broker might not have sufficient memory to allow this and stop. Use the techniques in the Large Messaging sample to limit the memory required to handle very large records.

Missing or duplicate messages after recovery from failure in a flow attached to a FileInput node:

Procedure

- **Scenario:** After the failure of a message flow containing a FileInput node processing the input file as multiple records, a subsequent restart of the flow results in duplicate messages being processed. If the flow is not restarted, some input records are not processed.

- **Explanation:** If a record produces a message which causes the flow to fail and retry processing does not solve the problem, the node stops processing the file and moves it to the backout directory. Records subsequent to the failing message are not processed. The FileInput node is not transactional; it cannot roll back the file input records. Transactional resources in the attached flow can roll back the effects of the failing input record but not preceding records. Records before the failing record will have been processed but records subsequent to the failing record will not have been processed. If you restart the flow by moving the input file from the backout directory to the input directory, messages from records preceding the point of failure are duplicated.
- **Solution:** If the input messages have unique keys, modify your flow to ignore duplicate records. If the messages do not have unique keys but each input file has a unique name, you can modify your flow to form a unique key based on the file name and record number. Define a database table and add a Database node to your flow to record the key of each record that is processed. Add a DatabaseRoute node to filter input messages so that only records without keys already in the database are processed. See the Simplified Database Routing sample to understand how to use the DatabaseRoute node to filter messages.

  If you cannot generate unique keys for each record, split your flow into two separate flows. In the first flow, wire the FileInput node to an MQOutput node so that each input record is copied as a BLOB to a WebSphere MQ queue. Ensure there are adequate WebSphere MQ resources, queue size for example, so that the first flow does not fail. In the second flow, wire an MQInput node to the flow previously wired to your FileInput node. Configure the MQInput and other nodes to achieve the desired transactional behavior.

No file is created in the output directory after FileOutput node processing: Procedure

- **Scenario:** A file created by the FileOutput node does not appear in the output directory. The node is configured so that the `Record definition` property has a value of `Record is Unmodified Data`, `Record is Fixed Length Data`, or `Record is Delimited Data` and the flow runs one or more times.
- **Explanation:** The FileOutput node accumulates messages, record by record, in an incomplete version of the output file in the transit subdirectory of the output directory. It moves the file from the transit subdirectory to the output directory only when it receives a message on its Finish File terminal; at this point, the file is complete. If the node's input processing fails before a message is sent to the Finish file terminal, the file remains in the transit directory. The file might be completed by a subsequent flow if it uses the same file name and output directory; if this does not happen, the file is never moved to the output directory
- **Solution:** If you need to ensure that incomplete files are moved to the output directory if the input flow fails, wire the input node's Failure terminal to the FileOutput node's Finish File terminal, in addition to all other flows that are wired to this terminal.

  If you need all output files to be available for a downstream process at a particular time or after a particular event, wire a separate flow to the FileOutput node's Finish File terminal to send a message at that particular time or on that particular event. If duplicate messages which identify the same file are sent to the Finish File terminal, the FileOutput node ignores them.

  If your flows use the `Request directory property location`, `Request file name property location` (default `Directory` and `Name` in the `$LocalEnvironment/Destination/File` folder), or `$LocalEnvironment/Wildcard/WildcardMatch`, ensure that messages sent to the Finish File terminal contain the correct elements and values to identify the output file and directory.

Output file name overrides have not been applied:
Procedure

- **Scenario:** The message elements set in the flow to override the output file name or directory values specified in the FileOutput node's **Basic** properties have not been applied. The output file is created using the name and directory set in the FileOutput node's **Basic** properties.
- **Explanation:** One of the following might be the cause of this problem:
  - The message sent to the FileOutput node does not contain the expected changes.
  - The FileOutput node is configured to use different elements in the message from the ones set to the new values.
  - Not all messages contain the overriding values.
- **Solution:** Use the debugger or a Trace node inserted in front of the FileOutput node's In terminal to check that the expected overriding values appear in the correct message elements. If they do not, check that the `Compute mode` property has been set correctly in Compute nodes that are upstream in the flow; for example, if $LocalEnvironment/File/Name has not changed following a Compute node, check that the Compute node has its `Compute mode` property set to `LocalEnvironment and Message`.

  If the message elements are set correctly, check that the FileOutput node's `Request directory property location` and `Request file name property location` properties identify the correct elements in the message.

  If you have specified `Record is Unmodified DataRecord is Fixed Length Data`, or `Record is Delimited Data` in the FileOutput node's `Record definition` property, ensure that messages that go to the Finish File terminal have the same override values as those that go to the in terminal. Unless you do this, the Finish file terminal message and the In terminal messages will apply to different files.

Resolving problems when you use HTTP and SOAP nodes

Use the advice given here to help you to resolve common problems that can arise when you develop Web Services message flows that contain HTTP and SOAP nodes.

About this task

Use the replies to the following questions to assist you in diagnosing problems with HTTP or SOAP nodes:

- "How do I tell which listener the HTTP nodes are using?"
- "How do I collect HTTPListener trace?" on page 3408

A HandshakeException is issued when you use an HTTPRequest node to make an HTTPS call:
Procedure

- **Scenario:** You are trying to make an HTTPS call to an external web service from your WebSphere Message Broker message flow by using an HTTPRequest node. You receive the following error:

```
javax.net.ssl.SSLHandshakeException:
com.ibm.jsse2.util.h: PKIX path building failed:

java.security.cert.CertPathBuilderException:
PKIXCertPathBuilderImpl could not build a valid CertPath.;

internal cause is:
java.security.cert.CertPathValidatorException:
The certificate issued by OU=Class 3 Public Primary Certification Authority,
O="VeriSign, Inc.", C=US is not trusted;

internal cause is:
java.security.cert.CertPathValidatorException: Certificate chaining error
```

- **Explanation:** The broker cannot build the entire certificate path. The keystore of this broker must contain all the certificates in this chain of certificate authorities (CA). For a broker to verify the digital signature on a signed certificate, the keystore must contain the public key of the certificate authority (CA) that issued that certificate. If this public key is itself issued on a signed certificate, the keystore must contain the public key of the CA that issued that certificate. This chain continues until the broker reaches a root certificate authority that issues a self-signed certificate.
- **Solution:** Verify that you added all the required certificates to your keystore. If any of the components in the certificate chain are missing from your keystore, re-create your keystore by using keytool with the `genkey` option, then reimport your application certificates.

How do I tell which listener the HTTP nodes are using?:
Procedure

- **Scenario:** HTTP nodes that you include in a message flow can use either the broker-wide listener or the embedded listener that is defined to the execution group to which the containing message flow is deployed. Both listeners can handle both HTTP and HTTPS messages by handling the different message types on different ports.
- **Solution:** Use the **mqsireportproperties** command to check the properties that define what listener is in use.
  1. Check whether the broker listener has been disabled:

```
mqsireportproperties MB7BROKER -b httplistener -o HTTPListener -n startListener
```

If this property is false, all HTTP nodes in all execution groups are using an embedded listener.

2. If the broker listener is active, you must check the specific execution group.

   For example, check whether the listener in EG_A is being used to process HTTP messages for HTTP nodes:

   ```
   mqsireportproperties TEST -e EG_A -o ExecutionGroup  -n httpNodesUseEmbeddedListener
   ```

   If this property is true, all HTTP nodes that you deploy to this execution group are using the embedded listener.

   Check all execution groups for which you want to know this information.

3. If both properties are false, all HTTP nodes that you deploy to all execution groups are using the embedded listener. The value for the execution group property is ignored.

Results

If you are experiencing problems with message flows that contain HTTP nodes, and you want to collect trace information to provide to your IBM Support Center, trace the execution group. If you are using the broker-wide listener for HTTP nodes, also trace the HTTPListener component.

How do I collect HTTPListener trace?:
About this task

To gather information about HTTP nodes and listeners, you must start trace, run your message flows, then retrieve and format the trace information.

Trace the execution group and the HTTPListener component:

Procedure

- Start trace for the execution group.

  For example:

  ```
  mqsichangetrace MB7BROKER -t -e default -l debug
  ```

- If you are using the broker-wide listener for one or more execution groups, start trace for the HTTPListener component in one of the following two ways:
  - Trace all broker components:
    1. Run the **mqsichangetrace** command to start trace with the following options:

       ```
       mqsichangetrace component -t -b -l debug
       ```

       where *component* is the broker name.

    2. Retrieve the HTTPListener trace log by using the **mqsireadlog** command with the HTTPListener qualifier for the **-b** parameter.

       For example:

       ```
       mqsireadlog brokerName -t -b httplistener -f -o listenertrace.xml
       ```

    3. Format the trace log by using the **mqsiformatlog** command to view its contents.
  - Trace only the HTTPListener component:
    1. Run the **mqsichangeproperties** command to start trace with the following options:

```
mqsichangeproperties brokerName -b httplistener -o HTTPListener
 -n traceLevel -v debug
```

2. Retrieve and format the HTTPListener trace log as shown in the previous example.

What to do next

Save the trace output so that you can send it to the IBM Support Center, if requested.

Turn trace off when you finish collecting information to avoid affecting the performance of the broker.

Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

Resolving implementation problems when developing message flows

Use the advice given here to help you to resolve some common problems that can arise when running message flows.

About this task

Messages are directed to the Failure terminal of an MQInput node: Procedure

- **Scenario:** Messages that are received at a message flow are directed immediately to the Failure terminal on the MQInput node (if it is connected), or are rolled back.
- **Explanation:** When a message is received by WebSphere MQ, an error is signalled if the following conditions are all true:
  - The MQInput node requests that the message content is converted (the Convert property is set to `yes` on the node).
  - The message consists only of an MQMD followed by the body of the message.
  - The message format, as specified in the MQMD, is set to MQFMT_NONE.

  This error causes the message to be directed to the Failure terminal.
- **Solution:** In general, you do not need to request WebSphere MQ to convert the message content, because the broker processes messages in all code pages and encodings that are supported by WebSphere MQ. Set the Convert property to `no` to ensure that messages flow from the MQInput node to successive nodes in the message flow.

Error message BIP2211 is issued on z/OS by the MQInput node: Procedure

- **Scenario:** The following error message is issued by the MQInput node, indicating an invalid attribute:

```
BIP2211: (Invalid configuration message containing attribute value [attribute value]
which is not valid for target attribute [target attribute name],
object [object name]; valid values are [valid values])
```

- **Explanation:** On z/OS, WebSphere MQ supports serialized access to shared resources, such as shared queues, through the use of a connection tag (serialization token) when an application connects to the queue manager that participates in a queue sharing group. In this case, an invalid attribute has been specified for the z/OS serialization token.
- **Solution:** Check that the value that is provided for the z/OS serialization token conforms to the rules as described in the *Application Programming Reference* section of the WebSphere MQ Version 7 Information Center online.

Messages enter the message flow but do not exit:

Procedure

- **Scenario:** You have sent messages into your message flow, and they have been removed from the input queue, but nothing appears at the other end of the message flow.
- **Explanation:** Several situations might cause this error to occur. Consider the following scenarios to try to identify the situation that is causing your failure:
  1. Check your message flow in the WebSphere Message Broker Toolkit.

     You might have connected the MQInput node Failure terminal to a successive node instead of the Out terminal. The Out terminal is the *middle* terminal of the three. Messages directed to an unconnected Out terminal are discarded.
  2. If the Out terminal of the MQInput node is connected correctly to a successive node, check the broker's local error log for an indication that message processing has been ended because of problems. Additional messages give more detailed information.

     If the Failure terminal of the MQInput node has been connected (for example, to an MQOutput node), these messages do not appear.

     Connecting a node to a Failure terminal of another node indicates that you have designed the message flow to deal with all error processing. If you connect a Failure terminal to an MQOutput node, your message flow ignores all errors that occur.
  3. If the Out terminal of the MQInput node is connected correctly to a successive node, and the local error log does not contain error messages, turn user tracing on for the message flow:
     a. Open the WebSphere Message Broker Explorer.
     b. In the Navigator view, expand the Brokers folder.
     c. Right-click the message flow, and click **User TraceNormal**.

     This action produces a user trace entry from only the nodes that the message visits.

     On distributed systems, you can retrieve the trace entries by using the **mqsireadlog** command, format them by using the **mqsiformatlog** command, and view the formatted records to check the path of the message through the message flow.

     z/OS For z/OS, edit and submit the BIPRELG job in COMPONENTPDS to execute the **mqsireadlog** and **mqsiformatlog** commands to process traces.
  4. If the user trace shows that the message is not taking the expected path through the message flow, increase the user trace level to Debug by selecting the message flow, right-clicking it, and clicking **User Trace** > **Debug**.

     Send your message into the message flow again. Debug-level trace produces much more detail about why the message is taking a particular route, and you can then determine the reasons for the actions taken by the message flow.

     Do not forget to turn tracing off when you have solved the problem, because performance might be adversely affected.
  5. If the MQPUT command to the output queue that is defined on the MQOutput node is not successful (for example, the queue is full or **put** is disabled), the final destination of a message depends on:
     - Whether the Failure terminal of the MQOutput node is connected.
     - Whether the message is being processed transactionally (which in turn depends on the transaction mode setting of the MQInput node, the MQOutput node, and the input and output queues).

– Whether the message is persistent or nonpersistent. When transaction mode is set to the default value of Automatic, message transactionality is derived from the way that it was specified at the input node. All messages are treated as persistent if transaction mode=yes, and as nonpersistent if transaction mode=no.

In general, if a path is not defined for a failure (that is, neither the Catch terminal nor the Failure terminal of the MQInput node is connected):

– Non-transactional messages are discarded.
– Transactional messages are rolled back to the input queue to be tried again:
  - If the backout count of the message is less than the backout threshold (BOTHRESH) of the input queue, the message is tried again and sent to the Out terminal.
  - When the backout count equals or exceeds the backout threshold, one of the following might happen:
    • The message is placed on the backout queue, if one is specified (using the BOQNAME attribute of the input queue.)
    • The message is placed on the dead-letter queue, if there is no backout queue defined or if the MQPUT to the backout queue fails.
    • If the MQPUT to the dead-letter queue fails, or if there is no dead-letter queue defined, then the message flow loops continuously trying to put the message to the dead-letter queue.
– If a path is defined for the failure, then that path defines the destination of the message. If both the Catch terminal and the Failure terminal are connected, the message is propagated through the Catch terminal.

6. If your message flow uses transaction mode=yes on the MQInput node properties, and the messages are not appearing on an output queue, check the path of the message flow.
   – If the message flow has paths that are not failures (but that do not end in an output queue), either:
     - The message flow has not failed and the message is not backed out.
     - The message flow is put to an alternative destination (for example, the Catch terminal, the dead-letter queue, or the queue's backout queue).
   – Check that all possible paths reach a final output node and do not reach a dead end. For example, check that you have:
     - Connected the Unknown terminal of a Filter node to another node in the message flow.
     - Connected both the True and False terminals of a Filter node to another node in the message flow.

Your execution group is not reading messages from the input queues: Procedure

- **Scenario:** Your execution group has started, but is not reading messages from the specified input queues.
- **Explanation:** A started execution group might not read messages from the input queues of the message flows because previous errors might have left the queue manager in an inconsistent state.
- **Solution:** Complete the following steps:
  1. Stop the broker.
  2. Stop the WebSphere MQ listener.
  3. Stop the WebSphere MQ channel initiator.

4. Stop the WebSphere MQ queue manager.
5. Restart the WebSphere MQ queue manager.
6. Restart the WebSphere MQ channel initiator.
7. Restart the WebSphere MQ listener.
8. Restart the broker.

The execution group ends while processing messages:
About this task

Procedure

- **Scenario:** While processing a series of messages, the execution group (DataFlowEngine) process size grows steadily without levelling off. This situation might cause the DataFlowEngine process to end if it cannot allocate more memory, and restart. The error message BIP2106 might be logged to indicate the out of memory condition.

  In addition, if you are using DB2 on distributed systems, you might get the message:

  ```
  SQL0954C  Not enough storage is  available in the application heap to process
  the statement.
  ```

  z/OS On z/OS, an SQLSTATE of HY014 might be returned with an SQL code of -99999, indicating that the DataFlowEngine process has reached the DB2 z/OS process limit of 254 prepared SQL statement handles.
- **Explanation:** When a database call is made from within a message flow node, the flow constructs the appropriate SQL, which is sent using ODBC to the database manager. As part of this process, the SQL statement is prepared using the SQLPrepare function, and a statement handle is acquired so that the SQL statement can be executed.

  For performance reasons, after the statement is prepared, the statement and handle are saved in a cache to reduce the number of calls to the SQLPrepare function. If the statement is already in the cache, the statement handle is returned so that it can be re-executed with newly bound parameters.

  The statement string is used to perform the cache lookup. By using hardcoded SQL strings that differ slightly for each message, the statement is not found in the cache, and an SQLPrepare function is always performed (and a new ODBC cursor is opened). When using PASSTHRU statements, use parameter markers so that the same SQL prepared statement can be used for each message processed, with the parameters being bound at run time. This approach is more efficient in terms of database resources and, for statements that are executed repeatedly, it is faster.

  However, it is not always possible to use parameter markers, or you might want to dynamically build the SQL statement strings at run time. This situation potentially leads to many unique SQL statements being cached. The cache itself does not grow that large, because these statements themselves are generally not big, but many small memory allocations can lead to memory fragmentation.
- **Solution:** If you encounter these types of situations, disable the caching of prepared statements by setting the MQSI_EMPTY_DB_CACHE environment variable to an arbitrary value. When this environment variable has been created, the prepared statements for that message flow are emptied at the end of processing for each message. This action might cause a slight performance degradation because every SQL statement is prepared.

Your execution group hangs, or ends with a core dump:

Procedure

- **Scenario:** While processing a message, an execution group either hangs with high CPU usage, or ends with a core dump. The stack trace from the core dump or abend file is large, showing many calls on the stack. Messages written to the system log might indicate "out of memory" or "bad allocation" conditions. The characteristics of the message flow in this scenario often include a hard-wired loop around some of the nodes.
- **Explanation:** When a message flow thread executes, it requires storage to perform the instructions that are defined by the logic of its connected nodes. This storage comes from the execution group's heap and stack storage. The execution of a message flow is constrained by the stack size, the default value of which differs depending on the operating system.
- **Solution:** If a message flow that is larger than the stack size is required, you can increase the stack size limit and then restart the brokers that are running on the system so that they use the new value. For information on setting the stack size for your operating system, see "System resources for message flow development" on page 3267.

Your XSLTransform node is not working after deployment and errors are issued indicating that the style sheet could not be processed:
Procedure

- **Scenario:** Your XSLTransform node is not working after deploying resources, and errors are displayed indicating that the style sheet could not be processed.
- **Solution:**
  - If the broker cannot find the style sheet or XML files that are required, migrate the style sheets or XML files with relative path references.
  - If the contents of a style sheet or XML file are damaged and therefore no longer usable (for example, if a file system failure occurs during a deployment), redeploy the damaged style sheet or XML file.

Output messages are not sent to expected destinations:
Procedure

- **Scenario:** You have developed a message flow that creates a destination list in the LocalEnvironment tree. The list might contain queues for the MQOutput node, labels for a RouteToLabel node, or URLs for an HTTPRequest node. However, the messages are not reaching these destinations, and there are no error messages.
- **Solution:**
  - Check that you have set Compute mode to a value that includes the LocalEnvironment in the output message, for example All. The default setting of Compute mode is Message, and all changes that you make to LocalEnvironment are lost.
  - Check your ESQL statements. The content and structure of LocalEnvironment are not enforced, so the ESQL editor (and content assist) does not provide guidance for field references, and you might have specified one or more of these references incorrectly.

    Some example procedures to help you set up destination lists are provided in "Populating Destination in the local environment tree" on page 2467. You can use these procedures unchanged, or modify them for your own requirements.

You experience problems when sending a message to an HTTP node's URL:

Procedure

- **Scenario:** Sending a message to an HTTP node's URL causes a timeout, or the message is not sent to the correct message flow.
- **Explanation:** The following rules are true when URL matching is performed:
  - There is one-to-one matching of HTTP requests to HTTPInput nodes. For each HTTP request, only one message flow receives the message. This statement is true even if two message flows are listening on the same URL. Similarly, you cannot predict which MQInput node that is listening on a particular queue will receive a message.
  - Messages are sent to wildcard URLs only if no other URL is matched. Therefore a URL of /* receives all messages that do not match another URL.
  - Changing a URL in an HTTPInput node does not automatically remove the entry from the HTTP listener. For example, if a URL /A is used first, then changed to a URL of /B, the URL of /A is still used to listen on, even though there is no message flow to process the message. This incorrect URL does get removed after the broker has been stopped and restarted twice.
- **Solution:** To find out which URL the broker is currently listening on, look at the file `wsplugin6.conf` in the following location:
  - Linux UNIX On Linux and UNIX: `/var/mqsi/components/broker_name/config`
  - Windows On Windows, `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\components/broker_name/config` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:
    - On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\components/broker_name/config`
    - On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\components/broker_name/config`

    The actual value might be different on your computer.

  If problems persist, empty `wsplugin6.conf`, restart the broker, and redeploy the message flows.

When using secure HTTP connections, you change a DNS host's destination but the broker is using a cached DNS host definition:
Procedure

- **Scenario:** You are using a broker with secure HTTP connections that use the Java virtual machine (JVM). You have changed a DNS destination, but the broker is using a cached DNS host definition, therefore you have to restart the broker to use the new definition.
- **Explanation:** By default, Java caches the host lookup from DNS, which is not appropriate if you want to look up the host name each time or if you want to cache it for a limited amount of time. This situation occurs only when you use SSL connections. (When using a secure HTTPS connection, the HTTPRequest node uses the SSL protocol, which issues Java calls, whereas a non-SSL protocol uses native calls.)

  To avoid this situation, you can empty the cache on the JVM by setting the **`networkaddress.cache.ttl`** property to zero. This property dictates the caching policy for successful name lookups from the name service. The value is specified as an integer to indicate the number of seconds for which to cache the successful lookup. The default value of this property is -1, which indicates that the

successful DNS lookup value is cached indefinitely in the JVM. If you set this property to 0 (zero), the successful DNS lookup is not cached.

- **Solution:** To pick up DNS entry changes without the need to stop and restart the broker and JVM, disable DNS caching. Edit file `$JAVA_HOME/jre/lib/security/java.security`, and set the value of the **`networkaddress.cache.ttl`** property to `0` (zero).

The TimeoutControl node issues error message BIP4606 or BIP4607 when the timeout request start time that it receives is in the past:
Procedure

- **Scenario:** When a TimeoutControl node receives a timeout request message that contains a start time in the past, it issues error message BIP4606 or BIP4607: `The Timeout Control Node '&2' received a timeout request that did not contain a valid timeout start date/time value.`
- **Explanation:** The start time in the message can be calculated by adding an interval to the current time. If a delay occurs between the node that calculates the start time and the TimeoutControl node, the start time in the message will have passed by the time it reaches the TimeoutControl node. If the start time is more than approximately five minutes in the past, a warning is issued and the TimeoutControl node rejects the timeout request. If the start time is less than five minutes in the past, the node processes the request as if it were immediate.
- **Solution:** Ensure that the start time in the timeout request message is a time in the future.

You are using a TimeoutControl node with a TimeoutNotification node, with multiple clients running concurrently, and messages appear to be being dropped:
Procedure

- **Scenario:** You are using a TimeoutControl node with a TimeoutNotification node, with multiple clients running concurrently, and messages appear to be being dropped. In the timeout request message, allowOverwrite is set to TRUE.
- **Explanation:** If multiple clients are running concurrently, and allowOverwrite is set to TRUE in the timeout request message, messages can overwrite each other.
- **Solution:** Ensure that different TimeoutNotification nodes that are deployed on the same broker do not share the same unique identifier.

Error message BIP5347 is issued on AIX when you run a message flow that uses a message set:
About this task

Procedure

- **Scenario:** Error message BIP5347 (`MtilmbParser2: RM has thrown an unknown exception`) is issued on AIX in either of these circumstances:
  - When you are deploying a message set
  - When you are running a message flow that uses a message set
- **Explanation:** BIP5347 is typically caused by a database exception, and it is issued when an execution group tries to load an MRM dictionary for use by a message flow. This process involves two steps:
  1. The execution group retrieves the dictionary and wire format descriptors from the broker data store.
  2. The execution group stores the dictionary in the memory that a message flow would use to process an MRM message.

BIP5347 is typically issued during step 1. This problem can appear to be intermittent; if you restart the execution group, the message is sometimes processed correctly.

BIP5347 might also be caused by the presence of a datetime value constraint in the message set, which causes the error each time the message set is deployed.

- **Solution:** To identify the cause of the error, capture a service level debug trace to confirm that the database exception is occurring.
  - If the error is caused by the presence of a datetime value constraint, a message similar to the following message appears in the service level debug trace (the exact message depends on the datetime constraint in the message set):

    ```
    Unable to parse datetime internally, 9, 2001-12-17T09:30:47.0Z,
    yyyy-MM-dd'T'HH:mm:ss.SZZZ
    ```

    This error occurs because the MRM element in question has a datetime value that is not compatible with the datetime format string, so the dictionary is rejected. To solve this problem, ensure that the datetime value is compatible with the datetime format string.

Error message BIP2130 is issued with code page value of -1 or -2: Procedure

- **Scenario:** The following error message is issued:

```
BIP2130: Error converting a character string to or from codepage [code page value]
```

where `[code page value]` is either -1 or -2. You have not, however, specified a code page of either -1 or -2 in your message tree. You have, however, used one of the WebSphere MQ constants MQCCSI_EMBEDDED or MQCCSI_INHERIT.

- **Explanation:** The WebSphere MQ constants MQCCSI_EMBEDDED and MQCCSI_INHERIT are resolved when the whole of the message tree is serialized to produce the WebSphere MQ bit stream. This happens when the message is put on the WebSphere MQ transport. Until that time, these values exist in the message tree as either -1 (for MQCCSI_EMBEDDED) or -2 (for MQCCSI_INHERIT). If one or more parts of the message tree are serialized independently, such as with a ResetContentDescriptor node or ESQL ASBITSTREAM function, this error occurs.
- **Solution:** You do not have to set MQCCSI_EMBEDDED or MQCCSI_INHERIT in the message tree's CodedCharSetId field. You can achieve the same result by explicitly setting the required CodedCharSetId to the previous header's CodedCharSetId value. For example, you would need to replace:

```
SET OutputRoot.MQRFH2.(MQRFH2.Field)CodedCharSetId = MQCCSI_INHERIT;
```

with

```
SET OutputRoot.MQRFH2.(MQRFH2.Field)CodedCharSetId = InputRoot.MQMD.CodedCharSetId;
```

where the MQMD folder is the header preceding the MQRFH2 header.

The execution group restarts before an MQGet node has retrieved all messages: Procedure

- **Scenario:** You have created a message flow that contains an MQGet node. Not all of the messages are retrieved from the queue because the execution group restarts before the node has retrieved all the messages. No abend files are generated.
- **Explanation:** In WebSphere Message Broker, processing that involves nested or recursive processing can cause extensive use of the stack. Message flow

processing occurs in a loop until the MQGet node has retrieved all the messages from the queue. Each time that processing returns to the MQGet node, the stack size increases.

- **Solution:** Use a PROPAGATE statement. The statement propagates each message through the message flow in a loop, but each time that processing returns to the PROPAGATE statement, the stack is cleared.

  Use an ESQL variable (for example, set Environment.Complete to true) in the environment tree to terminate the ESQL loop, stop the propagations, and wait for the next trigger message. If you need to store content from the messages, store it in the environment tree because other trees are deleted when message flow processing returns to the PROPAGATE statement. For more information about how to use this statement, see "PROPAGATE statement" on page 5150.

Resolving problems when you use IMS nodes

Advice for dealing with common problems that can arise when you develop message flows that contain IMS nodes.

Before you begin

Before you start:

- Read about IMS in "IBM Information Management System (IMS)" on page 2129.
- Ensure that you have set up the broker runtime environment correctly, as described in "Preparing the environment for IMS nodes" on page 731.

About this task

If you experience problems when you use IMS nodes in message flows, follow the instructions for the following scenarios to diagnose and solve the problem.

- "How can I tell if my broker is connected to IMS Connect?"
- "How can I discover the correct settings for `Hostname`, `Portnumber`, and `DataStoreName`?" on page 3420
- "What should I do when my transaction times out?" on page 3421
- "How many physical connections should I expect in IMS Connect?" on page 3421

How can I tell if my broker is connected to IMS Connect?:
Procedure

- **Scenario:** You need to check if your broker is connected to IMS Connect.
- **Explanation:** You can use SDSF on z/OS to issue a command to see which ports have clients connected to them.
- **Solution:** Using SDSF, enter the following **`QUERY MEMBER`** command, where *IM0ACONN* is the name of your IMS Connect job:

  ```
  /F IM0ACONN,QRY MEMBER TYPE(IMSCON)
  ```

  The output is in the following format:

  ```
  /F IM0ACONN,QRY MEMBER TYPE(IMSCON)
  HWSC0001I   HWS ID=IM0ACONN RACF=Y  PSWDMC=N
  HWSC0001I      MAXSOC=50  TIMEOUT=0
  HWSC0001I      RRS=N   STATUS=REGISTERED
  HWSC0001I      VERSION=V10 IP-ADDRESS=009.017.252.024
  HWSC0001I      SUPER MEMBER NAME=
  HWSC0001I    ADAPTER=N
  HWSC0001I    DATASTORE=IM0A     STATUS=ACTIVE
  HWSC0001I      GROUP=IM0AGRNM MEMBER=IM0ACONN
  HWSC0001I      TARGET MEMBER=IM0A
  HWSC0001I      DEFAULT REROUTE NAME=HWS£DEF
  HWSC0001I      RACF APPL NAME=
  HWSC0001I      OTMA ACEE AGING VALUE=2147483647
  ```

```
HWSC0001I      OTMA ACK TIMEOUT VALUE=120
HWSC0001I      OTMA MAX INPUT MESSAGE=5000
HWSC0001I    NO ACTIVE IMSPLEX
HWSC0001I    PORT=1080     STATUS=ACTIVE
HWSC0001I      CLIENTID USERID   TRANCODE STATUS       SECOND  CLNTPORT  IP-ADDRESS
HWSC0001I      HWSEHYMO JDOE   IVTNO    RECV            21      1109  009.017.137.11
HWSC0001I      TOTAL CLIENTS=1  RECV=1 CONN=0 XMIT=0 OTHER=0
```

This example shows that one client is connected on TCP port 1109, and that the client is connecting from the IP address 9.17.137.11.

You can run netstat on that system to find out in which process that client is running.

Use the following IMS command to view the TPIPEs that are created for those connections:

```
/DISPLAY TMEMBER IMSConnect_Name TPIPE ALL
```

– For transactions that have a commit mode of 1, the TPIPE name is the port number that is used for that interaction (for example, 1080 in the previous example).
– For transactions that have a commit mode of 0, the TPIPE name is the same as the client ID (for example, HWSEHYMO in the previous example). The client ID is generated automatically in the IMSRequest node.

How can I discover the correct settings for `Hostname`, `Portnumber`, and `DataStoreName`?:

Procedure

- **Scenario:** Your broker fails to connect to IMS and you want to verify your settings.
- **Explanation:** You can use SDSF on z/OS to issue a command to see members of the XCF group to which your IMS control region belongs. One of these members should be IMS Connect. You can then run a command against IMS Connect to discover these properties.
- **Solution:** Use SDSF to enter the following command:

  ```
  /xx/display OTMA
  ```

  where *xx* is the reply ID for your IMS control region job.

  For example, if you see `....... *26 DFS996I *IMS READY*  IM0A` in `S.log`, run the command `/26/DISPLAY OTMA`.

  The output from that command shows the name of the IMS Connect that is in the same XCF group as this IMS control region:

```
DFS000I     GROUP/MEMBER      XCF-STATUS   USER-STATUS    SECURITY  TIBINPT SMEM   IM0A
DFS000I                         DRUEXIT  T/O                                      IM0A
DFS000I     IM0AGRNM                                                              IM0A
DFS000I     -IM0A             ACTIVE       SERVER         CHECK                    IM0A
DFS000I     -IM0A               N/A        0                                       IM0A
DFS000I     -IM0ACONN         ACTIVE       ACCEPT TRAFFIC CHECK       05000        IM0A
DFS000I     *08350/175112*   IM0A
```

  Use SDSF to enter the following **`QUERY MEMBER`** command, where *IM0ACONN* is the name of your IMS Connect job that was reported by the previous command:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
```

  The output is in the following format:

```
/F IM0ACONN,QRY MEMBER TYPE(IMSCON)
HWSC0001I   HWS ID=IM0ACONN RACF=Y  PSWDMC=N
HWSC0001I      MAXSOC=50  TIMEOUT=0
HWSC0001I      RRS=N   STATUS=REGISTERED
```

```
HWSC0001I      VERSION=V10 IP-ADDRESS=009.017.252.024
HWSC0001I      SUPER MEMBER NAME=
HWSC0001I    ADAPTER=N
HWSC0001I    DATASTORE=IM0A     STATUS=ACTIVE
HWSC0001I      GROUP=IM0AGRNM MEMBER=IM0ACONN
HWSC0001I      TARGET MEMBER=IM0A
HWSC0001I      DEFAULT REROUTE NAME=HWS£DEF
HWSC0001I      RACF APPL NAME=
HWSC0001I      OTMA ACEE AGING VALUE=2147483647
HWSC0001I      OTMA ACK TIMEOUT VALUE=120
HWSC0001I      OTMA MAX INPUT MESSAGE=5000
HWSC0001I    NO ACTIVE IMSPLEX
HWSC0001I    PORT=1080     STATUS=ACTIVE
HWSC0001I      CLIENTID USERID   TRANCODE STATUS       SECOND  CLNTPORT  IP-ADDRESS
HWSC0001I      HWSEHYMO JDOE   IVTNO    RECV             21      1109  009.017.137.11
HWSC0001I      TOTAL CLIENTS=1  RECV=1 CONN=0 XMIT=0 OTHER=0
```

What should I do when my transaction times out?:
Procedure

- **Scenario:** The transaction times out and the message is sent to the Timeout terminal, or an exception is issued.
- **Explanation:** Your transaction is taking longer than the values that are set for the execution or socket timeouts, therefore the node stops waiting for a response, and issues an exception or sends the message to the Timeout terminal.

  If the transaction subsequently completes successfully, the result depends on the commit mode that is set on the IMSRequest node:

  – If the `Commit mode` property is set to `0: COMMIT_THEN_SEND`, the unit of work is committed and the response is discarded.
  – If the `Commit mode` property is set to `1: SEND_THEN_COMMIT`, the response is not sent and the unit of work is rolled back.
- **Solution:** Increase the execution or socket timeout values to give enough time for the transaction to complete.
  – Configure the execution timeout by using the `Timeout waiting for a transaction to be executed` property on the IMSRequest node.
  – Configure the socket timeout on the configurable service.

How many physical connections should I expect in IMS Connect?:
Procedure

- **Scenario:** You need to set the values for the number of connections that are required by clients that are connecting to IMS Connect.
- **Explanation:** The number of physical connections that can be opened in IMS Connect is limited. The limit depends on the MAXSOC and MAXFEILEPROC settings.
  – The MAXSOC setting in IMS Connect determines the number of sockets that can be opened in IMS, which is the number of ports on which IMS listens for connections, plus the number of physical connections.
  – MAXFILEPROC is a UNIX System Services (USS) setting, which must be greater than or equal to MAXSOC, otherwise IMS reaches this limit before it reaches its own MAXSOC limit.

  If the IMS Connect process is granted superuser authority in USS, it sets MAXFILEPROC automatically.

  If the MAXSOC value is reached, IMS Connect issues warning message HWSS0771W, and refuses new requests for connections from clients. This behavior continues until the number of open sockets is below the limit (for example, after some clients have disconnected).

If the MAXFILEPROC value is reached, USS issues information message BPXI040I.

- **Solution:** When you set values for MAXSOC and MAXFILEPROC, consider how many clients are likely to connect concurrently to IMS Connect, and how many connections those clients will require.

  WebSphere Message Broker acts as a client to IMS Connect, and opens connections to IMS Connect. Therefore, find out how many connections are required by WebSphere Message Broker by gathering the following information:

  – The number of message flows with IMS nodes that are deployed
  – For those message flows, the values of the `Additional instances` property

  The maximum number of connections required for each broker is determined by the number of threads that can be running concurrently in the IMS nodes. In the following example, three message flows with IMS nodes exist:
  – Message flow A has 0 additional instances, therefore one thread is running.
  – Message flow B has 3 additional instances, therefore four threads can be running concurrently.
  – Message flow C has 4 additional instances, therefore five threads can be running concurrently.

  In this example, the maximum number of connections required by the broker is 10 (1+4+5). If you have four other similar brokers, all connecting to the same instance of IMS Connect, which has five ports configured, you would set the maximum number of sockets (MAXSOC) to at least 55 (the maximum number of connections for five brokers plus the number of ports: 10x5+5).

Related concepts:

"IBM Information Management System (IMS)" on page 2129
IMS is a message-based transaction manager and hierarchical-database manager for z/OS. External applications can use transactions to interact with applications that run inside IMS.

"Execution and threading models in a message flow" on page 1279
The execution model is the system used to start message flows which process messages through a series of nodes.

Related tasks:

"Changing connection information for the IMSRequest node" on page 732
You can create a configurable service that the IMSRequest node or message flow refers to at run time for connection information, instead of defining the connection properties on the node or the message flow. The advantage being that you can change the host name, performance, and security values without needing to redeploy your message flow.

Related reference:

"IMSRequest node" on page 4504
Use the IMSRequest node to send a request to run a transaction on a local or remote IMS system, and wait for a response. IMS Connect must be configured and running on the IMS system.

"Configurable services properties" on page 3766
The supplied configurable services, and the configurable services that you create, are defined by their names and properties. You can use the supplied services.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

"Issuing commands to the z/OS console" on page 3980
You operate the broker using the z/OS START, STOP, and MODIFY commands.

Resolving mapping and message reference problems when developing message flows

Advice for dealing with some common mapping and message reference problems that can arise when developing message flows:

Resources that are referenced by the mapping file cannot be resolved:
Procedure

- **Scenario:** You have imported some message flows into the WebSphere Message Broker Toolkit that contain mappings. An error is issued, indicating that the resources that are referenced by the mapping file cannot be resolved.
- **Explanation:** Mappings can use resources that exist in other projects. For example, a mapping reference to a message set might exist in a different project. If the reference cannot be resolved, it probably means that the reference to the other project has been lost.
- **Solution:** To reference a project:
  1. Right-click the project with the error, and click **Properties**.
  2. Under Project References, a list of the projects in your workspace is displayed. Select the required projects to reference the resources in these projects.
  3. Click **OK**.

Errors are issued when you import table schemas into the Message Mapping editor:
Procedure

- **Scenario:** When you try to import and add table schemas in the Message Mapping editor, you encounter errors like:

  ```
  /flow2/schema1/SAMPLE.conxmi cannot be loaded.
  The following error was reported: schema1/SAMPLE.conxmi
  ```

- **Explanation:** This error usually means that you have the same database files under the same broker schema name in another project. The relative paths are the same, so the Message Mapping editor cannot resolve this ambiguity and does not know which table to add.
- **Solution:** There are two courses of action:
  - If the table file already exists in the workspace, and this is what you want to use for mapping, reuse the file by clicking the **Add database table schemas from workspace** option in the Add Database Table Schemas dialog box.
  - If you want a different copy of the tables, rename the broker schema.

Warnings or errors are issued for message references:
Procedure

- **Scenario:** Warnings or errors are issued for message references, yet you are certain that your references are correct.
- **Explanation:** This is never the case with messages that are using the XML parser. For these message references, direct validation is not performed because the references could be used for generic XML.

  There is an ESQL editor preference that allows you to choose to ignore message reference mismatches, or to have them be reported as a warning or an error. By default, this type of problem is reported as a warning, so that you can still deploy the message flow.

- **Solution:** To use the validation feature, ensure that you have set up a project reference from the project that contains the ESQL to the project that contains the message set.

  If you are using reference in a subroutine, take the following steps:

  1. Create a reference to the tree and the parser in the module's main procedure.
  2. Associate the reference to the correlation name, for example InputRoot or Root. Alternatively, create the OutputRoot.*parser* node, where *parser* is the name of the parser that you want to use.
  3. Pass the reference as a parameter to an ESQL subroutine that identifies the XSD type of the reference.

Results

This practice is beneficial because the passed reference supports content assistance and validation for ESQL. The message type content properties `open`, or `open defined` are not used in validation, and the assumption is that this property is `closed`.

A `$db:select out of scope` error is generated when you map from a database source:
Procedure

- **Scenario:** You have specified a database as the data source and when you save the map file, there is an error saying `$db:select out of scope`
- **Explanation:** A $db:select expression must be within the scope of the $db:select entry in the Map Script column of the Spreadsheet pane, meaning that it must be a descendant of the select statement. If a $db:select expression is out of scope the Message Mapping editor moves the $db:select entry to a position where the $db:select expression is in scope. The $db:select expression can remain out of scope if it is positioned above the $db:select entry in the Map Script column of the Spreadsheet pane.
- **Solution:** Delete the out of scope $db:select expression or move the $db:select entry in the Map Script column. You can drag the element out of the 'for' row, and then drag the $db:select entry in the Map Script column higher in the message, above the out of scope $db:select expression. Ensure that the out of scope $db:select expression is now a descendant of the $db:select entry. See “Mapping a target element from database tables” on page 2288 topic for more information about database selects.

A `$db:proc out of scope` error is generated when you map from a database stored procedure:
Procedure

- **Scenario:** You have specified a stored procedure as the source and when you save the map file, there is an error saying `$db:proc out of scope`
- **Explanation:** A $db:proc expression must be within the scope of the $db:proc entry in the Map Script column of the Spreadsheet pane, meaning that it must be a descendant of the stored procedure statement. If a $db:proc expression is out of scope the Message Mapping editor moves the $db:proc entry to a position where the $db:proc expression is in scope. The $db:proc expression can remain out of scope if it is positioned above the $db:proc entry in the Map Script column of the Spreadsheet pane.
- **Solution:** Delete the out of scope $db:proc expression or move the $db:proc entry in the Map Script column. You can drag the $db:proc entry in the Map Script column higher in the message, above the out of scope $db:proc expression. Ensure that the out of scope $db:proc expression is now a

descendant of the $db:proc entry. See “Mapping a target element from database stored procedures” on page 2290 for more information about database stored procedures.

A `$db:func out of scope` error is generated when you map from a database user-defined function:
Procedure

- **Scenario:** You have specified a user-defined function as the source and when you save the map file, there is an error saying `$db:func out of scope`
- **Explanation:** A $db:func expression must be within the scope of the $db:func entry in the Map Script column of the Spreadsheet pane, meaning that it must be a descendant of the user defined function statement. If a $db:func expression is out of scope the Message Mapping editor moves the $db:func entry to a position where the $db:func expression is in scope. The $db:func expression can remain out of scope if it is positioned above the $db:func entry in the Map Script column of the Spreadsheet pane.
- **Solution:** Delete the out of scope $db:func expression or move the $db:func entry in the Map Script column. You can drag the $db:func entry in the Map Script column higher in the message, above the out of scope $db:func expression. Ensure that the out of scope $db:func expression is now a descendant of the $db:func entry. See “Mapping a target element from database user-defined functions” on page 2292 for more information about database user-defined functions.

Target is not referencing a valid variable warning when you set the value of a target:
Procedure

- **Scenario:** You have set the value for a target to a variable, such as a WebSphere MQ constant, and when you save the map file the warning `The target "$target" is not referencing a valid variable` is generated.
- **Explanation:** The variable that you have referenced is not recognized. For example, you might have entered an expression of the form `$mq:` followed by a WebSphere MQ constant, but the constant is not recognized. This might be because the variable has been entered incorrectly or it is not supported. Alternatively, you might be referencing a new variable or constant that can be resolved only at run time. If this is the case you can ignore the warning.
- **Solution:** Try one of the following to solve the problem:
  - Check that the variable has been entered correctly.
  - If you are using WebSphere MQ constants, use **Edit** > **Content Assist** to select from the list of available WebSphere MQ constants.

There are missing or unexpected targets in a message map:
Procedure

- **Scenario:** In your message map, warning messages are displayed that indicate a target element is missing, or a target element is at an unexpected location. As a result the output message generated by the message map might be incorrect.
- **Explanation:** If target elements are missing from the Spreadsheet pane when you edit and save the message map, a warning is displayed that a target is missing. This situation can occur if you use the Insert Children wizard and do not select all the required elements, or if you create mappings using the drag-and-drop method and do not create mappings for all the required fields. If target elements in the Spreadsheet pane are in an unexpected order, a warning that the element is unexpected at that location is displayed. This situation can occur if you drag elements to new locations in the Spreadsheet pane.

- **Solution:** To solve the problem:
  - Use **Insert Children** on the parent element to add any missing target elements to the Spreadsheet pane.
  - Drag any target elements that are in an unexpected location to the correct location. Use the message tree in the Target pane as a guide to the expected structure of the output message.

Error message BIP6118 is issued: `The remaining bitstream is too small contain the indicated structure.`:
Procedure

- **Scenario:** You have used an unsupported message domain for a target message in your message map.
- **Explanation:** The message domain that is associated with a target message is determined by the **`Message Domain`** property of your message set. Mapping nodes generate a target message that matches the message domain of the message set. Using a message domain that is not supported by the message mapper can result in an output message with a structure that is not valid for the chosen parser.
- **Solution:** To solve the problem, change the target message domain for your message set.

Error message BIP4680 is issued: `Unsupported message domain encountered in mapping node.`:
Procedure

- **Scenario:** You have used an unsupported message domain for a target message in your message map, for example BLOB.
- **Explanation:** The message domain that is associated with a target message is determined by the **`Message Domain`** property of your message set. Mapping nodes generate a target message that matches the message domain of the message set. Using a message domain that is not supported by the message mapper can result in an output message with a structure that is not valid for the chosen parser.
- **Solution:** To solve the problem, change the target message domain for your message set.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Resolving trace problems when developing message flows

Follow this advice to deal with some common trace problems that can arise when you develop message flows.

About this task

- "You cannot determine which node is being referenced in your trace file"
- "You cannot see any alerts when you change user trace"
- "Data that the Trace node sends to the syslog on UNIX is truncated" on page 3428

You cannot determine which node is being referenced in your trace file:
Procedure

- **Scenario:** You have generated a service trace file for your message flow, to trace the path of a message. However, you cannot determine which node is being referenced in the trace file.
- **Explanation:** In the trace file you might see text such as:

  ```
  Video_Test#FCMComposite_1_1 ComIbmMQInputNode , Video_Test.VIDEO_XML_IN
  ```

  The elements in the text have the following meanings:

  Video_Test
  is the name of the message flow

  FCMComposite_1_1
  is the internal name for the node

  ComIbmMQInputNode
  is the type of node

  VIDEO_XML_IN
  is the node label, and is the name you see in your flow

  The number at the end of the internal name is incremented; for example, FCMComposite_1_4 would be the fourth node you added to your flow. In the example, this section of the trace is referring to the first node in the message flow.

You cannot see any alerts when you change user trace:
Procedure

- **Scenario:** You cannot see any alerts for an execution group or message flow in the Alerts viewer when you use the **mqsichangetrace** command to change the user trace setting.

- **Explanation:** No alert is generated when an execution group runs user trace at normal or debug level. Alerts are generated only for message flow trace. For message flow trace, the WebSphere Message Broker Toolkit is not notified of trace changes that are initiated by the **mqsichangetrace** command.
- **Solution:** To see the alert, refresh the message flow, or disconnect, then reconnect to the domain.

Data that the Trace node sends to the syslog on UNIX is truncated: Procedure

- **Scenario:** You are using a Trace node on UNIX and have set the `Destination` property to `Local Error Log`. You send a message to the Trace node that consists of multiple lines, but the message that appears in the syslog is truncated at the end of the first line.
- **Explanation:** On UNIX, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the new line character.
- **Solution:** To record a large amount of data in a log on UNIX, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Resolving problems when developing message flows" on page 3395
Use the advice given here to help you to resolve common problems that can arise when developing message flows.

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

"Handling errors in message flows" on page 2823
The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

"Using trace" on page 3533
You can use different types of trace to help you with problem determination and troubleshooting.

Resolving problems when developing message flows with WebSphere Adapters nodes

Advice for dealing with common problems that can arise when you develop message flows that contain WebSphere Adapters nodes.

About this task

WebSphere Adapters nodes

- "Error messages BIP3414 and BIP3450 are issued when you deploy a WebSphere Adapters input node" on page 3429

- "Error messages are issued when classes cannot be found, or when problems occur with Java initialization"
- "The WebSphere Adapters are not visible when you run ITLM" on page 3430
- "A message flow with an SAPRequest, SiebelRequest, or PeopleSoftRequest node has deployed successfully, but message BIP3540 is issued indicating that connection failed" on page 3430

SAP nodes

- "You have deployed an SAP inbound adapter but do not receive expected messages" on page 3431
- "You have imported an existing project into your workspace, but messages are issued when you try to build SAP message sets" on page 3431
- "An error is issued when you use the message set that is generated by the Adapter Connection wizard" on page 3431
- "When you run the SAP samples on Linux or UNIX, WebSphere Message Broker does not connect to the SAP gateway" on page 3431
- "SAP inbound messages (ALE and BAPI) appear to be missing" on page 3432
- "When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs" on page 3432

Siebel nodes

- "You are using a SiebelInput node with the delivery type set to unordered, and error message BIP3450 is issued with a NullPointer exception" on page 3432

JD Edwards nodes

- "Error message BIP3450 is issued when you include a JDEdwardsRequest node in a message flow and try to connect to a JD Edwards EnterpriseOne server" on page 3433

Error messages BIP3414 and BIP3450 are issued when you deploy a WebSphere Adapters input node:
Procedure

- **Scenario:** When you deploy a message flow that contains a SiebelInput node, error message BIP3414 is issued.
- **Explanation:** The error messages explain that the SiebelInput node could not register with the adapter component to receive events. This problem can be caused when the broker does not know where to find the client libraries for the Siebel Enterprise Information Service (EIS). You might also encounter this problem if you are using the WebSphere Adapter for Siebel on an unsupported operating system.
- **Solution:** Use the **mqsireportproperties** and **mqsichangeproperties** commands to configure the broker with the location of the Siebel client libraries, as described in "Preparing the environment for WebSphere Adapters nodes" on page 717.

Error messages are issued when classes cannot be found, or when problems occur with Java initialization:
Procedure

- **Scenario:** You are deploying WebSphere Adapters, and error messages are issued that indicate that classes cannot be found, or problems are occurring with Java initialization. BIP3521 and BIP3522 error messages might also be issued.

- **Explanation:** The SAP, Siebel, and PeopleSoft adapters need client libraries from the manufacturer of the Enterprise Information System (EIS). If these libraries are missing, not installed correctly, or at an incorrect level, errors are issued.
- **Solution:** To solve this problem, complete the following steps.
  1. On the broker that you are using to change the configurable service of the adapter, run the **mqsichangeproperties** command to identify the location of the Java and native libraries.
  2. Ensure that the libraries are installed correctly, are valid for your operating system, and have the correct permission so that the broker can access them.
  3. Ensure that your operating system is supported by WebSphere Message Broker and the EIS provider. For details about supported operating systems, visit the WebSphere Message Broker Requirements Web site.

The WebSphere Adapters are not visible when you run ITLM:
Procedure

- **Scenario:** The adapter is not visible when you run the IBM Tivoli License Manager (ITLM).
- **Explanation:** If you want to use ITLM with the WebSphere Adapters, you must activate the ITLM file for each adapter.
- **Solution:** Follow the instructions in "Activating IBM Tivoli License Manager for WebSphere Adapters" on page 2036.

A message flow with an SAPRequest, SiebelRequest, or PeopleSoftRequest node has deployed successfully, but message BIP3540 is issued indicating that connection failed:
Procedure

- **Scenario:** From an SAPRequest, SiebelRequest, or PeopleSoftRequest node, an exception is thrown to indicate that the node is unable to make a connection even though the message flow has deployed successfully. The exception contains message BIP3540 with inserted text that indicates that connection failed. For example, for SAP, the inserted text is:

  ```
  Exception in connecting to SAP:Connect to SAP gateway failed
  Connect_PM GWHOST= invalidhost.test.co, GWSERV=sapgw00, ASHOST= invalidhost.test.co,
    SYSNR=00
  LOCATION CPIC (TCP/IP) on local host ERROR partner not reached (host
    invalidhost.test.co, service 3300) TIME Mon Dec 01 16:43:52 2008 RELEASE 640
  COMPONENT NI (network interface) VERSION 37 RC -10 MODULE nixxi_r.cpp LINE 8719
  DETAIL NiPConnect2 SYSTEM CALL SiPeekPendConn ERRNO 10061 ERRNO TE
  ```

  For PeopleSoft, the inserted text is:

  ```
  001DOWNbea.jolt.ServiceException: Invalid Session
  ```

- **Explanation:** The connection details are not verified when the message flow is deployed. For request nodes, the connection is made at first use.
- **Solution:** If you have configured a configurable service for this adapter, review the connection properties on that configurable service and review the text in the BIP3540 message to determine if the connection properties are incorrect. If the properties are incorrect, use the **mqsichangeproperties** command to correct them or use the **mqsideleteconfigurableservice** command to revert to the properties that are set on the adapter. Reload the execution group or stop and restart the broker.

  If no configurable service exists for this adapter, review the connection properties on the adapter. If the properties are incorrect, correct them and redeploy the adapter. Alternatively, use the **mqsicreateconfigurableservice** command to create a new configurable service with the correct properties to override the properties that are set on the adapter.

You have deployed an SAP inbound adapter but do not receive expected messages:
Procedure

- **Scenario:** You have deployed an SAP inbound adapter but do not receive the IDoc messages that you expected to receive.
- **Explanation:** If you have not received IDoc messages from SAP, it is possible that deployment was unsuccessful or the SAP server has not started.
- **Solution:** Check user trace for message BIP3484 occurring at the time of deployment. The adapter component writes diagnostic information to this message, in an insert that begins "CWYAP...". If this message is issued, it explains the cause of the problem.

You have imported an existing project into your workspace, but messages are issued when you try to build SAP message sets:
Procedure

- **Scenario:** You have imported an existing project into your workspace, but when you try to build an SAP message set, you see the message set compile error message BIP0182.
- **Explanation:** This error occurs when you choose the option to "Import existing projects into your workspace" from the Import dialog box. By choosing this option when you import, a link is created from the workspace to the existing projects in an external location and a required file is not available to the workspace. To copy the entire project into your workspace, use the option to import the Project Interchange (PI) file.
- **Solution:** When you import an exiting SAP project into your workspace, click **File** > **Import**, expand the **Other** folder, and click **Project Interchange**. For more information, see “Importing and exporting resources in a Project Interchange file” on page 1452.

An error is issued when you use the message set that is generated by the Adapter Connection wizard:
Procedure

- **Scenario:** You run the Adapter Connection wizard and select an inbound SAP IDoc. You run the wizard again, but this time you select an outbound SAP IDoc. When you use the message set that is generated, the following error is issued:

```
'Selector exception caught from generateEISFunctionname', 'commonj.connector.runtime.SelectorException:
commonj.connector.runtime.SelectorException: For the IDoc type SapYwmspgi01, operation key=YWMSPGIWMS not
found using the application-specific information {Create={MsgType=, MsgCode=, MsgFunction=}} verify appropriate
combination of MsgType, MsgCode, MsgFunction is set in SapYwmspgi01, application-specific information.
```

- **Explanation:** If you run the Adapter Connection wizard for an inbound SAP IDoc, then you run the wizard again for an outbound SAP IDoc, the outbound IDoc definition replaces the inbound IDoc definition. Information that is stored in the inbound definition is used to map MsgType, MsgCode, and MsgFunction to a method binding. The outbound definition does not contain these mappings, so processing of the inbound IDoc fails.
- **Solution:** To avoid this error, ensure that inbound and outbound SAP IDocs have different names if they are stored in the same message set.

When you run the SAP samples on Linux or UNIX, WebSphere Message Broker does not connect to the SAP gateway:
Procedure

- **Scenario:** When you run the SAP samples on Linux or UNIX, the message flow deploys successfully, but a connection is not established between WebSphere Message Broker and the SAP system. You might see the following error message:

```
message: Connect to SAP gateway failed
Connect parameters: TPNAME=SAMPRFC GWHOST=sapdev10 GWSERV=sapgw00
ERROR service 'sapgw00' unknown
```

- **Explanation:** For the SAP Java Connector (SAP JCo) to communicate across the network, you need to configure the TCP/IP service. If you have installed a working SAP GUI on your workstation, the TCP/IP service is configured as part of the installation. If you have not installed an SAP GUI, you must configure the TCP/IP service manually so that the SAP samples run successfully.
- **Solution:** Locate the services file in `/etc/services` and edit it so that it includes the appropriate gateway service IDs and the port numbers for the TCP/IP service in the format `sapgw`*`SID portnumber`*`/tcp`, where *SID* is the SAP system ID. For example:

  ```
  sapgw00  3300/tcp
  sapgw01  3301/tcp
  sapgw02  3302/tcp
  ```

  and so on.

  For more information about TCP/IP configuration, see the Network Integration section of the SAP Service Marketplace.

SAP inbound messages (ALE and BAPI) appear to be missing:
Procedure

- **Scenario:** SAP inbound messages (ALE and BAPI) appear to be missing. You might find that every other message does not reach the broker but no errors are issued.
- **Explanation:** This problem is typically caused when two brokers share the same program ID (SAP RFC Destination). For example, a developer has deployed a message flow, but someone else has used the same broker archive (BAR) file without having changed the program ID.
- **Solution:** Ensure that no other brokers are running with the same program ID. Use SAP transaction SMGW to determine whether other brokers are connected to the SAP system.

When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs:
Procedure

- **Scenario:** When two ALE inbound modules use the same RFC program ID with SAP JCo version 3.0.2, NullPointer exceptions are logged in the JCo trace and the Adapter does not receive IDocs.

  The following example shows a typical exception in the JCo trace.

  ```
  JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] Dispatcher.getNextListener() returns dispatch n
  JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] caught Throwable in DispatcherWorker.run() whil
   at java.util.Hashtable.get(Hashtable.java:518)
   at com.sap.conn.jco.rt.DefaultServerManager$DispatcherWorker.run(DefaultServerManager.java:268)
   at java.lang.Thread.run(Thread.java:735)

  JCoDispatcherWorkerThread [16:44:42:140]: [JCoApi] Dispatcher.getNextListener() returns no calls
  ```

- **Explanation:** SAP JCo version 3.0.2 does not support the use of two ALE inbound modules with the same RFC program ID.
- **Solution:** To solve this problem, download a hotfix from SAP; the SAP ticket reference number is 584247/2009.

You are using a SiebelInput node with the delivery type set to unordered, and error message BIP3450 is issued with a NullPointer exception:

Procedure

- **Scenario:** You are using a SiebelInput node, you have set the delivery type to unordered in the Adapter Connection wizard, and the minimum number of connections is 1 or less. The following exception is shown in user trace: `RecoverableException BIP3450E: An adapter error occurred during the processing of a message. The adapter error message is java.lang.NullPointerException`.
- **Explanation:** When using unordered events, the minimum connections (`MinimumConnections`) and maximum connections (`MaximumConnections`) properties must be greater than 1 for event delivery to be successful.
- **Solution:** Set the `MinimumConnections` and `MaximumConnections` properties on the Adapter Connection wizard to values greater than 1. For example, set the minimum number of connections to 2 and the maximum number of connections to 4.

Error message BIP3450 is issued when you include a JDEdwardsRequest node in a message flow and try to connect to a JD Edwards EnterpriseOne server: Procedure

- **Scenario:** You have created a message flow that contains a JDEdwardsRequest node, but error message BIP3450 is issued, indicating that the node is unable to connect to the JD Edwards EnterpriseOne server.
- **Explanation:** This error message indicates that the JDEdwardsRequest node is trying to connect to the JD Edwards EnterpriseOne server but is unable to do so. This error can be caused by the following situations.
  - The JD Edwards EnterpriseOne server is not running.
  - The JD Edwards adapter has been configured with incorrect connection details; for example, the name of the JD Edwards EnterpriseOne Environment to which to connect.
  - The JDBC drivers that are required to connect to the JD Edwards EnterpriseOne server are missing from the class path. The following table lists the required JDBC driver files for each database.

Database	JDBC driver files	Implementation class
Oracle	tsnames.ora classes12.zip	oracle.jdbc.driver.OracleDriver
SQLServer	sqljdbc.jar	com.ibm.microsoft.sqlserver.jdbc.SQLServerDr
AS/400	jt400.jar	com.ibm.as400.access.AS400JDBCDriver
DB2 Type-2 (JDK 1.4/1.5)	db2java.zip	com.ibm.db2.jdbc.app.DB2Driver
DB2 Type-4 (JDK 1.4/1.5)	db2jcc.jar db2jcc_license_cu.jar	com.ibm.db2.jcc.DB2Driver
DB2 Type-4 (JDK 1.6)	db2jcc4.jar	com.ibm.db2.jcc.DB2Driver

- **Solution:** Ensure that the following conditions have been met.
  - The JD Edwards EnterpriseOne server is running.
  - The JD Edwards adapter has been configured with the correct connection details.
  - The drivers that are required to connect to the JD Edwards EnterpriseOne server are in the class path.

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and

PeopleSoft.

Related tasks:

"Developing message flows that use WebSphere Adapters" on page 2033
For information about how to develop message flows that use WebSphere Adapters, see the following topics.

"Preparing the environment for WebSphere Adapters nodes" on page 717
Before you can use the WebSphere Adapters nodes, you must set up the broker runtime environment so that you can access the Enterprise Information System (EIS).

"Deploying a message flow that uses WebSphere Adapters" on page 3240
Deploy the resources that are generated when you run the Adapter Connection wizard by adding them to a broker archive (BAR) file.

"Changing connection details for SAP adapters" on page 719
SAP nodes can get SAP connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

"Changing connection details for Siebel adapters" on page 720
Siebel nodes can get Siebel connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"**mqsicreateconfigurableservice** command" on page 3849
Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

"**mqsideleteconfigurableservice** command" on page 3866
Use the **mqsideleteconfigurableservice** command to delete a configurable service, such as a JMS provider, JDBC provider, or FTP server, that you have created by using the **mqsicreateconfigurableservice** command.

WebSphere Message Broker Requirements

Resolving other problems when developing message flows

Use the advice given here to deal with problems that can arise when developing message flows, and that are not covered in the specific categories listed in "Resolving problems when developing message flows"

About this task

- "The values of your promoted properties are lost after editing" on page 3435
- "The Message Flow editor experiences problems when opening a message flow, and opens in error mode" on page 3435
- "A message flow has subflows with the same user-defined property set to different values, but only one value is set at run time" on page 3435
- "You want to move resources to a new broker schema that you have created but it is not visible in the Broker Development view" on page 3435

- "A selector exception is raised when you use WebSphere Adapters" on page 3436

The values of your promoted properties are lost after editing:
Procedure

- **Scenario:** You edited a message flow using the Message Flow editor, and the values of your promoted properties are lost.
- **Explanation:** The values of promoted properties for nodes with more than a single subflow definition (that is, two identically named subflows in the same project reference path) are lost if the flow is edited and saved.
- **Solution:** To avoid this problem, ensure that each subflow in your project has a different name.

The Message Flow editor experiences problems when opening a message flow, and opens in error mode:
Procedure

- **Scenario:** You attempt to open an existing message flow in the Message Flow editor and it opens in read-only error mode, displaying a list of parsing or loading errors. The message flow is not open and a message is displayed indicating that the message flow file is not valid.
- **Explanation:** The message flow file is unreadable or is corrupted, and the Message Flow editor cannot render the model graphically.
- **Solution:** Contact IBM Customer Support for assistance with the corrupted file.

A message flow has subflows with the same user-defined property set to different values, but only one value is set at run time:
Procedure

- **Scenario:** You have a message flow that contains identical subflows. Each subflow has the same user-defined property (UDP), but with different values. At run time, only one of the values is set.
- **Explanation:** A UDP has global scope and is not specific to a particular subflow. If you reuse a subflow in a message flow, and those subflows have identical UDPs, you cannot set the UDPs to different values.
- **Solution:** If you need to set a different value for each subflow, use a different UDP for each subflow.

You want to move resources to a new broker schema that you have created but it is not visible in the Broker Development view:
Procedure

- **Scenario:** You have created a new broker schema and you want to move a resource to it, but the schema is not visible in the Broker Development view.
- **Explanation:** If category mode is selected, you cannot see the broker schema in the Broker Development view.
- **Solution:** To move resources to a broker schema that you have created, take one of the following steps.
  - Click **Hide Categories** () on the Broker Development view toolbar. The new broker schema appears in the Broker Development view and you can drag resources onto it.
  - Right-click a resource, click **Move**, then select the schema that you have created. When you click **OK**, the resource is moved to the selected schema.

A selector exception is raised when you use WebSphere Adapters:
Procedure

- **Scenario:** You run the Adapter Connection wizard for an inbound IDOC, then you run the wizard again for an outbound IDOC. When the message set is generated, you see the following error message:

```
'Selector exception caught from generateEISFunctionname' ,
'commonj.connector.runtime.SelectorException:
commonj.connector.runtime.SelectorException: For the IDoc type
SapYwmspgi01, operation key=YWMSPGIWMS not found using the
application-specific information {Create={MsgType=, MsgCode=, MsgFunction=}}
verify apropriate combination of MsgType,MsgCode, MsgFunction is set in
SapYwmspgi01, application-specific information.
--
```

- **Explanation:** When you run the Adapter Connection wizard for an inbound IDOC, then you run the wizard again for an outbound IDOC, the outbound IDOC definition replaces the inbound IDOC definition. Information that is stored in the inbound definition is used to map MsgType, MsgCode, and MsgFunction to a method binding. The outbound definition does not contain these mappings, so processing of the inbound IDOC fails.
- **Solution:** To avoid this error, ensure that inbound and outbound IDOCs have different names if they are stored in the same message set.

Resolving problems when deploying message flows or message sets

Use the advice given here to help you to resolve common problems that can arise when you deploy message flows or message sets.

Initial checks

Procedure

1. To debug problems when deploying, check the following logs:
   - The administration log
   - The local error log (the Windows Event log or the syslog)
   - The WebSphere MQ logs

These logs might be on separate computers, and must be used with the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit output to ensure that the deployment was successful.

Use the **mqsilist** command to check that the deployment was successful, or look in the Windows Event or Administration Log view.

2. Use this checklist when you have deployment problems:
   - Make sure that the mode that your broker is working in is appropriate for your requirements. See "Operation modes" on page 48.
   - Make sure that the remote queue manager is running.
   - Make sure that channels are running.
   - Display the channel status to see if the number of system messages sent increases.
   - Check the channel from the remote end.
   - Check the queue manager name.
   - Determine whether the channel is a cluster channel.

Common problems

About this task

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Resolving problems that occur when preparing to deploy message flows

Use the advice given here to help you to resolve common problems that can occur during preparations to deploy message flows or message sets.

An error is issued when you add a message set to a broker archive file: Procedure

- **Scenario:** An error is issued when you add a message set to a broker archive (BAR) file.
- **Explanation:** After you create a BAR file and add a message set project to it, two files are created in the BAR file: `messageset.user.txt` and `messageset.service.txt`. The `user.txt` file contains user log information, such as warning message BIP0177W, which states that the dictionary that you have created is not compatible with earlier versions.
- **Solution:** Use the information in the `user.txt` file to diagnose the error. The `service.txt` file contains detailed information that is used by the broker, and can be used by the IBM Support Center to diagnose problems.

You cannot drag a broker archive file to a broker:

Procedure

- **Scenario:** You cannot drag a broker archive (BAR) file to a broker.
- **Explanation:** BAR files can be deployed only on an execution group.
- **Solution:** Select an execution group in the deploy dialog.

You cannot deploy a message flow that uses a user-defined message flow:
Procedure

- **Scenario:** You have created a message flow that contains an input node in a user-defined node project. However, you cannot deploy a message flow that uses this node.
- **Explanation:** Validation, compilation, and deployment do not recognize that a user-defined message flow contains an input node.
- **Solution:** To work around the problem, add a dummy input node to the flow that you intend to deploy.

The compiled message flow file (`.cmf`) has not been generated:
Procedure

- **Scenario:** The compiled message flow file (`.cmf`) has not been generated. Therefore, it is not added to the broker archive file, and cannot be deployed.
- **Explanation:** When you create files that define message flow resources in the WebSphere Message Broker Toolkit, the overall file path length of those files must not exceed 256 characters, because of a Windows file system limitation.

  If you have a message flow that includes resource files that have a path length that exceeds 256 characters, the message flow cannot be compiled when you try to add it to a BAR file, and therefore cannot be deployed.

  You might also be affected by this restriction when you use the Adapters Connection wizard; names discovered and returned by the EIS can be very long. The Adapters Connection wizard attempts to write these files to the message set on the local file system, but their path exceeds the operating system limit, and the files appear corrupted.
- **Solution:** To ensure that the path length does not exceed 256 characters, use names that are as short as possible for all resources; for example:
  - The installation path
  - Project names and broker schema names
  - ESQL and mapping file names
  - Inbound and outbound adapter files

Resolving problems that occur during deployment of message flows

Use the advice given here to help you to resolve problems that can arise during deployment of message flows or message sets.

Procedure

You receive a warning message about your broker mode:
About this task

Message BIP1806

- **Scenario:** Warning message BIP1806 is displayed.

  ```
  The broker 'Broker_Name' did not reveal its mode in time;
   any reported information might not be up-to-date.
  ```

- **Explanation:** Your broker timed out before the command completed. You can set the timeout value on the **-w** parameter of the **mqsimode** command, or accept the default value of 60 seconds; see "**mqsimode** command" on page 3899.
- **Solution:** Check that the broker is started: if it is not started, start it by using the **mqsistart** command. If it is started, increase the timeout value and run the command again.

Message BIP1808

- **Scenario:** Warning message BIP1808 is displayed.

  ```
  Broker 'Broker_Name' is not at the required software level
   to change the mode.
  ```

- **Explanation:** Your broker is running in a previous version of the product. You must migrate brokers that you created in a version earlier than V6.1.0.2 before you can change the operation mode.
- **Solution:** Upgrade your broker to at least V6.1.0.2, and run the command again.

Message BIP1821

- **Scenario:** Warning message BIP1821 is displayed.

```
WARNING: Broker 'Broker_Name' is in 'Mode_Name' mode but has 'x' execution groups,
 which exceeds the allowed maximum for this mode.
```

- **Explanation:** Your broker is running in a mode that restricts the number of execution groups that you can use; see "Restrictions that apply in each operation mode" on page 3657.
- **Solution:** Contact your IBM representative to upgrade your license, or remove the required number of execution groups; see "Deleting an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 947.

Message BIP1822

- **Scenario:** Warning message BIP1822 is displayed.

```
WARNING: Broker 'Broker_Name' is in 'Mode_Name' mode but has 'x' message flows
 deployed, which exceeds the allowed maximum for this mode.
```

- **Explanation:** Your broker is running in a mode that restricts the number of message flows that you can use; see "Restrictions that apply in each operation mode" on page 3657.
- **Solution:** Contact your IBM representative to upgrade your license, or delete the required number of message flows; see "Deleting a message flow" on page 1441.

Message BIP1823

- **Scenario:** Warning message BIP1823 is displayed.

```
WARNING: Broker 'Broker_Name' has a message flow called 'Message_Flow' in execution
 group 'Execution_Group', which contains one or more nodes that
 are not valid in this mode: Mode_Name
```

- **Explanation:** Your broker is running in a mode that restricts the types of node that you can use in a message flow; see "Restrictions that apply in each operation mode" on page 3657.
- **Solution:** Contact your IBM representative to upgrade your license, rework your message flow to use nodes that are valid in the current mode, or remove the message flows that contain unsupported nodes; see "Deleting a message flow" on page 1441.

Message BIP1824

- **Scenario:** Warning message BIP1824 is displayed.

```
WARNING: The trial period for broker 'Broker_Name' expired on 'Day_Month_Year'.
```

- **Explanation:** Your broker is running in the Trial Edition mode and your trial period of 90 days has expired; see "Restrictions that apply in each operation mode" on page 3657.
- **Solution:** Contact your IBM representative to upgrade your license.

The message flow deploys on the test system, but not elsewhere: Procedure

- **Scenario:** The message flow that you have developed deploys on the test system, but not elsewhere.

- **Solution:** Carry out the following checks:
  - Ensure that you have verified the installation on the target system by creating and starting a broker, and deploying a single execution group. These actions confirm that the broker is correctly defined.
  - Ensure that the broker archive (BAR) file's `broker.xml` file contains references to the correct resources for the new system.
  - Ensure that any referenced message sets are deployed.
  - If database resources or user-defined nodes are not accessible or authorized from the target system, the deploy fails. On distributed systems, ensure that you have defined either ODBC or JDBC connections to your databases so that they can be accessed from the broker. Also, set the broker environment to allow access to the databases. On Linux or UNIX systems, you might have to run a database profile.
  - Any user-defined extensions that you are using in your message flow might not load if they cannot be found, or are not linked correctly. Consult the documentation for your operating system for details of tools that can help you to check the binary files of your user-defined extension.

Error messages about your broker mode are issued when you create an execution group:
About this task

Message BIP1825

- **Scenario:** Error message BIP1825 is displayed.

```
You attempted to create an execution group 'Execution_Group' on broker 'Broker_Name',
 but the broker is running in 'Mode_Name' mode which
 limits the number of execution groups that can exist at any one time.
 The execution group cannot be created.
```

- **Explanation:** The execution group cannot be created because the maximum number of execution groups for the mode of the target broker has been reached, and creating the execution group causes this limit to be exceeded; see "Restrictions that apply in each operation mode" on page 3657. The execution group was not created.
- **Solution:** Reuse an existing execution group, or delete an existing execution group and try the command again; see "Deleting an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 947. Alternatively, contact your IBM representative to upgrade your license.

Error messages about your broker mode are issued when you deploy:
About this task

Message BIP1826

- **Scenario:** Error message BIP1826 is displayed.

```
You attempted to deploy a broker archive (BAR) file to execution group
 'Execution_Group' on broker 'Broker_Name',
 but the broker is running in 'Mode_Name' mode which limits the
 number of message flows that can exist at any one time.
 The BAR file cannot be deployed.
```

- **Explanation:** The BAR file cannot be deployed because it causes the broker to run more message flows than are valid for the current mode of operation of the target broker; see "Restrictions that apply in each operation mode" on page 3657. The BAR file was not deployed.

- **Solution:** Delete message flows from the broker and try the command again; see "Deleting a message flow" on page 1441. Alternatively, contact your IBM representative to upgrade your license.

Message BIP1827

- **Scenario:** Error message BIP1827 is displayed.

```
You attempted to deploy a broker archive (BAR) file to execution group
 'Execution_Group' on broker 'Broker_Name',
 but the broker is running in 'Mode_Name' mode which has a restriction
 on the types of node that can be deployed.
 The BAR file cannot be deployed.
 The set of node types found in the BAR file that are not
 valid are: Node_Type.
```

- **Explanation:** The BAR file cannot be deployed because it contains nodes that are not valid for the current mode of the target broker; see "Restrictions that apply in each operation mode" on page 3657. The BAR file was not deployed.
- **Solution:** Rework your message flow to use nodes that are valid in the current mode, or remove the message flows that contain unsupported nodes; see "Deleting a message flow" on page 1441. Alternatively, contact your IBM representative to upgrade your license.

Message BIP1828

- **Scenario:** Error message BIP1828 is displayed.

```
You attempted to deploy a broker archive (BAR) file to execution group
 'Execution_Group' on broker 'Broker_Name',
 but the trial period for the broker has expired.
 The BAR file cannot be deployed.
```

- **Explanation:** The target broker is running in a trial mode that has expired; see "Restrictions that apply in each operation mode" on page 3657. The BAR file was not deployed.
- **Solution:** Contact your IBM representative to upgrade your license. If you have already purchased a valid license for the target broker, change the broker to the correct mode by using the **mqsimode** command; see "**mqsimode** command" on page 3899.

Message BIP1829

- **Scenario:** Error message BIP1829 is displayed.

```
You attempted to deploy a broker archive (BAR) file to execution group
 'Execution_Group' on broker 'Broker_Name',
 but the broker is running in 'Mode_Name' mode which
 limits the number of execution groups that can exist at any one time.
 The BAR file cannot be deployed.
```

- **Explanation:** The BAR file cannot be deployed because the maximum number of execution groups for the mode of the target broker has been reached; see "Restrictions that apply in each operation mode" on page 3657. The BAR file was not deployed.
- **Solution:** Delete an existing execution group and try the command again; see "Deleting an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 947. Alternatively, contact your IBM representative to upgrade your license.

Error messages about your function level are issued when you deploy:

About this task

Message BIP2276

- **Scenario:** Error message BIP2276 is displayed.

  ```
  The flow 'Message_flow', which includes a message flow of
  node type 'Node_type', cannot be deployed because the current
  fix pack function level of '<version>.<release>.<modification>.<fix>'
  does not support this node.
  Use mqsichangebroker -f all' to enable this functionality.
  ```

- **Explanation:** The broker received an instruction to create a message flow node of type *Node_type* in message flow *Message_flow*. The broker cannot create nodes of this type because the new functions have not been enabled for this broker. Use the following command to enable this function, and all other functions:

  ```
  mqsichangebroker MB7BROKER -f all
  ```

- **Solution:** Either change the flow to avoid using the unavailable node, or enable the new functions by using the **mqsichangebroker** command; see "**mqsichangebroker** command" on page 3723.

Error messages are issued when you deploy to z/OS:
Procedure

- **Scenario:** The following messages are written to the log when you deploy to z/OS:

  ```
  +(MQ05BRK) 0 BIP2070E: A problem was detected with WebSphere MQ while issuing
  MQPUT for WebSphere MQ queue SYSTEM.BROKER.ADMIN.REPLY, WebSphere MQ queue
  manager QM_01.  MQCC=2, MQRC=2030.
  +(MQ05BRK) 0 BIP2068E: The broker was unable to put an internal configuration
  message to message queue SYSTEM.BROKER.ADMIN.REPLY.
  ```

- **Explanation:** The transmission queue is not large enough for the messages that are issued by WebSphere Message Broker.
- **Solution:** See the WebSphere MQ documentation for details on how to increase the size of the transmission queue.

Expected serialization of input is not occurring for a shared queue that serves multiple instances of a message flow on z/OS:
Procedure

- **Scenario:** Expected serialization of input is not occurring for a shared queue that serves multiple instances of a message flow on z/OS.
- **Explanation:** On z/OS, WebSphere MQ supports serialized access to shared resources, such as shared queues, through the use of a connection tag (serialization token) when an application connects to the queue manager that participates in a queue sharing group.

  This problem can occur for a number of reasons:

  – You have assigned different serialization tokens to the input nodes of the flows that get messages from the shared queue.
  – The message flows are running in the same execution group. Serialization can only be effected between flows that are running in different execution groups, either on the same broker, or on different brokers whose queue managers participate in the same queue sharing group.
  – The queue managers on which the brokers are running are not participating in a queue sharing group, or not participating in the same queue sharing group.

- **Solution:** Carry out the following checks:

- Check that the same z/OS serialization token has been configured for the MQInput nodes in each flow that use the shared queue.
- Check that the message flows are running in different execution groups.
- Check that the broker queue managers are part of the same queue sharing group, and that no errors are reported from the queue managers in the z/OS system log (SDSF log).

You create a configurable service, then deploy a message flow and inbound adapter, but the deployment fails:
Procedure

- **Scenario:** You create a configurable service, then deploy a message flow and inbound adapter, but the deployment fails.
- **Explanation:** When you create a configurable service for an adapter that has not yet been deployed, the connection properties are not fully validated until you deploy the adapter and the message flow that uses that adapter. Therefore, the properties that you set on the configurable service might be invalid.
- **Solution:** Inspect the error message that is returned from the deployment and determine whether the deployment failed because of invalid connection properties on the configurable service. If so, use the **mqsichangeproperties** command to correct the properties, or use the **mqsideleteconfigurableservice** command to use the properties that are set on the adapter. Restart the broker and redeploy the message flow.

You have created a WebSphere Adapters message flow that uses secondary adapters, and a naming clash has occurred in the secondary adapters or message sets:
Procedure

- **Scenario:** You have created a WebSphere Adapters message flow that uses secondary adapters, and a naming clash has occurred. You need to know which adapters and message sets the WebSphere Adapters node is using, and if the method names in the adapters or the message type names in the message sets are clashing.
- **Explanation:** Method names must be unique across all primary and secondary adapters, and the message set that is created must not contain any types that share the same name and namespace of existing message sets. Information about secondary adapters and message sets is written to user trace at the following stages.
  - When the node is first deployed, information about the current set of secondary adapters and message sets is reported.
  - When adapters and message sets are deployed subsequently, information about them is reported at the time of deployment.
  - When the message flow, broker, or execution group is stopped then restarted, information about the entire set of secondary adapters and message sets is written to user trace, including those secondary adapters and message sets that are deployed after the message flow was first deployed.

  This information is reported by the following messages.
  - BIP3432 and BIP3434 list the adapters and message sets that are available when the node is deployed or when the broker, execution group, or message flow are restarted.
  - BIP3433 reports that a secondary adapter is being deployed and added to the set.
  - BIP3435 reports that a secondary message set is being deployed.
  - BIP3436 identifies the message set in which each type is being defined.

- BIP3437 identifies message sets that attempt to redefine a type that is already defined.
- BIP3438 identifies the adapter in which each method is being defined.
- BIP3439 identifies adapters that attempt to redefine a method that is already defined.

Messages BIP3436, BIP3437, BIP3438, and BIP3439 are issued when a message is processed to report whether definitions are used for that message.

- **Solution:** The following steps describe how to use user trace when working with secondary adapters.
  - **When you deploy the flow for the first time**
    1. Start user trace.
    2. Deploy your message flow, primary adapter, primary message set, and any secondary adapters or message sets that are ready.
    3. Read user trace, looking out for the messages described.
    4. Optional: Reset user trace, stop and restart the message flow, then read user trace again, looking out for the messages described.
  - **When you add new adapters and message sets**
    1. Start user trace.
    2. Deploy the secondary adapters and message sets.
    3. Read user trace, looking out for the messages described.
    4. Optional: Reset user trace, stop and restart the message flow, then read user trace again, looking out for the messages described.

  When you have identified where the naming clash has occurred, you can ensure that names are unique by editing them in the following ways:
  - Edit method names by clicking **Edit Operations** on the Service Generation and Deployment Configuration panel of the Adapter Connection wizard.
  - Edit the namespaces of the types in the message set by using the Business Object Namespace control on the Adapter Connection wizard.

You get an authority check failure when you deploy to z/OS: Procedure

- **Scenario:** You deploy a BAR file to z/OS, and you get an authority check failure like the following message:

```
ICH408I USER(MI09STC ) GROUP(TSOUSER ) NAME(WMB TASK ID         ) 672
  MI09.SYSTEM.BROKER.AUTH.default CL(MQQUEUE )
  PROFILE NOT FOUND - REQUIRED FOR AUTHORITY CHECKING
  ACCESS INTENT(READ   )  ACCESS ALLOWED(NONE   )
```

- **Explanation:** The z/OS queue manager accesses the MQQUEUE security profile class by default. If you have enabled broker administration security, and you have specified the names of one or more execution groups in mixed case, the security profiles that you set up are defined in MXQUEUE, because the associated authority queue names are also in mixed case. MQQUEUE does not hold the expected information.
- **Solution:** Change the security profile case parameter for the queue manager. You can use the ALTER QMGR command to update the SCYCASE parameter to M, or you can modify your start job JCL to set or change this parameter, and restart the queue manager.

Deployment fails when you have circular project dependencies:

Procedure

- **Scenario:** Circular project dependencies exist in the projects that you are deploying and deployment fails.
- **Explanation:** A circular project dependency occurs when two or more projects depend on each other.

  For example, File A in Project X depends on File B in Project Y, and File C in Project Y depends on File D in Project X. For Project X to build successfully, Project Y must be built first so that Project X can resolve the dependency on File B. However, for Project Y to build successfully, Project X must be built first so that Project Y can resolve the dependency on File D. The WebSphere Message Broker Toolkit is based on the Eclipse platform, which does not support circular project dependencies.
- **Solution:** To deploy successfully, avoid circular project dependencies.

  For example, if Project X depends on File B in Project Y, and Project Y depends on File D in Project X, move File B to Project Z. The projects must be built in the order Project Z, Project X, then Project Y so that the dependencies can be resolved.

Error messages are issued when you deploy:
About this task

Additional error messages that might be generated during a deployment are explained in this section.

Message BIP1106 with WebSphere MQ reason code 2030

- **Scenario:** Error message BIP1106 is issued with reason code 2030 when you are deploying a large message set.
- **Explanation:** The size of the message exceeds the maximum message length of the transmission queue to the broker queue manager.
- **Solution:** Increase the maximum message length for the transmission queue using the WebSphere MQ **alter qlocal** command, where the maximum message length (maxmsgl) is in bytes:

  ```
  alter ql(transmit_queue_name) maxmsgl(104857600)
  ```

  For more information about this command, see the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

Message BIP1835

- **Scenario:** Error message BIP1835 is displayed.
- **Explanation:** The message set that you are deploying produces a message set dictionary that is larger than the internal limit of 4 MB. This problem can occur if you have many large message definitions defined to the same message set.

  The size of an exported message set is not a good indication of the size of the message set dictionary that is generated at the time of deployment, because the exported message set is stored as XML. XML can be verbose, but the dictionary has a more compact internal format.
- **Solution:** Split the message definitions into several smaller message sets.

Message BIP2066

- **Scenario:** You have initiated a deployment request; for example, you have deployed a BAR file to an execution group. Error message BIP2066 is returned one or more times.

- **Explanation:** The deployment request was not acknowledged by the execution group before the sum of the values for the broker timeout parameters **ConfigurationChangeTimeout** and **InternalConfigurationTimeout** expired.
- **Solution:** Increase these timeout values by specifying the **-g** and **-k** parameters of the **mqsicreatebroker** or **mqsichangebroker** command. See "Setting configuration timeout values" on page 3258 for information about factors that affect timeout values, and how to set appropriate values.

Message BIP2080

- **Scenario:** The broker has started an execution group; for example, if you have issued **mqsistart** for the broker, or an error has occurred and the execution group is being recovered. Error message BIP2080 is displayed one or more times.
- **Explanation:** The internal configuration request was not acknowledged by the execution group before the value of the **InternalConfigurationTimeout** (default 60 seconds) expired.
- **Solution:** Change the configuration timeout by specifying the **-k** parameter of the **mqsicreatebroker** or **mqsichangebroker** command. See "Setting configuration timeout values" on page 3258 for information about factors that affect timeout values, and how to set appropriate values.

Message BIP2241

- **Scenario:** Error message BIP2241 is displayed.
- **Explanation:** You are attempting to deploy a message flow containing a node that is not available on the target broker.
- **Solution:** Ensure that the version of the WebSphere Message Broker Toolkit in which the message flow has been developed matches the version of the broker to which the message flow is being deployed. If the message flow is using a user-defined node, or a node supplied in a SupportPac, ensure that the runtime node implementation has been correctly installed on the computer on which the broker is running. If your message flow includes a user-defined node, see "Installing user-defined extension runtime files on a broker" on page 3125. If your message flow includes a node provided in a SupportPac, see the installation information, if supplied, for the SupportPac.

Message BIP2242

- **Scenario:** Error message BIP2242 is displayed.
- **Explanation:** The deployment request (configuration change) was not accepted before the timeout value set by the broker parameter **ConfigurationChangeTimeout** expired. This configuration timeout value must be long enough for the message flow to complete processing its current message, then accept the deploy request; the default is 300 seconds.
- **Solution:** Set the configuration timeout values by specifying the **-g** and **-k** parameters of the **mqsicreatebroker** or **mqsichangebroker** command.

Message BIP3226

- **Scenario:** Error message BIP3226 is displayed; for example:

  ```
  (Semipersistent_Compute1.Main, 27.89) : Array index evaluated to '0' but must
  evaluate to a positive, nonzero integer value.
  ```

  The first insert in BIP3226 (in this example, `Semipersistent_Compute1.Main`) identifies the node and routine in which the statement occurs. The second insert (in this example, `27.89`) identifies the approximate line and column of the index value shown in the third insert (in this example, '0').

- **Explanation:** The validity of using a field reference index of zero was corrected in WebSphere Message Broker Version 7.0. If you have statements in your ESQL modules that include an index of zero, error BIP3226E is generated.

  For example, your ESQL module might contain the following statement:

  ```
  SET OutputRoot.XMLNSC.Top.A[0].B = 42;
  ```

- **Solution:**

  You must correct all ESQL statements that use an index of zero to use an index of 1. Statements might use a variable as well as a literal value for the index; check for both possible situations. For example, your changed code might read:

  ```
  SET OutputRoot.XMLNSC.Top.A[1].B = 42;
  ```

Message BIP7053S

- **Scenario:** When you deploy to a broker, error message BIP7053S is displayed.
- **Explanation:** This error occurs in a multi TCP/IP stack environment, and indicates that the UNIX System Services (USS) TCP/IP environment has not been set up correctly.

  WebSphere Message Broker uses USS functions to obtain the host name for a particular system. The following error message is displayed if the default host name is not set up correctly in the USS environment:

  ```
  BIP7053S: Broker $SYS_mqsi 0 unexpected Java exception java.lang.Error:
  -2103399272!java.net.UnknownHostException :
  Hostname: Hostname
  ```

  The host name that is reported in the error message is the one that has been returned to the broker as a result of the `gethostname` call.

- **Solution:** Ensure that the TCP/IP environment is configured correctly in USS.

Tagged/Delimited String (TDS) Validator error

- **Scenario:** You try to deploy a message set with a TDS wire format that has an error.
- **Explanation:** The following extract from an error log illustrates what you might see for a TDS Validator error. In this case, the cause of the problem is that the element `Town` does not have a tag defined.

  ```
  TDS Extractor Trace File

Resolving problems that occur after deployment of message flows

Use the advice given here to help you to resolve common problems that can arise after deploying message flows or message sets.

You receive exception ('MQCC_FAILED') reason '2042' ('MQRC_OBJECT_IN_USE'): Procedure

- **Scenario:** This exception message occurs when the following conditions are met:
  1. You have a message flow containing a SOAPRequest node that is using the JMS Transport.
  2. The message flow has additional instances defined, and is running under load.
  3. You are using the WebSphere MQ JMS provider.
  4. You have not specified a reply-to destination, and so are using JMS temporary dynamic queues.
- **Explanation:** If you do not specify a reply-to destination, and you are using the WebSphere MQ JMS provider in a message flow with additional instances, you must configure JMS temporary dynamic queues before deploying your message flow.
- **Solution:** Complete the steps in the topic "Configuring JMS temporary dynamic queues for the WebSphere MQ JMS provider" on page 4848.

Your XSLTransform node does not work after deployment: About this task

Two scenarios explain why your XSLTransform node might not work after deployment:

Error messages are displayed indicating that the style sheets were not found

Procedure

- **Scenario:** Error messages are displayed indicating that the style sheets were not found.
- **Explanation:** This error message is displayed if the broker cannot find the style sheets or XML files required, or if the content of a style sheet or XML file is damaged and therefore no longer usable. This error message can happen if a file system failure occurs during a deployment.
- **Solution:** If the style sheets or XML files are damaged, redeploy the damaged style sheets or XML files.

What to do next

You get unexpected transformation results

- **Scenario:** You get unexpected transformation results.
- **Explanation:** For complex message flows, incompatibility might arise among style sheets and XML files after a deployment. The two typical reasons for this error are:
  - Only part of the cooperating style sheets or XML files are deployed and updated (a file system failure could cause this failure).
  - Multiple XSLTransform nodes that are running inside the same execution group are supposed to use compatible style sheets, but are using different versions to process the same incoming message.
- **Solution:** If only part of the cooperating style sheets or XML files are deployed and updated, resolve all incompatibility by redeploying the compatible versions. To avoid multiple XSLTransform nodes using different versions of the style sheet, pause relevant message flows in the target execution group before performing the deployment, then restart the flows.

Resolving problems that occur when starting and stopping the debugger

Use the advice given here to help you to resolve common problems that can arise when you debug message flows.

An endless "waiting for communication" progress bar is displayed when you start the debugger:
Procedure

- **Scenario:** After you click **Start Debugging**, you get an endlessly cycling progress bar entitled "waiting for communication". The "debug session started" message is not displayed in the information pane.
- **Explanation:** If the message flow has nodes with ESQL statements, the flow might not deploy even if the statements are correct syntactically. This situation can occur, for example, because of multiple declarations or uninitialized variables (that is, semantic problems that the syntax parser does not pick up). Always check the WebSphere Message Broker Toolkit Administration log to confirm that the debugged version of your message flow has deployed successfully; it has the same name as the original message flow, with the suffix `_debug_`.

  If the message flow does not deploy properly, the debugger cannot establish communication with the flow, and you see the endless progress bar.
- **Solution:** Click **Cancel** to clean up and return to a good state, then fix your errors and try again. As a check, see if your flow can deploy without the debugger.

The debugger seems to stop:
Procedure

- **Scenario:** You are debugging a message flow and continue after encountering a breakpoint. However, nothing seems to happen and after about a minute, a progress bar appears, indicating that the debugger is waiting for communication.
- **Explanation:** This situation can occur for the following reasons:
  - The message flow might have encountered a time-intensive operation, such as a huge database query, and you must wait for the flow to complete the action.
  - The broker ended, or some other extraordinary condition occurred, and communication was lost. In this case, click **Cancel** to stop the debug session.

The session ends abnormally while debugging:
Procedure

- **Scenario:** After debugging a message flow, the session ends abnormally and you still have the debug instance of the message flow (mf_debug_) deployed to the broker's execution group. You are concerned that this is going to affect the operation of the flow, and want to put the execution group back to its original state.
- **Explanation:** The orphaned message flow should behave as the flow would have done normally, and the Debug nodes have no effect on message processing. If you have a small number of nodes in the message flow, corrective action makes no noticeable difference to the flow, apart from its name. However, if you have a large message flow (that is, more than 15 nodes or several subflows), take the corrective action described later in this section, because the performance of message processing might be affected.
- **Solution:** Redeploy the broker.

A full redeploy of the broker should replace the orphaned flow with the original message flow. If this action has no effect, remove the orphaned flow from the execution group, deploy, then add the flow and deploy to restore the original state of the broker as it was before the debugging session.

An error message is displayed indicating that the debug session cannot be launched:
Procedure

- **Scenario:** You try to relaunch or invoke a new debug session but when you click the green **Debug** icon  , an error message is displayed stating: `Cannot launch this debug session`.
- **Explanation:** When you click **Debug** , it relaunches the last debug session. It fails if you have not created a debug session previously. It also fails if the broker and execution group that were attached previously in a debug session are no longer running, or have been restarted; the session cannot be reattached without re-selection of the broker and execution group process instance.
- **Solution:**
  1. Close the error message and click the arrow immediately to the right of the **Debug** icon.
  2. Re-select or modify the broker and execution group information from the previous debug launch configuration by clicking **Debug** in the menu and selecting the previous debug launch configuration. See "Attaching the flow debugger to an execution group for debugging" on page 3160 for more information.

Errors are generated when you copy a message map into a message flow project:
Procedure

- **Scenario:** You are copying a message map into a message flow project and errors have appeared in the task list.
- **Explanation:** The message flow project did not have the correct references set before you copied the message mapping.
- **Solution:** These errors remain in the task list, even if you reset the project references immediately after copying. Therefore, you must perform a clean build of the message flow project.

Resolving problems when debugging message flows

This topic contains advice for dealing with some of the common problems that can arise when debugging message flows.

The debugger does not pause at the next breakpoint:
Procedure

- **Scenario:** The message flow debugger does not pause at the next breakpoint in your message flow.
- **Solution:** Perform the following checks:
  1. Check whether your DataFlowEngine is running; if it is not, restart it.
  2. Check the input queue. If your input queue has the leftover messages from the previous time that you used the debugger, clear them before you send a new message.

The message does not stop executing at any breakpoint:
Procedure

- **Scenario:** The message does not stop executing at any breakpoint after you attach to the debugger.
- **Explanation:** This error could be caused by a timing problem, or if you have set the wrong parameters for the debug session.
- **Solution:** Perform the following steps.
  1. Check your launch configuration settings, ensuring that you have specified the correct Flow Project, HostName and Flow Engine for the debug session.
  2. Restart the debug session.

Editing problems occur in the Message Flow editor:
Procedure

- **Scenario:** While debugging a message flow, editing problems occur when you are using the Message Flow editor.
- **Solution:** Do not attempt to edit the message while the flow debugger is attached. To edit a message flow, detach the debugger, edit the message flow, then redeploy the message flow.

Editing the MQ message descriptor (MQMD) causes unexpected behavior in the debugger:
Procedure

- **Scenario:** You edit properties of the message MQMD descriptor in the Message Set editor, but this causes unexpected behavior in the debugger.
- **Explanation:** If you edit the content of the MQMD descriptor, these fields take a certain range of values. You need to know these ranges before editing the properties. Unless you explicitly specify the value of these fields, they take default values, and certain fields might not have been specified in the message. The values in the fields that are not set explicitly in the message are default values; do not change these unless you are aware of their importance or the possible range of values.

You cannot see the message content when debugging your message flow:

Procedure

- **Scenario:** You are using the message flow debugger, and you can see the message passing through the message flow, but you cannot see the content of the message.
- **Solution:** Open the Flow Debug Message view by clicking **Window** > **Show View** > **Other** > **Message Flow** > **Flow Debug Message**, then **OK**.

An exclamation mark appears above a node during debugging:
Procedure

- **Scenario:** In the Message Flow editor, an exclamation mark (!) is displayed above a node during debugging.
- **Explanation:** An exception has occurred in the node during debugging.
- **Solution:** Look under the ExceptionList in the Variables view of the Debug perspective to find out what error has occurred.

The message does not stop processing at breakpoints:
Procedure

- **Scenario:** Message processing continues when a breakpoint is encountered.
- **Explanation:** This error could be caused by a timing problem, or if you have set the wrong parameters for the debug session.
- **Solution:** Check your launch configuration setting. Ensure you have specified the correct Flow Project, HostName and Flow Engine for the debug session. Restart the debug session.

You cannot see where the debugger is in the message mapping editor:
Procedure

- **Scenario:** The message mapping editor has opened in the toolkit, but it is unclear where the debugger is in the map.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

When debugging a message map, the debugger does not move to the next field:
Procedure

- **Scenario:** You are debugging a message map, and the debugger does not move to the next field. You have to click the **Step over** button multiple times.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

When debugging a message map, the debugger does not move out of the mapping node:
Procedure

- **Scenario:** You are debugging a message map, and the debugger does not move out of the message map.
- **Explanation:** The source lookup path for the message map file is not configured correctly.
- **Solution:** Check your debug launch configuration settings and ensure you have configured the source lookup path for the message map file correctly.

The message flow stops at a collector node:
Procedure

- **Scenario:** Message processing stops after selecting the Step into Source Code icon on a Collector node.
- **Explanation:** The collector node is a multithreaded node and the thread is ended by selecting Step into Source Code.
- **Solution:** Set a breakpoint manually after the collector node.

Resolving problems that occur after debugging:

This topic contains advice for dealing with some of the common problems that can arise after debugging message flows.

You cannot change a message flow after debugging:
Procedure

- **Scenario:** You were debugging, but now your message flow seems to be stuck. When you put a new message in, nothing happens.
- **Explanation:** This might be because a message was backed out, but you have not set the **`Backout requeue name`** property of your input queue.
- **Solution:** Set the **`Backout requeue name`** property to a valid queue name (such as the name of the input queue itself) and your flow will become unstuck.

You redeployed a debugged message flow but deployment hangs:
Procedure

- **Scenario:** You found problems in your message flow by using the debugger. You changed your message flow and then redeployed it, but now the deployment hangs.
- **Solution:** Make sure that when you redeploy the flow to an execution group, the execution group is not still attached to the debugger.

If you want to change your message flow while you are debugging it, you must redeploy it to the execution group, then reattach the flow debugger.

Resolving problems when developing message models

This topic contains advice for dealing with some common problems that can arise when working with message sets.

About this task

Message definition files:

- "Error message BIP5505 is issued because input data is not valid for the data type" on page 3464

Other:

- "A deprecation error is issued on an imported `.mrp` file" on page 3465
- "User trace detects an element length error" on page 3465
- "MRM dateTime value has changed after it has been parsed" on page 3466

Your message definition file does not open

Procedure

- **Scenario:** You have created a complex type with a base type that causes the types to be recursive, and now your message definition file does not open.
- **Solution:** Recover the last saved version of your message definition file from the local history or from your repository.

A message definition file error is written to the task list

Procedure

- **Scenario:** An error is written to the task list indicating that the message definition file has been corrupted.
- **Explanation:** This error message appears when the base type of the complex type is itself, or a circular definition of two or more simple types. This type of recursion is not supported.
- **Solution:** Examine your code and ensure that the type of recursion described above does not occur.

Your physical format property values have reverted to defaults

Procedure

- **Scenario:** Someone has sent you a message definition file. You have added it to a message set project, but all the physical format property values have reverted to defaults.
- **Explanation:** You cannot transfer message definition files on their own in this way because these files are not entirely independent. It is the `messageSet.mset` file that lists all the physical formats that are applicable to a message set. For example, if you have a message set *A* with CWF format *Binary1*, and a message set *B* without any physical formats, a message definition file copied from *A* to *B* does not show *Binary1* as a known physical format (although the properties are still in the message definition file).
- **Solution:** If possible, request the entire message set project.

  Alternatively, add physical formats to the receiving message set so that they match the originating message set. Then any dormant properties become visible. However, make sure that the message set level physical format properties match, or those object properties that inherit defaults from the message set level will be incorrect.

You are unable to enter text in the Message Definition editors

Procedure

- **Scenario:** You are unable to enter text in the Message Definition Overview editor, or change the text of an enumeration or pattern facet in the Message Definition Properties editor.
- **Solution:** The Message Definition editors are cell editors, and to enable them you have to double-click the cell. The first click selects the cell; the second click puts the cell into active state, allowing you to edit it.

Objects in your message definition file are not listed in alphabetic order

Procedure

- **Scenario:** The objects in your message definition file (`.mxsd`) are listed in the order that you created them, but you want them to be in alphabetic order.
- **Solution:**
  1. In the Broker Application Development perspective, double-click the message definition file to open it in the Outline view.
  2. Click **az** (at the top of the Outline view).

  This action changes the order of objects within each of the message definition file's folders (the Messages, Types, Groups, Elements, and Attributes folders) to be alphabetic.

Error messages are written to the task list after you have imported related XML Schema files

Procedure

- **Scenario:** When you have finished importing a collection of related XML Schema files, you find that the WebSphere Message Broker Toolkit task list contains error messages for the message set project, indicating that referenced types or other objects cannot be found.
- **Explanation:** These errors are typically an indication that one message definition file includes or imports another message definition file, but that the Message Definition editor is unable to resolve the specified link.
- **Solution:**
  - Check that a message definition file exists in the WebSphere Message Broker Toolkit for each of the related XML Schema files that you are importing. If the new message definition files have been created, they appear in the Broker Development view.
  - Using the Properties Hierarchy in the Message Definition editor, check that any message definition files that include or import other message definition files are correctly locating the target files.

  One common scenario is where you have two XML Schema files *X* and *Y*, which both exist in the same directory in the file system but where *X*, which includes *Y*, is defined with a real target namespace, while *Y* is defined in the notarget namespace. After you import the two files, *X* is placed into the location that is determined by its namespace, but *Y* is placed into the default namespace location used for files defined in the notarget namespace. This situation causes the link between the two files to break, and you must modify *X* so that it correctly includes *Y* in its new relative location.

A group contains two different elements with the same XML name in the same namespace

Procedure

- **Scenario:** A warning is written to the task list because a group contains two different elements that have the same XML element name, in the same namespace.
- **Explanation:** When a message that has an XML physical format is validated, the validation includes a test to identify any part of a message definition where the parser might not be able to uniquely determine which element is represented by the XML name. This test generates a warning when a group contains two different XML elements with the same element name in the same namespace, even in cases where the duplication is legitimate.

- **Solution:** Determine whether the duplication that is identified in the warning message is in fact a problem that needs to be corrected, or whether it has arisen because of two elements on opposite sides of a choice sharing the same XML name, in which case the duplication is legitimate because no ambiguity can occur.

You are unable to set up a message definition file to include a message definition file within another message definition file

Procedure

- **Scenario:** You are unable to set up the include property of a message definition file to include a second message definition file that is included within another message definition file.
- **Explanation:** A message definition file can reference objects in another message definition file only if the first file references the second file directly. For example, if three message definition files exist, *A*, *B* and *C*, where *A* includes *B* and *B* includes *C*, *A* can reference objects in *B*, and *B* can reference objects in *C*, but *A* cannot reference objects in *C*.

  You might also encounter this problem after importing XML Schema files that have nested includes.
- **Solution:** You can work around this problem by including the message definition file directly, which, in the above example, would mean including *C* directly in *A*. Alternatively, you can define all the message set definitions that are in *C* directly in *B*, then delete *C* so that *A* needs to include only *B*.

You want to make the Properties tab the default tab in the Message Definition editor

Procedure

- **Scenario**: When using the Message Definition editor to edit your message definition files, you prefer to use the **Properties** tab rather than the **Overview** tab, but the **Overview** tab is always selected as the default.
- **Solution:** Use the WebSphere Message Broker Toolkit preferences to choose the **Properties** tab as the default tab:
  1. From the menu, click **Windows** > **Preferences**.
  2. Expand **Broker Development**, then **Message Set**.
  3. Expand **Editors** and select **Tab Extensions**.
  4. In the **Message Definition Editor** section, select the **Properties** and the **Overview** check boxes.
  5. Click **OK**.

Error message BIP5410 is issued because a union type cannot be resolved

Procedure

- **Scenario:** Error message BIP5410 is raised indicating that an element or attribute is based on a union type and that the element or attribute could not be cast to any member of the union.
- **Explanation:** When parsing an element or attribute that is based on a union type, the MRM XML parser uses an xsi:type attribute, where present, to resolve the union.

  If an xsi:type attribute is not present, or an attribute is being parsed, the parser tries each union member type in turn, attempting to cast to the associated simple type, until the cast succeeds. The order of precedence for the attempted cast is the order in which the member types are listed in the message model, under the union type, in the Outline view.

If the data cannot be cast to any of the simple types within the union, the union cannot be resolved and a parser error is reported.

- **Solution:** Perform the following checks:
  - Check that the message contains a valid value for the element or attribute that is identified in the error message.
  - Check that the member types of the union that are identified in the error message contain the correct list of simple types.
  - If possible, use an xsi:type attribute to resolve the union explicitly.

Error message BIP5395 is issued because an xsi:type attribute value does not correspond to a valid member type of the union

Procedure

- **Scenario:** Error message BIP5395 is issued, indicating that an element is based on a union type that has an xsi:type attribute with a value that should resolve the union explicitly to one of its modeled member types and that the xsi:type attribute value does not correspond to a valid member type of the union.
- **Explanation:** When parsing or writing an element or attribute that is based on a union type, the MRM XML parser or writer uses an xsi:type attribute, where present, to resolve the union. The parser resolves the value of the xsi:type attribute to a simple type in the dictionary and checks that the simple type is a valid member type of the union.

  If the xsi:type attribute identifies a type that is not a member type of the union, it reports an error.
- **Solution:** Perform one of the following steps:
  - Modify the message so that the xsi:type attribute identifies a valid member type of the union.
  - Check that the member types of the union identified in the error message contain the correct list of simple types.

Error message BIP5396 is issued because a data type does not correspond to any of the valid data types of the union

Procedure

- **Scenario:** Error message BIP5396 is issued, indicating that an element or attribute is based on a union type but the data type does not correspond to any of the valid data types in the union.
- **Explanation:** When writing an element or attribute that is based on a union type, the MRM XML writer uses an xsi:type attribute, where present, to resolve the union. If an xsi:type attribute is not present, the writer tries to match the data type of the literal value in the tree to a simple type in the union. If the literal value cannot be matched to any of the simple types in the union, it reports a writing error.
- **Solution:** Perform one of the following steps:
  - Check that the message or ESQL contains a valid value for the element or attribute.
  - Check that the union type on which the element is based contains the correct list of simple types.
  - Consider using an xsi:type attribute to resolve the union explicitly.
  - Consider changing the type of the element in the tree to correspond with one of the union member types.

A union type contains two or more simple types that are derived from the same fundamental type

Procedure

- **Scenario:** A warning is issued during logical validation indicating that a union type contains two or more simple types that are derived from the same fundamental type.
- **Explanation:** The broker does not apply value constraints until the data is in the logical tree. Therefore, it is not possible to choose between two simple types that are derived from the same fundamental type but with different constraints. For example, the broker cannot differentiate between a member type of integer with a range of 1-10 and another member type of integer with a range of 11-20, therefore it resolves the union to the first member type of integer.
- **Solution:** Ensure that the union type that is identified in the warning does not contain more than one simple type that is derived from the same fundamental type or ensure that the ordering of such member types is as desired.

A list type is based on a union that also contains a list type

Procedure

- **Scenario:** An error message is issued during logical validation, indicating that a list type is based on a union type that includes a list type as one of its member types.
- **Explanation:** Lists of lists are not legal. An item type of a list type cannot be a list type itself nor can it be derived at any level from another list type. Therefore, a list type cannot have an item type of a union type that includes a list type as one of its member types.
- **Solution:** Ensure that any union type specified as an item type for a list type does not include a list type as one of its member types.

A union type contains an enumeration or pattern facet

Procedure

- **Scenario:** An error message is raised during logical validation, indicating that a union type contains an enumeration or pattern facet that is not supported because enumeration and pattern facets must be specified directly on the member type.
- **Explanation:** The broker cannot support the union type facets of pattern and enumeration applied directly to a restriction of a union type. It can support facets directly on the chosen member type only. The Message Definition editor provides support for these facets to enable the import of schemas using direct facets on a restriction of a union type but it issues a warning notifying that they will be ignored by the broker.
- **Solution:** If you want to use the enumeration or pattern facets, specify them directly on the member type and not on the union type itself.

Error message BIP5505 is issued because input data is not valid for the data type

Procedure

- **Scenario:** A data conversion fails while a message is being read or written. Error message BIP5505 is issued, indicating that the input data was not valid for the data type.
- **Solution:** Perform the following checks:

- Ensure that the bit stream is correctly aligned to the model. If the incoming message is not consistent with the model, the wrong bytes are allocated to fields, and the data presented to a field is unlikely to contain valid data for the logical type.
- Ensure that the correct encoding and CodedCharSetId are applied to the body of the input message. If the wrong encoding is used, the input message bit stream is subject to byte swapping and changes to the byte order. This change can affect the nature of data that applies to a field and make it unusable.
- Ensure that an appropriate WebSphere MQ format is applied to the body of the input message. For example, if MQSTR is applied to a bit stream that contains numeric data, character conversions, rather than encodings, are used to translate the bytes. This use can change the meaning of bytes and make them not valid for the logical data type. If character conversions are used with negative external decimals, consider using the EBCDIC custom option.
- If the error is on a numeric field, ensure that the input data is compatible with the physical format settings. For example, if the field is signed, ensure that a valid sign byte has been passed in, that it corresponds to the orientation of the sign, and that it is included or excluded as appropriate.
- If the input message is found not to be compatible with the MRM message definitions, check the message at the source. If it is sent over channels, check that the conversion settings on the channels are correct.

A deprecation error is issued on an imported `.mrp` file

Procedure

- **Scenario:** You have imported an `.mrp` file, and get an error message indicating that complex elements or embedded simple types are deprecated.
- **Explanation:** Complex elements and embedded simple types have no exact equivalent in XML Schema. The closest equivalent to a complex type in XML Schema is to derive a complex type from a simple type. However, such a type is not allowed to contain elements; only attributes are allowed.
- **Solution:** If your complex type contains elements that cannot be modeled as attributes, set the **`Mixed content`** flag on the complex type. If you need to parse messages that contain mixed content, set the **`Mixed content`** flag on the parent complex type. The anonymous data that used to be modeled by the complex type or the embedded simple type, then appears as a self-defining node in the parsed message tree.

User trace detects an element length error

Procedure

- **Scenario:** You have defined an MRM message and when you execute the message flow, an error message is written to the user trace indicating that the length of an element is invalid.
- **Explanation:** You have added an element of type string to the complex type making up the message, but you have not defined the length of the string in the instance of the element in its type.
- **Solution:**
  1. Open the message definition file in the Message Definition editor.
  2. In the Outline view, expand the appropriate complex type, then click the element to display its properties in the editor area.
  3. In the Properties Hierarchy, make sure that the element is selected within the CWF physical format under **Physical Properties**.

4. Specify the properties that this element will have when it is part of the complex type; for example, in the above case, make sure that the **Length Count** value is set.
5. Save any changes in the Message Definition editor and redeploy the message.

MRM dateTime value has changed after it has been parsed

Procedure

- **Scenario:** You have defined an MRM dateTime element but the value created in the message tree is different from the value that you defined.
- **Explanation:** The parser uses lenient dateTime checking, converting out-of-band data values to the appropriate in-band value.
- **Solution:** See the information about lenient dateTime checking in "DateTime as string data" on page 6311 with particular reference to how years and fractional seconds are represented.

Related concepts:

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

"Message model objects" on page 1174
An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

"Message model objects: simple types" on page 1180
A *simple type* is an abstract definition of an item of data such as a number, a string, or a date.

Resolving problems when using messages

Use the advice given here to help you to resolve common problems that can arise when you use messages.

About this task

Procedure

A communication error is issued when you use the enqueue facility

Procedure

- **Scenario:** You use the enqueue or dequeue tools to put a message on a queue, but an error message is issued indicating that a communication error has occurred with the queue manager name.

- **Explanation:** The WebSphere MQ queue manager has not started.
- **Solution:** Restart the WebSphere MQ queue manager.

The enqueue facility is not picking up changes made to a message

Procedure

- **Scenario:** You are using the WebSphere Message Broker Toolkit message enqueue facility to put messages to WebSphere MQ queues. You have updated a message and want to put the message to the queue, but your changes do not seem to have been picked up.
- **Solution:**
  1. Close, then reopen your enqueue file.
  2. Select the message that you want to put to the queue.
  3. Save and close the enqueue file.
  4. Select the menu next to the **Put a message to a queue** icon.
  5. Click **Put message**.
  6. Click the enqueue file in the menu.
  7. Click **Finish**.

  This action puts your updated message to the queue.

You do not know which header elements affect enqueue

Procedure

- **Scenario:** When using the Enqueue editor, the accounting token, correlation ID, group ID, and message ID in the message header do not seem to affect behavior.
- **Explanation:** These fields do not affect behavior because they are not serialized properly.

Enqueue message files are still listed after they have been deleted

Procedure

- **Scenario:** Enqueue message files are still listed in the menu after they have been deleted.
- **Explanation:** Deleted enqueue files are not removed from the menu. Nothing happens if you selecting these files.

The ESQL transform of an XML message gives unexpected results

Procedure

- **Scenario:** You have created an XML message that looks like the following content:

  ```
  <?xml version ="1.0" standalone="no"?><!DOCTYPE doc
  [<!ELEMENT doc (#PCDATA)*>]><doc><I1>100</I1></doc>
  ```

  You apply the ESQL transform:

  ```
  SET OutputRoot.XMLNS.doc.I1 = 112233;
  ```

  This transform generates the XML message (after serialization):

  ```
  <?xml version ="1.0" standalone="no"?><!DOCTYPE doc
  [<!ELEMENT doc (#PCDATA)*>]<I1>112233<I1>><doc><I1>100</I1></doc>
  ```

  The new value for *I1* has been put inside the `DOCTYPE`, and has not replaced the value of *100*, as you expected.

- **Explanation:** The XML in your message contains two `doc` elements:
  - The `doctype` element
  - The `xmlElement` that represents the body of the message

  The parser has found the first instance of an element called `doc` and has created a child *I1* with the value *112233*.
- **Solution:** To assign a new value to the element *I1* within the message body element `doc`, explicitly identify the second `doc` element, in the following way:

  ```
  SET OutputRoot.XMLNS.(XML.tag)doc.I1 = 112233;
  ```

An XML message loses carriage return characters

Procedure

- **Scenario:** You are parsing an input XML message that contains carriage return or line feed characters, or you are writing an output XML message that contains carriage return line feed characters in an XML element. However, some or all the carriage return characters are not present in the output message.
- **Explanation:** This behavior is correct, as described by the XML specification, and occurs in the XML, XMLNS, or XMLNSC domains.

  In XML, the main line separator characters is a line feed character. Carriage return characters are accepted in an XML document, but an XML parser normalizes any carriage return line feed characters into a single-line feed character. For more information, see the latest XML specification at Extensible Markup Language (XML), in particular, Section 2.11 *End of Line Handling*.

  You cannot work around this problem by embedding your data into a CDATA section; the XML specification states that a CDATA section is intended only to escape blocks of text that contain characters that could be interpreted as markup. In addition, CDATA sections are not protected from the parser.

  You cannot use the `xml:space` attribute to preserve carriage return line feed characters; the XML specification states that normalization of carriage return and line feed characters is done before any other processing is performed.
- **Solution:** XML-compliant data must not rely on the presence of carriage return line feed characters because in XML, the line feed character is only a line feed character and XML-compliant applications or data must be aware that the parser normalizes any carriage return line feed characters.

The broker is unable to parse an XML message

Procedure

- **Scenario:** You receive a large XML file and wrap it in a SOAP envelope to be passed to a .NET web service. The broker is unable to parse the XML message
- **Explanation:** The message that you receive is defined as UTF-8 but it contains UTF-16 characters, such as £. The presence of these characters causes a problem with the parser: the broker is unable to parse the XML message because it contains an invalid character.
- **Solution:** Force the coded character set ID (CCSID) to 1208 instead of the default 437.

Unexpected characters are displayed when using the XSLTransform node on z/OS

Procedure

- **Scenario:** When using the XSLTransform node on z/OS, all the uppercase Os that are in an XML file on the incoming message are changed to underscore characters.

- **Explanation:** The XSLTransform node input message must come in as ASCII for the transform to work correctly. The XSLTransform node does not work with XML or XSL data in EBCDIC code. Java assumes a conversion from EBCDIC 1047. WebSphere Message Broker then converts to EBCDIC 500, because the CCSID is set to 500. EBCDIC 1047 and EBCDIC 500 are similar. Only uppercase 0, J, and Z are different. (J and Z are also converted incorrectly.) The conversions leave a string that is unreadable because it is really in ASCII. However, it does convert the 0 from an EBCDIC 1047 character to an EBCDIC 500 character.
- **Solution:** Change your program either to do a string assignment without any conversions, or specify that the string is in ASCII ISO-8859-1 (CCSID 819).

Error message BIP5004 is issued by the XMLNS parser

Procedure

- **Scenario:** Error message BIP5004 is issued, indicating that the XMLNS parser has encountered a problem with an input XML message.
- **Explanation:** This message is issued for a number of reasons. Some of the more commonly occurring scenarios when this message is issued are:
  - You have specified an invalid XML character in the input XML message.
  - You have included binary data in your XML message that, when treated as character data, is invalid.
  - The message has arrived as part of a WebSphere MQ message and the MQMD.CodedCharSetId does not correctly represent the XML text bit stream.
  - You have used characters that are recognized as markup.
- **Solution:**
  - Check that your sending application is sending only valid data. If, however, it is not possible to prevent invalid characters from being included in the XML message, represent it in BLOB domain and use the ESQL REPLACE function to replace or remove the invalid characters. You can then assign the modified bit stream to the required XML parser.

    In accordance with XML specification, a CDATA section can be used only to protect characters that would be interpreted as markup. It cannot be used to protect invalid characters or binary data from the XML parser.
  - If the input XML message contains binary data, ensure that the sending application is changed to represent this data as base encoded binary encoded data. If the application cannot be changed, represent the message in the BLOB domain, and extract and replace the binary data before the bit stream is assigned to the required XML parser.
  - Check that the incoming XML message is being represented by the correct MQMD.CodedCharSetId.

Error message BIP5378 is issued by the MRM parser

Procedure

- **Scenario:** Error message BIP5378 is issued, which reports a problem with a missing mandatory repeating element in an MRM message.
- **Explanation:** This message indicates that a mandatory repeating element is not present in the message. In previous releases, this condition was reported by error message BIP5374 which now reports only when a mandatory repeating element exists in the message but has the incorrect number of instances.

  If you have programmed automated error checking routines, review and change these routines if appropriate.
- **Solution:** Check your message definition to ensure that the element must be mandatory, and repeating. The error message tells you the elements that occur

before and after the expected location of the missing element. If the definition is correct, the message has not been created correctly by the sending application, which must be amended.

Error message BIP5005 is issued by the Compute node

Procedure

- **Scenario:** You send a simple XML message into a simple message flow. The message is:

  ```
  <doc><I1>100</I1></doc>
  ```

  The Compute node in the message flow contains the following ESQL:

  ```
  SET OutputRoot.XMLNS.abc = InputBody;
  ```

  You expect the following output message to be created:

  ```
  <abc><doc><I1>100</I1></doc></abc>
  ```

  The Compute node generates error message BIP5005 and does not implement the ESQL.
- **Explanation:** You are assigning an element of one type (`root`) to an element of another type (`xmlElement`). The parser does not do this implicit cast for you.
- **Solution:** You can do the cast yourself in the ESQL to achieve the result that you want, using either of the following two casts:

  ```
  SET OutputRoot.XMLNS.(XML.Element)abc = InputBody;
  ```

  or:

  ```
  SET OutputRoot.XMLNS.(XML.tag)abc = InputBody;
  ```

A message is propagated to the Failure terminal of a TimeoutControl node

Procedure

- **Scenario:** The TimeoutControl node receives a message with invalid, corrupt, or missing timeout information. The message is propagated to the Failure terminal of the TimeoutControl node and an exception list is generated.
- **Explanation:** The following error conditions can cause propagation to the Failure terminal:
  - A timeout request has no Action or no Identifier.
  - A SET request has an Identifier that matches an existing stored SET request for this TimeoutControl node (identified by the Unique Identifier property) and AllowOverwrite of the original request is set to FALSE.
  - A CANCEL request has an Identifier that does not match an existing stored SET request for this TimeoutControl node (identified by the Unique Identifier property).
  - A SET request has a Count of 0 or is less than -1.
  - The StartDate or StartTime are not in the correct format (or one of the understood keywords).
  - The calculated timeout is in the past.
  - The Interval is less than 0, or 0 with a Count of -1.
- **Solution:** Check for one or more of the error conditions listed here, and correct them.

Message processing fails within a TimeoutNotification node

Procedure

- **Scenario:** A message is propagated to the Failure or Catch terminal of a TimeoutNotification node.
- **Explanation:** If the processing of a timeout generates an error within the TimeoutNotification node, an exception list is generated and a message is propagated to the Failure terminal. This action is done under the same transaction, if one is being used. If the Failure terminal is not connected, propagation does not occur.

  If an error happens downstream of the TimeoutNotification node after a successful propagation (either to the Out or Failure terminal), the message is propagated to the Catch terminal (all under the same transaction). If the Catch terminal is not connected, or the propagation along the Catch flow fails, the processing of that timeout is rolled back.
- **Solution:** Ensure that the Failure and Catch terminals of your TimeoutNotification node have been connected correctly.

An MRM CWF message is propagated to the Failure terminal

Procedure

- **Scenario:** Your MRM CWF message is propagated to a Failure terminal, and generates error messages BIP5285, BIP5125, and BIP5181 or messages BIP5285, BIP5125, and BIP5288.
- **Explanation:** These errors report an inconsistency between the length of the message being processed, and the length of the message that is defined in the message model.
- **Solution:** Ensure that the length of the message as defined in the CWF layer is accurate. Check and correct the definition.

Problems with XML attributes

About this task

XML tags are written where XML attributes are expected, and vice versa.

Procedure

- **Explanation:** The XML domains and the XML Wire Format in the MRM domain have their own representation of XML attributes.
  - XML domains rely on setting a field type of XML.Attribute in the message tree, because they have no model to parse against.
  - For the XML Wire Format in the MRM domain, the message model indicates whether an element is an attribute or a tag, therefore the message tree does not need to reflect whether a field is an attribute or a tag.

  Therefore, if fields are copied out of the XMLNS or MRM domains, the fact that fields are attributes is lost. This loss happens if they are copied out to each other, or to another message tree, such as the environment tree.

  This problem typically appears in the following situations:
- **Scenario 1:** You are writing an XML message in the MRM domain, and XML tags are being written instead of XML attributes.
- **Solution 1:** Check that your message tree has the same structure and sequence as the message model. If the message tree does not match the message model, the field is written as self-defining, and consequently the XML Render property is not used.

- Switch on message validation. Validation shows where the message tree and message definition do not match.
- Alternatively, take a user debug trace of the message flow; BIP5493W messages indicate which fields are being written as self-defining. Use this information to ensure that the message tree matches the model. When you have corrected any discrepancies, attributes are correctly written.

- **Scenario 2:** An MRM message has been copied to an XMLNS domain, and the XML attributes are now written as tags.
- **Solution 2:** Take one of these actions:
  - Serialize the XML message in the MRM domain, for example using the ESQL ASBITSTREAM function, then use the ESQL CREATE PARSE clause to reparse the message using the required XML domain.
  - When copying fields between the MRM domain and XMLNS, copy attribute fields individually, and specifically specify XML.Attribute on the target XML field.
- **Scenario 3:** An XML message has been copied to another message tree, such as Environment. When the message is copied back to the XML message tree, XML attributes are now seen as XML tags.
- **Solution 3:** Serialize the XML message, for example using the ESQL ASBITSTREAM function, then use the ESQL CREATE PARSE clause to reparse the XML message into the required target message tree. See "CREATE statement" on page 5082 for an example.
- **Scenario 4:** A portion of a non-XML message tree has been detached and attached to an XML tree, and XML tags are now written as XML attributes.
- **Solution 4:** Do not detach and attach portions of message trees that are owned by different parsers. Instead, use a tree copy.
- **Scenario 5:** An XML tag is copied to an XML attribute and the XML attribute is not written in the output message.
- **Solution 5:** When referencing the source XML tag, use the ESQL FIELDVALUE function to copy the specific field value to the target XML attribute field.

An MRM XML message exhibits unexpected behavior

Procedure

- **Scenario:** Your message flow is processing a message that you have modeled in the MRM. The message tree has not been created as you expected, the output XML message does not have the expected contents, or the message contents are not being validated. No error message has been issued.
- **Explanation:** Two reasons might cause this problem:
  - **Explanation 1:** The XML physical format settings for a message set contain a property called Root Tag Name. This property defaults to MRM, in order to remain compatible with previous releases of the product. If you have not deleted the contents of this field, the MRM XMLNS parser expects the root tag for all XML messages to be MRM.

    Solution 1: Clear this field, or set it to the root tag used by all your XML messages. If you provide a value in this field, the root tag does not need to be modeled in all your message definitions.
  - **Explanation 2:** In order to remain backwards compatible, the broker recognizes the format XML and invokes the XMLNS parser with specific default values. If you have created an XML physical layer for this message with the name XML, the broker uses your definition. However, if you have not created an XML physical layer with this name, but have specified XMLNS as the format, either in the input node or the MQRFH2 header (when the

input bit stream is parsed to a message tree), the broker accepts the value specified and passes default values to the parser to create the message tree.

Similarly, if you set XML in the Properties folder for the output message in the Compute node, this value is passed to the parser when it creates the message bit stream from the message tree, typically in the output node.

The use of these default values by the parser might result in different content, structure, or both, for either message tree or output message. You can find further information about the action taken by the broker in the user trace log where the following information might be written:

```
XMLWorker::initializeParse file:C:\s000\src\cpi\pwf\xml\xmlworker.cpp
line:126 message:5409.BIPmsgs
No dictionary present have you specified Wire Format 'XML' in error? ,
UserTrace   BIP5409E: XML Worker: Wire Format 'XML' specified.
                      Default MRM XML settings are being used because wire format
                      identifier 'XML' was specified and not found.
                      This can be due to an incorrect setting of the wire format
                      identifier in a message.
```

Solution 2: If you have incorrectly entered the identifier of the format that you have defined, correct your code and try again. If you do not want the default action to be taken, define a physical layer that produces the required results.

The MRM parser has failed to parse a message because two attributes have the same name

Procedure

- **Scenario:** Two attributes in different name spaces have identical names. Error message BIP5117 is issued.
- **Explanation:** The MRM parser has failed to parse the message.
- **Solution:** Modify the attribute names so that they are not identical. This problem is a known limitation with the parser.

You encounter problems when messages contain EBCDIC newline characters

Procedure

- **Scenario:** If your bit stream input message contains EBCDIC newline (NL) characters, problems might arise if your message flow changes the target CCSID to an ASCII CCSID. For example, during conversion from CCSID 1047 (EBCDIC used for z/OS Open Edition) to CCSID 437 (US PC ASCII), an NL character is translated from hex '15' to hex '7F', which is an undefined character. The error occurs because no corresponding code point for the newline character exists in the ASCII code page.
- **Solution:** You can overcome the problem in these cases:
  - On a system where the queue manager uses an ASCII code set, make sure that incoming messages do not contain any EBCDIC NL characters by:
    - Specifying that WebSphere MQ performs the conversion at the input node
    - Setting the queue manager attribute to convert NL to Line Feed (LF)
  - Where the input bit stream is character data, you can use MRM Tagged/Delimited message sets in a Compute node to replace the NL character with the required output.

The MIME parser produces a runtime error while parsing a message

Procedure

- **Scenario:** A MIME message is received by a message flow and produces a runtime error when the message is parsed.
- **Explanation:** The following errors can cause the MIME parser to reject a message:
  - The MIME header is not correctly formatted.
  - Either the top-level MIME header block, or a MIME header block for a nested multipart part, does not have a valid Content-Type header.
  - The top-level Content-Type has a media type of `message`.
  - The top-level Content-Type has a media type of `multipart` and no boundary definition.
  - A MIME header block is not correctly terminated by a blank line.
  - The constituent MIME parts are not correctly separated by boundary lines.
  - A boundary parameter value occurs in the content of a MIME part.
- **Solution:** Check the MIME message for one or more of the error conditions listed here, and correct them.

Runtime errors are issued when you write a MIME message from the logical message tree

Procedure

- **Scenario:** You are writing a MIME logical message tree as a bit stream and the parser generates a runtime error.
- **Explanation:** The following errors can cause the MIME parser to reject a logical message tree:
  - The root of the tree is not called MIME.
  - The last child of MIME is not called Parts or Data.
  - The Parts element has a value-only element, and this element is not the first or last child of Parts.
  - The Parts element has children that are not value-only elements or Part children.
  - The Parts element does not have any children called Part.
  - The last child of a Data element is not a BLOB.
- **Solution:** Check the MIME logical message tree for one or more of the error conditions listed here, and correct them.

Output message has an empty message body

Procedure

- **Scenario:** You have unexpectedly encountered an empty message body, or the ASBITSTREAM function has produced a zero length BLOB.
- **Explanation:** This error can happen for the following reasons:
  - You have created a message tree folder in a user-defined node but have not associated it with an owning parser. An owning parser is not associated with the message tree if you have created standard elements by using code similar or equivalent to:

```
MbElement createElementAfter(int)
MbElement createElementAfter(int, String, Object)
MbElement createElementAsFirstChild(int)
MbElement createElementAsFirstChild(int, String, Object)
MbElement createElementAsLastChild(int)
```

```
MbElement createElementAsLastChild(int, String, Object)
MbElement createElementBefore(int)
MbElement createElementBefore(int, String, Object)
```

– You have used ESQL to create a message tree folder by using ESQL CREATE but without setting an owning parser for it. You might have used code similar or equivalent to:

```
CALL CopyMessageHeaders();
   DECLARE outRef REFERENCE TO OutputRoot;
   CREATE LASTCHILD OF outRef AS outRef NAME 'BLOB';
   CREATE LASTCHILD OF outRef NAME 'BLOB' VALUE X'01';
```

or the `outRef` reference variable was passed to an ESQL function or procedure that contained similar CREATE statements. You have not specified an owning parser by using the DOMAIN clause on the CREATE statement.

– An MRM message tree has been constructed, then only part of it has been passed, by specifying a subfolder or field, to the ASBITSTREAM function with the parser mode option set to RootBitStream. This combination is not valid, and results in a zero length BLOB.

– You have copied a message tree, or part of a message tree, to a folder and the owning parser association is not maintained.

• **Solution:** Depending on the reason for the empty message body or zero length BLOB, ensure that:

– When you create a message tree folder in a user-defined node, associate an owning parser with it. Use code similar or equivalent to:

```
createElementAfter(String parserName)
   createElementAsFirstChild(String parserName)
   createElementAsLastChild(String parserName)
   createElementBefore(String parserName)
```

– When you use ESQL CREATE to create a message tree folder, use the DOMAIN clause to associate an owning parser with the message tree, for example:

```
CALL CopyMessageHeaders();
   DECLARE outRef REFERENCE TO OutputRoot;
   CREATE LASTCHILD OF outRef AS outRef DOMAIN 'BLOB' NAME 'BLOB';
   CREATE LASTCHILD OF outRef NAME 'BLOB' VALUE X'01';
```

This code creates a BLOB folder that has the BLOB parser associated with it.

– When copying a message tree, or part of a message tree, ensure that the owning parser association is maintained, by first serializing, then reparsing the message into the appropriate message tree. An example scenario is where you have created a field:

```
SET Environment.Variables.myMsg = InputRoot.XMLNS;
```

Now you must pass it to the ASBITSTREAM function. Unless you use ESQL similar or equivalent to:

```
DECLARE xmlMsgBlob BLOB
          ASBITSTREAM(InputRoot.XMLNS, InputRoot.MQMD.Encoding, InputRoot.MQMD.CodedCharSetId);
  CREATE LASTCHILD OF Environment.Variables.myMsg DOMAIN('XMLNS')
         PARSE(xmlMsgBlob,
               InputRoot.MQMD.Encoding,
               InputRoot.MQMD.CodedCharSetId);
```

the result is a zero length bit stream.

Output message has an invalid message body indicated by error message BIP5005, BIP5016, or BIP5017

Procedure

- **Scenario:** You have unexpectedly encountered a multi-root message body or a message without any root.
- **Explanation:** This error can occur when you have created an XML message tree folder with multiple roots or no root at all by:
  - Using a user-defined node
  - Using an MQGet node
  - Using ESQL
- **Solution:** Ensure that the final output message tree has one, and only one, XML root node.

Error message BIP5651 is issued when receiving a SOAP with Attachments message from a WebSphere Application Server client

Procedure

- **Scenario:** When a WebSphere Application Server client sends a SOAP with Attachments message to the broker over JMS, error message BIP5651 is issued stating that no valid Content-Type header has been found.
- **Explanation:** When a WebSphere Application Server client sends a SOAP with Attachments message to the broker over JMS, the MIME Content-Type value appears in the MQRFH2 header and not in the MIME message body.
- **Solution:** To solve this problem, the Content-Type value needs to be copied from the MQRFH2 header to the beginning of the message as a MIME header before the message is parsed. The following ESQL adds the Content-Type value to the beginning of the WebSphere Application Server message, then invokes the MIME parser on the result.

```
create procedure parseWAS_JMS(IN InputMessage reference,IN OutputMessage reference)
/**********************************************************************
* convert a WAS/JMS message to the correct format for the MIME parser
**********************************************************************/
begin
  -- get the data as a BLOB
  declare body BLOB InputMessage.BLOB.BLOB;

  -- get the Content-Type value from the RFH2 header. Content-Type is the only
  -- header which is critical for the MIME parser, but the same approach can be
  -- used for any MIME headers which have been stored under the RFH2 header.
  declare contentType char InputMessage.MQRFH2.usr.contentType;

  -- add the contentType to the bit stream as part of an RFC822 header block
  set body = cast(('Content-Type: '||contentType) as blob ccsid 819)||x'0d0a0d0a'||body;

  -- invoke MIME parser on the modified bit stream
  CREATE LASTCHILD OF OutputMessage DOMAIN('MIME') PARSE(body);
end;
```

A message flow can take in the JMS message in the BLOB domain, and call the procedure shown here from a Compute node. The procedure can be called by using the following ESQL from a Compute node:

```
CALL CopyMessageHeaders();                -- standard procedure to copy headers
CALL parseWAS_JMS(InputRoot, OutputRoot); -- parse the 'body' as MIME
```

WebSphere Application Server produces an error when receiving a SOAP with Attachments message

Procedure

- **Scenario:** When sending a SOAP with Attachments message to a WebSphere Application Server client using JMS, an error is generated stating that the bit stream contains unexpected characters.
- **Solution:** When the broker sends a SOAP with Attachments message to WebSphere Application Server over JMS, the MIME Content-Type value must appear in the MQRFH2 header and not in the body of the message. The following procedure removes any MIME style headers from the front of the message bit stream and adds the Content-Type value to the MQRFH2 header. The supplied boundary value allows you to locate the start of the multipart MIME content.

```
create procedure writeWAS_JMS(IN OutputTree reference,IN boundary char)
/*****************************************************************************
* Serialise a MIME tree as normal, but then strip off any initial headers
* and save the Content-Type value in the RFH2 header as expected by WAS/JMS.
* Note: boundary - must be supplied with the leading hyphen pair
*****************************************************************************/
begin
  -- convert MIME subtree to BLOB
  declare body BLOB asbitstream(OutputTree.MIME);

  -- locate first occurrence of boundary and discard any data before this
  declare firstBoundary integer;
  set firstBoundary = position (cast(boundary as blob ccsid 819) in body);
  set body = substring(body from firstBoundary);

  -- save the MIME Content-Type value in the RFH2 header. Any other MIME
  -- headers which need to be preserved in the RFH2 header can be handled
  -- in the same way
  set OutputTree.MQRFH2.usr."contentType" = OutputTree.MIME."Content-Type";

  -- clear the MIME tree and create a new BLOB child for the modified body
  set OutputTree.MIME = null;
  CREATE LASTCHILD OF OutputTree DOMAIN('BLOB')PARSE(body);
end
```

Before calling this procedure, the message flow needs to be able to obtain the value of the boundary. This value might be available only within a Content-type header. The following procedure allows you to extract the Boundary value:

```
create procedure getBoundary(IN ct reference,OUT boundary char)
/*****************************************************************
* return value of the boundary parameter from a Content-Type value
*****************************************************************/
begin
  declare boundaryStart  integer;
  declare boundaryEnd    integer;

  set boundaryStart  = position('boundary=' in ct) + 9;
  set boundaryEnd    = position(';' in ct from boundaryStart);
  if (boundaryStart <> 0) then
    if (boundaryEnd <> 0) then
     set boundary  = substring(ct from boundaryStart for boundaryEnd-boundaryStart);
    else
      set boundary  = substring(ct from boundaryStart);
    end if;
  end if;
end;
```

A Compute node can invoke these procedures for sending a MIME message using the following ESQL:

```
SET OutputRoot = InputRoot;

declare boundary char;
CALL getBoundary(OutputRoot.Properties.ContentType, boundary);

CALL writeWAS_JMS(OutputRoot,boundary);
```

java_lang_StackOverflowError on AIX when processing a message flow that contains Java nodes and uses Java 5

Procedure

- **Scenario:** You get an abend on AIX when processing a message flow that contains Java nodes and uses Java 5. The abend file shows that there was an abend which indicates a segmentation fault, but a check of the `stderr` file shows a stack overflow in the JVM:

```
Exception in thread "Thread-15" java/lang/StackOverflowError: operating system stack overflow
        at com/ibm/broker/plugin/MbOutputTerminal._propagate    (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate    (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate    (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate (MbNode.java:1434)
        at com/ibm/broker/plugin/MbOutputTerminal._propagate   (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate   (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate   (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate   (MbNode.java:1434)
        at com/ibm/broker/plugin/MbOutputTerminal._propagate   (Native Method)
        at com/ibm/broker/plugin/MbOutputTerminal.propagate   (MbOutputTerminal.java:103)
        at com/ibm/xsl/mqsi/XMLTransformNode.evaluate   (XMLTransformNode.java:1002)
        at com/ibm/broker/plugin/MbNode.evaluate (MbNode.java:1434)
```

- **Explanation:**Java 5 has a parameter to adjust the stack size for Java threads. The default operating system stack size for Java 5 is only 256 KB. In certain message flows (for example, flows that contain Java user-defined nodes or XMLT nodes) this size might not be sufficient, and so you see a stack overflow error in the `stderr` file. Use the JVM option `-Xmso` to adjust the operating system stack for Java. You can display information about the stack by using the following command:

```
export MQSIJVERBOSE=-verbose:stack,sizes
```

  This command creates in the `stderr` file on startup an entry that has the folllowing content, or similar:

```
  -Xmca32K        RAM class segment increment
  -Xmco128K       ROM class segment increment
  -Xmns0K         initial new space size
  -Xmnx0K         maximum new space size
  -Xms125000K     initial memory size
  -Xmos125000K    initial old space size
  -Xmox250000K    maximum old space size
  -Xmx250000K     memory maximum
  -Xmr16K         remembered set size
  -Xlp0K          large page size
                  available large page sizes: 4K 16M
  -Xmso256K       OS thread stack size
  -Xiss2K         java thread stack initial size
  -Xssi16K        java thread stack increment
  -Xss256K        java thread stack maximum size
  -Xscmx16M       shared class cache size
```

  Note: The stack size defaults to 256K.

- **Solution:**

  1. Issue the following command to set the operating system stack size for Java to 2 MB:

     ```
     export IBM_JAVA_OPTIONS=-Xmso2m
     ```

2. Restart the broker.

Problems when using code page translation on HP-UX Procedure

- **Scenario:** You experience code page translation problems on HP-UX.
- **Solution:** Check the WebSphere MQ queue manager attribute *CodedCharSetID*. The default value for this attribute is 1051. Change this value to 819 for queue managers that host WebSphere Message Broker components.

Related concepts:

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"MIME messages" on page 1120
A MIME message consists of both data and metadata. MIME metadata consists of HTTP-style headers and MIME boundary delimiters.

"MIME tree details" on page 1123
A MIME message is represented in the broker as a logical tree. When it writes a message, the MIME parser creates a message bit stream by using the logical message tree.

You can define your own nodes to use in WebSphere Message Broker message flows.

Resolving problems when you use the WebSphere Message Broker Toolkit

Use the advice given here to help you to resolve common problems that might occur you use the WebSphere Message Broker Toolkit.

About this task

Resolving problems that occur when connecting:

- "Your broker is not recognized by the WebSphere Message Broker Toolkit" on page 3482
- "You cannot connect to the broker from the WebSphere Message Broker Toolkit or command line" on page 3482

- "You cannot connect to a migrated broker" on page 3483
- "Connection to the broker is slow" on page 3483

Resolving error messages that occur when using the WebSphere Message Broker Toolkit:

- "Errors occur while you are using the WebSphere Message Broker Toolkit" on page 3484
- "An error is issued when you access the help system" on page 3484
- "The WebSphere Message Broker Toolkit displays an error message after the error has been fixed" on page 3485
- "The message `Unable to create part: filename.extension` is issued" on page 3485

Resolving problems relating to the appearance of the workbench:

- "A view is missing from the workbench" on page 3486
- "You cannot close a message dialog box" on page 3486
- "You want to filter entries in the Problems view" on page 3486
- "Your message flow and message set projects have changed their appearance" on page 3486

Resolving non-specific problems when using the workbench:

- "Main menu entries missing on Linux on x86" on page 3487
- "Editors do not update automatically when the same file is open in multiple windows" on page 3487
- "Deleting or closing a project takes a long time" on page 3487
- "You are experiencing poor performance when working with large or complex projects" on page 3488
- "You do not know how to return to the welcome page" on page 3488

Related concepts:

"WebSphere Message Broker Toolkit perspectives" on page 34
A perspective is a group of views and editors that shows various aspects of the resources in the WebSphere Message Broker Toolkit.

"Editors" on page 35
An editor is a component of the WebSphere Message Broker Toolkit. Editors are typically used to edit or browse resources, which are the files, folders, and projects that exist in the workbench.

Related tasks:

"Changing WebSphere Message Broker Toolkit preferences" on page 571
The WebSphere Message Broker Toolkit has a large number of preferences that you can change to suit your requirements. Some of these are specific to the product plug-ins that you have installed within the workbench, including those for WebSphere Message Broker. Others control more general options, such as the colors and fonts in which information is displayed.

"Viewing the Eclipse error log" on page 3532
The Eclipse error log captures internal errors that are caused by the operating system or your code.

The Broker Application Development perspective is the default perspective that is displayed when you start the WebSphere Message Broker Toolkit.

"WebSphere Message Broker logs" on page 6867
WebSphere Message Broker writes information to a number of product-specific logs to report the results of actions that you take.

Resolving problems that occur when connecting the WebSphere Message Broker Toolkit and a broker

Use the advice given here to help you to resolve common problems that can arise when you connect to a broker.

Your broker is not recognized by the WebSphere Message Broker Toolkit: Procedure

- **Scenario:** Your broker is not recognized by the WebSphere Message Broker Toolkit.
- **Explanation:** Broker names in the workbench are case sensitive.
- **Solution:** When you identify a broker in the WebSphere Message Broker Toolkit, make sure that you use the same case that was used when it was created. On some operating systems, the name of the broker might be folded to uppercase when it was created, even though you entered its name in lowercase.

You cannot connect to the broker from the WebSphere Message Broker Toolkit or command line:
Procedure

- **Scenario:** Error messages are issued when you try to connect to the broker from the WebSphere Message Broker Toolkit or the command line.
- **Solution:** The following table shows the checks to carry out when an error message is issued in the WebSphere Message Broker Toolkit, or returned to the command line, when you try to connect to the broker:

Error message		Actions
WebSphere Message Broker Toolkit	**Command line**	
BIP0914E	BIP1046E with WebSphere MQ reason code 2059	Check that the broker queue manager and listener are running, and that the correct port is specified for the queue manager. (The WebSphere MQ documentation describes the WebSphere MQ return codes.)
BIP0889E	BIP1047E	Check that the broker is running. Check the system event log to ensure that the broker is available for use, and correct all errors that are shown.
BIP0915E	BIP1046E with WebSphere MQ reason code 2035	Check that the WebSphere Message Broker Toolkit local user ID is created on the broker system. If it is not, create it. Check if the WebSphere Message Broker Toolkit local user ID that is created on the broker system is authorized to connect to the broker queue manager. • Use the WebSphere MQ **dspmqaut** command to determine what WebSphere MQ authorities the user has. • If necessary, add the WebSphere Message Broker Toolkit local user ID to the mqm group on the broker system.

You cannot connect to a migrated broker:
Procedure

- **Scenario:** You cannot connect from the WebSphere Message Broker Toolkit, the WebSphere Message Broker Toolkit, or a WebSphere Message Broker Toolkit application to a broker that you have migrated to Version 7.0.
- **Explanation:** The connection is failing because the WebSphere MQ channel does not exist. When you migrate a broker to Version 7.0, the default server connection channel SYSTEM.BKR.CONFIG is created if it does not exist. However, if the broker shared a queue manager with a Configuration Manager, this channel is deleted when you delete the Configuration Manager.
- **Solution:** Re-create the server connection channel SYSTEM.BKR.CONFIG on the queue manager.

You cannot connect to a remote broker:
Procedure

- **Scenario:** You have correctly configured your WebSphere Message Broker Toolkit to connect to a remote broker, but attempting to connect to the remote broker by using the WebSphere Message Broker Toolkit results in error MQRC 2059. You can connect to your remote broker from the same computer without error by using the WebSphere Message Broker Explorer, or by completing the following steps:
  1. Set the following environment variable:
     - On Windows: `set MQSERVER=ChannelName/TCP/server-address(port)`
     - On Linux: `export MQSERVER=ChannelName/TCP/'server-address(port)'`
  2. Open a WebSphere Message Broker command prompt, and enter the following test command:

     `amqsputc` *`queueName qmgrName`*
- **Explanation:** The network configuration of your WebSphere Message Broker Toolkit installation is incorrect.
- **Solution:**
  1. In the WebSphere Message Broker Toolkit, click **Window** > **Preferences** > **General** > **Network Connection**. The Preferences window opens, and the Network Connections preferences are displayed.
  2. From the Active Provider list, select **Direct connection to the internet**. This is the default setting. You can now connect to your remote broker by using the WebSphere Message Broker Toolkit.

Connection to the broker is slow:
Procedure

- **Scenario:** Connection to the broker is slow and you cannot complete other actions in the WebSphere Message Broker Toolkit when you request the following operations:
  - Creating a broker
  - Creating an execution group
  - Deploying a broker archive file, using the Deploy a BAR File wizard
  - Opening the Administration log editor
- **Solution:** Click **Cancel** on the progress monitor dialog box to cancel the in-progress connection. Connection to the broker is canceled, so that you can perform other actions in the WebSphere Message Broker Toolkit. You can then resubmit the canceled operation.

Resolving error messages that occur when using the WebSphere Message Broker Toolkit

Use the advice given here to help you to resolve common problems that can occur when you use the WebSphere Message Broker Toolkit.

Errors occur while you are using the WebSphere Message Broker Toolkit: Procedure

- **Scenario:** An error has occurred while you are using the WebSphere Message Broker Toolkit, and you want information to help you to diagnose the problem.
- **Solution:** Some errors that occur in the WebSphere Message Broker Toolkit are logged in the `.log` file in your `workspace\.metadata` directory. You can view this log by switching to the Plug-in Development perspective, and clicking the Error Log tab in the lower-right pane. The log shows in which plug-in the error occurred, and gives further information.

  You can also use trace to try and determine the cause of your problem. See "Using trace" on page 3533 for more information about tracing.

An error is issued when you access the help system:

Procedure

- **Scenario:** You are accessing the help system through the WebSphere Message Broker Toolkit, and an error message is issued stating that the Web page that you requested is not available offline.
- **Explanation:** This error might occur if you previously had a connection to a Web-based version of the help system and lost it, or if you have **Work Offline** selected in your Internet Explorer options.
- **Solution:** Click **Connect** to load the help system.

The WebSphere Message Broker Toolkit displays an error message after the error has been fixed:
Procedure

- **Scenario:** The WebSphere Message Broker Toolkit is in an inconsistent state, or displays an error message after the error has been fixed
- **Solution:** Clean the workspace:
  1. From the WebSphere Message Broker Toolkit, click **Project** > **Clean**.
  2. Click **Clean all projects** and **Finish**.

     This action cleans the whole workspace of any internal files, which are then re-created so that none of your data is lost.

The message Unable to create part: *filename.extension* is issued:
Procedure

- **Scenario:** You open an editor in the WebSphere Message Broker Toolkit, and an error message is raised stating that a file cannot be created. This problem is caused by one of following situations:
- **Explanation 1:** The given file is not associated with a recognized editor.
  - **Solution 1:** Right-click the file and choose the default editor to open it, or choose another editor if the default editor cannot open it.
- **Explanation 2:** The given file contains syntax errors and cannot be loaded into the chosen editor. However, if you then try to open a valid file, you get the same error message repeatedly.
  - **Solution 2:** Restart the WebSphere Message Broker Toolkit; do not load the file into an editor again until you have fixed the syntax errors.

Resolving problems relating to the appearance of the workbench

Use the advice given here to help you to resolve common problems that relate to the appearance of the WebSphere Message Broker Toolkit.

A view is missing from the workbench:
Procedure

- **Scenario:** A view you are expecting to be displayed in the workbench is not visible, or you have closed a view.
- **Explanation:** The perspective has changed since it was first created, and the default views are no longer visible.
- **Solution:** To restore the default views in a perspective you can reset the perspective. Click **Window** > **Reset perspective**.

You cannot close a message dialog box:
Procedure

- **Scenario:** You have opened a menu, and a message dialog box tells you that previous changes made have been processed successfully by the broker. You cannot close the dialog.
- **Solution:** If you cannot close the dialog box by clicking **OK**, press Esc.

You want to filter entries in the Problems view:
Procedure

- **Scenario:** The Problems view has many entries, and it is difficult to find the entry that you want.
- **Solution:** At the top of the Problems View, click the icon with the arrows pointing to the right. This action opens a dialog box, in which you can tailor your selections to display only a subset of the entries in the view. For example, you can select only those entries for the project that you have selected.

Your message flow and message set projects have changed their appearance:

Procedure

- **Scenario:** You have created a new simple project in the WebSphere Message Broker Toolkit and now all your message flow and message set projects look different.
- **Explanation:** When you create a new simple project, the WebSphere Message Broker Toolkit switches automatically to the Broker Application Development perspective.
- **Solution:** To return to the previous view, switch to the perspective with which you were working..

Resolving non-specific problems when using the WebSphere Message Broker Toolkit

Use the advice given here to help you to resolve some common problems that can occur when you use the WebSphere Message Broker Toolkit that are not dealt with in previous categories.

Main menu entries missing on Linux on x86:
Procedure

- **Scenario:** The main menu on Linux on x86 no longer contains items that relate to the WebSphere Message Broker Toolkit.
- **Explanation:** If you have installed the WebSphere Message Broker Toolkit in more than one package group, and have now removed one of those installations, a known restriction causes the main menu items to be removed when the component is uninstalled.
- **Solution:** Invoke the WebSphere Message Broker Toolkit from the command line. Navigate to the installation directory for the package group in which you have installed the WebSphere Message Broker Toolkit, and enter the following command:

  ```
  ./eclipse -product com.ibm.etools.msgbroker.tooling.ide
  ```

Editors do not update automatically when the same file is open in multiple windows:
Procedure

- **Scenario:** You are working in the Broker Application Development perspective, and are using the associated editor to work with one or more resources; for example, you are editing a message flow in the message flow editor or an ESQL module in the ESQL editor. You have clicked **Window** > **New Window** to create a second Eclipse view, and have opened the same resource in the second window. Changes that you make to the resource in the first editor window are not reflected in the second editor window.
- **Explanation:** The WebSphere Message Broker Toolkit editors do not automatically update multiple windows in which you have opened the same resource.
- **Solution:** Save the contents of the resource file in the first editor window, then close and reopen additional windows. The reopened windows reflect the updated content.

Deleting or closing a project takes a long time:
Procedure

- **Scenario:** Deleting or closing a project to save memory takes a long time.

- **Explanation:** If a project is referenced by other projects, removing that project requires all the other projects, and the projects that refer to them recursively, to be built fully. This process occurs to keep the content-assist and validation models current.
- **Solution:** To keep a project open in the workspace requires very little memory, therefore you do not need to close or delete projects.

You are experiencing poor performance when working with large or complex projects:
Procedure

- **Scenario:** You are experiencing poor performance in the WebSphere Message Broker Toolkit when working with large or complex projects.
- **Explanation:** Frequent project changes, such as adding and removing projects, or using **Project** > **Clean**, use large amounts of memory because of the size and number of files and the connections between them.
- **Solution:** Increase your system memory.

You do not know how to return to the welcome page:
Procedure

- **Scenario:** You do not know how to return to the welcome page that was displayed in the WebSphere Message Broker Toolkit when you first started using it.
- **Solution:** To open the welcome page:
  1. From the **Help** menu, select **Welcome**. If only one welcome page is available, it is displayed. If more than one is available, a list is displayed.
  2. Select the welcome page that you want, for example, WebSphere Message Broker WebSphere Message Broker Toolkit.
  3. Click **OK**.

Resolving problems when using the WebSphere Message Broker Explorer

Work through the advice provided to help you to deal with problems that can arise when you are using the WebSphere Message Broker Explorer.

About this task

- "Tracing problems with accounting and statistics"
- "The Brokers folder is missing"
- "You cannot open the information center on Red Hat Enterprise Linux" on page 3490
- "Accounting and statistics do not work for a remote broker" on page 3490
- "SYSTEM.DEF.SVRCONN error" on page 3490

Tracing problems with accounting and statistics

Procedure

- **Scenario:** When you view accounting and statistics data using the WebSphere Message Broker Explorer you encounter a problem, and you want to collect trace.
- **Explanation:** The WebSphere Message Broker Explorer uses the Java Message Service (JMS) to retrieve the accounting and statistics data from the broker. To trace problems with this connection, you must turn on JMS tracing in WebSphere MQ.
- **Solution:** See the WebSphere MQ documentation for information about how to turn on JMS tracing. You can find this information in the following part of the information center: **Using Java** > **Using WebSphere MQ classes for JMS** > **Solving problems** > **Tracing programs**.

The Brokers folder is missing

Procedure

- **Scenario:** You have opened the WebSphere MQ Explorer to work with brokers and broker resources, but you cannot see the Brokers folder.
- **Explanation:** The WebSphere Message Broker Explorer is an extension to the WebSphere MQ Explorer, and provides the Brokers and Broker Archive Files folders, and related actions. You must install the WebSphere Message Broker Explorer component on all computers on which you want to use the WebSphere MQ Explorer to manage WebSphere Message Broker resources, including brokers, execution groups and BAR files.
- **Solution:** Close your MQ Explorer session, follow the instructions to install the WebSphere Message Broker Explorer, then start the MQ Explorer again.

You cannot open the information center on Red Hat Enterprise Linux

Procedure

- **Scenario:** You are using the WebSphere Message Broker Explorer on Red Hat Enterprise Linux Server 5.2 or Red Hat Enterprise Linux Server 5.3 but you cannot open the information center from inside WebSphere Message Broker Explorer.
- **Solution:** Set the environment variable MOZILLA_FIVE_PATH then run the **strmqcfg** command. For more information, see the question about running the SWT browser inside Eclipse at: Eclipse SWT FAQ

Accounting and statistics do not work for a remote broker

Procedure

- **Scenario:** You try to view broker statistics, but instead see a message box:

  ```
  Could not connect to broker brokerName.
  Is MQ configured for JMS?
  ```

- **Explanation:** Java Message Service (JMS) has not been correctly configured. Either JMS has not been enabled for the queue manager, or you do not have access to the channel that the broker uses for JMS activity. Check the log for more details. Note: In WebSphere MQ Version 7.0, 7.0.1, 7.1 and 7.5 onwards JMS is automatically configured, so the problem could be due to the security settings on the publish/subscribe queues. Verify that WebSphere Message Broker Explorer can communicate with the queue manager's publish/subscribe queues. For more information on WebSphere MQ publish/subscribe security, see IBM Education Assistant module: WebSphere MQ V7 Publish/subscribe security.
- **Solution:** If the log shows that JMS has not been correctly set up, take the following steps:

  1. In a WebSphere Message Broker command console, change to the *MBExplorerInstallLocation*\eclipse\plugins\com.ibm.etools.wmadmin.broker.stats_*releaseNumber* directory.
  2. Run the following command:

     ```
     runmqsc queuemanager < setup_jms.mqsc
     ```

  If the log shows that you do not have permission to access the channel:

  1. Check which channel is being used by viewing the Statistics panel for the broker in WebSphere Message Broker Explorer. The channel is normally SYSTEM.DEF.SVRCONN.
  2. In a WebSphere Message Broker command console, issue the following command to allow any user on your broker machine, who is a member of the mqm and mqbrkrs groups, to run with the permissions of the broker user:

  ```
  alter chl (SYSTEM.DEF.SVRCONN) CHLTYPE(SVRCONN) MCAUSER(brokerUser)
  ```

  Note: Setting SYSTEM.DEF.SVRCONN MCAUSER(*brokerUser*) when the broker user is a member of the mqm group requires security protocols, such as Transport Layer Security (TLS), Secure Sockets Layer (SSL), channel authentication security, or a security exit, to be set up. For more information on security, see "Security overview" on page 351.

SYSTEM.DEF.SVRCONN error:

Procedure

- **Scenario:** When you try to connect to a broker to view accounting and statistical information, an error message reports that WebSphere Message Broker Explorer cannot connect to SYSTEM.DEF.SVRCONN.

- **Explanation:** This error might indicate that the SHARECNV parameter on the SVRCONN channel of the queue manager is not compatible with the current WebSphere MQ level of JMS.
- **Solution:**
  1. For more information about the error, turn on service trace; see "Changing trace settings from the WebSphere Message Broker Explorer" on page 3549.
  2. In WebSphere MQ Explorer, set **Sharing Conversations** (SHARECNV) to at least 1.

Related concepts:

Resolving problems when using databases

Use the advice given here to help you to resolve problems that can arise when using databases.

Before you begin

Before you start:

- Read "Is there a problem with a database?" on page 3356

Procedure

DB2 error message SQL0443N is issued

Procedure

- **Scenario:** After you upgrade your DB2 server to a new fix pack level, a DB2 error message SQL0443N is issued if you invoke a DB2 Call Level Interface (CLI) catalog function, such as SQLTables(), SQLColumns(), or SQLStatistics(). An example of the error message is:

  ```
  SQL0443N Routine "SYSIBM.SQLTABLES" (specific name "TABLES") has returned
  an error SQLSTATE with diagnostic text SYSIBM:CLI:-805". SQLSTATE=38553.
  ```

- **Solution:** Bind the `db2schema.bnd` file against each database by entering the following commands at a command prompt:

  ```
  db2 terminate
  db2 connect to database-name
  db2 bind path\db2schema.bnd blocking all grant public sqlerror continue
  db2 terminate
  ```

  where *database-name* is the name of the database to which the utilities must be bound, and *path* is the full path name of the directory where the bind files are located. For example, the default location on Windows is `C:\Program Files\IBM\SQLLIB\bnd\`(on Windows 32-bit editions) or `C:\Program Files(x86)\IBM\SQLLIB\bnd\` (on Windows 64-bit editions).

  To list all the names of databases for a particular DB2 instance, run the DB2 CLI command **`db2 list database directory`**. For further information, see the DB2 documentation.

DB2 error message SQL0805N is issued

Procedure

- **Scenario:** When a message flow that includes a Database node runs, SQL error `SQL0805N NULLID.SQLLF000` is issued.
- **Solution:** Open a DB2 Command Line Processor window and issue a bind command to the database.

  Linux UNIX On Linux and UNIX systems, enter the commands:

```
connect to db
bind ~/sqllib/bnd/@db2cli.lst grant public CLIPKG 5
connect reset
```

where *db* is the database name.

Windows On Windows systems, enter the commands:

```
connect to db
bind x:\sqllib\bnd\@db2cli.lst blocking all grant public
connect reset
```

where *x:* identifies the drive onto which you installed DB2, and *db* is the database name.

DB2 error message SQL0998N is issued on Linux

Procedure

- **Scenario:** You are trying to use a globally coordinated message flow with DB2 on Linux and error message SQL0998N is issued with Reason Code 09 and Subcode " ".
- **Solution:** Check that the `LD_ASSUME_KERNEL` environment variable is not set. If it is set, use the **`unset`** command to remove it from your environment and ensure that you modify your profile scripts so that it remains unset.

DB2 error message SQL0998N or SQL1248N is issued

Procedure

- **Scenario:** When you try to use a globally coordinated message flow with a DB2 database, you get one of the following error messages:
  - SQL0998N with Reason Code 09 and Subcode ""
  - SQL1248N with a message indicating that the database is not defined with the transaction manager
- **Solution:** Use the instructions in “Configuring global coordination with DB2” on page 700 to configure the database and XAResourceManager stanza.

DB2 error message SQL1040N is issued

Procedure

- **Scenario:** You are using a DB2 database, and error message BIP2322 is issued with error SQL1040N.
- **Explanation:** The following DB2 message indicates that the value of the DB2 database configuration parameter **`maxappls`** has been reached:

```
"SQL1040N The maximum number of applications is already connected to the database.
SQLSTATE=57030"
```

  DB2 has rejected the attempt to connect.
- **Solution:**
  1. Stop all brokers that connect to the affected database.
  2. Increase the value of the **`maxappls`** configuration parameter. Also, check the value of the associated parameter **`maxagents`**, and increase it in line with **`maxappls`**.
  3. Restart the DB2 database.
  4. Restart the brokers.

DB2 error message SQL1224N is issued when you connect to DB2

Procedure

- **Scenario:** DB2 error message SQL1224N is issued when you connect to a DB2 database. This error indicates that a database agent could not be started, or was ended because of a database shutdown or force command.
- **Solution:** On AIX, use TCP/IP to connect to DB2 databases, to avoid the shared memory limit of 10 connections. To set up AIX and DB2 loop-back to use a TCP/IP connection:
  1. Configure DB2 to use TCP/IP, and to start the TCP/IP listener. On the database server machine, log in as the DB2 instance owner, typically `db2inst1`, and issue the following commands:
     ```
     db2set DB2COMM=tcpip
     db2stop
     db2start
     ```
  2. If the DB2 connection port is not defined in `/etc/services`, edit the services file to add the DB2 connection and interrupt ports. You must use unique names, and port numbers that are not already defined in the services file; for example:
     ```
     db2svc1     3700/tcp          # DB2 Connection Service
     db2isvc1    3701/tcp          # DB2 Interrupt Service
     ```
  3. Update the DB2 configuration; for example:
     ```
     db2 update dbm cfg using svcename db2svc1
     ```

     where *db2svc1* is the name of the DB2 Connection port service in `/etc/services`.

     Alternatively, you can specify a port number directly.
  4. Stop and restart the database by using the following commands:
     ```
     db2stop
     db2start
     ```
  5. Catalog a new TCP/IP connection node:
     ```
     db2 catalog tcpip node NODENAME remote HOSTNAME server db2svc1
     ```

     where:

     NODENAME
     : is the name of the new TCP/IP connection node. You can use `local` as your node name, if it is a unique identifier.

     HOSTNAME
     : is the name of your computer.

     db2svc1
     : is the name of the DB2 connection port service in `/etc/services`.

     Message DB20000I is displayed when the command completes successfully.
  6. Catalog the database with a new alias name; for example:
     ```
     db2 catalog database DATABASE as DBALIAS at node NODENAME
     ```

     where:

     DATABASE
     : is the physical name of the database.

     DBALIAS
     : is the database alias name that you want to use.

Specify the new alias name in all subsequent references to the local database.

7. Stop and start DB2:

```
db2 terminate
db2stop
db2start
```

8. Log on with the user ID under which the broker is running.
9. Update the ODBC configuration file for each broker to add definitions for the database:
   a. At the top of the file, add a definition for the database alias name:

```
DBALIAS=IBM DB2 ODBC Driver
```

   b. Add a new stanza for the database alias:

```
 [DBALIAS]
Driver=INSTHOME/sqllib/lib/libdb2.a
Description=Database Alias
Database=DBALIAS
```

   where *INSTHOME* is the path to your DB2 Instance directory.
10. Update your message flows to specify the alias database name, redeploy the BAR file to the broker, and test the flows.

DB2 or ODBC error messages are issued on z/OS

Procedure

- **Scenario:** DB2 or ODBC messages are issued on z/OS indicating one or more of the following errors:
  - An exception was caught while issuing the database SQL connect command.
  - A database error occurred with an ODBC return code of -1, an SQL state of 58004 and a native error code of -99999.
- **Solution:** If an ODBC message is displayed:
  1. Turn ODBC application tracing on to produce the `traceodbc` file.
  2. Locate the `traceodbc` file, which is written to the `/output` subdirectory. For example, the full path might be `/u/argo/VCP0BRK/output/traceodbc`.
  3. Go to the bottom of this file and search for previous instances of SQLerror.

  Common DB2 problems include:
  - ODBC return code -1, SQL state 58004, Native error code -99999

    These codes might be returned for the following reasons:
    - No SQL code. The DB2 subsystem is not started
    - RRS is not started.
  - SQLCODE 922.

    The user ID of the started task is not authorized to use plan DSNACLI.
  - ODBC return code -1, SLQ state 42503, Native error code -553

    These codes might be returned if the user ID of the started task is not authorized to use the current SQL ID. Reconfigure the broker and specify `DB2_TABLE_NAME` as a valid name, or create a RACF group, and connect the started task user ID to this group.

You do not know how many database connections a broker requires

Procedure

- **Scenario:** You do not know how many database connections to set up for your broker.

- **Solution:** Determine the number of database connections required by a broker for capacity and resource planning. On DB2, the default action taken is to limit the number of concurrent connections to a database to the value of the **maxappls** configuration parameter; the default value for **maxappls** is 40. The associated parameter **maxagents** also affects the current connections.

  The connection requirements for a single broker are:

  – Five are required by internal broker threads.
  – One is required for each message flow thread that parses MRM messages.
  – One is required for each database access node to separate ODBC data source names for each message flow thread (that is, if the same DSN is used by a different node, the same connection is used).

You want to use XA with DB2 databases

Procedure

- **Scenario:** You want to use XA with one or more DB2 databases.
- **Solution:** Ensure that your queue manager is configured to use **ThreadOfControl=THREAD**.

  – Linux UNIX On Linux and UNIX systems, configure this parameter in the XAResourceManager stanza in the file `qm.ini` for the broker queue manager.

  – Windows On Windows systems, configure this parameter in WebSphere MQ Explorer.

XA coordination fails if the database restarts while the broker is running

Procedure

- **Scenario:** XA global coordination fails, and you get an error like the following example, which is from a DB2 user database:

  ```
  Database error: SQL State '40003'; Native Error Code '-900';  Error Text '[IBM]
  [CLI Driver] SQL0900N  The application state  is in error. A database connection
  does not exist.SQLSTATE=08003'.
  ```

- **Explanation:** A globally coordinated message flow cannot automatically reconnect to a user database if the user database is restarted while the broker is still running.
- **Solution:** Stop and restart the broker if the user database goes down, or is brought down for a scheduled maintenance.

Error message BIP2322 is issued when you access DB2 on z/OS

Procedure

- **Scenario:** You are running a message flow in which a node attempts to access a table on a DB2 data-sharing group. If ODBC tracing is turned on, an error message is written to the `traceodbc` file:

```
SQLError( hEnv=0, hDbc=0, hStmt=1, pszSqlState=&302f8ecc, pfNativeError=&302f8ec8,
pszErrorMsg=&28f6a6d0, cbErrorMsgMax=1024, pcbErrorMsg=&302f8eb4 )
SQLError( pszSqlState="51002", pfNativeError=-805, pszErrorMsg="{DB2 for OS/390}
{ODBC Driver}{DSN06011}
 DSNT408I SQLCODE = -805, ERROR:  DBRM OR PACKAGE NAME DSN610GH..DSNCLICS.16877-
          BE5086005F4 NOT FOUND IN PLAN DSNACLI. REASON 02
 DSNT418I SQLSTATE   = 51002 SQLSTATE RETURN CODE
 DSNT415I SQLERRP    = DSNXEPM SQL PROCEDURE DETECTING ERROR
 DSNT416I SQLERRD    = -350  0  0  -1  0  0 SQL DIAGNOSTIC INFORMATION
 DSNT416I SQLERRD    = X'FFFFFEA2'  X'00000000'  X'00000000'  X'FFFFFFFF'
          X'00000000'  X'00000000' SQL DIAGNOSTIC INFORMATION
```

This error is accompanied by the following BIP2322 error message in the syslog:

```
BIP2322E: DATABASE ERROR: SQL STATE '51002'; NATIVE ERROR CODE '-805'
```

- **Explanation:** This error occurs when the DSNACLI plan has not been bound in the correct way.
- **Solution:** Ensure that the DSNACLI plan is bound correctly. See "Binding a DB2 plan to use data-sharing groups on z/OS" on page 3990 for information about how to complete this task.

Error message BIP2322 IM004 is issued when you connect to an Informix database

Procedure

- **Scenario:** You are using the **mqsicvp** command to connect to an Informix database, and you see the following error message.

  ```
  BIP2322E: Database error: SQL State 'IM004'; Native Error Code '0'; Error Text '[DataDirect][ODB
  failed'.
  ```

- **Explanation:** This error can be caused when the environment for the database has not been initialized.
- **Solution:** Check the documentation for the client on your broker system for details of the actions that you must take. For example, you might have to specify the following environment variables:

  ```
  export INFORMIXDIR=/installation_directory_of_informix_client_software
  export PATH=${INFORMIXDIR}/bin:${PATH}
  export INFORMIXSERVER=server_name
  export INFORMIXSQLHOSTS=${INFORMIXDIR}/etc/sqlhosts
  export TERMCAP=${INFORMIXDIR}/etc/termcap
  export TERM=vt100
  export LIBPATH=${INFORMIXDIR}/lib:${INFORMIXDIR}/lib/esql:
                 ${INFORMIXDIR}/lib/cli:$LIBPATH
  ```

  where *server_name* is defined in the file `sqlhosts` (the required value is typically the machine name), and the location of the file `sqlhosts` is set up as part of the installation process.

  To configure your system to run this setup at the start of every session, add these statements to the login profile of the user that is going to run the broker.

  For more information, see "Command environment: Linux and UNIX systems" on page 310.

On Oracle, a database operation fails to return any rows, even though the rows exist

Procedure

- **Scenario:** You are using Oracle databases in your message flows, and ESQL binds against columns that are declared as data type CHAR, and those parameter markers are referenced in a WHERE clause. The database operation fails to return any rows, even though the rows exist.
- **Explanation:** Fixed-length character strings must be padded with blank characters on Oracle for this type of comparison to succeed.
- **Solution:** Define the CHAR columns as VARCHAR2 columns, or pad the ESQL variable with blank characters to the required column length, so that the comparison locates the required rows from the table.

Broker commands fail when the Oracle 10g Release 2 client runs on Linux on POWER with Red Hat Enterprise Linux Advanced Server V4.0

Procedure

- **Scenario:** Broker commands fail in an environment where an Oracle 10g Release 2 client runs on Linux on POWER with Red Hat Enterprise Linux Advanced Server V4.0. Abend files might be created, with contents like the following data:

  ```
  /opt/mqsi/lib/libCommonServices.so(.ImbAbendSignalHandler+0x10)[0x800017d3c0]
  [0x80022b33f0]
  /lib64/tls/libpthread.so.0[0x80cc2339d8]
  /lib64/tls/libpthread.so.0[0x80cc230e4c]
  /lib64/tls/libpthread.so.0[0x80cc22af54]
  bipservice[0x10005e38]
  /lib64/tls/libpthread.so.0[0x80cc22a1d8]
  /lib64/tls/libc.so.6[0x80cc0dd3e4]
  ```

  or

  ```
  /opt/mqsi/lib/libImbCmdLib.so(._ZN15ImbCreateTables15createAllTablesEv+0x38)
  [0x800014c9bc]mqsicreatebroker[0x10023324]mqsicreatebroker[0x1002c0c4]
  /opt/mqsi/lib/libImbCmdLib.so(._ZN10ImbCmdBase20processCommandStringEv+0x6c)
  [0x80001dcad4]mqsicreatebroker[0x1000d728]/lib64/tls/libc.so.6[0x80cc02423c]
  /lib64/tls/libc.so.6[0x80cc0243c4]
  ```

- **Explanation:** The Oracle installation library contains copies of `libgcc` library files. The Oracle user profile adds the directory containing these files to the environment variable LD_LIBRARY_PATH. This action causes the `libgcc` library files to be found before the system libraries, and leads to the failure of broker commands and the production of abend files.
- **Solution:** Ensure that you add `/lib64` to the environment variable LD_LIBRARY_PATH before the Oracle library path. Before you run **mqsiprofile**, include a string like:

  ```
  /lib64::/usr/lib:/oracle/app/oracle/product/10.2.0/db_1/lib
  ```

  which shows `/lib64` preceding the Oracle library directory.

Error message BIP2322 `Driver not capable` is issued when you use an Informix database

Procedure

- **Scenario:** When you try to access an Informix database from a node in a message flow, the following error message is issued:

  ```
  BIP2322E: Database error: SQL State 'HYC00'; Native Error Code '-11092';
  Error Text '[Informix][Informix ODBC Driver]Driver not capable.'.
  ```

- **Explanation:** The broker uses transaction statements, therefore the database must be created, and configured to enable logging.
- **Solution:** Consult your database administrator to ensure that transaction logging has been enabled on the Informix database that the broker is trying to access. For example, create the database with a buffered log:

  ```
  create database with [buffered] log;
  ```

Database updates are not committed as expected

Procedure

- **Scenario:** You have included a Database node, Compute node, or Filter node in a message flow, and you have set the **Transaction** property to Commit. The message flow has raised an exception and has rolled back, but the database updates have not been committed.

- **Explanation:** When you set **Transaction** to Commit, the database updates performed by the node are committed when the node completes successfully. If an exception is raised before the node has completed, and causes the message flow to be rolled back, the commit is not issued and the database updates are also rolled back. The conditions under which this situation can occur are:
  - The node itself causes an exception to be raised. The commit is never performed.
  - The ESQL contains a PROPAGATE statement. This statement does not complete until all processing along the path taken by the propagated message has completed, and control returns to the node. Only then can the commit be performed. If an exception is raised along this path, control is not returned and the database updates are rolled back as part of the message flow.
- **Solution:** Review the operation of the node that performs the database updates. For example, you might be able to split the work between two nodes, with the first updating the database, and the second propagating the output message. Consider changing the ESQL code to process the message in a different way.

You want to list the database connections that the broker holds

Procedure

- **Scenario:** You want to list the database connections that the broker holds.
- **Solution:** The broker does not have any functionality to list the connections that it has to a database. Use the facilities that your database supplies to list connections. Refer to the documentation for your database to find out how to perform this task.

The queue manager finds the XA resource manager is unavailable when configured for XA with DB2 on Windows

Procedure

- **Scenario:** You have configured a queue manager for XA coordination with DB2 on your Windows computer. When you restart the queue manager, it reports error AMQ7604 in the queue manager error log. All subsequent attempts at XA coordination between WebSphere MQ and DB2 fail.

  The error message has the following content, or similar:

  ```
  23/09/2008 15:43:54 - Process(5508.1) User(MUSR_MQADMIN) Program(amqzxma0.exe)
  AMQ7604: The XA resource manager 'DB2 MQBankDB database' was not available
  when called for xa_open.
  The queue manager is continuing without this resource manager.
  ```
- **Explanation:** The user ID that runs the WebSphere MQ Services process `amqmsrvn.exe`, which has a default value of MUSR_MQADMIN, is running with an access token that does not contain group membership information for the group DB2USERS.
- **Solution:** Check that the WebSphere MQ Services user ID is a member of the group DB2USERS, stop the WebSphere MQ service (for example, by issuing the command **net stop "IBM MQSeries"**), and all other processes that are running under the same user ID, and then restart these processes. You can restart your computer to stop and restart these processes after you have checked the user ID status, but this action is typically not required.

Error messages are received when you are trying to remove a DB2 database on Windows when you are using a sample

Procedure

- **Scenario:** You are running a sample, and you are trying to remove a DB2 database on your Windows computer, and you receive a BIP9835E error message with the error code SQLSTATE=57019.

The error message has content like the following data:

```
BIP9830I: Deleting the DB2 Database <Your database name>.
BIP9835E: The DB2 batch command failed with the error code SQLSTATE=57019.
The database <Your database name> could not be created/deleted.
The error code SQLSTATE=57019 was returned from the DB2 batch command.
```

- **Explanation:** If you use the DB2 Control Center to perform a query, a connection is opened against the database. This connection stays open until the DB2 Control Center is closed, at which point the connection is ended.
- **Solution:** Close the DB2 Control Center application, and try to run the sample again.

DB2 error message SQL7008N is issued

Procedure

- **Scenario:** You are using DB2 and encounter error SQL7008N when updating or inserting into tables on iSeries.
- **Explanation:** SQL7008N is a common error when the tables being accessed on an iSeries server are not being journaled.
- **Solution:** To correct the error, take one of the following steps:
  - Journal your tables.
  - Change the isolation level to `No Commit`. You can change the isolation level of the database alias referenced by your ODBC data source to `No Commit` by using the following DB2 command:

    ```
    db2 update cli cfg for section <db_alias> using TxnIsolation 32
    ```

SQLCODE -981 is issued when you access DB2 on z/OS

Procedure

- **Scenario:** You are running a message flow that uses ODBC database interaction. When a commit or rollback is attempted, DB2 reports an error with SQLCODE=-981 and SQLSTATE=57015. An error message is seen similar to: {DB2 FOR OS/390}{ODBC DRIVER}{DSN09015} DSNT408I SQLCODE = -981, ERROR: THE SQL STATEMENT FAILED BECAUSE THE RRSAF CONNECTION IS NOT IN A STATE THAT ALLOWS SQL OPERATIONS, REASON 00C12219
- **Explanation:** You can choose for ODBC database operations to be committed or rolled back irrespective of the success or failure of the message flow transaction as a whole. This error can be seen if you attempt to use more than one uncoordinated ODBC database connection on a single message flow thread.
- **Solution:** Only one uncoordinated ODBC database connection per thread is supported. Update your message flow to perform ODBC database operations outside of the message flow transaction on only one database. Any number of different databases are supported as part of a coordinated message flow transaction.

Related concepts:

"ESQL procedures" on page 2386
An ESQL procedure is a subroutine that has no return value. It can accept input parameters from, and return output parameters to, the caller.

Related tasks:

"Database security" on page 495
You can access databases from the message flows that you deploy to your brokers, and must therefore consider the steps you might want to take to secure that access.

"Is there a problem with a database?" on page 3356
If you have database problems, complete a set of initial checks to identify errors.

"ODBC trace" on page 3551
You can use various methods to trace for ODBC activity, depending on the operating system that you are using.

"Invoking stored procedures" on page 2503
To invoke a procedure that is stored in a database, use the ESQL CALL statement. The stored procedure must be defined by a CREATE PROCEDURE statement that has a Language clause of DATABASE and an EXTERNAL NAME clause that identifies the name of the procedure in the database and, optionally, the database schema to which it belongs.

Related reference:

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"Database facilities" on page 6891
The database products used by WebSphere Message Broker also record information that might be useful if you have any problems with their access.

Resolving problems when using publish/subscribe

Use the advice given here to help you to resolve common problems that can occur when you run publish/subscribe applications.

About this task

Procedure

- "Application responses are not received"
- "Your application is not receiving publications" on page 3502
- "Publishing a message causes a filter error" on page 3502
- "Symbols in subscription filters cause problems" on page 3503
- "The Publication node fails with MQRC 2035" on page 3503
- "There are performance problems on AIX when the JIT compiler is not loaded" on page 3503

Application responses are not received

Procedure

- **Scenario:** Application responses are not received.
- **Explanation:** Depending on the application code, a publisher or subscriber might request confirmation that its message was processed successfully. Responses can make debugging client problems much easier, because a response code is given if a problem occurs.

  Typically, a response is always returned to a subscriber. However, for the publishing side, a message might be published without the knowledge of the originating application (for example, by using the default topic property on the input node, or by using a Compute node to modify this property in a message flow). The results of processing that message are still logged in user trace, which might give clues as to what is happening.

  If a response is not received, it is typically due to one of the following causes:

- The system is busy. Messages might build up on the input queue, and the client might not be waiting long enough for its response.
- WebSphere MQ expiry is being used. There are cases where this option is what is required, but the expiry of the input message is copied to the response. As a result, the message might expire on the input queue, or it might expire on the way back to the client. This situation is not an error, even with a persistent message.
- The input message or response might have been put to the dead-letter queue, if one is configured. Look on this queue to see if any new messages are there. This situation is typically accompanied by error messages in the log written by the broker that describe the problem. For example, the reply-to queue might have been specified incorrectly in the input message, therefore the reply message has been put to the dead-letter queue.

- **Solution:** If your application is not asking for responses (that is, not using messages of type MQMT_REQUEST) consider doing so, particularly when developing applications.

Your application is not receiving publications

Procedure

- **Scenario:** Your application is not receiving publications.
- **Explanation:** If an application has subscribed successfully (that is, has received an OK response to a RegSub message), it receives publications that match its subscription.

  Subscribers are sent messages only if they match the topic, the subscription point, *and* the filter. Because the subscription point is specified in the message flow, not in the publication message, an incorrect message flow setting can cause unexpected failures.

  A user trace of the flow that contains the Publication node shows you whether publications are matching anything.
- **Solution:** If a filter is being used, a user trace shows you whether this message is being evaluated as expected.

  The case with multiple execution groups, or multiple brokers, is more complex. A response is sent to a subscriber after the message has been processed by the target execution group. Other execution groups (and brokers) are updated asynchronously. As a result, there might be a delay before publications made elsewhere are received. If the broker is busy, there can be a delay before messages are processed fully. In a multi-broker setup, if communications have been suspended, subscription changes are propagated through the network of brokers. Check the channels.

  With multiple execution groups or brokers, it might be possible to fill intermediate WebSphere MQ queues if the load is high. This situation might be reported in the syslog (if a broker cannot put to a queue because it is full) or in the WebSphere MQ log (if a message coming across a channel cannot be put to the target queue because it is full). If you see messages of this type, display the queue depths on all your queue managers to see if any are almost full.

Publishing a message causes a filter error

Procedure

- **Scenario:** When you publish a message, you receive an error response message with reason text MQRCCF_FILTER_ERROR.
- **Explanation:** A broker returns this message to a publication when subscriptions have been registered that specify filter expressions (for Content Based Routing) and an error has been encountered when the broker attempts to filter the

published message. This situation can occur, for example, if a message is published that includes unsupported data types, or if the message body is corrupted.

Symbols in subscription filters cause problems

Procedure

- **Scenario:** If you specify certain symbols when you use filters in a subscription, the filter does not work. Sometimes your subscription messages are put to the dead-letter queue, and a number of error messages are written to the local error log indicating MQRFH2 parsing errors.
- **Explanation:** The MQRFH2 header employs standard XML encoding, so that its parser interprets some symbols in a special way.
- **Solution:** If you want to include these symbols in your filters, use the appropriate escape character to ensure that they are parsed correctly:

Symbol	Escape character
<	&lt;
>	&gt;
"	&quot;
'	&apos;
&	&amp;

For example, if you want to use:

```
<Filter>Body.e_ALERT_BODY.eqnum<6</Filter>
```

specify:

```
<Filter>Body.e_ALERT_BODY.eqnum&amp;lt;6</Filter>
```

The Publication node fails with MQRC 2035

Procedure

- **Scenario:** The Publication node fails with MQRC 2035.
- **Explanation:** WebSphere Message Broker publishes messages with the user ID in the original message, not the broker service ID.
- **Solution:** You can force WebSphere Message Broker to use the broker service ID in all circumstances by setting the environment variable *MQSI_PUBSUB_USE_BROKER_USERID* to any value. If there is no MQMD header, or if there is an MQMD header but its `UserIdentifier` field is blank, WebSphere Message Broker continues to use the broker's user ID.

There are performance problems on AIX when the JIT compiler is not loaded

Procedure

- **Scenario:** There are performance problems on AIX when the JIT compiler is not loaded.
- **Explanation:** The environment variable LIBPATH can affect the loading of the Java JIT (just-in-time) compiler on AIX. WebSphere Message Broker for AIX runs correctly without the JIT compiler, but publish/subscribe performance is adversely affected.
- **Solution:** Ensure that the JIT compiler runs.

  The JIT compiler loads and runs correctly if LIBPATH is not set, therefore do not set LIBPATH. You can make libraries available by linking them into `/var/wmqi/lib` (for all WebSphere Message Broker for AIX processes) or

`/usr/lib` (for all processes on the system). AIX WebSphere Message Broker for AIX configuration does this action for DB2 libraries.

If it is necessary to set LIBPATH, update it to include the directory `/usr/java130/bin`. For example, you can use the following command to start the broker:

```
LIBPATH=/usr/local/lib:/usr/java130/bin mqsistart mybroker
```

Related concepts:

"Publish/Subscribe" on page 2215
Publish/subscribe is a style of messaging application in which the providers of information (publishers) are decoupled from the consumers of that information (subscribers).

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

"Routing using publish/subscribe applications" on page 2215
You can route your messages to applications using the publish/subscribe method of messaging.

Related tasks:

"Viewing Administration log information" on page 1007
You can view Administration log information by using either the WebSphere Message Broker Explorer, or the CMP API.

Use the reference information in this section to help you develop publish/subscribe applications.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"WebSphere MQ logs" on page 6869
WebSphere MQ messages are written to the local error log in the same way as WebSphere Message Broker messages.

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Resolving problems with performance

Use the advice given here to help you to resolve common problems with performance.

About this task

- **Scenario:** You are experiencing problems with performance, such as:
  - Poor response times in the WebSphere Message Broker Toolkit when developing message flows
  - Poor response time at deployment
  - Individual messages taking a long time to process
  - Poor overall performance, or performance that does not scale well
- **Solution:** Possible solutions are:
  - Tune the broker
  - Speed up WebSphere MQ persistent messaging by optimizing the I/O (input/output)
  - Speed up database access by optimizing I/O
  - Increase system memory
  - Use additional instances or multiple execution groups
  - Optimize ESQL statements for best performance

A good source of information about performance is the set of reports in WebSphere MQ Family Category 2 (freeware) SupportPacs, available for download from the WebSphere MQ SupportPacs web page.

For more information, read "Do you have a component that is running slowly?" on page 3360.

This topic contains advice for dealing with some common performance problems that can arise:

The system is continuously running slower

Procedure

- **Scenario:** The system is continuously running slower.
- **Explanation:** When a process ends abnormally, an entry is made in the local error log, and a dump data file might be written to the errors or z/OS log directory. This directory is unbounded, and if you do not clear it of unwanted files, you might find that your system performance degrades due to significant space being used by old abend files.
- **Solution:** Periodically clear the errors or z/OS log directory of unwanted files.

On Windows, use the **-w** parameter of the **mqsicreatebroker** command to create the errors directory in a hard disk drive partition that does not contain WebSphere Message Broker or Windows itself.

You experience configuration problems with many components

Procedure

- **Scenario:** You are experiencing configuration problems with many components.
- **Explanation:** If you are running WebSphere Message Broker with many configured components, the memory footprint of the broker processes (particularly the execution groups or DataFlowEngines) might exceed their memory limits. In particular, the user process limit might be exceeded, or the address space limit might be reached. You might encounter problems, such as the BIP2106E or BIP2137E error messages, when running a broker with:
  - Many message flows
  - Multiple databases
  - Large input or output messages
- **Solution:** Use tools that are specific to your operating system to check the maximum size of the failing process, then check for any user limits (if applicable) or computer limits on process size.
  1. On Windows, the maximum process size is 2 GB. Increasing user limits beyond this value does not make any difference. If your broker processes regularly reach this size, consider spreading your message flows across more execution groups to reduce the size of each one below these limits.
  2. On HP-UX, the number of threads per process is limited by the kernel parameter **max_thread_proc**. The more flows you add to an execution group, the more threads you use for each process. If you need many flows in an execution group, increase the value of the **max_thread_proc** kernel parameter. Try setting the kernel parameter **max_thread_proc** to 256, or to 512 if you are using WebSphere Transformation Extender (WTX).

A WHILE loop in a large XML array takes a long time to process

Procedure

- **Scenario:** A WHILE loop in a large XML array takes a long time to process.
- **Explanation:** This problem arises when you use the CARDINALITY() function to determine the size of the array in the WHILE statement. With large arrays, the cost of determining the number of elements is proportional to the size of the array. The CARDINALITY function is invoked each time the WHILE statement is executed. The message has many elements, therefore takes a long time to process when running the loop in this way.
- **Solution:** Unless you have a message in which the number of elements of the array grows dynamically, determine the size of the array before entering the WHILE loop. Use code like the following example:

```
DECLARE i,c INTEGER;
SET i = 1;
SET c=CARDINALITY(OutputRoot.XMLNS.MyMessage.Array[ ]);
WHILE i <= c DO
      . . .
      . . .  loop processing
      . . .
END WHILE;
```

Remote waitForMessages calls with WebSphere MQ Everyplace are slow

Procedure

- **Scenario:** Remote waitForMessages calls with WebSphere MQ Everyplace are slow.
- **Explanation:** A remote waitForMessages() call necessarily results in a polling action: the client queue manager attempts to get a message repeatedly until one is available on the remote queue or a timeout is reached.
- **Solution:** Define a store-and-forward queue on the broker queue manager and a home-server queue on the client. These queues provide a level of de-coupling that allows the arrangement to work in the event of the client queue manager becoming unavailable. Alternatively, specify a remote queue in the WebSphere MQ Everyplace output node, so that a local GET call is sufficient on the client side.

Performance is reduced for stored procedures

Procedure

- **Scenario:** Stored procedures that do not return results sets do not perform as well as they did when using the DataDirect version 4.1 drivers.
- **Explanation:** The new DataDirect version 5 Oracle drivers now use the configuration parameter **`ProcedureRetResults`** to allow the driver to return results sets from stored procedures. This parameter applies only to Oracle. By default, the parameter is set to 1 and has to be 1 if you use stored procedures that return results sets. When this parameter is set to 0, the driver does not return results sets from stored procedures, which can result in better performance.
- **Solution:** If your stored procedures do not return any results sets, set the **`ProcedureRetResults`** parameter to 0 (zero).

Message flow performance is reduced when you access message trees with many repeating records

Procedure

- **Scenario:** Message flow performance is reduced when the following conditions are true:
  - You are using ESQL processing to manipulate a large message tree.
  - The message tree consists of repeating records or many fields.
  - You have used explicit SET statements with field reference paths to access or create the fields.
  - You have observed a gradual slowing of message flow processing as the ESQL processes more fields or repetitions.
- **Explanation:** This problem occurs when you use field references, rather than reference variables, to access or create consecutive fields or records.

  Consider the following example, in which independent SET statements use field reference paths to manipulate the message tree. The SET statement takes a source and target parameter, where either or both parameters are field references:

  ```
  SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field = '1';
  ```

  The problem arises when the SET statement is used to create many more fields, as shown in the following example:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field2 = '2';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field3 = '3';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field4 = '4';
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field5 = '5';
```

In this example, the five fields that are created are all children of ParentA. Before the specified field can be created or modified, the broker must navigate the named message tree to locate the point in the message tree that is to be altered. For example:

- To access field 1, the SET statement navigates to ParentA, then to the first field, therefore involving two navigations.
- To access field 5, the SET statement navigates to ParentA, then traverses each of the previous fields until it reaches field 5, therefore involving six navigations.

Navigating over all the fields that precede the specified field causes the loss in performance.

Now consider a scenario that accesses repeating fields in an input message tree; for example:

```
DECLARE myChar CHAR;
DECLARE thisRecord INT 0;
WHILE thisRecord < 10000 DO
 SET thisRecord = thisRecord + 1;
 SET myChar = InputRoot.MRM.myParent.myRepeatingRecord[thisRecord];
END WHILE;
```

When index notation is used, as the count increases, the processing needs to navigate over all the preceding fields to get the one it wants; that is, it has to count over the previous records to get to the one that is represented by the current indexed reference.

- When accessing InputRoot.MRM.myParent.myRepeatingRecord[1], one navigation takes place to get to the first record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[2], two navigations take place to get to the second record.
- When accessing InputRoot.MRM.myParent.myRepeatingRecord[N], *N* navigations take place to get to the N-th record.

Therefore, the total number of navigations for this WHILE loop is: 1 + 2 + 3 + ... + *N*, which is not linear.

- **Solution:** If you are accessing or creating consecutive fields or records, use reference variables. When you use reference variables, the statement navigates to the main parent, which maintains a pointer to the field in the message tree. The following example shows the ESQL that can be used to reduce the number of navigations when creating new output message tree fields:

```
SET OutputRoot.XMLNS.TestCase.StructureA.ParentA.field1 = '1';
DECLARE outRef REFERENCE TO OutputRoot.XMLNS.TestCase.StructureA.ParentA;
SET outRef.field2 = '2';
SET outRef.field3 = '3';
SET outRef.field4 = '4';
SET outRef.field5 = '5';
```

When referencing repeating input message tree fields, you could use the following ESQL:

```
DECLARE myChar CHAR;
DECLARE inputRef REFERENCE TO InputRoot.MRM.myParent.myRepeatingRecord[1];
WHILE LASTMOVE(inputRef) DO
 SET myChar = inputRef;
 MOVE inputRef NEXTSIBLING NAME 'myRepeatingRecord';
END WHILE;
```

For further information, see "Creating dynamic field references" on page 2431.

You are experiencing poor performance in the WebSphere Message Broker Toolkit when working with large projects

Procedure

- **Scenario:** You are experiencing poor performance in the WebSphere Message Broker Toolkit when working with large or complex projects.
- **Explanation:** Performance is reduced because of frequent project changes, such as adding and removing projects, or using **Project** > **Clean**. Complete project updates use large amounts of memory due to the size, number, and connections between files.
- **Solution:** Increase your system memory.

Performance is reduced when you run Web Services with small message sizes

Procedure

- **Scenario:** You see poor response times and throughput rates when you run Web Services using HTTP, and send smaller messages sizes (typically less than 32 KB). Throughput rates can fluctuate with message size. WebSphere Message Broker running on the AIX platform might be affected.
- **Explanation:** The default configuration of HTTP enables the Nagle algorithm, which seeks to improve the efficiency of Internet Protocol networks by reducing the number of packets sent. It works by buffering small packets together, creating a smaller number of large packets. The HTTPRequest node uses the platform default for the **tcpnodelay** setting of its sockets. You can disable the Nagle algorithm at either the operating system level (system wide) or through WebSphere Message Broker (affecting only the WebSphere Message Broker HTTP sockets).
- **Solution:** Use the following commands to disable the Nagle algorithm:

  HTTP Request node

  ```
  mqsichangeproperties <BrokerName> -e <ExecutionGroupName>
        -o ComIbmSocketConnectionManager -n tcpNoDelay -v true|false
  mqsichangeproperties <BrokerName> -e <ExecutionGroupName>
        -o ComIbmSocketConnectionManager -n tcpNoDelaySSL -v true|false
  ```

  HTTP Listener / Tomcat servlet engine

  ```
  mqsichangeproperties <BrokerName> -b httplistener
        -o HTTPConnector -n tcpNoDelay -v true|false
  mqsichangeproperties <BrokerName> -b httplistener
        -o HTTPSConnector -n tcpNoDelay -v true|false
  ```

  To determine the value set, take the following steps:

  HTTP Request node

  Use the following command:

  ```
  mqsireportproperties <BrokerName> -e <ExecutionGroupName>
        -o ComIbmSocketConnectionManager -r
  ```

  HTTP Listener / Tomcat servlet engine

  Check the WebSphere Message Broker registry.

You are experiencing reduced Java performance, or Java performance degrades after debugging a message flow

Procedure

- **Scenario:** The Java code in the JavaCompute, the Java user-defined node, or the XSLTransform node does not run as quickly as expected, or performance in these nodes degrades after debugging a message flow. This performance degradation might particularly affect the deployment of XML schemas. Other Java based nodes might also experience degraded performance: for example, adapter nodes (SAP, PeopleSoft, JD Edwards, Siebel), SOAP nodes, CORBA nodes, IMS nodes, CICS nodes and JMS nodes.
- **Explanation:** The broker disables the Java JIT (just-in-time) compiler on the Java virtual machine (JVM) that is created when the execution group is started if you are debugging a message flow. A disabled Java JIT compiler provides a greater choice of debugging options, however any optimizations typically performed during JIT compilation are prevented, which might result in degraded performance.
- **Solution:** If you are not debugging a message flow, set the JVM debug port to zero using this command:

  ```
  mqsichangeproperties broker_name -e execution_group_name
  -o ComIbmJVMManager -n jvmDebugPort -v 0
  ```

  For example:

  ```
  mqsichangeproperties TEST -e default
  -o ComIbmJVMManager -n jvmDebugPort -v 0
  ```

Chapter 12, “Performance and monitoring,” on page 3251
You can change various aspects of your broker configuration to tune brokers and message flows, and monitor message flows and publish/subscribe applications.

“Considering performance in the broker environment” on page 586
When you design your broker environment, and the resources associated with the brokers, decisions that you make can affect the performance of your brokers and applications.

“Tuning the broker” on page 3254
You can complete several tasks that enable you to tune different aspects of the broker performance.

Resolving problems when developing Administration API applications

Use the advice given here to help you to resolve problems that can arise when developing Administration API for WebSphere Message Broker (also known as the CMP API) applications.

About this task

- “Your CMP application hangs if the broker is not available”
- “You set a property of an object and query its value, but the value has not changed” on page 3511
- “You cannot connect to a broker when using a `.broker` file” on page 3511

Your CMP application hangs if the broker is not available

Procedure

- **Scenario:** When the broker is unavailable, the CMP application hangs.

- **Explanation:** Communication between the CMP and the broker is asynchronous, therefore the CMP hangs because it is waiting for a message from the broker.
- **Solution:** Configure the maximum amount of time that the CMP waits by using the following method:

  ```
  // Wait for a maximum of 10 seconds
  BrokerProxy.setRetryCharacteristics(10000);
  ```

  The value specified represents the time in milliseconds that the CMP will wait for information before throwing the `BrokerProxyPropertyNotInitializedException` exception.

  If you set this timeout value too low, an exception is thrown, even if the broker is available.

You set a property of an object and query its value, but the value has not changed

Procedure

- **Scenario:** You have set a property of an object, then queried its value; the value has not changed.
- **Explanation:** Methods that change properties of broker objects are not processed immediately. If you call a property change method on a CMP object, the CMP API sends a message that requests the specified change to the broker. The broker processes the request asynchronously, and notifies all AdministeredObjectListeners of the affected object when the change has been attempted.
- **Solution:** Methods that change state typically return to the calling program as soon as the request has been put to the queue manager of the broker, or, following a call to BrokerProxy.beginUpdates(), as soon as the request has been added to the current batch. If the property has still not been updated after the action's response to the request has been returned to the application, consult the response message for more details.

You cannot connect to a broker when using a `.broker` file

Procedure

- **Scenario:** You cannot connect to a broker when you use a `.broker` file.
- **Explanation:** If your CMP applications use the MQPropertyFileBrokerConnectionParameters class, they can connect to a broker by using a connection file that has a `.broker` extension. However, this file can be parsed only if an XML parser is available.
- **Solution:** Ensure that a supported parser is available on the CLASSPATH. A supported parser is shipped with WebSphere Message Broker.

  Alternatively, your application can use the MQBrokerConnectionParameters class instead of the MQPropertyFileBrokerConnectionParameters class. This class connects to a broker by specifying the host name, queue manager name, and queue manager port of the target broker directly. This method does not require an XML parser.

Resolving problems with user-defined extensions

Advice for dealing with some common problems that can arise when you work with user-defined extensions

About this task

Procedure

- "You cannot deploy one of your user-defined nodes, despite having a plug-in LIL in the correct directory."
- "You cannot deploy a flow with one of your user-defined nodes in it."
- "You get problems when nodes try to use the ESQL path interface in the plug-in API"
- "After migration your custom property editor does not work" on page 3513
- "Interpreting problems in user-defined extensions" on page 3513
- "You want to debug classloading" on page 3515
- "An error is issued when you deploy a user-defined extension on z/OS" on page 3516
- "You cannot determine which user-defined extensions have been loaded by the broker on startup" on page 3516
- "You are migrating a C user-defined node and cniDefineNodeClass returns CCI_INV_IMPL_FUNCTION." on page 3517

You cannot deploy one of your user-defined nodes, despite having a plug-in LIL in the correct directory.

Procedure

- **Scenario:** You cannot deploy one of your user-defined nodes, despite having a plug-in LIL in the correct directory.
- **Explanation:** You have `memset()` the data area to zero and have not initialized the CNI_VFT structure with the initialization constant `{CNI_VFT_DEFAULT}`.
- **Solution:** Initialize by copying a predefined initialization structure over the function table area, as follows:

  ```
  static CNI_VFT virtualFunctionTable = {CNI_VFT_DEFAULT};
  ```

  In addition, implement logging from your user-defined node so that you can see if the plug-in API is producing error codes; the broker does not log these to its own log, unless you take a service trace.

You cannot deploy a flow with one of your user-defined nodes in it.

Procedure

- **Scenario:** You cannot deploy a flow with one of your user-defined nodes in it.
- **Explanation:** Your LIL file has failed to load.
- **Solution:** Check system log (syslog or Eventviewer) of broker startup; did you see a BIP2308 message saying a LIL file failed to load? If there are any problems loading a LIL file, a BIP2308 message appears in the system log.

You get problems when nodes try to use the ESQL path interface in the plug-in API

Procedure

- **Scenario:** When you attempt to use the ESQL path interface in the plug-in API, the return value is CCI_PATH_NOT_NAVIGABLE.
- **Explanation:** The plug-in API allows you to specify a path in the form of an ESQL path expression and navigate to that element, returning a handle to it if it exists. It also allows you to create elements along the path to the requested element.

The navigate path utility function (`cniSqlNavigatePath`) executes the SQLPathExpression created with the `cniSqlCreateReadOnlyPathExpression` or `cniSqlCreateModifiablePathExpression` utility functions, as defined by the `sqlPathExpression` argument.

If the path is not navigable, the return code is set to CCI_PATH_NOT_NAVIGABLE. This might be returned when embedding a path expression in another path expression. The input `cciMessage*` functions must not be NULL; however, any of the output `cciMessage*` functions can be NULL. If you embed a path expression that can be NULL inside a path expression that cannot be NULL, CCI_PATH_NOT_NAVIGABLE is returned.

- **Solution:** If the return code is set to CCI_PATH_NOT_NAVIGABLE, ensure that if a correlation name is specified in a path, the respective parameter is not NULL.

After migration your custom property editor does not work

Procedure

- **Scenario:** You have migrated to a new version of WebSphere Message Broker and your custom property editor no longer works.
- **Explanation:** Custom property editors can use Eclipse or RAD APIs. If any of those APIs are changed in a new version of WebSphere Message Broker, your property editor might not work.
- **Solution:** Update your property editor code to comply with the changed API.

Interpreting problems in user-defined extensions

Procedure

- **Scenario:** You want to debug problems in user-defined nodes and parsers.
- **Solution:** Start user trace at debug level. In order to see BIP4142, BIP4144, BIP4145, and BIP4146 messages, this must be done at the execution group level. For example, use the **`mqsichangetrace`** command without the **`-f`** parameter.

  The following debug messages are available to help you to understand the execution of your user-defined nodes and parsers:

  – BIP2233 and BIP2234: a pair of messages that are traced before and after a user-defined extension implementation function is invoked. These messages report the input parameters and returned value. For example:

    BIP2233 `Invoking user-defined extension function [function name] ([function call parameters])`

    BIP2234 `Returned from user-defined extension function [function name] with result: [result of call]`

    Note: In these messages, an *implementation function* can be interpreted as either a C implementation function or a Java implementation method.

  – BIP2308: a message that is logged when the broker fails to load a LIL file.

    BIP2308 `File [name of LIL file] could not be loaded; operating system return code [error code return from operating system]`

  – BIP3904: a message that is traced before invoking the Java `evaluate()` method of a user-defined node. For example:

    BIP3904 `(for Java): Invoking the evaluate() method of node (class=[node class name], name=[label of node in flow])` where *node class name* is the name of the Java user-defined extension class.

  – BIP3905: a message that is traced before invoking the C `cniEvaluate` implementation function (iFpEvaluate member of CNI_VFT) of a user-defined node. For example:

BIP3905 (for C): Invoking the cniEvaluate() implementation function of node (class=[node class name], name=[label of node in flow]) where *node class name* is the name of the user-defined extension class that is provided by the user-defined extension while calling C cniDefineNodeClass.

– BIP4142: a debug message that is traced when invoking a user-defined node utility function, where the utility function alters the state of a syntax element. This includes all utility functions that start with cniSetElement*, where * represents all nodes with that stem. For example:

  BIP4142 Evaluating cniSetElement [element identifier type]. Changing value from [value before user's change] to [value after user's change]"

– BIP4144 and BIP4145: a pair of messages that are traced by certain implementation functions that, when invoked by a user-defined extension, can modify the internal state of a message broker's object. Possible message broker objects include syntax element, node, and parser. These messages report the input parameter provided to the invoked method and the returned value. For example:

  BIP4144 Entered function [function name] ([function call parameters])

  BIP4145 Exiting function [function name] with result: [result to be returned]

  In these messages, an *implementation function* can be interpreted as either a C implementation function or a Java implementation method.

  The C implementation functions that invoke messages BIP4144 and BIP4145 include:

For user-defined parsers	For user-defined nodes
cpiCreateParserFactory	cniCreateElement*
cpiDefineParserClass	cniDeleteMessage
cpiAppendToBuffer	cniAdd*
cpiCreateElement	cniDetach
cpiCreateAndInitializeElement	cniCopyElementTree
cpiAddBefore	cniFinalize
cpiAddAfter	cniWriteBuffer
cpiAddAsFirstChild	cniSql*
cpiAddAsLastChild	cniSetInputBuffer
cpiSetNameFromBuffer	cniDispatchThread

  (* represents all nodes with that stem; for example, cniAdd* includes cniAddAfter, cniAddasFirstChild, cniAddasLastChild, and cniAddBefore.)

  The Java methods that invoke messages BIP4144 and BIP4145 are:

For user-defined nodes
com.ibm.broker.plugin.MbElement.CreateElement*
com.ibm.broker.plugin.MbElement.add*
com.ibm.broker.plugin.MbElement.detach
com.ibm.broker.plugin.MbElement.copyElementTree

– BIP4146: a debug message that is traced when invoking a user-defined parser utility function, where the utility function alters the state of a syntax element.

This includes all utility functions that start with `cpiSetElement*`, where * represents all nodes with that stem. For example:

BIP4146 `Evaluating cpiSetElement [element identifier type]. Changing value from [value before user's change] to [value after user's change]`

For information on the C user-defined API, see the "C language user-defined parser API" on page 6538 and the "C language user-defined node API" on page 6416.

- BIP4147: an error message that is traced when a user-defined extension passes an invalid input object to a user-defined extension utility API function. For Example:

  BIP4147 `User-defined extension input parameter failed debug validation check. Input parameter [parameter name] passed into function [function name] is not a valid object.`

- BIP4148: an error message that is traced when a user-defined extension damages a broker's object. For Example:

  BIP4148 `User-defined extension damaged broker's object. Function [function name] has damaged broker's object passed as parameter [parameter name].`

- BIP4149: an error message that is traced when a user-defined extension passes an invalid input data pointer to a user-defined extension utility API function. For Example:

  BIP4149 `User-defined extension input parameter failed debug validation check. Input parameter [parameter name] passed into function [function name] is a NULL pointer.`

- BIP4150: an error message that is traced when a user-defined extension passes invalid input data to a user-defined extension utility API function. For example:

  BIP4150 `User-defined extension input parameter failed debug validation check. Input parameter [parameter name] passed into function [function name] does not have a valid value.`

- BIP4151: a debug message that is traced when `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to an unexpected value. Expected values are CCI_SUCCESS, CCI_ATTRIBUTE_UNKNOWN, and CCI_BUFFER_TOO_SMALL. Any other value is an unexpected value. For example:

  BIP4151 `An unexpected value was returned from User-defined extension implementation function [function name].`

- BIP4152: a debug message that is traced when `cniGetAttribute2` or `cniGetAttributeName2` sets the return code to CCI_BUFFER_TOO_SMALL, and then `cniGetAttribute2` or `cniGetAttributeName2` is called again, this time with the correct size buffer, however the return code is still set to CCI_BUFFER_TOO_SMALL. For example:

  BIP4152 `User-defined extension Implementation function [function name] returned CCI_BUFFER_TOO_SMALL on 2nd attempt.`

You want to debug classloading

Procedure

- **Scenario:** You want to debug classloading.
- **Solution:** Classes and the location from which they are loaded are written to user trace. Use this information to check that the correct classes are being loaded.

An error is issued when you deploy a user-defined extension on z/OS

Procedure

- **Scenario:** When you deploy a user-defined extension on z/OS, Linux, or UNIX, an error is displayed in the log of each execution group, stating that there is insufficient authority to open the LIL file.
- **Explanation:** On Linux and UNIX, the user-defined extension must have group read permission. On z/OS, the user-defined extension must have group execute permission.
- **Solution:**
  - On Linux and UNIX, set the file permissions of the user-defined extension to group read by issuing the command **chmod a+r**.
  - On z/OS, set the file permissions of the user-defined extension to group read and execute by issuing the command **chmod a+rx**.

You cannot determine which user-defined extensions have been loaded by the broker on startup

Procedure

- **Scenario:** You cannot determine which user-defined extensions have been loaded by the broker on startup.
- **Solution:** Use the **mqsireportproperties** command for each type of user-defined extension.
  - For a Java user-defined extension, issue the command:

```
mqsireportproperties WBRK_BROKER -e default -o ComIbmJavaPluginNodeFactory -r
```

You see a report similar to this example:

```
ComIbmJavaPluginNodeFactory
 uuid='ComIbmJavaPluginNodeFactory'
 userTraceLevel='none'
 traceLevel='none'
 userTraceFilter='none'
 traceFilter='none'
 NodeClassName='ComIbmJMSClientInputNode'
 NodeClassName='ComIbmJMSClientOutputNode'
 NodeClassName='ComIbmJavaComputeNode'
 NodeClassName='ComIbmXslMqsiNode'
 NodeClassName='SearchFilterNode'

BIP8071I: Successful command completion.
```

The user-defined extension called SearchFilter has a NodeClassName of SearchFilterNode.

  - For a C user-defined extension (assuming that CONST_PLUGIN_NODE_FACTORY was set to ComIbmSamplePluginNodeFactory in the `NodeFactory.h` file, as in the sample NumComputeNode), issue the command:

```
mqsireportproperties WBRK_BROKER -e default -o ComIbmSamplePluginNodeFactory -r
```

You see a report similar to this example:

```
ComIbmSamplePluginNodeFactory
 uuid='ComIbmSamplePluginNodeFactory'
 userTraceLevel='none'
 traceLevel='none'
 userTraceFilter='none'
 traceFilter='none'
 NodeClassName='NumComputeNode'

BIP8071I: Successful command completion.
```

The user-defined extension called NumCompute has a NodeClassName of NumComputeNode.

You are migrating a C user-defined node and cniDefineNodeClass returns CCI_INV_IMPL_FUNCTION.

Procedure

- **Scenario:** When you attempt to migrate a C user-defined node, `cniDefineNodeClass` returns CCI_INV_IMPL_FUNCTION.
- **Explanation:** New fields have been added to the CNI_VFT struct. CNI_VFT_DEFAULT has been updated to initialize these new fields in the header file BipCci.h. If you initialize your CNI_VFT with CNI_VFT_DEFAULT, you should not need to make any code changes. However, if you do not initialize CNI_VFT with CNI_VFT_DEFAULT, these new fields are initialized with random values.
- **Solution:** Initialize your CNI_VFT with CNI_VFT_DEFAULT.

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

"User-defined message processing nodes" on page 2996
A user-defined message processing node is a node that you can create to complement the supplied built-in node types.

Related tasks:

Install the compiled runtime files for your user-defined extension on the broker on which you want to test its function.

"Starting user trace" on page 3197
Use user trace for debugging your applications; you can trace brokers, execution groups, and deployed message flows. Start user trace facilities using the **mqsichangetrace** command or the WebSphere Message Broker Explorer.

"Is there a problem with a database?" on page 3356
If you have database problems, complete a set of initial checks to identify errors.

"Has the message flow run successfully before?" on page 3353
Sometimes a problem appears in a message flow that has previously run successfully.

Related reference:

"cciGetLastExceptionData" on page 6647
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_ST output structure. The user-defined extension can use this function to determine whether any recovery is required when a utility function returns an error code.

"Utility function return codes and values" on page 6686
By convention, the return code output parameter of all utility functions is set to indicate successful completion, or an error. The table lists all return codes with their meanings.

Resolving problems when installing

Work through the advice provided to help you to deal with problems that can arise when the product is installed.

About this task

The following list describes typical problems when installing, with a corresponding solution or workaround:

- Broker component:
  - "Dealing with problems during installation"
  - "Installation process is interrupted" on page 3519
  - "java.lang.UnsatisfiedLinkError" on page 3519
  - "RPM query fails" on page 3519
  - "Display problems" on page 3520
  - "Insufficient temporary space" on page 3520
  - "Fix Pack installation fails with license agreement error" on page 3521
  - "Installation fails with version error" on page 3521
- WebSphere Message Broker Toolkit:
  - "Dealing with problems during installation" on page 3521
- WebSphere Message Broker Explorer:
  - "Dealing with problems during installation" on page 3522
- Installation Manager:
  - "Installation Manager hangs" on page 3522
  - "Installation Manager does not show the WebSphere Message Broker Toolkit components" on page 3523
  - "Error restoring Installation Manager state" on page 3523
- WebSphere Message Broker Launchpad:
  - "WebSphere Message Broker Launchpad return code indicates that an installation has failed" on page 3524

Dealing with problems during installation

Before you begin

Broker component on all operating systems:

Procedure

- **Scenario:** You have problems during the installation of the Broker component.
- **Solution:** Complete the following steps:
  1. If you experience problems when installing on z/OS, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.
  2. Refer to the readme file `readme.html` for any late changes to the installation instructions.
  3. If you transferred the installation media to your local or networked filesystem, you might see the following error:

     ```
     The Install executable launcher was unable to locate its companion shared library.
     ```

     Ensure that you have read and execute privileges on all installation directories and files. Also ensure that the length of the path to the installation media is within the limits imposed by your operating system.
  4. If installation is successful, the installation wizard returns a return code of zero. If a non-zero return code is returned, check the installation log file for

errors and explanations. Problems associated with the installation of the Broker component are recorded in the log file `mqsi7_install.log`, which is stored in your installation directory.

If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

Linux `/opt/ibm/mqsi/v.r`

UNIX `/opt/IBM/mqsi/v.r`

Windows 32-bit
`C:\Program Files\IBM\MQSI\v.r`

Windows 64-bit
`C:\Program Files\IBM\MQSI\v.r` for the 64-bit version of WebSphere Message Broker

`C:\Program Files (x86)\IBM\MQSI\v.r` for the 32-bit version of WebSphere Message Broker

These locations define the default value of *install_dir* on each platform.

5. If you are still unable to resolve the problem, contact your IBM Support Center.

Installation process is interrupted

Before you begin

Broker component on all operating systems:

Procedure

- **Scenario:** You are installing the Broker component but the process is interrupted before completion.
- **Explanation:** The process might be interrupted because of a problem, such as a power failure.
- **Solution:** Delete the *install_dir* and all its contents before you restart the program.

java.lang.UnsatisfiedLinkError

Before you begin

Broker component on Linux:

Procedure

- **Scenario:** You are using the Broker component graphical interface to install on Linux but the interface does not work correctly.
- **Explanation:** The additional packages that are required to complete the installation are not installed.
- **Solution:** You must install additional packages for the interface to work correctly. For more information about the required additional packages, see "Operating system requirements" on page 3590.

RPM query fails

Before you begin

Broker component on Linux:

Procedure

- **Scenario:** You start a Red Hat package manager (RPM) query after you have installed the product, but nothing is returned. An information message like the following example might have been reported in the installation log file:

```
(01-Jun-2005 09:02:27), mqsi.Setup,
   com.ibm.wizard.platform.linux.LinuxProductServiceImpl, wrn,
   The installer could not successfully add the product information
   into the RPM database. Installation will continue as this is not
   critical to the installation of the product.
```

- **Explanation:** It is likely that your system does not have the required RPM support.
- **Solution:** Install the additional RPM build package that is described in "Operating system requirements" on page 3590.

Display problems

Before you begin

Broker component on Linux and UNIX:

Procedure

- **Scenario:** You try to install the Broker component by using the graphical interface and see one of two common errors reported.
- **Explanation:** Both errors typically occur if you log in remotely, or you switch user ID.
- **Solution:** Address the appropriate error with the following corresponding solution:

  `Can't open display localhost:1.0`
  Check that the DISPLAY variable is set to the correct value. If you are logged in locally, the typical value is `:0.0` or `localhost:0.0`.

  `Connection to ":0.0" refused by server`
  Run the following command, where *user* is the user ID you are logged in as:

  ```
  xauth merge ~user/.Xauthority
  ```

  If you are unable to correct these errors, contact your systems administrator for further help.

Insufficient temporary space

Before you begin

Broker component on Linux and UNIX:

Procedure

- **Scenario:** You install the Broker component and the installation program tries to unpack product files into the temporary file space of the local system. On Linux and UNIX systems, the temporary space is typically located in `/tmp`.
- **Explanation:** If sufficient file space is not available in this directory, the command might fail without reason and returns no comment, or reports a lack of file space.
- **Solution:** Give the installation wizard a temporary file system to use, for example; `setupaix`. The command-line option is `-is:tempdir` *name of temp directory*. For example, on AIX, enter the following command:

  ```
  ./setupaix -is:tempdir /largetemp
  ```

Do not specify a temporary directory that is NFS-mounted from another server; if you do so, the installation might fail because user permission checks made by the installer sometimes report an error that security principals mqm and mqbrkrs do not exist on the local machine.

For more information about checking how much temporary space is required, see "Memory and disk space requirements" on page 3584.

Fix Pack installation fails with license agreement error

Before you begin

Broker component on AIX with WPAR configuration:

Procedure

- **Scenario:** You are installing a Fix Pack for the Broker component on an AIX WPAR system but the installation fails with the message: "The License Agreement could not be properly loaded."
- **Explanation:** Fix Pack installations check that the license agreement was accepted by checking that the Broker component exists on the target system. On AIX, the installer performs this check by searching the `/usr/lib/objrepos/vpd.properties` file for an entry that matches this version and release of WebSphere Message Broker. If the `/usr` file system is read-only, the base product installation succeeds, but cannot update the `vpd.properties` file. Subsequent Fix Pack installations cannot determine that the Broker component is installed.
- **Solution:** Ensure that the user ID root can write to file `/usr/lib/objrepos/vpd.properties`. Reinstall the base product and check that `/usr/lib/objrepos/vpd.properties` was successfully updated. Then apply a Fix Pack.

Installation fails with version error

Before you begin

Broker component on all operating systems:

Procedure

- **Scenario:** You are installing the WebSphere Message Broker runtime component, but the installation fails with the message: "Installed product has newer version."
- **Explanation:** Files or directories left behind from previous uninstallation.
- **Solution:** Manually delete the residual files and directories from the installation location.

Dealing with problems during installation

Before you begin

WebSphere Message Broker Toolkit on all operating systems:

Procedure

- **Scenario:** You have problems during the installation of the WebSphere Message Broker Toolkit.
- **Solution:** Complete the following steps:
  1. Refer to the readme file `readme.html` for any late changes to the installation instructions.
  2. If installation is successful, the installation wizard returns a return code of zero. If a non-zero return code is returned, check the Installation Manager log file for errors and explanations. Problems associated with the installation

of the WebSphere Message Broker Toolkit are recorded in the Installation Manager log file *YYYYMMDD_TIME*`.xml`. Where *YYYYMMDD_TIME* is the date and time of installation. The Installation Manager log file is stored in the following location:

Linux `/var/ibm/InstallationManager/logs`

Windows
On Windows systems, the directory is created in the following default location, however the actual location might differ on your computer:

`%ALLUSERSPROFILE%\Application Data\IBM\Installation Manager\logs`Where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003:
  `C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs`
- On Windows Vista and later operating systems:
  `C:\ProgramData\IBM\Installation Manager\logs`

3. If you are still unable to resolve the problem, export the Installation Manager related information from **Installation Manager** > **Help menu** > **Export Data for Problem Analysis**, and contact your IBM Support Center with the exported information.

Dealing with problems during installation

Before you begin

WebSphere Message Broker Explorer on all operating systems:

Procedure

- **Scenario:** You have problems during the installation of the WebSphere Message Broker Explorer.
- **Solution:** Complete the following steps:
  1. See the *Program Directory for WebSphere Message Broker for z/OS* if you experience problems when installing on z/OS.
  2. Refer to the readme file `readme.html` for any late changes to the installation instructions.
  3. If installation is successful, the installation wizard returns a return code of zero. If a non-zero return code is returned, check the log file for errors and explanations. Problems associated with the installation of the WebSphere Message Broker Explorer are recorded in the log file `MBExplorer_install.log`, which is stored in the installation directory. The default installation directories are as follows:

     Linux `opt/IBM/MBExplorer`

     Windows
     `C:\Program Files\IBM\MBExplorer`

Installation Manager hangs

Before you begin

Installation Manager on Linux on x86 and Windows:

Procedure

- **Scenario:** You click **Next** in the Installation Manager when it first opens and the Installation Manager hangs.
- **Solution:** Close the window and reopen it.

Installation Manager does not show the WebSphere Message Broker Toolkit components

Before you begin

Installation Manager on Linux on x86 and Windows:

Procedure

- **Scenario:** You are installing the WebSphere Message Broker Toolkit but the initial Install Packages page that is displayed by the Installation Manager does not show the WebSphere Message Broker Toolkit components.
- **Explanation:** The location of the update repository has not been set correctly.
- **Solution:** Select **File** > **Preferences** and click **Add Preferences**. Enter the web address or directory where the installation packages are stored or click **Browse** to search for the correct location. Click **OK**. The packages are listed in the Install Packages page.

Error restoring Installation Manager state

Before you begin

Installation Manager on Linux and Windows:

Procedure

- **Scenario:** You already have the IBM Installation Manager installed on your workstation and the version is earlier than Installation Manager Version 1.3.4.1. While installing a newer version of the IBM Installation Manager, as supplied with WebSphere Message Broker Toolkit, you cancel the installation before completion. When you try to restart the installed Installation Manager from your workstation, you receive the following error:

  ```
  Error restoring Installation Manager state
  Installation data has incompatible version 0.0.4; expected [0.0.2,0.0.3].
  Newer version of the Installation Manager was used on the system
  ```

- **Solution:** To work around this error, complete the following steps:

  1. Open the Installation Manager `installRegistry.xml` file, which is in the Installation Manager agent data location. The location of this file depends on your platform. See the Installation Manager Information Center to find out the location on your workstation: http://publib.boulder.ibm.com/infocenter/install/v1r2/index.jsp?topic=/com.ibm.silentinstall12.doc/topics/r_app_data_loc.html.
  2. When you have located the `installRegistry.xml` file, change the following line in the file and the Installation Manager should start correctly:

     ```
     <?installRegistry version='0.0.4'?>
     ```

     to match the following line:

     ```
     <?installRegistry version='0.0.3'?>
     ```

WebSphere Message Broker Launchpad return code indicates that an installation has failed

Before you begin

WebSphere Message Broker Launchpad on Windows:

Procedure

- **Scenario:** You install products by using the WebSphere Message Broker Launchpad. The Launchpad waits for a return code from each installation wizard that it initiates, but the return code indicates that an installation has failed. The Launchpad reports the error and refers you to the documentation for the product that has failed.
- **Explanation:** Most installation wizards roll back from the point of the error and return your system to the state it was in before the failed attempt, and you can therefore try again after you have corrected the error. However, in this scenario, the Launchpad has already installed one or more products successfully before the error occurred, so does not roll back these installations. When you restart the Launchpad, the status of installed products reflects successful installations from the previous invocation.
- **Solution:** To resolve the failed installation, you must either correct the error and restart the Launchpad, or click **Refresh** and clear the selection of the product that failed.

  If you are unable to install the failed product, complete the following steps:

  – Refer to the readme file `readme.html` for late changes to the installation instructions.

  – If the Broker component fails to install, check the contents of the installation log file `mqsi7_install.log`, which is stored in your installation directory.

    If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

    Linux `/opt/ibm/mqsi/v.r`

    UNIX `/opt/IBM/mqsi/v.r`

    Windows 32-bit
    `C:\Program Files\IBM\MQSI\v.r`

    Windows 64-bit
    `C:\Program Files\IBM\MQSI\v.r` for the 64-bit version of WebSphere Message Broker

    `C:\Program Files (x86)\IBM\MQSI\v.r` for the 32-bit version of WebSphere Message Broker

    These locations define the default value of *install_dir* on each platform.

  – If the WebSphere Message Broker Toolkit fails to install, check the contents of the installation log file *YYYYMMDD_TIME*`.xml`, where *YYYYMMDD_TIME* is the date and time of installation.

  – If the WebSphere Message Broker Explorer fails to install, check the contents of the installation log file `MBExplorer_install.log`. The log file is stored in the installation directory.

  – If WebSphere MQ fails to install, check the contents of `MQV7_install.`*date_time*`.log` stored in the `temp` directory of your home directory.

  If you are still unable to resolve the problem, contact your IBM Support Center.

Resolving problems when uninstalling

Work through the advice provided to help you to deal with problems that can arise when the product is uninstalled.

About this task

The following list describes typical problems when uninstalling, with a corresponding solution or workaround:

- Broker component:
  - "Space problems uninstalling on Solaris"
  - "Files left behind after uninstallation completes" on page 3526
  - "The uninstallation process is interrupted" on page 3526

Space problems uninstalling on Solaris

Procedure

- **Scenario:** When you uninstall the Broker component on Solaris on x86-64, the process fails and reports an error that there is no space on the device.
- **Explanation:** The process is trying to use temporary files in the `/var` directory, but insufficient space is available.
- **Solution:** Delete unwanted files from the `/var` directory, then rerun the process.

Files left behind after uninstallation completes

Procedure

- **Scenario:** When you uninstall the WebSphere Message Broker runtime components, the wizard completes successfully, but some files and directories are left behind in the installation directory.
- **Explanation:** Some processes might still be running during the uninstallation, which might be locking the directories.
- **Solution:** When the uninstallation wizard for the WebSphere Message Broker runtime components has completed, manually delete all remaining files and directories in the installation directory.

The uninstallation process is interrupted

Procedure

- **Scenario:** When you uninstall the Broker component on any distributed system, the process is interrupted, for example by a power failure.
- **Solution:** Delete the *install_dir* and all its contents. You can now reinstall if required.

Related reference:

"Local error logs" on page 6867
WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

"WebSphere Message Broker logs" on page 6867
WebSphere Message Broker writes information to a number of product-specific logs to report the results of actions that you take.

Windows: Viewing the local error log

The Windows Event Viewer is where WebSphere Message Broker writes records to the local system. Use Windows system facilities to view this log.

Viewing the system log

About this task

The system log contains events logged by the Windows system components. For example, the failure of a driver or other system component to load during startup is recorded in the system log. To view the system log:

Procedure

1. Open a command prompt.
2. At the prompt, type **eventvwr**. This opens the Windows Event Viewer.
3. On Windows XP and Windows Server 2003, click **System Log** in the left pane of this window. This option might be selected by default.

   On Windows Vista and Windows Server 2008, expand the Windows Logs tree in the left pane of this window, and click **System**. This option might be selected by default.

   All the events that have been written to the local system are displayed.

Viewing the application log

About this task

The application log contains events that are logged by applications or programs. For example, a database program might record a file error in the application log. To view the application log:

Procedure

1. Open a command prompt.
2. At the prompt, type **eventvwr**. This opens the Windows Event Viewer.
3. On Windows XP and Windows Server 2003, click **Application Log** in the left pane of this window. This option might be selected by default.

   On Windows Vista and Windows Server 2008, expand the Windows Logs tree in the left pane of this window, and click **Application**. This option might be selected by default.

   All the events that have been written by applications or programs to the local system are displayed.

Interpreting log information

About this task

In both logs, each event is displayed on a separate row, in date and time order (most recent first), with the following information:

- **Type:** The event type, which can be information, a warning, or an error.
- **Date and time:** The date and time when the event was written to the log.
- **Source:** What action has caused the event.
- **Category:** The category of the event. The default category is `none`.
- **Event:** The event number.
- **User:** The name of the user at the time of the event.
- **Computer:** The name of the local machine.

To view an individual log entry:

Procedure

1. Within the system or application log, find the log entry.
2. Right-click the entry.
   - On Windows XP and Windows Server 2003, click **Properties** to open the Information Properties window.

     The window shows a description of the event and a Data section that details bytes or words that were parsed when the record was written to the log.
   - On Windows Vista and Windows Server 2008, click **Events** to open the Event Properties window.

     The window shows a description of the event. Select the Details tab to view bytes or words that were parsed when the record was written to the log.
3. In the Information Properties or Event Properties window, use the up and down arrows to move through the events of the log.
4. To close the Information Properties or Event Properties window, click **OK** to return to the system or application log.

"Local error logs" on page 6867
WebSphere Message Broker components use the local error log (also known as the system log) to record information about major activities within the system. When an error occurs, check the local error log first.

Linux and UNIX systems: Configuring the syslog daemon

On Linux and UNIX systems, all WebSphere Message Broker messages (other than messages that are generated by the command-line utilities) are sent to the syslog subsystem.

About this task

UNIX You must configure this subsystem so that all diagnostic messages that enable you to monitor the performance and behavior of your broker environment are displayed.

The configuration steps you make to ensure that all relevant messages are displayed depend on the version of Linux and UNIX that you are using. Refer to your operating system documentation relating to syslog (or syslog-ng for some versions of Linux) for information about how to configure the syslog subsystem.

WebSphere Message Broker processes call the syslog commands on the operating system but only those messages that correspond to the filter defined for the output destination are displayed. WebSphere Message Broker messages have:

- A facility of `user`.
- A level of `err`, `warn`, or `info`, depending on the severity of the situation causing the message to be issued.

To record all WebSphere Message Broker messages, create a filter on the `user` facility for messages of level `info` or greater. It is good practice to write these messages to a separate file; there might be a high number of them and they are more likely to be of interest to broker administrators rather than to system administrators.

The following line in a `syslog.conf` file causes all WebSphere Message Broker events to be written to a file `/var/log/user.log`

```
user.info /var/log/user.log
```

Many UNIX systems provide a command-line utility, known as logger, to help you test and refine your configuration of the syslog subsystem.

On UNIX, syslog entries are restricted in length and messages that are sent to the syslog are truncated by the new line character. To record a large amount of data in a log on UNIX, set the `Destination` property on the Trace node to `File` or `User Trace` instead of `Local Error Log`.

What to do next

See the documentation for your operating system.

On z/OS, the broker writes messages to the appropriate z/OS system log and job logs. These messages might include information, warning, error, and severe messages to indicate various situations and events.

Understanding the broker address spaces

About this task

The broker runs in multiple address spaces. A single control address space is always running when the broker is active, and is responsible for communicating with the WebSphere Message Broker Toolkit.

Each execution group within the broker is mapped to its own address space, and as these execution groups start and stop, the corresponding address spaces are started and stopped. The control address space is assigned a JOBNAME and STEPNAME, which is the same as the broker name. The execution groups have a JOBNAME that is also the same as the broker name, and a STEPNAME that matches the last seven characters of the execution group name.

Viewing the z/OS system console log
About this task

The broker writes all its messages to the z/OS system console log. You can see messages from all address spaces running on the z/OS system in this log. It is easy to identify jobs that are associated with the broker in the console log, because of the naming of broker address spaces. By using the console log, you can see the order of event reporting for different products. This information can be helpful for cross-product problem determination.

Viewing the broker job logs
About this task

The broker control address space, and each of the execution group address spaces, has its own job log. When you select the job log for the appropriate address space, you can see all messages relating to that address space. Use this option in a busy system where the system console log might have many messages from different products obscuring the information in which you are interested.

Interpreting log information
About this task

In both logs, each message is displayed on its own, in date and time order; it might span multiple lines, if necessary. For each message, the following information is available:

- **Date and time**: The exact date and time when the event was written to the log.
- **JOBID**: The started task job identifier of the address space.
- **Message Number**: The message number that identifies whether the event is information, a warning, or an error, with diagnostic text.
- **JOBNAME**: The JOBNAME of the address space issuing the message. This name is always the same as the broker name.
- **STEPNAME**: The STEPNAME of the address space that is issuing the message. For the control address space, this name is the same as the broker name; for execution groups, it is the same as the last eight characters of the execution group that is issuing the message.
- **PROCSTEP**: The procedure STEPNAME, which equals BROKER for the main broker control address space. For execution group address spaces, this is either **EGNOENV**, if there is not an execution group specific profile, or **EGENV** if there is an execution group specific profile.

Viewing the Eclipse error log

The Eclipse error log captures internal errors that are caused by the operating system or your code.

About this task

To view the Eclipse error log:

Procedure

1. Switch to the Plug-in Development perspective.
2. From the main menu, select **Window** > **Show view** > **Other**. Then select **General** > **Error Log**.

   The error log is displayed, showing the following information for each error:
   - The status of the error (for example, error or warning)
   - A brief description of the error
   - From which plug-in the error derived
   - The date and time that the error was produced
3. If an error has a plus sign (+) at the start of it, it is a complex problem, and there are a number of errors contributing to it. Click the plus sign to view the individual errors.
4. To see the details of a particular problem, double-click the entry in the Problems view. A separate window is displayed, showing more details of the error.

Related concepts:

Using trace

You can use different types of trace to help you with problem determination and troubleshooting.

About this task

How to use the optional trace.

For user trace:

- "Starting user trace" on page 3197
- "Checking user trace options" on page 3199
- "Changing user trace options" on page 3201
- "Retrieving user trace" on page 3204
- "Stopping user trace" on page 3202

For service trace:

- "Starting service trace" on page 3534
- "Checking service trace options" on page 3537
- "Changing service trace options" on page 3538
- "Retrieving service trace" on page 3542
- "Stopping service trace" on page 3540

For both types of trace:

- "Formatting trace" on page 3543
- "Interpreting trace" on page 3546
- "Clearing old information from trace files" on page 3548
- "Changing trace settings from the WebSphere Message Broker Explorer" on page 3549

Other types of trace:

- "ODBC trace" on page 3551
- "Administration API (CMP) trace" on page 3554
- "Switching Trace nodes on and off" on page 3555

You can also use the "IBM Support Assistant Data Collector" on page 3565 to help with data collection.

Related concepts:

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

Related tasks:

Chapter 13, "Troubleshooting and support," on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

"Making initial checks" on page 3347
Before you start problem determination in detail, consider whether there is an obvious cause of the problem, or an area of investigation that is likely to give useful results. This approach to diagnosis can often save a lot of work by highlighting a simple error, or by narrowing down the range of possibilities.

"Contacting your IBM Support Center" on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

"IBM Support Assistant Data Collector" on page 3565
You can collect diagnostic documents by using IBM Support Assistant Data Collector, and submit a problem report to IBM. IBM Support Assistant Data Collector is included with your WebSphere Message Broker installation.

Related reference:

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

"Database facilities" on page 6891
The database products used by WebSphere Message Broker also record information that might be useful if you have any problems with their access.

Starting service trace

Service trace is used to get detailed information about your environment for use by your IBM Support Center.

About this task

Activate service traces only when you receive an error message that instructs you to start service trace, or when directed to do so by your IBM Support Center

Use the **mqsichangetrace** command to start WebSphere Message Broker service trace facilities.

You can select only one broker on each invocation of the command, but you can activate concurrent traces for more than one broker by invoking the command more than once.

To limit the scope of a trace, you must specify the individual broker that you want to trace.

If the trace cannot be associated with a specific component, the component name part of the file name is set to `utility`; for example, when tracing a command such as **mqsilist**, when no arguments are used.

To trace the **mqsichangeresourcestats**, **mqsicreateexecutiongroup**, **mqsideleteexecutiongroup**, **mqsideploy**, **mqsilist**, **mqsimode**, **mqsireloadsecurity**, **mqsireportresourcestats**, **mqsistartmsgflow**, and **mqsistopmsgflow** commands, use the **-v** parameter. This parameter takes an argument that is the name of the file to which trace records are written. For example, the following command outputs trace of the **mqsistartmsgflow** command to the specified file:

```
mqsistartmsgflow MB7BROKER -e eg1 -m simpleflow -v .\trace.txt
```

If you want to trace the command executable files themselves, set the environment variables MQSI_UTILITY_TRACE and MQSI_UTILITY_TRACESIZE before you run the command.

MQSI_UTILITY_TRACE
: Set this variable to `normal` for a basic level of trace, or `debug` for a fuller trace.

MQSI_UTILITY_TRACESIZE
: The size, in kilobytes, of the binary trace file. See the **-c** parameter of the **mqsichangetrace** command.

Ensure that you reset these variables when the command that you are tracing has completed. If you do not do so, all subsequent commands are also traced, and their performance is therefore degraded.

To enable service trace of your CMP applications, take one of the following steps:

- Call the method BrokerProxy.enableAdministrationAPITracing(String filename).
- Before running your CMP application, set the environment variable MQSI_CMP_TRACE to the name of the file to which trace is sent.

You can also use the WebSphere Message Broker Explorer to activate service trace on execution groups and message flows.

To enable service trace for execution groups or messages flows in the WebSphere Message Broker Explorer:

1. In the Navigator view, expand the Brokers folder and right-click the execution group or message flow with which you want to work.
2. Click **Service Trace** > **Normal** or **Service Trace** > **Debug** to select the level of service trace that you require.

Example: starting service trace for the broker

About this task

To start debug level service tracing for the broker `A` on distributed systems, enter the following command:

```
mqsichangetrace BrokerA -t -b -l debug
```

where:

-t specifies service trace
-b specifies that trace for the `agent` subcomponent of the specified component is to be started
-l specifies the level of trace (in this case, debug)

z/OS On z/OS, enter the following command:

```
F MQPIBRK,ct t=yes, b=yes, l=debug
```

Example: starting service trace for an execution group

About this task

To start debug level service tracing for an execution group `EG1` on broker `A` on distributed systems, enter the following command:

```
mqsichangetrace BrokerA -t -e EG1 -l debug -m fast -c 200000 -r
```

where:

-t specifies service trace
-l specifies the level of trace (in this case, debug)
-m specifies the way trace information is to be buffered (in this case, fast)
-c specifies the size of the trace file in KB (in this case, 200000)
-r specifies that the trace file is reset

z/OS On z/OS, enter the following command:

```
F MQPIBRK,ct t=yes, e=EG1, l=debug, m=fast, c=20000, r=yes
```

Checking service trace options

Use the **mqsireporttrace** command or the WebSphere Message Broker Explorer to check what tracing options are currently active for your brokers.

About this task

Specify the component for which the check is required. The command responds with the current trace status for the component that you have specified.

Example: checking service trace options for an execution group using the WebSphere Message Broker Explorer

About this task

To check what options are currently set for the execution group by using the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the execution group with which you want to work.
2. Click **Service** to view user trace settings for your execution group.

Example: checking service trace options for a broker

About this task

To check what options are currently set for the broker, on distributed systems, enter the following command:

```
mqsireporttrace brokerA -t
```

where **-t** specifies service trace.

z/OS On z/OS, enter the following command:

```
F MQP1BRK,reporttrace t=yes
```

Results

If you have started tracing by following the example in "Starting service trace" on page 3534, the response to the **mqsireporttrace** command is:

```
BIP8098I: Trace level: debug, mode: safe, size: 1024 KB
BIP8071I: Successful command completion
```

Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Stopping service trace

Use the **mqsichangetrace** command or the WebSphere Message Broker Explorer to stop an active service trace.

Procedure

- Use the **mqsichangetrace** command with a trace level of `none` to stop an active trace. This action stops the trace activity for the component that you specify on the command. It does not affect active traces on other components. For example, if you stop tracing on the execution group `test`, an active trace on another execution group continues.
- Click **Service Trace** > **None** on an execution group or message flow, in the WebSphere Message Broker Explorer, to stop an active service trace on the selected object.

Results

If you redeploy a component from the WebSphere Message Broker Toolkit, trace for that component is returned to its default setting of `none`.

Example: stopping service trace on an execution group, using the WebSphere Message Broker Explorer

About this task

To stop the service trace using the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the execution group with which you want to work.
2. Click **Service TraceNone**.

Example: stopping service trace on an execution group, using the `mqsichangetrace` command

About this task

To stop debug level service tracing for an execution group`EG1` on broker `A` on distributed systems, enter the command

```
mqsichangetrace BrokerA -t -e EG1 -l none
```

where:

-t specifies service trace
-l specifies the level of trace (in this case, none)

z/OS On z/OS, enter the command

```
F MQPIBRK,ct t=yes, b=yes, l=none
```

Example: stopping service trace on the broker

About this task

To stop the trace started by the command shown in "Starting service trace" on page 3534, on distributed systems, enter the following command:

```
mqsichangetrace BrokerA -t -b -l none
```

where:

-t specifies service trace
-b specifies that trace for the `agent` subcomponent of the specified component is to be stopped
-l specifies the level of trace (in this case, none)

z/OS On z/OS, enter the following command:

```
F MQP1BRK,ct t=yes, b=yes, l=none
```

Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Retrieving service trace

Use the **mqsireadlog** command to access the trace information recorded by the service trace facilities.

Procedure

This command retrieves the trace details according to parameters that you specify on the command, and writes the requested records to a file, or to the command-line window, in XML format.

Example: retrieving service trace information in XML format

Procedure

To retrieve information for the service trace activated with the **mqsichangetrace** command, and write it to an output file, on distributed systems, enter the following command:

```
mqsireadlog brokerName -t -b agent -f -o /path/to/strace.xml
```

where:

-t specifies service trace.

-b *agent* specifies that trace for the `agent` subcomponent of the specified component is to be retrieved.

-f specifies that the log file is to be read directly from the file system (this flag is mandatory for service trace).

-o specifies the output file (in this case, `/path/to/strace.xml`.) If you do not specify a path to the file, the file is created in the current directory. Ensure that there is enough space for the output file.

Results

This command sends a log request to the broker to retrieve the service trace log, and stores the responses in the specified file. You can view this file using a plain text editor.

Example: retrieving service trace information in XML format for an execution group

Procedure

To retrieve information for the service trace activated with the **mqsichangetrace** command and associated with execution group EG1 on broker A, and write it to an output file, on distributed systems, enter the following command:

```
mqsireadlog BrokerA -t -e EG1 -f -o /path/to/strace.xml
```

where:

-t specifies service trace.

-f specifies that the log file is to be read directly from the file system (this flag is mandatory for service trace).

-o specifies the output file (in this case, `/path/to/strace.xml`.) If you do not specify a path to the file, the file is created in the current directory. Ensure that there is enough space for the output file.

Results

This command sends a log request to the broker to retrieve the service trace log, and stores the responses in the specified file. You can view this file using a plain text editor.

Service trace is inactive by default; you must activate it explicitly by using a command.

"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

Formatting trace

Use the **mqsiformatlog** command to format trace information.

About this task

The trace information that is generated by the **mqsireadlog** command is not easy to read unless you use an XML viewer (such as an Internet browser) or an XML editor that understands the document type descriptor (DTD) in the file.

Procedure

WebSphere Message Broker provides the command **mqsiformatlog** to format the trace information to a flat file, so that you can view it using a text editor.

Results

The **mqsiformatlog** command takes a file generated by the **mqsireadlog** command as input, and flattens the XML log into structured records. It also retrieves the inserts for the XML message in your current locale. You can direct the formatted output to a file, or view it in the command line window.

Each trace entry contains a time stamp and a WebSphere Message Broker message that contains a number (for example, BIP2622) and a text string containing variable inserts.

Example: formatting service trace information for an execution group

About this task

To format the service trace file for an execution group, enter the command

```
mqsiformatlog -i </path/to/output.xml> -o </path/to/output.txt>
```

where:

-i specifies the path to the input file that contains the unformatted service trace information for the execution group

-o specifies the path to the output file that is to contain the formatted service trace information

Example: formatting user trace information on Windows

About this task

Windows On Windows, to format the trace file that is created in "Starting user trace" on page 3197, enter the command

```
mqsiformatlog -i trace.xml -o formattrace.log
```

where:

-i specifies the input file (in this case, trace.xml)

-o specifies the output file (in this case, formattrace.log)

This command reads the trace information in the file trace.xml, formats it, and writes it to the file formattrace.log. The following example shows a portion of the output of the **mqsiformatlog** command for a normal level trace file.

Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

Interpreting trace

Use the information in a formatted trace file to identify unexpected behavior.

About this task

A formatted log file, like the one in "Formatting trace" on page 3543, contains a sequence of WebSphere Message Broker messages. These messages record the activity in a specific part of the system (the part that you identify when you start the trace). You can use this sequence to understand what is happening, and to check that the behavior that is recorded is what you are expecting.

For example, message flow trace records the path that a message takes through the message flow. You can see why decisions result in this path (where a choice is available).

Procedure

1. Verify that the trace file is complete.

   If the size of the trace log is too small to contain all events, trace output continues at the start of the trace log, overwriting existing entries. This is known as *wrapping*.

   An indication that a trace has wrapped is the relationship between the first and last timestamp in it, and the time that trace was enabled. For example, assume that you start tracing at 10:15, and collect the trace at 10:30. If the trace timestamps run from 10:20 to 10:30, it is probable that trace wrapped. Of course it could mean that nothing happened between 10:15 and 10:20.

   Examine the trace and decide whether the beginning of it makes sense, and whether it looks complete. For example, if you want to trace the passage of three messages through a flow, and trace starts half way through the second message, it could have wrapped, or trace might not have been enabled early enough.
2. If trace has wrapped, increase the size of the trace file, and rerun trace. For information on trace settings, see "**mqsichangetrace** command" on page 3822.
3. If you see unexpected behavior in a message flow or execution group, use this trace information to check the actions that have been taken and identify the source of an error or other discrepancy.

Results

The messages contain identifiers for the resources that are being traced, for example the execution groups and message flows. The identifier that is given is typically the label (the name) that you gave to the resource when you defined it.

Here is an extract from a user trace file. In the example, each column has been labeled:

```
Timestamp                 Thread ID Trace type  Message
2005-07-12 16:17:18.242605   5344   UserTrace   BIP2537I: Node 'Reply.MapToRequestor':
                                                Executing statement   ''SET I = I + 1;''
                                                at ('.MapToRequestor.CopyMessageHeaders',
                                                '6.4').

Clearing old information from trace files

If the component that you are tracing has stopped, you can delete its trace files from the log subdirectory of the WebSphere Message Broker home directory.

About this task

If you are tracing an execution group, you can use the **-r** parameter of the **mqsichangetrace** command to reset (clear) the trace log (the **-r** parameter can be specified only if you specify the **-e** parameter). You might clear the log when you start a new trace, to ensure that all the records on the log are unique to the new trace.

Example: clearing the user trace log for the default execution group

About this task

To clear the user trace log for the default execution group, on distributed systems, enter the command: **mqsichangetrace WBRK_BROKER -u -e default -r** where:

WBRK_BROKER specifies the name of the broker
-u specifies user trace
-e specifies the execution group (in this case the default execution group)
-r clears the trace log

z/OS On z/OS, enter the command `F MQP1BRK,ct u=yes, e='default', r=yes`

Changing trace settings from the WebSphere Message Broker Explorer

Collect trace information, in addition to user and service trace, by selecting options in the WebSphere Message Broker Explorer.

About this task

- Trace for the broker and WebSphere Message Broker Explorer components.
- Trace for the Administration API (also known as the CMP API)

The following sections tell you how to change the settings for these types of trace.

Changing the WebSphere MQ Java Client trace settings

About this task

You control tracing of the WebSphere MQ Java Client from the WebSphere Message Broker Explorer:

Procedure

1. Click **Window** > **Preferences**.
2. In the left menu, expand **Broker Explorer**.
3. Click **Service Trace**.
4. In the **WebSphere MQ Java Client** section, select the check box to enable tracing on the WebSphere MQ Java Client. The default file to which trace is written is `C:/Documents and Settings/`*`userid`*`/Application Data/IBM/MQ Explorer/.metadata/MQClientTraceEnabled.log` where *userid* is your user ID.
5. Click **OK** to apply your changes and to close the Preferences window.

Changing the CMP trace settings

About this task

You control tracing of the CMP API from the WebSphere Message Broker Explorer:

Procedure

1. Click **Window** > **Preferences**.
2. In the left menu, expand **Broker Explorer**.
3. Click **Service Trace**.
4. In the **CMP Administration API** section, select the check box to enable tracing on the CMP. The default file to which trace is written is `C:/Documents and Settings/`*`userid`*`/Application Data/IBM/MQ Explorer/.metadata/AdminAPITrace.log` where *userid* is your user ID.
5. Click **OK** to apply your changes and to close the Preferences window.

Changing the Broker Explorer trace settings

About this task

You can control tracing of the WebSphere Message Broker Explorer using the Broker Explorer Preferences page:

Procedure

1. Click **Window** > **Preferences**.
2. In the left menu, expand **Broker Explorer**.
3. Click **Service Trace**.
4. Select the check box for the component that you want to trace, and select a location for the log file for the trace. The default location for the trace files in is the WebSphere MQ Explorer workspace directory.
5. Set a value for the log file size in the Maximum Broker Explorer Trace File Size field. When the size of the log file you set is exceeded, the original log file is copied to `filename.ext.bak`. A new log file with the selected name is started.
6. Click **OK** to apply your changes and to close the Preferences window.

The WebSphere Message Broker Toolkit provides your application development environment on Windows and Linux on x86.

ODBC trace

You can use various methods to trace for ODBC activity, depending on the operating system that you are using.

About this task

Windows For Windows, use the **Tracing** tab of the ODBC function:

1. Click **Start** > **Settings** > **Control Panel** > **Administrative Tools**.
2. Double-click **Data Sources**.
3. Click the **Tracing** tab.
4. Click **Start Tracing Now**.
5. Click **OK**.

To stop ODBC tracing, on the **Tracing** tab, click **Stop Tracing Now**, then **OK**.

Linux UNIX For Linux and UNIX operating systems using DataDirect drivers:

- To initiate trace for ODBC activity, edit the [ODBC] stanza in the file pointed to by your ODBCINI environment variable as follows:
  1. Change `Trace=0` to `Trace=1`.
  2. Specify a path and file name for `TraceFile`
  3. Ensure that the `TraceFile` entry points to a file system that has enough space to receive the trace output

Trace information is written to the location that is specified in the `odbc.ini` file.

Linux UNIX For Linux and UNIX operating systems using WebSphere Message Broker ODBC Database Extender (IE02) drivers:

- To initiate trace for ODBC activity, edit the [ODBC] stanza in the file pointed to by your ODBCSYSINI environment variable as follows:
  1. Change `Trace=no` to `Trace=yes`.
  2. Specify a path and file name for `TraceFile`
  3. Ensure that the `TraceFile` entry points to a file system that has enough space to receive the trace output

z/OS For z/OS, to initiate application trace for ODBC activity:

1. Edit the BIPDSNAO file in the component dataset and under the stanza entry [COMMON], change APPLTRACE=0 to APPLTRACE=1
2. Remove the comment from the COMPDIR variable declaration and the APPLTRC DD from the steps EGNOENV and EGENV, in the WebSphere Message Broker started task JCL.
3. Stop and restart the broker after you have made all the changes to the BIPDSNAO file and the started task JCL.

   By default, the trace output file is written to <component_HFS>/output/, into a file called db2appltrace.. Each address space has a unique number, and the eight character execution group label appended to the end of db2appltrace.

   This unique number, appended to the ODBC file, is the SE number in the execution group address space JOBLOG.

   If the eight character execution group label is not unique across multiple execution groups, look for the value of SE in the JOBLOG for which you want to view the ODBC trace, and find the file that specifies this value.

Results

Example

DB2 on WebSphere Message Broker for z/OS

The following sample ODBC trace files show the layout of a trace file, together with some examples of successful and error returns. The general layout of each group in an ODBC file is that:

- Each line is preceded by a time stamp.
- The first line displays what the call does.
- The second line displays the return.
- The third line displays the result.

The first trace file shows a trace where a call fails because an object does not have the correct authority to perform an action:

You can use different types of trace to help you with problem determination and troubleshooting.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"Database facilities" on page 6891
The database products used by WebSphere Message Broker also record information that might be useful if you have any problems with their access.

Administration API (CMP) trace

Enable or disable service trace for the Administration API for WebSphere Message Broker (also known as the CMP API).

Enabling CMP API trace

About this task

To enable tracing for the CMP API for your application, set the environment variable MQSI_CMP_TRACE, where <*filename*> is the name of the file to which the trace is sent:

```
export MQSI_CMP_TRACE=<filename>
```

Or you can enable tracing by using the following API call in your code:

```
// Enable Message Broker Administration service trace
   BrokerProxy.enableAdministrationAPITracing("outputfile.txt");
```

This request logs all calls to the CMP API to the `outputfile.txt` file in the current directory. All CMP API activity in the entire Java virtual machine is logged.

You can also enable CMP API service trace from the **File** menu of the CMP API Exerciser.

In addition, because the CMP API uses the WebSphere MQ Java client, you can enable WebSphere MQ Java client tracing.

Disabling CMP API trace

About this task

To disable tracing for the CMP API for your application, use the following API call in your code:

```
// Disable Message Broker Administration service trace
   BrokerProxy.disableAdministrationAPITracing();
```

You can also disable CMP API service trace from the **File** menu of the CMP API Exerciser.

Related concepts:

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

"The Administration API for WebSphere Message Broker" on page 54
The Administration API for WebSphere Message Broker is a programming interface that your applications can use to control brokers and their resources through a remote interface.

"Using trace" on page 3533
You can use different types of trace to help you with problem determination and troubleshooting.

"Resolving problems when developing Administration API applications" on page 3510
Use the advice given here to help you to resolve problems that can arise when developing Administration API for WebSphere Message Broker (also known as the CMP API) applications.

Related reference:

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

Switching Trace nodes on and off

Use the **mqsichangetrace** command or the WebSphere Message Broker Explorer to switch Trace nodes on and off.

About this task

When an execution group is created, or a message flow is deployed, its Trace node switch is set to `on` by default. Execution groups and message flows that you have migrated from a previous version are also handled in this way. The message flow level Trace node switch setting is not changed on redeployment. You can significantly improve the performance of a flow that includes Trace nodes by switching Trace nodes off.

Restriction: If you switch off Trace nodes in a flow that was migrated from a version earlier than 6.1, you can no longer revert that flow to its earlier state.

If the Trace node setting for an execution group is off, all Trace nodes in its flows are disabled. You can change the settings for Trace nodes in individual message flows; the settings are applied when you turn on Trace nodes for the execution group. If the Trace node setting for an execution group is on, the Trace node switch setting of each message flow determines the effective settings. Use the "**mqsireporttrace** command" on page 3947 to check the settings for message flows and execution groups.

Example: switching off Trace nodes for an execution group on distributed systems, using the command line

Procedure

To disable the Trace node switch settings of all message flows in an execution group of a broker called MB7BROKER, (that is, stop all the Trace nodes in any of the message flows deployed to the execution group from executing), enter the following command:

```
mqsichangetrace MB7BROKER –n off -e default
```

In this example, `-n off` switches off Trace nodes in the default execution group (`-e default`).
All Trace nodes are switched off, even if the message flow that contains them has its Trace node switch set to *on*.

Example: switching off Trace nodes for an execution group on z/OS systems, using the command line

Procedure

To disable the Trace node switch settings of all message flows in an execution group of a broker called MQP1BRK, (that is, stop all the Trace nodes in any of the message flows deployed to the execution group from executing), enter the following command:

```
F MQP1BRK,ct n='off', e='default'
```

In this example, `n='off'` switches off Trace nodes in the default execution group (`e='default'`).
All Trace nodes are switched off, even if the message flow that contains them has its Trace node switch set to *on*.

Example: switching off Trace nodes for a message flow on distributed systems, using the command line

About this task

Trace nodes for the default execution group in broker MB7BROKER are switched on. You want to turn off Trace nodes for the myFlow message flow.

Procedure

Enter the following command:

```
mqsichangetrace MB7BROKER -n off -e default -f myFlow
```

Example: switching on Trace nodes for a message flow and an execution group on distributed systems, using the command line

About this task

Trace nodes for the default execution group in broker MB7BROKER are switched off. You want to turn on Trace nodes for the myFlow message flow, then turn on Trace nodes for the execution group.

Procedure

1. To turn on Trace nodes for the message flow, enter the following command:

   ```
   mqsichangetrace MB7BROKER -n on -e default -f myFlow
   ```

   Trace nodes for the myFlow message flow are turned on, but this setting is not applied until you turn on trace nodes for the execution group.
2. To turn on Trace nodes for the execution group, enter the following command:

   ```
   mqsichangetrace MB7BROKER –n on -e default
   ```

   Trace nodes are turned on for the default execution group. Within that execution group, Trace nodes are enabled in all message flows that have Trace nodes turned on, including the myFlow message flow.

Example: switching off Trace nodes for a message flow on z/OS systems, using the command line

About this task

Trace nodes for the default execution group in broker MQP1BRK are switched on. You want to turn off Trace nodes for one of the message flows (myFlow).

Procedure

Enter the following command:

```
F MQP1BRK,ct n='off', e='default', f='myFlow'
```

Example: switching on Trace nodes for an execution group, using the WebSphere Message Broker Explorer

About this task

Trace nodes are enabled by default. If you have switched them off, follow these steps to enable Trace nodes for an execution group from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the execution group with which you want to work.
2. Click **Trace Nodes All Flows** > **Enable**. An alert saying Trace nodes are switched on is displayed in the Alert Viewer. The Trace node switch setting of each message flow determines the effective settings.

Example: switching on Trace nodes for a message flow, using the WebSphere Message Broker Explorer

Before you begin

If the Trace node setting for an execution group is off, all Trace nodes in its flows are disabled. You can change the settings for Trace nodes in individual message flows; the settings are applied when you turn on Trace nodes for the execution group. If the Trace node setting for an execution group is on, the Trace node switch setting of each message flow determines the effective settings.

About this task

Follow these steps to enable Trace nodes for one of your message flows from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the message flow with which you want to work.
2. Click **Trace Nodes** > **Enable** An alert is displayed in the Alert Viewer.

Use the Trace node to generate trace records that you can use to monitor the behavior of a message flow.

Using dumps and abend files

A dump or an abend file might be produced when a problem occurs. Dumps and abend files can be used by IBM to resolve the problem.

About this task

This section contains the following topics:

Procedure

- "Checking for dumps" on page 3559
- "Using the DUMP command on z/OS" on page 3560
- "Checking for abend files" on page 3562

What to do next

You can also use the "IBM Support Assistant Data Collector" on page 3565 to help with data collection.

Related tasks:

Chapter 13, “Troubleshooting and support,” on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

“Contacting your IBM Support Center” on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

“IBM Support Assistant Data Collector” on page 3565
You can collect diagnostic documents by using IBM Support Assistant Data Collector, and submit a problem report to IBM. IBM Support Assistant Data Collector is included with your WebSphere Message Broker installation.

Related reference:

“Abend files” on page 6880
When a process does not end normally an abend file is generated.

“Dumps” on page 6877
Under exceptional circumstances, Windows MiniDumps, UNIX core dumps, or z/OS SVC or core dumps might be produced.

Checking for dumps

If a dump occurs on your system, an error message is produced.

Procedure

- **On Windows**

  BIP2111 error message (message broker internal error). The error message contains the path to the MiniDump file in your errors directory.

- **On UNIX**

  BIP2060 error message (execution group terminated unexpectedly). Look in the directory where the broker was started, or in the service user ID's home directory, to find the core dump file.

- **On z/OS**
  - BIP2060 error message (execution group ended unexpectedly) from the main Broker Address Space. This message should be accompanied by one of the following messages and dump.
  - IEF450I message in the syslog, or component's joblog, showing an abend code followed by a reason code, for example:

    ```
    IEF450I MQ83BRK DEFAULT - ABEND=S2C1 U0000 REASON=000000C4
    ```

    Look in the system's dump dataset `hlq` for the dump dataset, or search the syslog for the appropriate IEA611I message to find out the dump dataset name.
  - IEA993I message in the syslog for a SYSMDUMP. Look in the started task user's directory for the `coredump.pid` file, as specified in the syslog:

    ```
    IEA993I SYSMDUMP TAKEN TO coredump.00500319
    ```
  - An error message for an SVC dump; see “Dumps on WebSphere Message Broker for z/OS” on page 6878 for further information on SVC dumps.

If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

"Using dumps and abend files" on page 3558
A dump or an abend file might be produced when a problem occurs. Dumps and abend files can be used by IBM to resolve the problem.

"Checking for abend files" on page 3562
Abend files are produced when a process ends abnormally. The information contained in an abend file helps the IBM Support Center to diagnose and fix the problem.

"Using the DUMP command on z/OS"
Follow the steps in this task to use the DUMP command on z/OS.

Related reference:

"Dumps" on page 6877
Under exceptional circumstances, Windows MiniDumps, UNIX core dumps, or z/OS SVC or core dumps might be produced.

"Abend files" on page 6880
When a process does not end normally an abend file is generated.

Using the DUMP command on z/OS

Follow the steps in this task to use the DUMP command on z/OS.

About this task

z/OS You might be asked to dump any or several of the following address spaces for IBM to resolve the problem:

- Control address space
- DataFlowEngine address space
- OMVS kernel address space

The following procedure demonstrates how to dump the DataFlowEngine address space. This procedure is the same for any of the address spaces.

Procedure

1. Find the address space ID of the address space that you want to dump using the display command on the z/OS syslog:

   ```
   D OMVS,U=your started task user ID
   ```

   This command displays the address spaces of all the processes that are running from your started task user ID, for example:

   ```
   D OMVS,U=MQ01BRK
   BPXO040I 16.14.30 DISPLAY OMVS 237
   OMVS     000D ACTIVE          OMVS=(14)
   USER     JOBNAME  ASID        PID       PPID STATE   START     CT_SECS

   MQ01BRK  MQ01BRK  009D   67306064   84083282 HRI--- 15.41.55     48.37
     LATCHWAITPID=         0 CMD=bipservice MQ01BRK AUTO
   MQ01BRK  MQ01BRK  009D   84083282          1 1WI--- 15.41.55     48.37
     LATCHWAITPID=         0 CMD=/argoinst/S000_L30307_P/usr/lpp/mqsi/bin
   MQ01BRK  MQ01BRK  009D   16974444   67306064 HRI--- 15.42.01     48.37
     LATCHWAITPID=         0 CMD=bipbroker MQ01BRK
   MQ01BRK  MQ01BRK  009F   16974445          1 1W---- 15.42.05   2914.22
     LATCHWAITPID=         0 CMD=/argoinst/S000_L30307_P/usr/lpp/mqsi/bin
   MQ01BRK  MQ01BRK  009F   33751662   16974445 HR---- 15.42.05   2914.22
     LATCHWAITPID=         0 CMD=DataFlowEngine MQ01BRK ca614eec-f300-000
   ```

   The infrastructure main program bipimain is the first process in every address space. For a control address space, bipimain starts the bipservice process, which

starts the bipbroker process, which might also start the biphttplistener process, depending on the configuration. For a DataFlowEngine address space, bipimain starts the DataFlowEngine process. For each execution group, an additional DataFlowEngine address space is started. In this example, only one execution group is deployed.

2. Use the z/OS DUMP command to dump the DataFlowEngine address space, which is shown in the above example as 9F.
   a. Enter the following command:

      ```
      DUMP TITLE=(DFE)
      ```

      The console returns:

      ```
      *`15 IEE094D SPECIFY OPERAND(S) FOR DUMP COMMAND
      ```

   b. Enter:

      ```
      R 15,ASID=9F,CONT
      ```

      The console returns:

      ```
      *16 IEE094D SPECIFY OPERAND(S) FOR DUMP COMMAND
      ```

   c. Enter:

      ```
      R 16,SDATA=(CSA,RGN,PSA,SQA,LSQA,LPA,TRT,GRSQ,SUM),END
      ```

      The console returns:

      ```
      IEE600I REPLY TO 16 IS;SDATA=(CSA,RGN,PSA,SQA,LSQA,LPA,TRT,GRSQ,SUM),END
      IEA794I SVC DUMP HAS CAPTURED: 356

      IEF196I         DSN (SYS3.DUMP.ARG5.#MASTER#.T142958.S00014      )
      IEF196I         STORCLAS (SMS) MGMTCLAS (DUMP) DATACLAS (        )
      IEF196I         VOL SER NOS= ARGSMR
      ```

      The dump is stored in either a pre-allocated dump data set called SYS1.DUMPxx, or an automatically allocated dump data set named according to an installation-specified pattern.

3. In some scenarios, all address spaces for a given broker, that is, all those listed in the example above, plus the OMVS address space and dataspaces, are needed by IBM to resolve the problem. Use the z/OS DUMP command to dump all MQ01BRK address spaces.
   a. Enter the command:

      ```
      DUMP TITLE=(ALL)
      ```

      The console returns:

      ```
      `15 IEE094D SPECIFY OPERAND(S) FOR DUMP COMMAND
      ```

   b. Enter:

      ```
      R 15,JOBNAME=(OMVS,MQ01BRK),DSPNAME=('OMVS'.*),SDATA=(PSA,SQA,LSQA,RGN,TRT,
        LPA,CSA,GRSQ,SUM,NUC)
      ```

      The console returns:

      ```
      IEE600I REPLY TO 15 IS;JOBNAME=(OMVS,MQ01BRK),DSPNAME=('OMVS'.*),S
      IEA794I SVC DUMP HAS CAPTURED: 303
      DUMPID=040 REQUESTED BY JOB (*MASTER*)
      DUMP TITLE=ALL
      IEE853I 13.40.40 SYS1.DUMP TITLES 306
      SYS1.DUMP DATA SETS AVAILABLE=000 AND FULL=000
      CAPTURED DUMPS=0001, SPACE USED=00000447M, SPACE FREE=00001053M
          DUMP.MVK4.#MASTER#.D030415.T134007.S00039 DATA UNAVAILABLE WHILE
      ```

```
        BEING DUMPED TO
IEA611I COMPLETE DUMP ON DUMP.MVK4.#MASTER#.D030415.T134007.S00039 309
DUMPID=040 REQUESTED BY JOB (*MASTER*)
FOR ASIDS(000D,009D,009F)
```

Results

You can also find information on the individual thread by issuing the **DISPLAY** z/OS console command, as in the example:

```
D OMVS,PID=83886535
```

Under exceptional circumstances, Windows MiniDumps, UNIX core dumps, or z/OS SVC or core dumps might be produced.

"Abend files" on page 6880
When a process does not end normally an abend file is generated.

Checking for abend files

Abend files are produced when a process ends abnormally. The information contained in an abend file helps the IBM Support Center to diagnose and fix the problem.

About this task

The following list contains examples of what might cause the broker to produce an abend file:

Procedure

- The broker runs out of memory.
- A user-defined extension causes an instruction in the broker process that is not valid.
- An unrecoverable error occurs in the broker.

Results

Abend files are never produced during normal operation. If an abend file is produced, contact the IBM Support Center for assistance.

Contacting your IBM Support Center

If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

About this task

Before you contact your Support Center, use the checklist shown here to gather important information. Some items might not be relevant in every situation, but provide as much information as you can to enable the IBM Support Center to re-create your problem. You can also use the "IBM Support Assistant Data Collector" on page 3565 to help with data collection.

For WebSphere Message Broker:

- The product version.
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or LinuxUNIX operating system syslog entries, and any abend or dump files from the *install_dir*\errors directory on Windows, or the /var/mqsi/errors directory on LinuxUNIX. Obtain user trace log files at debug level for all relevant message flows and preferably format them. Also include any requested service trace files.

  To send files from distributed systems, create a compressed file using any compression utility.

  To send a file from the file system to IBM, use **tar** to compress the file. For example `tar -cx -f coredump.0002009E coredump.toibm`. To send

MVS data sets to IBM, terse them using `TRSMAIN`, which you can download from z/OS tools download.

- A list of the components installed. Include details of the number of computers and their operating systems, the number of brokers and the computers on which they are running, and the existence and details of each User Name Server.
- The compressed file obtained by exporting your workspace and appropriate message flows and message sets. This action is performed from the WebSphere Message Broker Toolkit.
- Details of the operation that you were performing, the results that occurred, and the results that you were expecting.
- A sample of the messages that were being used when the problem arose
- If relevant, the report file from the C or COBOL importer. This file is located in the directory from which the file import was attempted.
- If you are using tagged delimited wire format on message sets, the TDS log files.

For WebSphere MQ:

- The product version.
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or Linux and UNIX operating system syslog entries and First Failure Support Technology™ (FFST™) output files. You can find these files, which have the extension `.fdc`, in the errors subdirectory in the WebSphere MQ home directory.
- Details of WebSphere MQ client software, if appropriate.

For each database that you are using:

- The product and release level (for example, DB2 9.1).
- Any fix packs applied.
- Any interim fixes applied.
- All current trace and error logs, including relevant Windows Event log or Linux and UNIX operating system syslog entries, for example the `db2dialog.log` file on DB2. Check the database product documentation for details of where to find these files.
- Definitions of any database tables.
- Any ODBC traces.

Windows **For Windows:**

- The version.
- The Service Pack level.
- The environment settings.

UNIX **For Linux and UNIX operating systems:**

- The product version. You can find the version installed by using the **`uname -a`** command.
- Any service level and patches that have been applied.
- The environment settings.

z/OS **For z/OS:**

- The product version

- The list of PTFs that have been applied
- The environment settings
- The job logs from all address spaces

Use the **mqsireadlog** command to retrieve trace records for the specified component.

“**mqsireporttrace** command” on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

IBM Support Assistant Data Collector

You can collect diagnostic documents by using IBM Support Assistant Data Collector, and submit a problem report to IBM. IBM Support Assistant Data Collector is included with your WebSphere Message Broker installation.

About this task

You might have other versions of IBM Support Assistant, but if you run the commands provided in the following topics, you will collect the appropriate information for WebSphere Message Broker.

Procedure

- "Collecting data in console mode with IBM Support Assistant Data Collector"
- "Selecting a problem collector for IBM Support Assistant Data Collector" on page 3568

What to do next

Note: The IBM Support Assistant Data Collector is not supported for z/OS.

Related concepts:

"Selecting a problem collector for IBM Support Assistant Data Collector" on page 3568
You can use the problem collectors installed with IBM Support Assistant Data Collector to gather diagnostic information.

Chapter 13, "Troubleshooting and support," on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

Collecting data in console mode with IBM Support Assistant Data Collector

You can use the IBM Support Assistant Data Collector in console mode to collect diagnostic documents for submission to IBM.

Before you begin

Before you start:

Before contacting IBM Software Support, ensure that your company has an active IBM software subscription and support contract, and that you are authorized to submit problems to IBM. See "Contacting IBM Software Support" on page 3571 for more details.

About this task

Procedure

To run the IBM Support Assistant Data Collector and collect diagnostic documents, complete the following steps:

1. Ensure that the WebSphere Message Broker run time variables are set correctly for your environment by using the **mqsiprofile** command. See "Environment variables after installation" on page 3642 for more information.
2. At a command prompt, enter the **mqsidc** command.

   Note: You can ensure that the script is executable by entering the following command to change the file permissions: **chmod 755 mqsidc**

   The IBM Support Assistant Data Collector starts in console mode.
3. Start the data collection. Available options are presented as numbered lists.
   a. Type a file name for saving the collected data, or press Enter to generate a unique file name.
   b. At the input field prompts, type the number of the required option and press Enter.
4. Choose a data transfer method.
   a. Type the number of the required option for transferring the diagnostic documents to IBM and press Enter. The available options are:
      1) Send the documents to IBM Software Support using secure transfer (HTTPS). You require a problem management record (PMR) number obtained through IBM Software Support.
      2) FTP the documents to IBM Software Support (unencrypted). You require a PMR number obtained through IBM Software Support. This option is less secure than option i.
      3) FTP the documents to another location (unencrypted). You are required to provide a target FTP location and appropriate authentication to access the documents.
      4) End the collection without sending.

      If you choose any of the first three options above, you are required to enter additional information to complete the upload.
   b. Type the number of the required option to confirm the data collection.

   When the IBM Support Assistant Data Collector completes, a .zip file is created at the location specified during the collection. You can extract the compressed files and examine the collected data by using a suitable tool.

What to do next

Note: The IBM Support Assistant Data Collector is not supported for z/OS.

Related concepts:

Chapter 13, "Troubleshooting and support," on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

Selecting a problem collector for IBM Support Assistant Data Collector

You can use the problem collectors installed with IBM Support Assistant Data Collector to gather diagnostic information.

Note: Before you can use the problem collectors, WebSphere Message Broker must have installed successfully, and an **mqsiprofile** must exist which you can start successfully (see "Environment variables after installation" on page 3642 for more information).

Generic problem collector
The generic problem collector gathers configuration information about WebSphere Message Broker, operating system details, WebSphere MQ levels, environment details, the application event log, and the syslog.

Broker problem collector
The broker problem collector gathers information about the broker's deployed configuration, the standard system logs (STDOUT and STDERR) for its components (admin agent, ExecutionGroup, and httplistener), and abend files. This problem collector also gathers the diagnostic data collected by the generic problem collector.

Related tasks:

Chapter 13, “Troubleshooting and support,” on page 3345
If you are having problems with your message flow applications, use the techniques described in this section to help you to diagnose and solve the problems.

Searching knowledge bases

If you have a problem with your IBM software, you want it resolved quickly. Begin by searching the available knowledge bases to determine whether the resolution to your problem is already documented.

Procedure

1. **Search the information center**

   IBM provides extensive documentation in the form of online information centers. An information center can be installed on your local machine or on a local intranet. An information center can also be viewed on the IBM Web site. You can use the powerful search function of the information center to query conceptual and reference information as well as detailed instructions for completing tasks.

2. **Search the Internet**

   If you cannot find an answer to your question in the information center, search the Internet for the latest, most complete information that might help you resolve your problem, including:

   - IBM technotes
   - IBM downloads
   - IBM Redbooks publications
   - IBM developerWorks
   - Forums and newsgroups
   - Internet search engines

Getting product fixes

A product fix might be available to resolve your problem. You can determine what fixes are available from the IBM support site.

About this task

To determine what fixes are available from the IBM support site:

1. Open the WebSphere Message Broker support web page.
2. Click **Downloads**, then **Recommended fixes**. This web page provides links to the latest available maintenance for the in service WebSphere Message Broker family of products.

To receive weekly email notifications about fixes and other news about IBM products, follow these steps.

Procedure

1. From the support site (WebSphere Message Broker support web page), locate the **Notifications** box in the center of the page.
2. If you are not signed in, click **Sign in to create, manage or view your subscriptions**. If you have not registered, click **register now** on the sign-in page and follow the on-screen instructions.
3. Click **Manage my subscriptions**.
4. Click the **Subscribe** tab. A list of products families is shown.
5. In the Software column, click **WebSphere**. A list of products is shown.
6. Select the product for which you want to receive notifications (for example, **WebSphere Message Broker**), then click **Continue**.
7. Set options to determine what notifications you receive, how often you receive them, and to which folder they are saved, then click **Submit**.

Contacting IBM Software Support

IBM Software Support provides assistance with product defects.

About this task

Before you contact IBM Software Support, you must ensure that your company has an active IBM software subscription and support contract, and that you are authorized to submit problems to IBM. The type of software subscription and support contract that you need depends on the type of product that you have:

- For IBM distributed software products (including, but not limited to, Tivoli, Lotus®, and Rational products, as well as DB2 and WebSphere products that run on Windows or UNIX operating systems), enroll in Passport Advantage in one of the following ways:
  - Online: Go to the Passport Advantage web page and click **How to Enroll**.

  - By telephone: For the telephone number to call in your country, go to the Software Support Handbook, click **Contacts**, then **Worldwide contacts**.
- For customers with Subscription and Support (S & S) contracts, go to the Open service request web page.
- For customers with IBMLink, CATIA, Linux, S/390®, iSeries, pSeries, zSeries, and other support agreements, go to the IBM Support Line web page.
- For IBM eServer™ software products (including, but not limited to, DB2 and WebSphere products that run in zSeries, pSeries, and iSeries environments), you can purchase a software subscription and support agreement by working directly with an IBM marketing representative or an IBM Business Partner. For more information about support for eServer software products, go to the Support for IBM Systems web page.

If you are not sure what type of software subscription and support contract you need, call 1-800-IBMSERV (1-800-426-7378) in the United States or, from other countries, go to the contacts page of the Software Support Handbook and click the name of your geographic region for telephone numbers of people who provide support for your location.

Follow the steps in this topic to contact IBM Software Support:

Procedure

1. "Determine the effect of the problem on your business"
2. "Describe your problem and gather background information" on page 3573
3. "Submit your problem to IBM Software Support" on page 3573

Determine the effect of the problem on your business

About this task

When you report a problem to IBM, you will be asked to supply a severity level. Therefore, you need to understand and assess the effect on your business of the problem that you are reporting. Use the following criteria:

Severity 1
: **Critical** effect on business: You are unable to use the program, resulting in a critical effect on operations. This condition requires an immediate solution.

Severity 2
: **Significant** effect on business: The program is usable but is severely limited.

Severity 3
: **Some** effect on business: The program is usable with less significant features (not critical to operations) unavailable.

Severity 4
: **Minimal** effect on business: The problem has little effect on operations, or a reasonable workaround to the problem has been implemented.

Describe your problem and gather background information

About this task

When you are explaining a problem to IBM, be as specific as possible. Include all relevant background information so that IBM Software Support specialists can help you to solve the problem efficiently. To save time, know the answers to these questions:

- What software versions were you running when the problem occurred?
- Do you have logs, traces, and messages that are related to the problem symptoms? IBM Software Support is likely to ask for this information.
- Can the problem be re-created? If so, what steps led to the failure?
- Have any changes been made to the system? (For example, hardware, operating system, networking software, and so on.)
- Are you currently using a workaround for this problem? If so, be prepared to explain it when you report the problem.

Submit your problem to IBM Software Support

About this task

You can submit your problem in one of two ways:

- Online: Go to the Software Support Handbook and enter your information into the appropriate problem submission tool.
- By telephone: For the telephone number to call in your country, go to the contacts page of the Software Support Handbook and click the name of your geographic region for telephone numbers of people who provide support for your location.

The IBM Support Assistant Data Collector can be used to submit diagnostic documents if you have an existing problem management record (PMR). For more information, see “IBM Support Assistant Data Collector” on page 3565.

If the problem that you submit is for a software defect or for missing or inaccurate documentation, IBM Software Support might create an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Software Support provides a workaround for you to implement until the APAR is resolved and a fix is delivered.

IBM publishes resolved APARs on the IBM product support Web pages daily, so that other users who experience the same problem can benefit from the same resolutions.

"Dealing with problems" on page 3363
Learn how to resolve some of the typical problems that can occur.

"Contacting your IBM Support Center" on page 3563
If you cannot resolve problems that you find when you use WebSphere Message Broker, or if you are directed to do so by an error message generated by WebSphere Message Broker, you can request assistance from your IBM Support Center.

Recovering after the broker fails

Check what recovery procedures are available, according to what has failed.

Before you begin

Try to get to the root of the problem first, using the diagnosis techniques described throughout the Chapter 13, "Troubleshooting and support," on page 3345 section of the information center. If your problem cannot be resolved using these techniques, contact your IBM Support Center. Use the procedure in this section only as a last resort.

If you are able to recover, and can start the broker again, the broker attempts to recover and re-establish all sessions with CMP applications that were active at the time of failure. CMP applications include the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit, and applications that you have written to this API.

About this task

If you cannot correct the current problem by using problem determination, complete the following sequence of operations to re-create the broker:

Procedure

1. Stop the broker by using the **mqsistop** command.
2. Stop the broker queue manager by using the **endmqm** command.
3. Delete the broker by using the **mqsideletebroker** command.
4. Re-create the broker by using the **mqsicreatebroker** command.
5. Start the broker by using the **mqsistart** command.
6. Redeploy all resources to the broker.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

"Deleting a broker" on page 930
Delete a broker using the command line on the system where the broker component is installed.

"Recovering after failure" on page 3574
Follow a set of procedures to recover after a serious problem.

Related reference:

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Recovering after an execution group fails

Follow the steps in this task to recover if an execution group fails.

Before you begin

Try to get to the root of the problem first, using the diagnosis techniques described throughout the Chapter 13, "Troubleshooting and support," on page 3345 section of the information center. If your problem cannot be resolved using these techniques, contact your IBM Support Center. Use the procedure in this section only as a last resort.

About this task

If a single execution group fails, and the problem cannot be corrected using problem determination, or by the IBM Support Center, perform the following sequence of operations to re-create the execution group:

Procedure

1. Delete the execution group.
2. Create an execution group of the same name.
3. Redeploy the configuration.

What to do next

If more than one execution group fails, you might need to re-create the broker. See "Recovering after the broker fails" on page 3575 for information on how to do this.

Related tasks:

"Recovering after failure" on page 3574
Follow a set of procedures to recover after a serious problem.

"Recovering after the broker fails" on page 3575
Check what recovery procedures are available, according to what has failed.

Recovering after the broker's queue manager fails

Check what recovery procedures are available, according to what has failed.

Before you begin

Try to get to the root of the problem first, by using the diagnosis techniques described throughout the Chapter 13, "Troubleshooting and support," on page 3345 section of the information center. If your problem cannot be resolved by using these techniques, contact your IBM Support Center. Use the procedure in this section only as a last resort.

About this task

If the broker's queue manager fails and cannot be corrected by using problem determination, or by the IBM Support Center, perform the following sequence of operations to re-create the queue manager:

Procedure

1. Ensure that no WebSphere Message Broker Toolkit users are deploying to the broker. You must wait until any such actions have completed.
2. Stop the broker by using the **mqsistop** command.
3. Delete the broker by using the **mqsideletebroker** command, with the **-q** parameter to remove the queue manager.
4. Re-create the broker by using the **mqsicreatebroker** command. The **mqsicreatebroker** command creates the queue manager and default queues automatically.
5. Re-create any specific queues that are needed for your message flows.
6. Start your brokers by using the **mqsistart** command.
7. Redeploy all resources to the broker to ensure that its configuration is consistent.

Use the **mqsistop** command to stop the specified component.

Chapter 14. Reference

Use the reference information in this section to accomplish the tasks that address your business needs.

Migration and upgrade

Consider the factors involved in the migration of components and resources from Version 6.0 or Version 6.1 to Version 7.0.

This section contains the following topics:

Related concepts:

Chapter 4, "Installing and uninstalling," on page 231
Install and uninstall WebSphere Message Broker components and service.

Related tasks:

Chapter 3, "Migrating and upgrading," on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Supported migration paths

You can migrate to WebSphere Message Broker Version 7.0 from previous versions of the product.

You cannot migrate from the Windows on x86 product (any version) to the Windows on x86-64 product. Similarly, you cannot migrate from the Linux on x86 product (any version) to the Linux on x86-64 product. You must re-create the brokers from scratch.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

From ...	You can migrate to ...
WebSphere Message Broker [1]	WebSphere Message Broker Version 7.0
WebSphere Message Broker with Rules and Formatter Extension	WebSphere Message Broker Version 7.0[2]
WebSphere Message Broker Version 6.0[3]	WebSphere Message Broker Version 7.0

From ...	You can migrate to ...
WebSphere Message Broker with Rules and Formatter Extension Version 6.0[3]	WebSphere Message Broker Version 7.0[2]
WebSphere Event Broker Version 6.0[3]	• WebSphere MQ Version 7.0.1[4] • WebSphere Message Broker Version 7.0
WebSphere Event Broker Version 6.0[3]	• WebSphere MQ Version 7.0.0.1[5] • WebSphere Message Broker Version 7.0
WebSphere Message Broker with Rules and Formatter Extension Version 6.0[3]	• WebSphere Message Broker Version 7.0.0.1 or later[2] • WebSphere Message Broker with Rules and Formatter Extension Version 7.0[2]
WebSphere Message Broker with Rules and Formatter Extension [3]	• WebSphere Message Broker Version 7.0.0.1 or later[2] • WebSphere Message Broker with Rules and Formatter Extension Version 7.0[2]

Notes:

1. You can migrate WebSphere Message Broker at Fix Pack 3 (Version 6.1.0.3) or later. You must upgrade your Version 6.1 installation to use WebSphere MQ Version 7.0.1 before migration.

   If you are using WebSphere Application Server with WebSphere Message Broker, or you have publish/subscribe applications that use the SubIdentity option, you must upgrade WebSphere Message Broker to Fix Pack 4 before you can migrate to WebSphere Message Broker Version 7.0.
2. You can migrate to WebSphere Message Broker Version 7.0 only if you do not use the additional features provided by Rules and Formatter, or you choose not to use them after migration. If you want to use the additional features provided by Rules and Formatter, you need to migrate to WebSphere Message Broker Version 7.0.0.1 or later, with WebSphere Message Broker with Rules and Formatter Extension Version 7.0.
3. You can migrate Version 6.0 products at Fix Pack 9 (Version 6.0.0.9) or later for runtime components, and Version 6.0.2 or later for the WebSphere Message Broker Toolkit. You must upgrade your Version 6.0 installation to use WebSphere MQ Version 7.0.1 before migration.

   If you are using WebSphere Application Server with WebSphere Message Broker, or you have publish/subscribe applications that use the SubIdentity option, you must upgrade WebSphere Message Broker Version 6.0 or WebSphere Event Broker Version 6.0 to Fix Pack 10 before you can migrate to WebSphere Message Broker Version 7.0.
4. If you use only publish/subscribe functions with WebSphere Event Broker Version 6.0, your typical migration path is to WebSphere MQ Version 7.0.1. This migration path is handled completely by WebSphere MQ; see the *Migration* section of the WebSphere MQ Version 7 Information Center online.
5. If you use only publish/subscribe functions with WebSphere Event Broker Version 6.0, your typical migration path is to WebSphere MQ Version 7.0.0.1. This migration path is handled completely by WebSphere MQ; see the *Migration* section of the WebSphere MQ Version 7 Information Center online.

System requirements

Use the reference information in this section to understand the hardware, software, and license requirements.

- “Hardware requirements” on page 3582
- “Software requirements” on page 3588
- “License requirements” on page 3606

The product readme file `readme.html` might contain updates to the information in this chapter. The readme file includes information pertinent to all components and platforms, and is maintained in US English on the product readmes web site:

`www.ibm.com/support/docview.wss?uid=swg27006913`

You must check this file to ensure that you have the latest information. Translated readme files are available on the documentation FTP site:

`ftp://public.dhe.ibm.com/software/integration/wbibrokers/docs/`

A readme file is included with the product; it contains a minimum level of information and directs you to the online version. It is available in these locations:

- Before installation, on the product media.

  The readme file is included in location `\readmes\locale\` (where *locale* identifies country, region, or language, for example `en_US`) on all of the following disks:
  - DVD (on Linux on x86, Linux on x86-64, and Windows only)
  - WebSphere Message Broker component Disk 1 (all operating systems)
  - WebSphere Message Broker component Disk 2 (Windows only)
  - WebSphere Message Broker Toolkit Disk 1
- After installation, in the installation directory:
  - For runtime components, in *install_dir*`\readmes\locale\` (where *locale* identifies country, region, or language, for example `en_US`).
  - For the WebSphere Message Broker Toolkit, in *package_group_directory*`\wmbt\documentation\locale\` (where *locale* identifies country, region, or language, for example `en_US`).

For further support information, including latest fixes and troubleshooting techniques, visit the WebSphere Message Broker support web page:

`www.ibm.com/software/integration/wbimessagebroker/support/`

The supported hardware and software environments are updated occasionally; view the latest requirements information about the WebSphere Message Broker Requirements web site:

`www.ibm.com/software/integration/wbimessagebroker/requirements/`

WebSphere Message Broker Requirements

Supported processors:

WebSphere Message Broker is supported on multiple processors.

The hardware requirements for each supported operating system are given in the following table. All support statements assume that the stated systems can run the required level of a compatible operating system and have enough storage for the WebSphere Message Broker components that you install, and all prerequisite products.

Table 31. Hardware requirements

Operating system	Requirements[1]
AIX	64-bit IBM System p systems Any hardware from IBM or other vendors that can run trademarked AIX systems[2]
HP-Itanium	Itanium systems
Linux on POWER	64-bit System i® and System p IBM POWER processor-based systems only
Linux on x86	IBM eserver System x or equivalent Intel-based servers[3]
Linux on x86-64	AMD64, EM64T, or compatible processor servers[3]
Linux on IBM z Systems	Any server capable of running one of the supported Linux on IBM z Systems releases
Solaris on SPARC	Sun Microsystems SPARC processor servers
Solaris on x86-64	AMD64, EM64T, and compatible processor servers
Windows 32-bit	Windows x86 technology-compatible PC hardware[3]
Windows 64-bit	AMD64, EM64T, or compatible processor servers[3]
z/OS[4]	Any server capable of running one of the supported z/OS releases

Notes:

1. Always check the WebSphere Message Broker Requirements web site and the `readme.html` file for the latest information about supported processors.

   The `readme.html` file that is supplied on the product DVD or CD (for all components) provides a minimum level of information, and directs you to the online file on the product readmes web page, which is updated regularly. Always use the online file to check that you have the latest level of information.
2. You can use AIX systems only if they have passed a set of verification tests for compliance with the AIX application binary and programming interfaces.
3. The WebSphere Message Broker Toolkit is supported on 32-bit and 64-bit systems. It requires a computer with an Intel Pentium III processor (or higher) that has a speed of at least 700 MHz. This specification is the minimum supported level; for improved performance use a 2 GHz processor.

A minimum display resolution of at least 1024 x 768 is required for some dialogs (for example, the Preferences dialog).

4. For further information, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

Related tasks:

WebSphere Message Broker requires additional software products to run successfully.

Related information:

WebSphere Message Broker Requirements

Memory and disk space requirements:

Check the memory and disk space that is required for your installation.

Requirements for memory and disk space depend on the installation operating system, and on the WebSphere Message Broker components and other products that you are installing.

Distributed systems

- 512 MB of RAM is required to support runtime operations (1 MB equals approximately 1 000 000 bytes).
- 512 MB of RAM is required to support WebSphere Message Broker Toolkit operations on Linux on x86, Linux on x86-64, or Windows. This specification is the minimum supported level; for improved performance, provide 1 GB (1 GB equals approximately 1 000 000 000 bytes).
- 512 MB of RAM is required to support the WebSphere Message Broker Explorer.
- Disk space requirements are dependent on the components that you install and the working space that is required by those components (for example, for WebSphere MQ queues and persistent messages).

  Check that your computer has at least the space shown in the table, which provides guidance for both permanent product requirements and temporary space. Check that these requirements have not been updated in the latest product readme file `readme.html`.

  If the installation directory and the temporary space are on the same partition or drive, add the two figures to check that you have enough space available. If you do not, increase the available storage or change the location of either the temporary space or the installation directory. The temporary files are deleted when installation is complete.

– On AIX, HP-UX, and Linux systems, the default temporary space directory is `/tmp`.
– On Solaris systems, the default temporary space directory is `/var/tmp`.
– On Windows, the default temporary space directory is pointed to by the *TEMP* system variable. On some systems, the variable *TMP* exists and is used before *TEMP*, therefore you must check or change the setting of both these variables.

The installation wizard displays requirements for permanent space, but not for temporary space. If the figure that the installation wizard displays is greater than the figure shown in the following tables, check that your computer has sufficient space before you continue with the installation.

Table 32. Disk space requirements (Linux and Windows systems)

Component / product	Linux on POWER	Linux on x86[1]	Linux on x86-64	Linux on IBM z Systems	Windows 32-bit[1]	Windows 64-bit[1]
Broker component	520 MB plus 330 MB temporary space	456 MB plus 330 MB temporary space	477 MB plus 330 MB temporary space	469 MB plus 330 MB temporary space	495 MB plus 330 MB temporary space	538 MB plus 330 MB temporary space
WebSphere Message Broker Toolkit	Unavailable	1.6 GB plus 1.6 GB temporary space	1.9 GB plus 220 MB temporary space	Unavailable	1.6 GB plus 1.6 GB temporary space	1.9 GB plus 220 MB temporary space
WebSphere Message Broker Explorer	Unavailable	250 MB plus 300 MB temporary space	250 MB plus 300 MB temporary space	Unavailable	200 MB plus 250 MB temporary space	200 MB plus 250 MB temporary space
WebSphere Message Broker ODBC Database Extender (IE02)	90 MB plus 90 MB temporary space	80 MB plus 80 MB temporary space	75 MB plus 75 MB temporary space	80 MB plus 80 MB temporary space	Unavailable	Unavailable

Note:

1. The space required for the WebSphere Message Broker Toolkit includes space for the shared resources directory and the package group directory.

Table 33. Disk space requirements (UNIX)

Component / product	AIX	HP-Itanium	Solaris on SPARC	Solaris on x86-64
Broker component	710 MB plus 330 MB temporary space	960 MB plus 330 MB temporary space	620 MB plus 330 MB temporary space	620 MB plus 330 MB temporary space
WebSphere Message Broker Toolkit	Unavailable	Unavailable	Unavailable	Unavailable
WebSphere Message Broker Explorer	Unavailable	Unavailable	Unavailable	Unavailable
WebSphere Message Broker ODBC Database Extender (IE02)	80 MB plus 80 MB temporary space	200 MB plus 200 MB temporary space	130 MB plus 130 MB temporary space	130 MB plus 130 MB temporary space

- On computers on which you create a broker, up to 60 MB is required for the broker configuration data within your file system.

- If you create user databases that are accessed by message flows, additional space is required on those computers.
- If you intend to create more than one broker on any one computer, you require additional memory and swap space. For example, you might create more than one broker at different versions to complete migration. Plan for 1 GB RAM and 1 GB of swap space for each broker, in addition to the space and memory requirements of other applications.

  You must increase these figures if you deploy complex message flows to the brokers, or if you process large messages (of many megabytes), or complex messages that contain many different tags.

z/OS Details are given in "Disk space requirements on z/OS." You must also check for later updates to this information in the section about DASD storage requirements in the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

"Uninstalling" on page 331
Remove the Broker component, the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer from your computer.

Related reference:

"System requirements" on page 3581
Use the reference information in this section to understand the hardware, software, and license requirements.

"Disk space requirements on z/OS"
The installation of WebSphere Message Broker for z/OS uses approximately 400 MB of disk space; plan on using 500 MB to allow for the component directories, and for new service fixes to be applied.

Disk space requirements on z/OS:

The installation of WebSphere Message Broker for z/OS uses approximately 400 MB of disk space; plan on using 500 MB to allow for the component directories, and for new service fixes to be applied.

When you apply service, if you do not replace your existing installation (for example, you apply the new fix pack level alongside your existing installation), you must plan the same amount of disk space for the higher service level libraries.

If you are transferring the files by using *tar* to package them, you need approximately 200 MB of space for the `.tar` file.

You can check how much space is used and how much is free in a file system by using the OMVS command:

```
df -P /pathname
```

100 MB is 3 276 800 512 byte sectors.

The following table gives guidance on the space required for a minimum installation (base installation and verification test) of WebSphere Message Broker for each component implemented on z/OS.

Component	Space required	Purpose
Component directory	20 MB	Holds the runtime-deployed configuration information and output directories for the component. This information includes all deployment information, such as ESQL, JAR files, message sets, XSLT files, and so on. This information also includes WebSphere Message Broker trace files and other user problem determination data, which might become large. Consideration must be given to the potential size of deployments to the WebSphere Message Broker runtime environment and, therefore, the size of this directory (including sub directories).
Component PDSE	1 MB	Holds the customization and administration jobs, procedures, and data for the component. The data set must be allocated with a fixed record length of 80 (`LRECL=80`) and a format of FB 80. Reserve directory space for 50 members, or use a PDSE if possible.
Started task user ID home directory	8 GB	Collects diagnostic materials: for example, dumps. Dumps are usually more than 500 MB in size. 8 GB of space must be available in the file system, but many user IDs can have their home directory in the file system.

The Component directory and the Started task user ID home directory must be separate to ensure that, when dumps are taken in the Started task user ID home directory, they do not cause problems with the runtime broker that still has to write to the Component directory.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

"Using the file system on z/OS" on page 596
If you have more than one MVS image, consider how you will use the file system. You can share files in a file system with different members of a sysplex. The file system is mounted on one MVS image and requests to the file are routed to the owning system using XCF from systems which do not have it mounted.

Communications:

Your system must have communications hardware that supports the protocols that brokers can use.

Choose one or more of the following protocols:
- NetBIOS
- SNA LU 6.2
- SPX
- TCP/IP

Related information:

WebSphere Message Broker Requirements

Support for 32-bit and 64-bit platforms:

WebSphere Message Broker operates in 32-bit mode or 64-bit mode, on supported operating systems.

The following table shows support for 32-bit and 64-bit mode. Changes since Version 6.1 are summarized beneath the table. If support on your platform has changed, you might need to make additional changes to your configuration. See "Migrating from Version 6.1 products" on page 163 and Chapter 7, "Configuring brokers for test and production environments," on page 579 for further details.

Table 34. Support for 32-bit and 64-bit operation

Platform	WebSphere Message Broker internal components and commands	32-bit execution groups	64-bit execution groups
AIX[1]	64-bit	No	Yes
HP-Itanium	64-bit	No	Yes
Linux on POWER	64-bit	No	Yes
Linux on x86	32-bit	Yes	No
Linux on x86-64[2]	32-bit	Yes	No
Linux on x86-64[2]	64-bit	No	Yes
Linux on IBM z Systems	64-bit	No	Yes
Solaris on SPARC[1]	64-bit	No	Yes
Solaris on x86-64	64-bit	No	Yes
Windows 32-bit	32-bit	Yes	No
Windows 64-bit[2]	32-bit	Yes	No
Windows 64-bit[2]	64-bit	No	Yes
z/OS[1]	64-bit	No	Yes

Changes since Version 6.1:

1. On this platform, you can no longer create or run with 32-bit execution groups. Execution groups can be only 64-bit mode.
2. On the Windows 64-bit and Linux on x86-64 platforms, you can install either the 32-bit or the 64-bit version of WebSphere Message Broker.

Execution groups

You can create an execution group by using one of the following:

- WebSphere Message Broker Toolkit
- WebSphere Message Broker Explorer
- **`mqsicreateexecutiongroup`** command
- CMP

If you do not specify the size of execution group that you require, the size that is created depends on how you create it, and the version of the target broker to which you deploy it. The following default values apply:

- If the target broker is Version 7.0 or later, the execution group is 64-bit except on those platforms that support 32-bit only (Linux on x86, and Windows).

Table 35. Execution group default sizes

Workbench	Command	CMP API	32-bit only platforms	32-bit and 64-bit platforms	64-bit only platforms
Default	no options	`createExecutionGroup(name)`	32-bit	64-bit	64-bit

Operating system requirements:

WebSphere Message Broker is supported on multiple operating systems.

The following operating systems support WebSphere Message Broker V7.0:

- AIX
- HP-Itanium
- Linux on POWER
- Linux on x86
- Linux on x86-64
- Linux on IBM z Systems
- Solaris on SPARC
- Solaris on x86-64
- Windows 32-bit

- Windows 64-bit
- z/OS

The software requirements for these operating systems are defined in the List of supported software for WebSphere Message Broker V7.0 web page.

In all operating environments except z/OS, defect support is available for virtualization environments where they relate to releases that are already supported by WebSphere Message Broker. Unless stated elsewhere in the system requirements, WebSphere Message Broker has not been tested in virtualization environments. WebSphere Message Broker support is therefore unable to assist in issues related to configuration and setup, or issues that are directly related to the virtualization environment itself.

WebSphere Message Broker Requirements

Supported databases:

You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

The information shown here indicates the support for databases on each operating system, valid when the information center was published. However, database support might be enhanced after the release is made available. For the latest information about database support, visit the WebSphere Message Broker Requirements website.

If you run message flows that access data that is held in databases, you must install and configure a supported database. Some data types supported by these databases are not supported by WebSphere Message Broker; for details, see "Data types of values from external databases" on page 5288.

In most environments, the broker and the database server must not be running on the same operating system. For details about local and remote database use, and the restrictions that apply, see "Database locations" on page 3595.

WebSphere Message Broker supports both transactional (XA) and non-transactional connections to databases. You can define an ODBC connection, or a JDBC type 4 connection, or both, to your database instances. XA support is referred to as a globally coordinated message flow.

On a single broker, you can use ODBC XA, or JDBC XA, but not both. This restriction applies to all supported platforms, and to all database servers for which XA is supported.

The following sections give details of this support, and describe restrictions where applicable:

- "ODBC support"
- "JDBC type 4 support" on page 3594

ODBC support

The following table lists the supported database servers for each broker platform for non-XA support. XA connections are supported by most of these servers: See the notes following the table for details.

For the latest details of the versions of the database servers that are supported, visit the WebSphere Message Broker Requirements website.

Unless otherwise stated, the ODBC client code for the database is at the same version and release as the server.

Operating system	DB2[1, 2]	Informix[5]	Microsoft SQL Server	Oracle[1, 3, 4]	solidDB	Sybase[1]

Windows Vista	Supported	Supported[8]	Supported	Supported[8]	Supported[8]	Supported[8]

Operating system	DB2[1, 2]	Informix[5]	Microsoft SQL Server	Oracle[1, 3, 4]	solidDB	Sybase[1]
Windows Server 2008	Supported	Supported[8]	Supported	Supported[8]	Supported[8]	Supported[8]
Windows Server 2008 R2	Supported	Not supported	Supported	Supported[9]	Supported[8]	Not supported
z/OS	Supported	Not supported	Not supported	Not supported	Not supported	Not supported

Notes:

1. XA support:

   Supported releases of DB2, Oracle, and Sybase can participate as a resource manager in a distributed XA transaction, and can be coordinated by WebSphere MQ as the XA Transaction Manager, unless otherwise stated in the following notes. On z/OS, all transactions are coordinated by Recoverable Resource Services (RRS).

   - Additional conditions forWebSphere MQ:
     - If you use WebSphere MQ Version 7 for XA coordination on Windows, you must configure the queue manager to run under the broker service user ID by specifying the **-si** option on the **strmqm** command; for example, `strmqm -si QM_name`
   - Additional conditions for databases:
     - DB2 on i5/OS and OS/400, is not supported for XA connections.
     - If you deploy message flows that access databases, you can define the message flows to be coordinated so that updates to those databases are synchronized with updates to other resources.
     - ODBC drivers for Oracle and Sybase on all relevant systems, and for SQL Server on Linux and UNIX systems, are supplied with WebSphere Message Broker. Alternative drivers are not supported on these systems. For other systems, and for other databases on all systems, obtain these files from your database vendor.
   - Additional conditions for z/OS
     - On z/OS all transactions are globally coordinated by using RRS. As with other platforms you can choose for ODBC database operations to be committed or rolled back irrespective of the success or failure of the message flow transaction as a whole. However only one uncoordinated ODBC database connection per thread is supported.
2. Automatic Client Reroute for DB2 is supported on all platforms.
3. If you install the Oracle Database Server on 32-bit systems, you must also install the Oracle Runtime Client.
4. On all Linux, UNIX, and Windows systems, you can use Oracle RAC (Real Application Clusters) databases. For Oracle RAC XA and non-XA, failover support is limited to the Connect-Time Failover feature only.
5. Each broker system requires only the Client SDK; install the Dynamic Server on the system on which you create databases.

   Large Objects (LOBs) are not supported.
6. On Linux and UNIX systems, you can remotely access an SQL Server database on Windows by using a supplied wire protocol driver.
7. You can configure message flows to access DB2 databases on i5/OS and OS/400 for user data. The message flows can run on all supported broker

platforms. For further details of these restrictions, and for information about the PTFs that are required with DB2 on these operating systems, see “Database locations” on page 3595.

8. Windows 32-bit edition of WebSphere Message Broker only.
9. WebSphere Message Broker for Windows 64-bit is supported only in non-XA environments.

JDBC type 4 support

For non-XA transactions, you can create a JDBC type 4 connection from a broker to all the database servers that are listed in the ODBC support table. Connections are supported from all broker platforms, including z/OS.

For XA connections, the following restrictions apply:

- On distributed platforms, only DB2 and Oracle are supported.
- On z/OS, XA connections are not supported.

JDBC type 4 drivers are not supplied with WebSphere Message Broker; obtain these files from your database vendor. For the latest details of the drivers that are supported, visit the WebSphere Message Broker Requirements website.

- DB2 V9.1 Information Center (distributed systems)
- DB2 Information Center (z/OS)

Database locations:

The broker can access databases set up on the local computer or on a remote server, subject to restrictions.

You can deploy message flows that access user databases to one or more of your brokers.

- You can use a local or remote database for user data, subject to the following restrictions:

  Databases on i5/OS and OS/400

  - You can use only DB2 (UDB) on iSeries (System i) under OS/400 or i5/OS.
  - You must install OS/400 V5R2, or i5/OS V5R3 or V5R4.
  - On Linux, UNIX, and Windows, you can connect using DB2 Connect. On Windows only, you can also use iSeries Access for Windows.
  - You cannot define globally coordinated (XA) transactions.
  - You can call stored procedures only if access to the remote database is provided by DB2 Connect.

  Databases on z/OS

  - You can use only DB2 (UDB) on z/OS.
  - You must use DB2 Connect on Linux, UNIX, and Windows.

    For further details, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

  WebSphere Information Integrator databases

  - You can configure message flows on all distributed systems to access user data in WebSphere Information Integrator for Linux, UNIX, and Windows Version 9.1.

    You can also configure message flows to access user data, by using JDBC only, in WebSphere Information Integrator Classic Federation (IICF) for z/OS Version 9.1, on operating systems for which the WebSphere IICF client code is provided.
  - You can configure message flows on z/OS brokers to access user data, by using JDBC only, in WebSphere Information Integrator Classic Federation for z/OS Version 8.2. This support provides connectivity with the following z/OS data sources:
    - IMS
    - VSAM
    - ISAM
    - Sequential files
    - CA-IDMS
    - CA-Datacom
    - Software AG ADABAS
    - DB2

    Brokers can connect directly to WebSphere Information Integrator Classic Federation for z/OS Version 9.1 by JDBC only.

    Brokers can connect indirectly to WebSphere Information Integrator Classic Federation for z/OS Version 9.1 through an intermediate DB2 system on z/OS. If you use this configuration, only an ODBC CAF (Call Attachment Facility) connection is supported between the broker and DB2; this connection therefore does not support two-phase commit.

You must configure all broker ODBC data resources as either CAF or RRSAF (Recoverable Resource Services Attachment Facility). If you use CAF, database operations are not coordinated by RRS.

- If you use a remote database, you must configure the ODBC connection to the database correctly. Refer to the documentation for the database product that you are using for further information.

See the documentation for the database product that you are using with WebSphere Message Broker to determine the best options for your specific environment and requirements, and information about how to configure remote database access.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"User database connections" on page 2110
User databases contain business data that is written and accessed by deployed message flows. You must create connections from the broker to the user database by using ODBC or JDBC.

WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Sample WebSphere Message Broker ODBC Database Extender (IE02) configuration files:

How you use WebSphere Message Broker ODBC Database Extender (IE02) to load the correct data source driver.

To use extended database support, the following configuration files need to be set up, and be accessible from the environment in which you are running the broker.

solidDB data sources

Client side

odbc.ini file

The `odbc.ini` configuration file is referenced by the environment variable `ODBCUOINI` on Linux and UNIX systems, or in the ODBC configuration on Windows.

The odbc.ini file must present, at least, the following two items for each data source:

- ODBC Data Source Name
- Logical name of the actual ODBC driver being used

For example, on AIX:

```
[ODBC DATA SOURCES]
SOLIDDB_DB=IBM solidDB Datasource

[SOLIDDB_DB]
Description=solidDB Datasource
Driver=solid_db
```

Note that all additional information is ignored.

odbcinst.ini file

The directory containing the odbcinst.ini file is referenced by the environment variable ODBCSYSINI on Linux and UNIX systems, or in the ODBC configuration on Windows.

The odbcinst.ini file must present, at least, the following two items for each data source:

- The logical name of the driver
- The full path to, and name of, the ODBC driver

For example, on AIX:

```
[solid_db]
Driver=<Your solidDB install Directory>/bin/saca5x6465.so
```

solid.ini file

This configuration file is located in the directory referenced by the environment variable SOLIDDIR.

The solid.ini mapping is from the data source name (as defined in ODBCUOINI) to the solidDB connection string.

The connection string takes the form <logical name of the driver> = <physical solidDB connect string>.

The Physical connection string specifies the:

- Protocol
- Machine name or IP address
- Port number to use

For example, on AIX:

```
[Data Sources]
SOLIDDB_DB=tcp my_aix_system 1964
```

Server side

solid.ini file

For example, on AIX:

```
[Data Sources]
SOLIDDB_DB=tcp my_aix_system 1964

[COM]
Listen=tcpip 1964

[SQL]
CharPadding=yes
NumericPadding=yes
```

Related tasks:

"Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02)" on page 682
WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager and this topic describes how you set up and configure the broker to use it.

Additional software requirements:

WebSphere Message Broker requires additional software products to run successfully.

- "WebSphere MQ"
- "Microsoft Visual C++ " on page 3599
- Java runtime environment
- "IBM Installation Manager" on page 3600
- "Browsers" on page 3600

WebSphere MQ

All WebSphere Message Broker components require WebSphere MQ at the minimum supported level shown in the table.

WebSphere MQ Version 7.0.1 (with tailored terms and conditions for use with WebSphere Message Broker) is supplied on DVD on Linux on x86, Linux on x86-64, and Windows only, and on CD on all other platforms. If you have a previous version of WebSphere MQ, you can use the supplied CD or DVD to upgrade your current installation.

A broker requires a WebSphere MQ queue manager. More than one broker cannot share a single queue manager.

Table 36. WebSphere MQ requirements

Operating system	Requirements
All distributed systems[1]	WebSphere MQ Version 7.0.1 (or later)[2, 3]
z/OS[4]	WebSphere MQ Version 7.0.1 (or later) with MQ Java Classes feature

Notes:

1. WebSphere MQ is not required on Linux on x86, Linux on x86-64, or Windows systems on which you install only the WebSphere Message Broker Toolkit.

   You can configure SSL connections between the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer and the broker. To configure an SSL connection you must have an SSL certificate manager installed on the computer on which you have installed the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer. If you choose to use WebSphere MQ to provide SSL management, install either the Client or the Server; both components include IBM Key Management tools.
2. The minimum set of components that you must install are the server and Java Messaging components.

   You can install WebSphere MQ before or after you have installed WebSphere Message Broker.

If you have already installed WebSphere MQ, check that your installation includes the Java Messaging component; add it from the WebSphere MQ media if it is not installed.

If you start the WebSphere MQ installation program directly on any platform, including Windows, select a custom installation and include the server and Java Messaging components.

If you want to use the WebSphere MQ Explorer, the graphical interface that is available on Linux on x86, Linux on x86-64, and Windows only, install the WebSphere Eclipse Platform Version 3.3 and the WebSphere MQ Explorer components. The WebSphere MQ Explorer is a required prerequisite if you want to use the WebSphere Message Broker Explorer.

Other WebSphere MQ components are optional.

3. On Windows, before WebSphere MQ Version 7.1 all configuration information, and most queue manager configuration information, was stored in the Windows registry. From WebSphere MQ Version 7.1 onwards all configuration information is stored in files. See the WebSphere MQ documentation for further information.
4. On z/OS, WebSphere MQ is a mandatory requirement and must be installed before you install WebSphere Message Broker.

   See the *Program Directory for WebSphere Message Broker for z/OS* for further details about required levels of WebSphere MQ.

For details of WebSphere MQ products and supported versions, see the WebSphere MQ product information website.

Microsoft Visual C++

When you install the Windows 64-bit version of WebSphere Message Broker on Windows 7 or Windows Server 2008 R2 only, Microsoft Visual C++ Runtime V10 for 32-bit and for 64-bit are required. The Visual C++ Runtime V10 installers supplied with the product media are in US English only. The installer for the Broker component installs Visual C++ Runtime V10 automatically for you. If you want to install Visual C++ Runtime V10 separately, the installers are on the root of Runtime Disk 1.

If you want to install a multicultural version of this product, which displays a translated installation interface and product license agreement, but is otherwise identical to the US English version, you must download both the required versions that you want from the Microsoft website and install them before you install the WebSphere Message Broker runtime.

JRE

A Java runtime environment (JRE) is required on all platforms:

- On distributed platforms, Java Runtime Environment (JRE) Version 6 is embedded in product components.
- On z/OS, you must acquire and install a JRE. See WebSphere Message Broker Requirements for the latest information on JRE requirements for z/OS.

  For more information, see the *Program Directory for WebSphere Message Broker for z/OS* available on the IBM Publications Center website. In particular, review the information in "Preventative Service Planning".

WebSphere Message Broker supports all JMS providers that conform to the Java Message Service Specification, version 1.1, and requires the minimum JRE levels

stated. You must consider both these factors when you select a JMS provider whose client is embedded in the broker.

Browsers

For best results when viewing the information center from the WebSphere Message Broker Toolkit, use Mozilla 1.4.2 (or later) on Linux on x86 and Linux on x86-64.

On Windows, an embedded browser is launched to view the information center.

Some Linux on x86 and Linux on x86-64 offerings do not install Mozilla by default. If you plan to install the WebSphere Message Broker Toolkit on your Linux on x86 or Linux on x86-64 system, check that a supported version of Mozilla is already installed. If not, install Mozilla from your Linux on x86 or Linux on x86-64 operating system media.

WebSphere Message Broker is supported on multiple operating systems.

Related information:

WebSphere Message Broker Requirements

IBM Installation Manager:

WebSphere Message Broker Toolkit is installed by the IBM Installation Manager.

All Rational products at Version 7.0 or later are installed by IBM Installation Manager, which also controls management, updates, licensing, and uninstallation. The WebSphere Message Broker Toolkit includes some Rational product components, and therefore includes and uses Installation Manager.

The following Rational products are controlled by Installation Manager:

- WebSphere Message Broker Toolkit Version 7.0 or later
- Rational Application Developer (RAD) Version 7.5 or later
- Rational Software Architect (RSA) Version 7.0 or later
- WebSphere Integration Developer (WID) Version 7.0.0.1 or later

Installation Manager is included with the WebSphere Message Broker Toolkit and with the other products in this list. When you first install the WebSphere Message Broker Toolkit (or another listed product), Installation Manager installs itself into a directory that you specify, and then drives the installation of the WebSphere Message Broker Toolkit (or other listed product). If you install another product, Installation Manager detects that it is already installed, and drives only the installation of that product.

The WebSphere Message Broker Toolkit shares certain resources with these other products, if installed; for example, Eclipse features and plug-ins. All common resources that are used by the installed products must be installed into a single directory, which is known as the *shared resources directory*. You are asked to specify the location of this directory when you first install the WebSphere Message Broker Toolkit or another Rational product.

If you install another product, Installation Manager finds the shared resources directory and uses its content during the installation process; you cannot change the location of this directory.

The shared resources directory must be on a drive that is local to this computer; you cannot specify a mapped or remote drive. The drive that you specify for the shared resources directory must be of sufficient size to handle all your expected installations; you cannot change or expand this directory after installation. When you specify the directory during a first installation, specify a new directory to ensure that it does not contain any files that might cause conflicts.

Memory requirements for the WebSphere Message Broker Toolkit are listed in "Memory and disk space requirements" on page 3584. If you plan to install additional Rational products, allow 2 GB for each additional product.

You must also allocate space in another directory in which you can manage the workspace resources that you create for the installed Rational products.

Package groups

When you install the WebSphere Message Broker Toolkit, you are also asked to specify a package group. Products that you install into a single package group share Eclipse features and plug-ins, and these resources are loaded and viewable in a single Eclipse instance. You can choose whether to install a product in a package group with other products, or to install WebSphere Message Broker Toolkit in a new package group.

Each package group is isolated from products in other package groups, although all package groups access a single shared resources directory. You are asked to specify the location for the package group directory; you must specify a new directory for each new package group. All product-specific files are installed into this directory.

You might choose to use separate package groups to install different combinations of the WebSphere Message Broker Toolkit and other Rational products, so that

users can gain access to tailored Eclipse instances. When you install the first product, the first package group is created with the name **IBM WebSphere Message Broker Toolkit**. This name is fixed; you cannot change it.

If you choose to install another product into a new package group, another group is created with the name **IBM Software Development Platform_1**. Each new package group name follows this same naming pattern with the numeric suffix incremented by one.

For example, you might have defined the following package groups:

- **IBM WebSphere Message Broker Toolkit** into which you have installed the WebSphere Message Broker Toolkit and RAD.
- **IBM WebSphere Message Broker Toolkit_1** into which you have installed the WebSphere Message Broker Toolkit and RSA.
- **IBM WebSphere Message Broker Toolkit_2** into which you have installed WID and RSA.

When you start an Eclipse session in one of these package groups, you can access only those resources that are associated with the products installed in that group.

If you install later versions of any of the products in a different package group, the updates are available only in that group. The shared resources directory is also updated with later versions of shared files, which are maintained separately from the original versions and are used only for the upgraded products.

Each Rational product specifies which versions of plug-ins and features it requires, if appropriate. Installation Manager ensures the integrity of these requirements in each package group. If the product that you are currently installing breaks this integrity, Installation Manager prevents the installation into that package group.

Installation Manager also controls uninstallation of the WebSphere Message Broker Toolkit and the other products previously listed; you cannot uninstall Installation Manager until all listed products in all package groups have been removed.

Installation Manager is not required for any of the Broker component prerequisite products, such as WebSphere MQ.

Related information:

WebSphere Message Broker Requirements

Optional software support:

The products listed here are not required, but might be useful. Except where stated, these products are not supplied with WebSphere Message Broker.

- "EIS client libraries"
- "WebSphere Adapters"
- "Tivoli License Manager"
- "Security providers"
- "JMS providers"
- "Compilers" on page 3604
- "Adobe Flash Player" on page 3604
- Citrix XenApp
- "WebSphere Process Server and WebSphere Integration Developer" on page 3604
- "WebSphere Service Registry and Repository" on page 3604

EIS client libraries

If you plan to use WebSphere Adapters on any supported operating system, you must obtain the appropriate Enterprise Information System (EIS) client libraries from the relevant EIS vendor (for example, PeopleSoft, Siebel, or SAP). The client libraries are required to complete connections between Adapters nodes and the EIS; install them on each computer on which you run a broker that hosts message flows that include Adapters nodes.

WebSphere Adapters

For details of the versions of WebSphere Adapters supported by WebSphere Message Broker Version 7.0, visit the WebSphere Message Broker Requirements website. For more information about the hardware and software requirements of WebSphere Adapters, see Supported software for WebSphere Adapters.

Tivoli License Manager

To monitor the use of software products including WebSphere Message Broker, install IBM Tivoli License Manager (ITLM). For the details of the version of ITLM that is required, visit the WebSphere Message Broker Requirements website.

Security providers

The message flow security manager interacts with external security providers:

- Lightweight Directory Access Protocol (LDAP) provides authentication and authorization services. For details of the LDAP version that your LDAP server must support, visit the WebSphere Message Broker Requirements website.
- WS-Trust V1.3 STS providers (including TFIM V6.2) provide authentication, mapping, and authorization services.
- Tivoli Federated Identity Manager (TFIM) V6.1 provides authentication, mapping, and authorization services.

JMS providers

For details of the version of the Java Message Service Specification that the JMSInput and JMSOutput nodes are compatible with, and work with, visit the WebSphere Message Broker Requirements website.

Compilers

C/C++ user-defined extensions that were built with older levels of compilers can be used when migrating an existing broker or setting up a new broker.

However, C/C++ user-defined extensions on Linux might cause problems if linked against libstdc++.so.5 as WebSphere Message Broker is now linked against libstdc++.so.6. Recompile your user-defined extensions using a supported compiler.

For details of the versions of the compilers that are supported, visit the WebSphere Message Broker Requirements website.

Adobe Flash Player

If you want to start the Quick Tour from the information center in the WebSphere Message Broker Toolkit, you must install the Adobe Flash Player. For details of the versions of the Adobe Flash Player that are supported, visit the WebSphere Message Broker Requirements website. You can freely download from the Adobe website an Adobe Flash Player plug-in for the web browsers that are supported by the WebSphere Message Broker Toolkit.

WebSphere Process Server and WebSphere Integration Developer

The SCA nodes allow interoperability with WebSphere Process Server, a business integration server that supports solutions that are based on service-oriented architecture (SOA). Service Component Architecture (SCA) is a specification that describes a model for building applications and systems using SOA and the SCA nodes support scenarios in which service components that run on WebSphere Process Server either are invoked from WebSphere Message Broker or invoke a WebSphere Message Broker message flow. For details of the versions of WebSphere Process Server that are supported by WebSphere Message Broker, visit the WebSphere Message Broker Requirements website.

WebSphere Integration Developer is the development environment for WebSphere Process Server. It is the tool for building and deploying SOA-based integration solutions on WebSphere Process Server. To enable WebSphere Message Broker to interoperate with WebSphere Process Server, SCA import and export components need to be imported into WebSphere Message Broker from WebSphere Integration Developer, and Broker SCA definitions need to be exported from WebSphere Message Broker to WebSphere Integration Developer. For details of the versions of WebSphere Integration Developer that are supported by WebSphere Message Broker, visit the WebSphere Message Broker Requirements website.

WebSphere Service Registry and Repository

WebSphere Service Registry and Repository provides a central repository of documents that describe services, service interfaces, and associated policies. For details of the versions of WebSphere Service Registry and Repository that are supported by WebSphere Message Broker, see the WebSphere Message Broker Requirements website.

Related concepts:

"WebSphere Service Registry and Repository" on page 1875
The WebSphere Service Registry and Repository (WSRR) is a central repository of entities. A wide range of entities can be stored and retrieved, including user-defined concepts and definitions related specifically to Web services, such as

WSDL services, service interfaces, and associated policies.

When you have created the code for your Java user-defined node, you must compile it for your operating system.

Quick Tour

System requirements for Citrix XenApp:

This topic gives information about licensing issues, and the software and hardware that you need to use WebSphere Message Broker in a Citrix XenApp environment.

Operating system

The required operating system is Windows 2003 Server. Client versions of Windows, such as Windows XP, cannot be used because Citrix XenApp requires Terminal Server, which is not available on client versions of Windows.

The recommended version of Windows Server 2003 is Enterprise Edition. You can also use Windows Server 2003 Standard Edition, but you might need to reduce the maximum heap size for the Java virtual machine that is used by the WebSphere Message Broker Toolkit.

Software prerequisites

Citrix XenApp (previously known as Citrix Presentation Server 4.0 or 4.5) and its prerequisites must be installed on the Windows 2003 server.

Hardware prerequisites

The server must have enough CPU, RAM, disk space, and network bandwidth for each concurrent user. Performance depends on the tasks that are being performed, and on the hardware, software and networking setup. As a guide, the server should have a minimum of 1 GB of RAM per concurrent user and at least 4 GB of RAM in total. If the tasks require frequent disk access, it should help performance to have a separate physical disk for each user so that they do not slow each other down.

Licensing

Any number of users can use the WebSphere Message Broker Toolkit through Citrix, provided they all connect only to a Message Broker that has a valid license.

Related concepts:

"Users and Citrix" on page 304
Review the categories of user that might want to use with Citrix, and how to configure for concurrent multi-users.

Related tasks:

"Publishing in a Citrix XenApp environment" on page 302
Supply application location and user details to Citrix to publish a WebSphere Message Broker command console or WebSphere Message Broker Toolkit.

License requirements

Use the reference information in this section to understand license requirements.

You can install WebSphere Message Broker to support a full range of transformation and routing operations. If appropriate, you can install an edition that supports a restricted set of functions, if that subset fulfills your business requirements. You must ensure that your use and configuration of the product conforms to the license agreement that you have purchased:

- WebSphere Message Broker Trial Edition. You can download this edition from the Web, at no charge. This edition has its own license and terms and conditions which is valid for 90 days. You can use all available function, and are not limited in the number of resources that you create and maintain.
- WebSphere Message Broker Starter Edition. If you expect to use all or most of the features that are available, but you configure a limited environment because of low capacity requirements, purchase this edition. You can use all available function, but are limited in the number of resources that you create and maintain.
- WebSphere Message Broker Entry Edition. If you expect to use only a basic set of features and have only low capacity requirements, purchase this edition. You can use a limited set of nodes, and you are limited in the number of resources that you create and maintain.
- WebSphere Message Broker Remote Adapter Deployment. If you expect your typical use of WebSphere Message Broker to be integration with Enterprise Information Systems (EIS), purchase this edition. This edition supports the subset of development resources that provide EIS interaction.
- WebSphere Message Broker. If you want to set up a full broker environment that uses most or all of the features available, you require a full (unrestricted) license.

WebSphere Message Broker for z/OS is unavailable in Remote Adapter Deployment, Starter Edition, Entry Edition, and Trial Edition.

If you choose to change your license agreement from a full license to either of the two specialized licenses, you might find that your current configuration is no longer supported. For further details about what features are available for each license, and how to configure your environment, see "WebSphere Message Broker technical overview" on page 27.

You can upgrade to the full license from another edition, if appropriate, by purchasing another license.

Your license also covers use of the product for development and unit test purposes. All developers in your organization, who are working on resources and applications for WebSphere Message Broker, can install one copy of all components on their computer. They can create and configure a broker environment without any functional or resource restrictions. Installation of the WebSphere Message

Broker Toolkit limits this use to Windows, Linux on x86, and Linux on x86-64 computers. The unit test environment is limited to these three platforms even if you have purchased a license for WebSphere Message Broker for z/OS.

You can also install the supplied WebSphere MQ product on the computers on which your developers create their development and test configurations, regardless of the license agreement that you have purchased.

You can view licenses after installation in your chosen language in directory *install_dir*/license/. Terms and conditions are also supplied for third-party products used by WebSphere Message Broker. The file containing these details is stored in the same license subdirectory when you install one or more runtime components.

Contact your IBM representative if you want further details about license agreements, or if you want to purchase additional licenses or change the type of license that you have purchased.

General industry standards supported by WebSphere Message Broker

WebSphere Message Broker supports general industry standards that are associated with message processing.

Supported standards

The following table details the general standards that are supported by WebSphere Message Broker, with additional comments and supported versions where appropriate.

Standard	Comments or supported releases in Version 7.0
Java	1.6 (Version 6)
SSL	
SOAP	1.1, 1.2
TLS	
WSDL	1.1

Standard	Comments or supported releases in Version 7.0
WS-Addressing	1.0 (Final 2005/08), Submission 2004/08
WS-Security	1.0
XPath	1.0
XSD	1.0
XSLT	1.0

WebSphere Message Broker Requirements

Packaging options

Both physical media and electronic images are available for the installation of WebSphere Message Broker.

Physical media

You can order the physical media for WebSphere Message Broker Starter Edition, Entry Edition, Remote Adapter Deployment, and the full (unrestricted) licenses. Contents are described in "Package contents" on page 3610.

When you install the product from the media, configure your brokers to operate in the mode that conforms to the license you have purchased. See the information center for further details.

Electronic images

If you are registered with IBM Passport Advantage, you can download electronic images from IBM Passport Advantage for WebSphere Message Broker Starter Edition, Entry Edition, Remote Adapter Deployment, and the full (unrestricted) licenses. You can also request one set of the physical media.

The electronic images exactly mirror the physical media that are described in "Package contents" on page 3610, although are not formatted as CD or DVD images. For further information, and to register, access the IBM Passport Advantage website.

Electronic images are available on request for WebSphere Message Broker for z/OS. Contact your IBM representative for further information and assistance.

When you install the product from these images, you must configure your brokers to operate in the mode that conforms to the license that you have purchased. See the information center for further details.

Trial Edition electronic images

For distributed systems only, you can download electronic images for WebSphere Message Broker Trial Edition from the developerWorks WebSphere Message Broker Trial package website.

Images are provided for the Broker component and the WebSphere Message Broker Toolkit. Use this edition to assess how the product can address your business requirements, and explore how you might use it with existing software in your enterprise.

For the latest information about supported trial versions, always check the WebSphere Message Broker `readme.html` file on the product readmes website.

The following restrictions apply:

- All product features are available, but the Broker component operates for only 90 days after installation.
- Electronic images of WebSphere MQ are not included with the WebSphere Message Broker Trial Edition. If you have not already ordered and installed WebSphere MQ, you can download a trial package from the Web. The WebSphere MQ trial versions include the required Java and Eclipse components. Download from the WebSphere MQ Trial package website.
- Physical images are not available for the Trial Edition.
- The Trial Edition is not available for z/OS.

If you choose to buy WebSphere Message Broker during or after the trial period, and want to continue to use the product components that you have installed, you do not have to reinstall them, but you must reconfigure existing brokers, and create new brokers, in the mode that conforms to the license that you have purchased. You can retain all the associated resources that you have developed or imported during the trial period. For further information, see "Changing the operation mode of your broker" on page 655.

Unless otherwise stated in this book, you can use electronic images in the same way as the physical CDs or DVDs, and all installation and set up procedures described are identical for the trial and full packages.

Package contents

Contents of the physical media packages for WebSphere Message Broker Starter Edition, Remote Adapter Deployment, Entry Edition, and the full (unrestricted) licenses. The electronic images that you can download have equivalent content.

Content for the Trial Edition packages is restricted; differences are described where they apply.

The contents of the package depend on the product that you have ordered:

WebSphere Message Broker

The package includes product code for all supported distributed operating systems, plus other optional software and documentation:

- The Quick Start CD, which contains documentation in PDF format. This CD is always at the top of the package. The CD includes the following documentation:
  - PDF files for the Quick Start Guide (US English and translations).
  - PDF files for the Installation Guide (US English and translations).
- A plastic wallet that contains four DVDs, one for Linux on x86, one for Linux on x86-64, one for Windows 32-bit, and one for Windows 64-bit. The DVDs contains all required and optional product code. The structure of the DVD content is described in "DVD package" on page 3616.

  The WebSphere Message Broker Toolkit package is contained on the DVDs. For more information about the contents of the WebSphere Message Broker Toolkit package, see "Toolkit package" on page 3614.
- A set of plastic wallets that contain CDs for installation of the broker, grouped by operating system, for systems other than Linux on x86, Linux on x86-64, and Windows. The CDs are listed in "The Broker component and WebSphere Message Broker Explorer package" on page 3611.
- The Quick Start Guide, printed in US English, French, and Japanese.

WebSphere Message Broker for z/OS

The package includes product code for the z/OS operating system on tape, plus other optional software and documentation. In addition, you receive WebSphere Message Broker for Linux on x86, Linux on x86-64, and Windows, because the WebSphere Message Broker Toolkit is available only on those operating systems.

The electronic images that you can download have equivalent content.

- A plastic wallet that contains four DVDs, one for Linux on x86, one for Linux on x86-64, one for Windows 32-bit, and one for Windows 64-bit. The DVDs contain all required and optional product code. The structure of the DVD content is described in "DVD package" on page 3616.

  The WebSphere Message Broker Toolkit package is contained on the DVDs. For more information about the contents of the WebSphere Message Broker Toolkit package, see "Toolkit package" on page 3614.
- z/OS tapes

  For information about tapes supplied with WebSphere Message Broker for z/OS, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

WebSphere Message Broker Requirements

The Broker component and WebSphere Message Broker Explorer package:

The Broker component and WebSphere Message Broker Explorer packages contain CDs and images supplied for WebSphere Message Broker and associated products.

The contents listed in the following table are supplied for installation of the Broker component. WebSphere MQ images are not included in the Trial Edition.

On Linux on x86, Linux on x86-64, and Windows, the product code is delivered on DVD. The structure of the DVD content is described in "DVD package" on page 3616. On these operating systems, the following table shows the contents of the downloaded images.

The physical package for the DVD is marked with the symbol 

.

On operating systems other than Linux on x86, Linux on x86-64, Windows, and z/OS, the product code is delivered on CD.

The physical packages for the CDs are marked with the symbol 
.

Table 37. CDs and images supplied for WebSphere Message Broker and associated products

Operating System[1]	CD label	Description
AIX	WebSphere Message Broker Version 7.0 AIX (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 AIX (Runtime Disk 2)	Product code

Linux on POWER	WebSphere Message Broker Version 7.0 Linux on POWER (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Linux on POWER platform (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]
Linux on x86	WebSphere Message Broker Version 7.0 Linux on x86 (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Linux on x86 (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]
Linux on x86-64	WebSphere Message Broker Version 7.0 Linux on x86-64 (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Linux on x86-64 platform (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]
Linux on IBM z Systems	WebSphere Message Broker Version 7.0 Linux on IBM z Systems (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Linux on IBM z Systems platform (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]
Solaris on SPARC	WebSphere Message Broker Version 7.0 Solaris (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Solaris (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]
Solaris on x86-64	WebSphere Message Broker Version 7.0 Solaris on x86-64 (Runtime Disk 1)	Product code[2]
	WebSphere MQ Version 7.0.1 Solaris on x86-64 (Runtime Disk 2)	Product code
	WebSphere Message Broker ODBC Database Extender (IE02) (Runtime Disk 1)	Product code[2]

Table 37. CDs and images supplied for WebSphere Message Broker and associated products (continued)

Operating System[1]	CD label	Description
Windows 32-bit	WebSphere Message Broker Version 7.0 Windows 32-bit (Runtime Disk 1)	Product code[3]
	WebSphere MQ Version 7.0.1 Windows 32-bit (Runtime Disk 2)	Product code[4]
Windows 64-bit	WebSphere Message Broker Version 7.0 Windows 64-bit (Runtime Disk 1)	Product code[3]
	WebSphere MQ Version 7.0.1 Windows 64-bit (Runtime Disk 2)	Product code[4]

Notes:

1. On all operating systems, the CDs and images for WebSphere MQ (Runtime Disk 2) are not included in the Trial Edition. You must obtain prerequisite software from other sources to support the Trial Edition of WebSphere Message Broker. See "Additional software requirements" on page 3598 for more information.
2. Disk 1 for all Linux and UNIX systems includes the following resources:
   - WebSphere Message Broker installation files.
   - WebSphere Message Broker Explorer installation file (Linux on x86 and Linux on x86-64 only).
   - WebSphere Message Broker ODBC Database Extender (IE02) (Linux and UNIX only).
   - License files. These files are used by the installation wizard and are supplied in all supported languages.
   - The readme file in English and supported languages. The `readme.html` file contains late updates about the product and its documentation. The latest version of the readme file is available in English only on the product readmes web page. The readme file that is included on the product media contains a link to the latest version on the product readmes web page.
   - The *Installation Guide* PDF file in English and supported languages. The *Installation Guide* PDF file is available after a major release of the information center, such as Version 7.0. If significant changes are accumulated between major releases, the *Installation Guide* PDF file is refreshed and provided in English, on the customer FTP site and the Library web page. The PDF file content is the same as the content that is provided in the information center at the time of publish. However the PDF file documentation is updated less frequently than the information center. For the latest information, see the "Installation" on page 3581 and "Installing" on page 231 sections in the online information center.
   - Sample scripts. Use the sample response files to run the silent interface to install and uninstall components.
3. Disk 1 for Windows includes the following resources:
   - WebSphere Message Broker installation files.
   - WebSphere Message Broker Explorer installation file.
   - The Launchpad.
   - The Quick Tour stand-alone executable program.
   - License files. These files are used by the installation wizard and are supplied in all supported languages.
   - The readme file in English and supported languages. The `readme.html` file contains late updates about the product and its documentation. The latest version of the readme file is available in English only on the product

readmes web page. The readme file that is included on the product media contains a link to the latest version on the product readmes web page.
- The *Installation Guide* PDF file in English and supported languages. The *Installation Guide* PDF file is available within a quarter of a year after a major release of the information center, such as Version 7.0, or when significant changes are accumulated. The PDF file content is the same as the content that is provided in the information center at the time of publish. However the PDF file documentation is updated less frequently than the information center. For the latest information, see the "Installation" on page 3581 and "Installing" on page 231 sections in the online information center.
- Sample scripts. Use the sample response files to run the silent interface to install and uninstall components.

4. The Launchpad and stand-alone Quick Tour are also included on Disk 2 on Windows.

WebSphere Message Broker Requirements

Toolkit package:

Contents of the Toolkit package.

The Toolkit package is supplied on the product DVDs for installation of the WebSphere Message Broker Toolkit. The structure of the DVD content is described in "DVD package" on page 3616.

The Toolkit package contains three directories, called disk1, disk2, and disk3. The contents of the disks in shown in the following table.

Table 38. DVD and images supplied for WebSphere Message Broker Toolkit

Operating System	Directory	Description
Linux on x86	disk1	• Product code • Installation Manager[1] • Additional resources[2]
	disk2	Product code
	disk3	Product code

Table 38. DVD and images supplied for WebSphere Message Broker Toolkit (continued)

Operating System	Directory	Description
Linux on x86-64	disk1	• Product code • Installation Manager[1] • Additional resources[2]
	disk2	Product code
	disk3	Product code
Windows 32-bit	disk1	• Product code • Installation Manager[1] • Additional resources[2]
	disk2	Product code
	disk3	Product code
Windows 64-bit	disk1	• Product code • Installation Manager[1] • Additional resources[2]
	disk2	Product code
	disk3	Product code

Notes:

1. Installation Manager is installed only if it does not exist on the target computer; this product is required to manage the WebSphere Message Broker Toolkit installation.
2. Disk 1 includes the following additional resources:
   - Readme files. The `readme.html` files contain late updates about the product and its documentation and are supplied in all supported languages.
   - Installation Guides. PDF files of the Installation Guide are supplied in all supported languages to which it has been translated.
   - Sample scripts. Use these sample response files to run the silent interface to install and uninstall components.
   - On Windows only, the Launchpad.
   - On Windows only, the Quick Tour stand-alone executable program.

   These files are identical to the equivalent files described in "The Broker component and WebSphere Message Broker Explorer package" on page 3611.

DVD package:

Use the DVD package to install the Broker component, the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, WebSphere MQ Version 7.0.1, and WebSphere Message Broker ODBC Database Extender (IE02) (Linux and UNIX only).

DVDs (type DVD-R, size DVD-5) are supplied only for Linux on x86, Linux on x86-64, and Windows. The DVD labels are WebSphere Message Broker Version 7.0 Linux on x86, WebSphere Message Broker Version 7.0 Linux on x86-64, WebSphere Message Broker Version 7.0 Windows 32-bit, and WebSphere Message Broker Version 7.0 Windows 64-bit.

DVD images are not included in the Trial Edition.

The physical package is marked with the symbol 

.

The DVDs contain code for the following products:
- Broker component
- WebSphere Message Broker Toolkit
- WebSphere Message Broker Explorer
- WebSphere MQ Version 7.0.1
- WebSphere Message Broker ODBC Database Extender (IE02) (Linux and UNIX only)

If you use the Launchpad to install on Windows, as described in "Installing by using the Windows Launchpad" on page 262, the Launchpad navigates the DVD to find the products and components that you have chosen to install; therefore, you do not need to be familiar with the structure of the DVD contents.

If you install on Linux on x86, Linux on x86-64, or Windows, and choose not to use the Launchpad, use the DVD structure shown in the following table to find what you need.

Table 39. DVD contents

Directory	Description
\ (root)	• WebSphere Message Broker installation files • (Windows only) Launchpad and Quick Tour[1]
\ie02	WebSphere Message Broker ODBC Database Extender (IE02) (Linux and UNIX only)
\installation_guide	Installation Guides[3, 4]
\license	License files[3]
\Message_Broker_Toolkit_V7.0	WebSphere Message Broker Toolkit installation repository [2]
\MBExplorer	WebSphere Message Broker Explorer installation repository
\readmes	Readme files[3]
\sample-scripts	Sample response files[3]
\WebSphere_MQ_V7.0.1	WebSphere MQ installation images

Notes:

1. This item is a stand-alone executable version of the Quick Tour, which is available only on Windows. On Linux on x86, Linux on x86-64, and Windows, you can access the Quick Tour from the WebSphere Message Broker Toolkit.
2. This directory contains WebSphere Message Broker Toolkit installation repository and Installation Manager. The version of the Installation Manager in this directory is specific to the target operating system.
3. The files in this directory are identical to the equivalent files described in "The Broker component and WebSphere Message Broker Explorer package" on page 3611.
4. On Linux on x86 and Linux on x86-64, this directory has two subdirectories: one for US English and one for translated PDF files.

Installation and uninstallation interfaces

You can use different interfaces for installation and uninstallation of the Broker component and the WebSphere Message Broker Toolkit.

When you install or uninstall the Broker component, you can choose a graphical, console, or silent interface. These options are described in "How to install and uninstall the Broker component" on page 3618.

When you install or uninstall the WebSphere Message Broker Toolkit, you can choose a graphical or silent interface. These options are described in "How to install and uninstall the WebSphere Message Broker Toolkit" on page 3623.

Examples of commands in the topics in this section use *installer* and *uninstaller* for the names of the installation or uninstallation wizard. Substitute the correct names for the platform on which you are using the wizard. Unless otherwise specified, you can use the examples for uninstalling components, or applying service; the same format is used for all three operations.

How to install and uninstall the Broker component

You can install and uninstall the Broker component by using one of three interfaces.

- "Graphical interface"
- "Console interface" on page 3619
- "Silent interface" on page 3619

Each interface has different advantages, which are discussed in the appropriate sections. When you have chosen the interface that you want to use, complete the following steps:

- Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.
- If you have multiple broker installations on your system, see "How to uninstall multiple installations of the Broker component" on page 3620.
- Follow the installation instructions in "Installing" on page 231 (for a new installation or to install service to existing components), or in "Uninstalling" on page 331 (for product components and service).

Graphical interface

The installation and uninstallation wizards open a graphical interface if you start them with no options (the default interface). The wizards guide you through the installation or uninstallation process with a series of pages that present options and defaults. You can accept the default values, or change them to suit your environment and requirements.

The graphical interface provides the highest level of information and guidance. Use this interface when you are unfamiliar with the product, or to monitor progress.

If you click **Cancel** before the Install Progress or Uninstall Progress panel appears, you can exit the setup. If you choose to exit, your system returns to the state that it was in before the wizard was started. However, if you cancel the installation wizard after installation or uninstallation has completed, and the final summary panel is displayed, your system is not restored to its previous state; the wizard stops immediately. If you want to remove any program that has been installed, invoke the uninstallation wizard.

When you use the wizards, you might have to wait a few seconds to move to the next panel after clicking **Next**. Progress is not always displayed on all panels. If you click **Next** twice, you might skip an entire panel. To ensure that the installer or uninstaller is progressing, monitor your processor usage, which increases greatly during both installation and uninstallation.

Console interface

The console interface is a character-based interface with which you interact in a command window. It presents the same options as the graphical interface.

Use the console interface if you want a command-line or text interface rather than a graphical interface. This interface is suitable for users who use only the keyboard to choose values and navigate through installation, and those users with screen reader software, such as JAWS.

Invoke the installer by using the following command. Use the same format for the uninstaller.

```
installer -console
```

Use these prompts to navigate through the wizard:

- 1 Move to the next panel
- 2 Return to the previous panel
- 3 Cancel and terminate the wizard
- 4 Redisplay the current screen

The default option is always displayed within brackets, for example [1]. If this default option is the correct choice, press Enter to continue.

Silent interface

Use the silent interface for automated installation or uninstallation over many identical systems. If you start a silent installation or uninstallation, the wizard runs without any interaction. Using this interface, the process is completed with default options, or according to a predefined set of options. The silent interface does not provide any feedback to the caller, therefore you must view the log to check whether the action was successful.

If you use the silent interface to uninstall the Broker component, the wizard always uninstalls components from the last known Version 7.0 installation location (that is, the most recent installation), regardless of the location of the uninstallation wizard that you invoke. To remove components from an earlier Version 7.0 installation, use the console or graphical interface.

You can perform a silent installation in the following ways:

- With default options:

  The installation wizard performs the following actions:
  - Checks that prerequisite software is installed
  - Installs to the default directory
  - Installs all selectable features

  Because the installation wizard checks for prerequisite software by using the silent interface, the program fails if the prerequisite software is not already installed. You can override this check if you use a response file (see “Using

response files with the Broker component" on page 3621), or include the appropriate parameter with a non-default value on the command invocation.

The uninstallation wizard performs the following actions:
– Removes all selectable features

To run the wizard with default options, specify the `-silent -G licenseAccepted=true` options on the command:

```
installer -silent -G licenseAccepted=true
```

- With one or more non-default options:

  If you want the wizard to use non-default values for one or more options, specify non-default options either on the command invocation, or in a response file, as described in "Using response files with the Broker component" on page 3621.

  A sample response file is provided in the `sample-scripts` directory of the root CD or DVD directory. This file includes detailed information about the options that you can change, and the values that you must enter to change them. Tailor this file to match your requirements, or generate a new response file.

  To run a tailored silent installation using a response file called `response1.txt`, specify the `-silent` option and the file name on the command:

  ```
  installer -silent -G licenseAccepted=true -options response1.txt
  ```

"Installation and uninstallation authorization" on page 3628
Check the authorization requirements for the user ID that you use to install or uninstall the Broker component and the WebSphere Message Broker Toolkit.

How to uninstall multiple installations of the Broker component:

Uninstalling the Broker component when you have multiple installations.

If you install the same version and release of the Broker component on a single computer (for example, Version 7.0) more than once, the installer support provided by the operating system cannot manage these installations in the normal way.

If you later want to uninstall one of the multiple installations, use the uninstallation program *uninstaller* in the `_uninst_runtime` directory of the specific installation that you want to remove, not the facilities provided by the operating system.

You can view the `install.properties` file to see current installations and their locations, and check the operating system representation:

AIX The first installation is recorded as mqsi*vr*, for example `mqsi70`. Subsequent installations at the same *vr* level are displayed under the first one when you list installed products with **`lslpp`**. If you use **`smitty`** and **`geninstall`** to manage those subsequent installations, results are unpredictable.

Linux, HP-UX, and Solaris
The first installation is recorded as mqsi/*vr*, for example `mqsi/70`. Subsequent installations at the same *vr* level are recorded as mqsi/*vr*-2, and so on.

Windows
The most recent installation that you completed for any given version and release is displayed in **Add/Remove Programs**. No other installations are shown here. Similarly, the **Command Console** option in the **Start** menu is that associated with the most recent installation for any given version and release.

If you uninstall the product at a specific version and release listed by **Add/Remove Programs**, earlier installations that you completed on the computer are not reinstated in that view.

To uninstall other instances, navigate to the directory that contains the uninstallation program. For details of uninstallation tasks, see the information center.

Using response files with the Broker component:

You can use a response file to define the behavior of an installation or uninstallation wizard that is running the silent interface.

A response file is a text file that contains options that define the choices that the wizard makes. You can use response files to install or uninstall the Broker component, or to apply service updates by using non-default values.

- "Editing the sample response files"
- "Recording a response file" on page 3622
- "Generating response files" on page 3622
- "Calling response files in commands" on page 3622

Editing the sample response files:
A sample response file is supplied. On Linux and UNIX systems, the file is `/sample-scripts/install.opt`. On Windows, the file is `\sample-scripts\install.opt`. The sample response files include detailed information about the options that you can change, and the values that you can enter to change them. You can tailor the file to match your requirements.

A number sign (#) at the start of a line denotes a comment. Remove the comment character to enable the line.

You must remove the comment character at the start of the following line. If you do not remove this character, your other options are ignored.

```
#    -W setupTypes.selectedSetypTypeId=
```

Some examples of how you can modify the installation response file follow:

- To accept the product license:

  ```
  -G licenseAccepted=true
  ```

- Choose a custom installation (typical is the default option):

  ```
  -W setupTypes.selectedSetupTypeId=custom
  ```

- Install to a non-default directory.

  Find the following line, remove the number signs, and insert your chosen installation directory:

  ```
  ### -P installLocation=new_location
  ```

- Specify whether the program is to check for prerequisite software.

  Add the following line to the file to instruct the installation wizard to ignore the check for WebSphere MQ:

  ```
  # don't check for WebSphere MQ
  -P mqPrerequisite.active=false
  ```

Recording a response file:
Use the following command to record a response file:

```
installer -options-record responsefile
```

where *responsefile* is the full path and name of your chosen response file. On Windows, surround the path and name with quotation marks if it contains spaces ("response file"). Create this file in a directory different from the one in which the product is installed.

The installation wizard starts its graphical interface and records your responses as it progresses. When installation is complete, the response file contains all the choices that you have made during installation.

If you want to record a response file during a console installation, use the following command:

```
installer -options-record responsefile -console
```

Generating response files:
Use the following command to generate a template installation response file. The wizard does not perform installation or uninstallation when you start it with these options:

```
installer -options-template responsefile
```

where *responsefile* is the full path and name of your chosen response file. On Windows, surround the path and name with quotation marks if it contains spaces. If you are uninstalling, create the response file in another directory to ensure that it is not deleted as part of the uninstallation.

The generated template response file contains full instructions on how to edit it to specify your required options.

To generate a response file during a console installation, use the following command:

```
installer -options-template responsefile -console
```

Calling response files in commands:
Use the following command to run the silent interface with a response file:

```
installer -options responsefile -silent
```

where *responsefile* is the full path and name of your chosen response file. On Windows, surround the path and name with quotation marks if it contains spaces.

The wizard runs, taking its input from the response file.

How to install and uninstall the WebSphere Message Broker Toolkit

Install and uninstall the WebSphere Message Broker Toolkit by using one of two interfaces.

- "Graphical interface"
- "Silent interface" on page 3624

Each interface has different advantages, which are explained in the appropriate sections. When you have chosen the interface that you want to use:

- Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.
- Before installing WebSphere Message Broker Toolkit on Linux, check that the default permissions are set correctly by running the following command under a user ID with root authority:

  ```
  umask
  ```

  A value of *0022* should be returned, indicating the permissions are correctly set. If any other value is returned, set the correct permissions by running the following command:

  ```
  umask 0022
  ```

- Follow the installation instructions in "Installing" on page 231 (for a new installation or to install service to existing components), or in "Uninstalling" on page 331 (for product components and service).

Graphical interface

The installation and uninstallation wizards open a graphical interface if you start them with no options (the default interface). The wizards guide you through the installation or uninstallation process with a series of pages that present options and defaults. You can accept the default values, or change them to suit your environment and requirements.

The graphical interface provides the highest level of information and guidance. Use this interface when you are unfamiliar with the product, or to monitor progress.

If you click **Cancel** before the Install Progress or Uninstall Progress panel appears, you can exit the setup. If you choose to exit, your system returns to its state that it was in before the wizard was started. However, if you cancel the installation wizard after installation or uninstallation has completed, and the final summary panel is displayed, your system is not restored to its previous state: the wizard stops immediately. If you want to remove any program that has been installed, start the uninstallation wizard.

When you use the wizards, you must wait a few seconds to move to the next panel after clicking **Next**. Progress is not always displayed on all panels. If you click **Next** twice, you might skip an entire panel. To ensure that the installer or uninstaller is progressing, you can monitor your processor usage, which increases greatly during both installation and uninstallation.

Silent interface

Use the silent interface for automated installations over many identical systems. If you start a silent installation or uninstallation, the wizard runs without any interaction; the process is completed with default options, or according to a predefined set of options. The silent interface does not provide any feedback to the caller; therefore, you must check the log to determine whether the action was successful.

You can run a silent installation with default settings, or with one or more non-default values:

- With default settings, the installation wizard performs the following actions:
  - Installs to the default directories
  - Installs all supported locales

  To run a default silent installation, change the path to the `/Message_Broker_Toolkit_V7.0/disk1` directory of the local or remote DVD, or the network drive, and run the following command:

  Linux **Linux on x86**

```
installToolkit-silent.sh
```

  Windows **Windows**

```
installToolkit-silent.bat
```

- With one or more non-default settings, the wizard applies the options that you specify in a response file to determine what actions to take.

  If you want the wizard to use non-default values for one or more options, specify a recorded response file, as described in "Using response files with the WebSphere Message Broker Toolkit" on page 3625.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

"Applying service to the WebSphere Message Broker Toolkit" on page 325
Apply maintenance updates and program fixes to the WebSphere Message Broker Toolkit.

"Uninstalling the WebSphere Message Broker Toolkit" on page 340

"Installation and uninstallation interfaces" on page 3617
You can use different interfaces for installation and uninstallation of the Broker component and the WebSphere Message Broker Toolkit.

"Installation and uninstallation authorization" on page 3628
Check the authorization requirements for the user ID that you use to install or uninstall the Broker component and the WebSphere Message Broker Toolkit.

Using response files with the WebSphere Message Broker Toolkit:

Specify a response file to define the behavior of the installation or uninstallation wizard.

You can use response files to install or uninstall the WebSphere Message Broker Toolkit, or to apply service updates.

- "Editing the sample response files"
- "Recording a response file"
- "Calling response files in commands"

Editing the sample response files:
A sample response file `mbtoolkit-silent.xml` is supplied on Linux on x86 and Windows. The files assume that IBM Installation Manager has not yet been installed, and sets options to install both Installation Manager and the WebSphere Message Broker Toolkit in the default locations.

Although you can tailor these files to match your requirements, for example by changing the installation locations, the record option on a graphical installation or uninstallation is preferable. If you use the record option, you do not have to modify the file content, which is complex because the files handle multiple installations, directories, and options.

Recording a response file:
Use the following command to record a response file:

- On Linux on x86:

```
./install -record response.xml
```

- On Windows:

```
install.exe -record response.xml
```

where *response.xml* is the full path and name of your chosen response file. On Windows, surround the path and name with quotation marks if it contains spaces. Create this file in a directory different from the one in which the product is installed.

The installation wizard opens its graphical interface, and requires your input as it progresses. Your responses are recorded during installation. When installation is complete, the response file contains all the choices that you have made during installation.

Calling response files in commands:

Use the following command to run the installation wizard with the silent interface and a recorded response file:

- On Linux on x86:

```
./install -nosplash --launcher.suppressErrors -silent -input response.xml
```

- On Windows:

```
install.exe -nosplash --launcher.suppressErrors -silent -input response.xml
```

where *response.xml* is the full path and name of the response file you recorded. On Windows, surround the path and name with quotation marks if it contains spaces.

The wizard runs, taking its input from the response file.

Installation wizard names

View the installation wizards that are used to install the Broker component, the WebSphere Message Broker Toolkit, and the WebSphere Message Broker Explorer.

The installation wizard has a different name on each operating system. To help you find these programs quickly, the names are shown in the following tables.

Installation wizard names for the Broker component

The following table shows the installation wizard names that are used to start the installers for the Broker component.

Table 40. Installation wizard names for the Broker component

Operating system	Installation wizard name
AIX	`setupaix`
HP-Itanium	`setuphpia64`
Linux on POWER	`setuplinuxppc`
Linux on x86	`setuplinuxia32`
Linux on x86-64	`setuplinuxx64`
Linux on IBM z Systems	`setuplinux390`
Solaris on SPARC	`setupsolaris`
Solaris on x86-64	`setupsolarisx64`
Windows 32-bit	`setup.exe`
Windows 64-bit	`setup.exe`

Installation wizard names for WebSphere Message Broker Toolkit

The following table shows the installation wizard names that are used to start Installation Manager that controls the installation of the WebSphere Message Broker Toolkit.

Table 41. Installation wizard names for WebSphere Message Broker Toolkit

Operating system	Installation wizard name
Linux on x86	`install`
Linux on x86-64	`install`
Windows 32-bit	`install.exe`[1]
Windows 64-bit	`install.exe`[1]

Note:

1. You can also use `installc.exe` to start Installation Manager. This program operates synchronously and does not return control to the command line until the installation has completed.

Installation wizard names for WebSphere Message Broker Explorer

The following table shows the installation wizard names that are used to start the installers for the WebSphere Message Broker Explorer.

Table 42. Installation wizard names for WebSphere Message Broker Explorer

Operating system	Installation wizard name
Linux on x86	`install`
Linux on x86-64	`install`
Windows 32-bit	`install.exe`
Windows 64-bit	`install.exe`

You can use different interfaces for installation and uninstallation of the Broker component and the WebSphere Message Broker Toolkit.

Installation and uninstallation authorization

Check the authorization requirements for the user ID that you use to install or uninstall the Broker component and the WebSphere Message Broker Toolkit.

Check that your user ID has the following authority to complete installation or uninstallation tasks:

- On AIX systems, you must log in as root.
- On Linux and other UNIX systems, your user ID must have root authority to complete installation. Follow your local security guidelines to acquire root authority; either log in as root, or log in as another user and become root.
- On all Windows operating systems and editions, your user ID must be a member of the Administrators group.
- On z/OS systems, your user ID must be no more than eight characters in length. It must also have suitable privileges to install in your environment with SMP/E. Use a supported external security manager, for example RACF or ACF2, to grant the required privileges. Your user ID must have a valid OMVS segment, because the product installs into the file system paths specified during the SMP/E APPLY processing.

Multicultural support

Multicultural support is available for a selection of languages on both distributed systems and z/OS.

The user interface and message catalogs are provided in the following languages on distributed systems:

- Brazilian Portuguese
- French

- German
- Italian
- Japanese
- Korean
- Simplified Chinese
- Spanish
- Traditional Chinese
- US English

The message catalogs are provided in the following languages on z/OS:
- Japanese
- Simplified Chinese
- US English

The messages written to the z/OS operator console (which are a subset of the messages written to the syslog) are in US English only, and are written in mixed case or in uppercase depending on your chosen system configuration.

WebSphere Message Broker provides a selection of message catalogs that are used by the product components to report any problems that occur. Products that are used in conjunction with WebSphere Message Broker might cause WebSphere Message Broker to report errors using its message catalogs, or might report problems using their own techniques.

You must refer to the documentation supplied with any other products that you use to determine the process they employ. In particular, you must check the documentation supplied by the databases that you use and documentation provided with any user-defined node or parser that you integrate into the WebSphere Message Broker environment.

You can install WebSphere Message Broker and WebSphere MQ in any supported language; all language versions for each product are compatible with all language versions for the other product. All languages for the WebSphere MQ messaging products are included on the WebSphere MQ server CD or DVD supplied with WebSphere Message Broker.

All messages generated for internal inter-component message exchange (for example, deployed configuration messages and log files for **mqsireadlog**) are generated in code page 1208 (utf-8).

Related tasks:

"Converting code page and message encoding" on page 2476
You can use ESQL within a Compute node to convert data for code page and message encoding.

"Changing locales" on page 819
You can change the locale for the system on which a runtime component is installed.

Locales

Message support is provided in a number of locales.

WebSphere Message Broker supports at least the following locales:

Windows	AIX	Solaris	HP-UX[1]	Linux[2]	z/OS
English (United States)	en_US	en_US	en_US.iso88591, en_US.roman8	en_US	En_US.IBM-1047, En_US.IBM-037

Windows	AIX	Solaris	HP-UX[1]	Linux[2]	z/OS
German (Standard)	de_DE, De_DE	de	de_DE.ISO88591, de_DE.roman8	de_DE	not supported
Spanish (Modern Sort)	es_ES, Es_ES	es	es_ES.ISO88591, es_ES.roman8	es_ES	not supported
French (Standard)	fr_FR, Fr_FR	fr	fr_FR.ISO88591, fr_FR.roman8	fr_FR	not supported
Italian (Standard)	it_IT, It_IT	it	it_IT.ISO88591, it_IT.roman8	it_IT	not supported
Portuguese (Brazilian)	pt_BR, Pt_BR	pt_BR	pt_BR.ISO88591, pt_BR.utf8	pt_BR	not supported
Japanese	Ja_JP, ja_JP	ja_JP.PCK, ja	ja_JP.SJIS, ja_JP.eucJP	ja_JP	Ja_JP.IBM-939, Ja_JP.IBM-930
Simplified Chinese (China)	Zh_CN, zh_CN	zh, zh.GBK	zh_CN.hp15CN	zh_CN	Zh_CN.IBM-1388, Zh_CN.IBM-935
Traditional Chinese (Taiwan)	Zh_TW, zh_TW	zh_TW, zh_TW.BIG5	zh_TW.big5, zh_TW.eucTW	zh_TW	not supported
Korean	ko_KR	ko	ko_KR.eucKR	ko_KR	not supported

Notes:

1. Because of limited syslog support on HP-Itanium operating systems, messages are written to the log in US English only.
2. These values are the same for all Linux systems.

Other locales might be supported; check your operating system for further details.

Related tasks:

"Changing locales" on page 819

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Start and main menu updates after installation

When you install WebSphere Message Broker components on Linux on x86 or Windows, the installation program updates the main or Start menus.

WebSphere Message Broker Toolkit on Linux on x86 running Red Hat

The main menu is populated with the following entries:

- **Programming** > **IBM WebSphere Message Broker Toolkit**
- **Programming** > **IBM Installation Manager**

If you install multiple products with Installation Manager on this operating system, a single entry exists in the main menu and refers to the last product that you installed. The package groups of installed products are not reflected in the main menu. To invoke applications that you installed previously, including other installations of the WebSphere Message Broker Toolkit, you must use the command-line interface.

If you want to start Installation Manager, for example to update or uninstall one or more packages, you cannot use the main menu items, because these actions require root authority. Become root and start the Installation Manager program `/eclipse/IBMIM` in the Installation Manager installation directory on the command line.

WebSphere Message Broker Toolkit on Linux on x86 running SUSE

The main menu is populated with the following entries:

- **All Applications** > **Development** > **IBM WebSphere Message Broker Toolkit**
- **All Applications** > **Development** > **IBM Installation Manager**

If you install multiple products with Installation Manager on this operating system, a single entry exists in the main menu and refers to the last product that you installed. The package groups of installed products are not reflected in the main menu. To invoke applications that you installed previously, including other installations of the WebSphere Message Broker Toolkit, you must use the command-line interface.

If you want to start Installation Manager, for example to update or uninstall one or more packages, you cannot use the main menu items, because these actions require root authority. Become root and start the Installation Manager program `/eclipse/IBMIM` in the Installation Manager installation directory on the command line.

WebSphere Message Broker Toolkit on Windows

The **Start** menu is populated with the following entries:

- **IBM Software Development Platform** > **IBM WebSphere Message Broker Toolkit** > **WebSphere Message Broker Toolkit**
- **IBM Software Development Platform** > **IBM WebSphere Message Broker Toolkit** > **Release Notes**
- **IBM Software Development Platform** > **IBM WebSphere Message Broker Toolkit** > **Start Toolkit Help**
- **IBM Software Development Platform** > **IBM WebSphere Message Broker Toolkit** > **Stop Toolkit Help**

These entries assume that you have installed into the first or default package group. Additional products that you install in this package group might also appear in this start list.

Entries are also added to the **Start** menu when Installation Manager is first installed:

- **Programs** > **IBM Installation Manager** > **IBM Installation Manager**
- **Programs** > **IBM Installation Manager** > **Release Notes**
- **Programs** > **IBM Installation Manager** > **Uninstall IBM Installation Manager**
- **Programs** > **IBM Installation Manager** > **View Installed Packages**

WebSphere Message Broker Explorer on Linux on x86

No additions are made to the main menu on either SUSE or Red Hat Linux systems.

WebSphere Message Broker Explorer on Windows

The **Start** menu is populated with the following entry:

- **Programs** > **IBM WebSphere Message Broker Explorer**

Broker component on Windows

The **Start** menu is populated with the following entries:

- **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console**
- **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **CMP API Documentation**
- **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **CMP API Exerciser**
- **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Java Programming APIs** > **Java Plugin API Documentation**

You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Directory structures after installation

When you install WebSphere Message Broker components, the installation program creates a structure of subdirectories under the directory that you specified as the installation directory. The exact structure depends on the platform on which you have installed WebSphere Message Broker, and the components that you have installed. If you install the WebSphere Message Broker Toolkit, other directories might be created for IBM Installation Manager, the Shared Resources Directory, and the package group in which you install the toolkit.

Platforms covered are:

- "AIX, Solaris on SPARC, and Linux on x86-64 for the 64-bit version of WebSphere Message Broker"
- "HP-Itanium, Linux on POWER, Linux on IBM z Systems, and Solaris on x86-64" on page 3634
- "Linux on x86, and Linux on x86-64 for the 32-bit version of WebSphere Message Broker" on page 3636
- "Windows" on page 3638
- "z/OS" on page 3641

AIX, Solaris on SPARC, and Linux on x86-64 for the 64-bit version of WebSphere Message Broker

On AIX, and Solaris on SPARC, you can install only the broker component.

On Linux on x86-64 for the 64-bit version of WebSphere Message Broker, in addition to the 64-bit broker component, you have the option of installing the 32-bit version of the WebSphere Message Broker Toolkit, and the WebSphere Message Broker Explorer. For more information, see the relevant Toolkit and Explorer sections under "Linux on x86, and Linux on x86-64 for the 32-bit version of WebSphere Message Broker" on page 3636.

The default home directory *install_dir* is `/opt/IBM/mqsi/v.r` or `/opt/ibm/mqsi/v.r`. The default directory includes the version and release of the product, in the format v.r (version.release).

The directories created in *install_dir* are shown in the following table.

Directories under *install_dir*	**Contents**
`_uninst_runtime`	Uninstall programs
`_uninst_runtime_jvm`	Uninstall programs (JVM)
`adapters`	WebSphere Adapters files
`bin`	Executable binary files
`catalina`	Web Services support files
`classes`	Java class files
`DD64`	Symbolic link to the ODBC driver files
`docs`	Java API files

Directories under *install_dir*	Contents
exmltConfig	XML transformation files
include	Header and other files for samples
itlm	Tivoli License Manager files
jplugin	Java plug-in files
jre16	IBM Runtime Environment for the Java Platform Version 6 (also known as Version 1.6)
lib	Shared library files
license	License files
lil	Loadable library files
messages	Description files for messages and exceptions
migration	Migration files
ODBC	ODBC driver and related files
ODBC64	Symbolic link to the ODBC driver files
readmes	Product readme files
sample	C, C++, and Java sample files
SecurityProviders	Security files
webservices	Web Services files
xlxpc	Product library files
xml4c	XML processing files
isadc	IBM Support Assistant Data Collector files

On AIX, Linux on x86-64, and Solaris on SPARC, the working directory is /var/mqsi/. The directories created are shown in the following table.

Directories under /var/mqsi	Contents
common/errors	Error files
common/locks	Resource locks
common/log	Trace files
common/profiles	User profiles
components	Component details
config	User configuration of profiles and shared classes
ODBC64	Symbolic link to the ODBC driver files
registry	Registry information
shared-classes	User installed user-defined node classes
XML	XML files
XSL	XSL style sheets

HP-Itanium, Linux on POWER, Linux on IBM z Systems, and Solaris on x86-64

On HP-Itanium, Linux on POWER, Linux on IBM z Systems, and Solaris on x86-64, you can install only the broker component.

The default home directory *install_dir* is `/opt/IBM/mqsi/v.r` or `/opt/ibm/mqsi/v.r`. The default directory includes the version and release of the product, in the format v.r (version.release).

The directories created in *install_dir* are shown in the following table.

Directories under *install_dir*	**Contents**
`_uninst_runtime`	Uninstall programs
`_uninst_runtime_jvm`	Uninstall programs (JVM)
`adapters`	WebSphere Adapters files
`bin`	Executable binary files
`catalina`	Web Services support files
`classes`	Java class files
`DD64`	Symbolic link to the ODBC driver files
`docs`	Java API files
`exmltConfig`	XML transformation files
`include`	Header and other files for samples
`itlm`	Tivoli License Manager files
`jplugin`	Java plug-in files
`jre16`	IBM Runtime Environment for the Java Platform Version 6 (also known as Version 1.6)
`lib`	Shared library files
`license`	License files
`lil`	Loadable library files
`messages`	Description files for messages and exceptions
`migration`	Migration files
`ODBC`	ODBC driver and related files
`ODBC64`	Symbolic link to the ODBC driver files
`readmes`	Product readme files
`sample`	C, C++, and Java sample files
`SecurityProviders`	Security files
`webservices`	Web Services files
`xlxpc`	Product library files
`xml4c`	XML processing files
`isadc`	IBM Support Assistant Data Collector files

On HP-Itanium, Linux on POWER, Linux on IBM z Systems, and Solaris on x86-64, the default working directory is `/var/mqsi/`. The directories created are shown in the following table.

Directories under /var/mqsi	**Contents**
`common/errors`	Error files
`common/locks`	Resource locks
`common/log`	Trace files
`common/profiles`	User profiles

Directories under /var/mqsi	Contents
components	Component details
config	User configuration of profiles and shared classes
ODBC64	Symbolic link to the ODBC driver files
registry	Registry information
shared-classes	User installed user-defined node classes
XML	XML files
XSL	XSL style sheets

Linux on x86, and Linux on x86-64 for the 32-bit version of WebSphere Message Broker

On this platform, you can install the broker, the WebSphere Message Broker Toolkit, and the WebSphere Message Broker Explorer.

Broker

The default home directory *install_dir* is /opt/ibm/mqsi/*v.r*. The default directory includes the version and release of the product, in the format v.r (version.release).

The directories created in *install_dir* are shown in the following table.

Directories under *install_dir*	Contents
_uninst_runtime	Uninstall programs
_uninst_runtime_jvm	Uninstall programs (JVM)
adapters	WebSphere Adapters files
bin	Executable binary files
catalina	Web Services support files
classes	Java class files
docs	Java API files
exmltConfig	XML transformation files
include	Header and other files for samples
itlm	Tivoli License Manager files
jplugin	Java plug-in files
jre16	IBM Runtime Environment for the Java Platform Version 6 (also known as Version 1.6)
lib	Shared library files
license	License files
lil	Loadable library files
merant	Symbolic link to the ODBC driver files
messages	Description files for messages and exceptions
migration	Migration files
ODBC	ODBC driver and related files
ODBC32	Symbolic link to the ODBC driver files
readmes	Product readme files

Directories under *install_dir*	Contents
sample	C, C++, and Java sample files
SecurityProviders	Security files
webservices	Web Services files
xlxpc	Product library files
xml4c	XML processing files
isadc	IBM Support Assistant Data Collector files

The default working directory is /var/mqsi/. The directories created are shown in the following table.

Directories under /var/mqsi	Contents
common/errors	Error files
common/locks	Resource locks
common/log	Trace files
common/profiles	User profiles
components	Component details
config	User configuration of profiles and shared classes
ODBC64	Symbolic link to the ODBC driver files
registry	Registry information
shared-classes	User installed user-defined node classes
XML	XML files
XSL	XSL style sheets

WebSphere Message Broker Toolkit

The default IBM Installation Manager installation directory is /opt/ibm/InstallationManager. The default Shared Resources Directory is /opt/IBM/SDPShared/. The default package group directory is /opt/IBM/WMBT700. These directories are defined and described in the "Installing the WebSphere Message Broker Toolkit" on page 276.

The directories created are shown in the following tables.

Directories under /opt/ibm/InstallationManager	Contents
eclipse	Eclipse plug-in directories and files
license	License files

Directories under /opt/IBM/SDPShared/	Contents
atoc	Eclipse plug-in directories and files
extra	License files
features	Product files for features installed on this computer
native	

Directories under /opt/IBM/SDPShared/	Contents
plugins	Eclipse plug-in directories and files common to features installed on this computer

Directories under /opt/IBM/WMBT700	Contents
bin	Directories and files for products within the package group
configuration	Configuration files
eclipse	Eclipse files
features	Directories and files for products within the package group
jdk	Java directories and files
lum	License files
plugins	Eclipse plug-ins and related files
ResourceAdapters	Rational directories and files
runtimes	Rational directories and files
samples	Sample response files
uninstall	Product uninstallation files
wmbt	Toolkit files

Other files are also stored by the Installation Manager in the directory /var/ibm/InstallationManager.

WebSphere Message Broker Explorer

Windows

On this platform, you can install the broker, the WebSphere Message Broker Toolkit, and the WebSphere Message Broker Explorer.

Broker

The default home directory *install_dir* is:

- On Windows 32-bit editions: C:\Program Files\IBM\MQSI*v.r*.
- On Windows 64-bit editions:
  - C:\Program Files\IBM\MQSI*v.r* for the 64-bit version of WebSphere Message Broker.
  - C:\Program Files (x86)\IBM\MQSI*v.r* for the 32-bit version of WebSphere Message Broker.

The default directory includes the version and release of the product, in the format v.r (version.release).

The directories created in *install_dir* are shown in the following table.

Directories under *install_dir*	Contents
_uninst_runtime	uninstallation programs
_uninst_runtime_jvm	uninstallation programs (JVM)

Directories under *install_dir*	**Contents**
`adapters`	WebSphere Adapters files
`bin`	Executable binary files
`catalina`	Web Services support files
`classes`	Java class files
`DataDirect`	ODBC driver and related files
`docs`	Java API files
`exmltConfig`	XML transformation files
`include`	Header and other files for samples
`itlm`	Tivoli License Manager files
`jplugin`	Java plug-in files
`jre16`	IBM Runtime Environment for the Java Platform Version 6 (also known as Version 1.6)
`lib`	Shared library files
`license`	License files
`messages`	Description files for messages and exceptions
`migration`	Migration files
`readmes`	Product readme files
`sample`	C, C++, and Java sample files
`webservices`	Web Services files
`WMQFTE`	Files for WebSphere MQ File Transfer Edition.
`isadc`	IBM Support Assistant Data Collector files

The default working directory is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI`
- On Windows Vista and later operating systems: `C:\ProgramData\IBM\MQSI`

The actual value might be different on your computer.

The directories created are shown in the following table.

Directories under *work_dir*	**Contents**
`Common/errors`	Error files
`Common/locks`	Resource locks
`Common/log`	Trace files
`Common/profiles`	User profiles
`components`	Component details
`config`	User configuration of profiles and shared classes
`odbc`	ODBC files
`registry`	Registry information
`shared-classes`	User installed user-defined node classes
`XML`	XML files

Directories under *work_dir*	Contents
XSL	XSL style sheets

WebSphere Message Broker Toolkit

On Windows 32-bit, the default IBM Installation Manager installation directory is C:\Program Files\IBM\InstallationManager, the default Shared Resources Directory is C:\Program Files\IBM\SDPShared\, and the default package group directory is C:\Program Files\IBM\WMBT700.

On Windows 64-bit, the default IBM Installation Manager installation directory is C:\Program Files(x86)\IBM\InstallationManager, the default Shared Resources Directory is C:\Program Files (x86)\IBM\SDPShared*v.r*, and the default package group directory is C:\Program Files (x86)\IBM\WMBT700.

These directories are defined and described in the "Installing the WebSphere Message Broker Toolkit" on page 276.

The directories created are shown in the following tables.

Directories under \IBM\InstallationManager	Contents
eclipse	Eclipse plug-in directories and files
license	License files

Directories under \SDPShared	Contents
atoc	Eclipse plug-in directories and files
extra	License files
features	Product files for features installed on this computer
native	
plugins	Eclipse plug-in directories and files common to features installed on this computer

Directories under \WMBT700	Contents
bin	Eclipse plug-in directories and files
configuration	License files
features	Product files for features installed on this computer
jdk	Java directories and files
lum	License files
plugins	Eclipse plug-in directories and files common to features installed on this computer
ResourceAdapters	Rational directories and files
runtimes	Rational directories and files
samples	Sample response files
uninstall	Product uninstall files
wmbt	Toolkit files

Other files are also stored by the Installation Manager in the following directories:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager` and `C:\Documents and Settings\Administrator\IBM\InstallationManagerInstaller`. Your computer might have a different value for `C:\Documents and Settings`, but the remainder of these paths are fixed.
- On Windows Vista and later operating systems: `C:\ProgramData\IBM\Installation Manager` and `C:\ProgramData\IBM\InstallationManagerInstaller`.

WebSphere Message Broker Explorer

z/OS

The default installation directory is `/usr/lpp/mqsi/`*`VxRxMx`* where *VxRxMx* represents Version X, Release X, Modification X, for example, `V7R0M0`.

For more details about locations, libraries, and file system paths, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

"Software requirements" on page 3588
View the operating system, database, and other software requirements.

Registry changes created by installation and configuration

When you install WebSphere Message Broker, the installation program creates a number of entries in a registry. Further changes are made by some configuration updates (for example, when you create a broker).

Runtime components

On Windows, the ALLUSERPROFILE environment variable is used; on Linux and UNIX systems, equivalent values are stored within the installation directory structure. On all platforms, the environment variable MQSI_REGISTRY is set to point to the exact location. Do not alter or remove these entries unless instructed to do so by your IBM Service representative.

On Windows, some entries are also added to the system registry under `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBCINST.INI` (for 32-bit brokers on 32-bit operating system editions and 64-bit brokers on 64-bit operating system editions) or under `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\ODBC\ODBCINST.INI` (for 32-bit brokers on 64–bit operating system editions); these entries record the installed 32–bit database drivers for Oracle and Sybase, which contain driver locations and parameters.

An entry is also added under the `HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphereMQIntegrator` (for 32-bit brokers on 32-bit operating system editions and 64-bit brokers on 64-bit operating system editions) or under `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\IBM\WebSphereMQIntegrator` (for 32-bit brokers on 64–bit operating system editions).

A final entry is added under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Eventlog\Application\WebSphere Broker v***` for Event Log information, where `v***` is the current three-digit product version number.

WebSphere Message Broker Toolkit

All registry entries are controlled by IBM Installation Manager. On Windows, the system registry is used; on Linux on x86, equivalent entries are stored in `/var/ibm/InstallationManager/`. Do not alter or remove these entries unless instructed to do so by your IBM Service representative.

The installation directory for Installation Manager is stored in `HKEY_LOCAL_MACHINE\SOFTWARE\IBM\Installation Manager` (for 32–bit operating system editions) or `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\IBM\Installation Manager` (for 64–bit operating system editions), under the location value.

Uninstall keys are created for all products that are installed by Installation Manager under `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\Current\Version\Uninstall\IBM Installation Manager`, under the name `IM-`*`packagegroupname`* where *packagegroupname* is the name of the package group in which the product is installed; for example, IBM Software Development Platform.

WebSphere Message Broker Explorer

Related reference:

"Supported processors" on page 3583
WebSphere Message Broker is supported on multiple processors.

"Operating system requirements" on page 3590
WebSphere Message Broker is supported on multiple operating systems.

"Directory structures after installation" on page 3633
When you install WebSphere Message Broker components, the installation program creates a structure of subdirectories under the directory that you specified as the installation directory. The exact structure depends on the platform on which you have installed WebSphere Message Broker, and the components that you have installed. If you install the WebSphere Message Broker Toolkit, other directories might be created for IBM Installation Manager, the Shared Resources Directory, and the package group in which you install the toolkit.

Environment variables after installation

On distributed systems, ensure that your environment is set up correctly.

If you have installed on z/OS, see "Customizing the z/OS environment" on page 591.

Sample profile files are provided with WebSphere Message Broker; check their content to ensure the variables are set correctly for your environment before you use the product or configure any resources.

- On Linux and UNIX systems, the profile is *`install_dir`*`/bin/mqsiprofile`.
- On Windows systems, a command console is set up when you install components. Access this through the **Start** menu. When you select this option, a command window containing the correct environment is opened.

  If you prefer, run *`install_dir`*`\bin\mqsiprofile.cmd` in a command window before working with WebSphere Message Broker in the same command window.

If you have more than one installation on a single system, ensure that you run the correct profile, or access the correct command console, for the installation that you want to work with. If an installation is at Version 6.0, the profile is incompatible with the Version 7.0 profile. You must log off and log on again before you run a second profile.

Check the readme file (`readme.html`) to ensure that you have the latest version of the profile.

Related tasks:

Chapter 7, "Configuring brokers for test and production environments," on page 579
Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

"Setting up a command environment" on page 213
After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

Use the **mqsiprofile** command to set a command environment.

Default WebSphere MQ resources created during installation and configuration

When you install WebSphere Message Broker and create components, WebSphere MQ resources are created for use by those components.

The names of these resources begin with the reserved characters SYSTEM. The resources are additional to the default WebSphere MQ objects that are created when you install that product. The following table lists the resources created.

Resource name	Type	Description
SYSTEM.BROKER.ADAPTER.FAILED	Queue	Failure messages generated by adapters.
SYSTEM.BROKER.ADAPTER.INPROGRESS	Queue	In progress messages generated by adapters.
SYSTEM.BROKER.ADAPTER.NEW	Queue	New request messages generated by adapters.
SYSTEM.BROKER.ADAPTER.PROCESSED	Queue	Processed messages generated by adapters.
SYSTEM.BROKER.ADAPTER.UNKNOWN	Queue	Unknown messages generated by adapters.
SYSTEM.BROKER.ADMIN.QUEUE	Queue	Target for request messages sent by CMP API applications (including commands) to modify the configuration and operation of the broker.
SYSTEM.BROKER.ADMIN.REPLYTODM	Queue	Target for internal messages sent by the broker.
SYSTEM.BROKER.AGGR.CONTROL	Queue	Used internally to store a control message for each aggregate group.
SYSTEM.BROKER.AGGR.REPLY	Queue	Used internally to store each known response message received by an AggregateReply node.
SYSTEM.BROKER.AGGR.REQUEST	Queue	Used internally to store each request message that forms part of an aggregate group.
SYSTEM.BROKER.AGGR.TIMEOUT	Queue	Used internally in the timeout and unknown timeout processing within an AggregateReply node.
SYSTEM.BROKER.AGGR.UNKNOWN	Queue	Stores each unknown response received by an AggregateReply node.
SYSTEM.BROKER.AUTH	Queue	Stores authorization records for administration requests against the broker.
SYSTEM.BROKER.DEPLOY.QUEUE	Queue	Target for publish/subscribe control requests that applications send to the broker.
SYSTEM.BROKER.DEPLOY.REPLY	Queue	Target for response messages sent by publish/subscribe control requests that applications send to the broker.

Resource name	Type	Description
SYSTEM.BROKER.EDA.COLLECTIONS	Queue	Used internally to store event handler information for message collections generated by the Collector node.
SYSTEM.BROKER.EDA.EVENTS	Queue	Used internally to store messages received by the Collector node.
SYSTEM.BROKER.EXECUTIONGROUP.QUEUE	Queue	Target for messages sent to execution groups by internal broker processes.
SYSTEM.BROKER.EXECUTIONGROUP.REPLY	Queue	Target for response messages sent by execution groups to internal broker processes.
SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS	Queue	Target for publish/subscribe messages sent by neighbor brokers.
SYSTEM.BROKER.MODEL.QUEUE	Queue	Model for dynamic response queues.
SYSTEM.BROKER.TIMEOUT.QUEUE	Queue	Used internally to support the TimeoutControl and TimeoutNotification nodes.
SYSTEM.BROKER.WS.ACK	Queue	Used internally for Web Services client support.
SYSTEM.BROKER.WS.INPUT	Queue	Used internally for Web Services client support.
SYSTEM.BROKER.WS.REPLY	Queue	Used internally for Web Services client support.
SYSTEM.BKR.CONFIG	SVRCONN	A connection channel for WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer clients.

Related reference:

"Designing the WebSphere MQ infrastructure" on page 584
You must create and manage the WebSphere MQ resources that are required to support your brokers, and the applications that connect to them to supply or receive messages.

"Software requirements" on page 3588
View the operating system, database, and other software requirements.

Security requirements for administrative tasks

You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

This section contains the following topics:

Related concepts:

Chapter 5, "Security," on page 351
Security is an important consideration for both developers of WebSphere Message Broker applications, and for system administrators configuring WebSphere Message Broker authorities.

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the

system.

Related tasks:

"Planning for security when you install WebSphere Message Broker" on page 353
The Installation Guide describes the security tasks that you must complete before, during, and after installation.

Tasks and authorizations for broker administration security

If you have enabled broker administration security, users require specific authority so that they can complete administration tasks.

The following table shows the list of actions that a user can perform, and the authorizations that you must set to allow them to complete these tasks when broker administrative security is enabled. The authority is required regardless of the way in which the user requests the action; from a CMP API application, the WebSphere Message Broker Explorer, or the WebSphere Message Broker Toolkit.

In addition to the permissions for the specific tasks that are shown in the following table, you must also be able to connect to the broker. For more information, see "Authorizing users for broker administration" on page 371.:

Tasks	Authorization	Queue
Set broker properties	Read and write	SYSTEM.BROKER.AUTH
View broker properties	Read	SYSTEM.BROKER.AUTH
Create or delete configurable services	Read and write	SYSTEM.BROKER.AUTH
Set configurable services properties	Read and write	SYSTEM.BROKER.AUTH
View configurable services properties	Read	SYSTEM.BROKER.AUTH
Create or delete execution groups	Read and write	SYSTEM.BROKER.AUTH
Rename execution groups	Read and write	SYSTEM.BROKER.AUTH
List execution groups	Read	SYSTEM.BROKER.AUTH
Start or stop execution groups	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH or SYSTEM.BROKER.AUTH.*E*
Set execution group properties	Read	SYSTEM.BROKER.AUTH
	Write	SYSTEM.BROKER.AUTH.*EG*
View execution group properties	Read	SYSTEM.BROKER.AUTH
	Read	SYSTEM.BROKER.AUTH.*EG*
Start or stop resource statistics collection	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH.*EG*[1]
Report resource statistics	Read	SYSTEM.BROKER.AUTH
	Read	SYSTEM.BROKER.AUTH.*EG*[2]
Deploy	Read	SYSTEM.BROKER.AUTH
	Write	SYSTEM.BROKER.AUTH.*EG*
List message flows and other deployed objects	Read	SYSTEM.BROKER.AUTH
	Read	SYSTEM.BROKER.AUTH.*EG*

Tasks	Authorization	Queue
Start or stop message flows	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH.*EG*
Delete resources from an execution group	Read	SYSTEM.BROKER.AUTH
	Write	SYSTEM.BROKER.AUTH.*EG*

Notes:

1. If you are changing resource statistics collection for all execution groups on the broker, you must grant execute authority for all execution groups.
2. If you are reporting resource statistics collection for all execution groups on the broker, you must grant read authority for all execution groups.
3. In the queue name SYSTEM.BROKER.AUTH.EG, the *EG* refers to the name of your execution group.
4. In the queue name SYSTEM.BROKER.AUTH.*EG*, the *EG* refers to the value of the *egForView* property that you specify in your DataCaptureStore configurable service.
5. In the queue name SYSTEM.BROKER.AUTH.*EG*, the *EG* refers to the value of the *egForReplay* property that you specify in your DataDestination configurable service.

If you grant a user ID authority at the broker level (on queue SYSTEM.BROKER.AUTH), it does not inherit authority for execution groups. You must explicitly grant authority to all, or to individual, execution groups.

Related tasks:

"Enabling broker administration security" on page 368
Enable broker administration security on a broker to control which users can complete specific tasks against that broker and its resources.

"Authorizing users for broker administration" on page 371
Grant authority to one or more groups or users to authorize them to complete specific tasks against a broker and its resources.

Commands and authorizations for broker administration security

If you have enabled broker administration security, users require specific authority to be able to run the administration commands.

The following table shows the list of commands, and the authorizations you must set up before users can to run them.

Command	Authorization	Queue
mqsichangeresourcestats	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH.*EG*[1]
mqsicreateexecutiongroup	Read and write	SYSTEM.BROKER.AUTH
mqsideleteexecutiongroup	Read and write	SYSTEM.BROKER.AUTH
mqsideploy	Read	SYSTEM.BROKER.AUTH
	Write	SYSTEM.BROKER.AUTH.*EG*

Command	Authorization	Queue
mqsilist	Read	SYSTEM.BROKER.AUTH
	Read	SYSTEM.BROKER.AUTH.**[2]
mqsimode	Read (to display) or read and write (to change)	SYSTEM.BROKER.AUTH
mqsireloadsecurity	Read	SYSTEM.BROKER.AUTH
	Write	SYSTEM.BROKER.AUTH.**[3]
mqsireportresourcestats	Read	SYSTEM.BROKER.AUTH
	Read	SYSTEM.BROKER.AUTH.*EG*[4]
mqsistartmsgflow[5]	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH.*EG*
mqsistopmsgflow[5]	Read	SYSTEM.BROKER.AUTH
	Execute	SYSTEM.BROKER.AUTH.*EG*

Notes:

1. If you are changing resource statistics collection for all execution groups on the broker, you must have execute authority for all execution groups.
2. You must have read authority for every broker and every execution group for which you are requesting information. If you request details about a resource for which you do not have authority, one or more of the following messages are returned to identify each resource with inappropriate authority:

   ```
   BIP1185S: You cannot view execution group '<egname>' on broker '<brokername>'.

   BIP1014S: You cannot view broker '<brokername>'.
   ```

   The command completes the request and returns results for all the resources for which authority is correct.
3. Where SYSTEM.BROKER.AUTH.** is specified, the user ID running the command must have authority for all execution groups. You can set up this level of authority by either creating a generic profile for all execution groups, or a specific profile for every execution group.
4. If you are reporting resource statistics collection for all execution groups on the broker, you must have read authority for all execution groups.
5. Exact requirements for this command depend on the combination of parameters that you specify on the command; for details, see the authorization section in "**mqsistartmsgflow** command" on page 3969 and "**mqsistopmsgflow** command" on page 3975.
6. In the queue name SYSTEM.BROKER.AUTH.EG, the *EG* refers to the name of your execution group.

Only the commands that are listed in this table are subject to broker administration security.

Note: The authorizations that are listed in this table are in addition to the authorizations required to run the command on specific platforms. Refer to the following topics for information about platform-specific authorizations:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

Security requirements for Linux and UNIX platforms

View a summary of the authorizations in a Linux or UNIX environment.

You must add the required user IDs to the appropriate group to enable them to complete the relevant tasks.

Note: If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Task	Command	Authorization
Create, delete or migrate a broker	**mqsicreatebroker** **mqsideletebroker** **mqsimigratecomponents**	• Member of mqbrkrs and mqm. • Using LDAP: Ensure that the registry is appropriately secured to prevent unauthorized access. The setting of **LdapPrincipal** and **LdapCredentials** parameters on **mqsichangebroker** is not required for correct operation of the broker. The password is not stored in clear text in the file system.
Change a broker	**mqsichangebroker**	• Member of mqbrkrs. • If you specify the **-s** parameter to activate broker administration security, the user ID used to run this command must be a member of the mqm group, because several queues are created for use by the broker. • Using LDAP: Ensure that the registry is appropriately secured to prevent unauthorized access. The setting of **LdapPrincipal** and **LdapCredentials** parameters on **mqsichangebroker** is not required for correct operation of the broker. The password is not stored in clear text in the file system.

Task	Command	Authorization
Add or remove a broker instance	**mqsiaddbrokerinstance** **mqsiremovebrokerinstance**	• Member of mqbrkrs and mqm. Additionally, you need to make the `uid` and `gid` for this user ID the same on all the systems, and the user ID needs to be the same one that created the first instance of the multi-instance broker, using the **mqsicreatebroker** command. • Change the `uid` and `gid` with caution, as it affects the permission levels of files on the system. Changing a `uid` or `gid` causes the ownership of all the files previously owned by that user or group to change to the integer of the previous owner of the file. Therefore, you must ensure that your system administrator manually restores the ownerships of the affected files and directories.
Backup or restore a broker	**mqsibackupbroker** **mqsirestorebroker**	• Member of mqbrkrs.
Start a broker, or verify a broker	**mqsistart** **mqsicvp**	• Member of mqbrkrs. • Member of mqm if the queue manager is not already running.
Stop a broker	**mqsistop**	• Member of mqbrkrs. However, the root user ID can stop a broker without membership of mqbrkrs. • The user ID must be the same as the user ID that started the broker. • Member of mqm if `-q` is specified.
Create or delete an execution group	**mqsicreateexecutiongroup** **mqsideleteexecutiongroup**	Member of mqbrkrs. • If broker administration security is active, the user ID that runs this command must be a member of the group mqm. If you do not want your broker to run with mqm authority, you must work with your WebSphere MQ administrator to create or delete the appropriate authority queue when you create or delete an execution group.
Start or stop a message flow	**mqsistartmsgflow** **mqsistopmsgflow**	• Member of mqbrkrs.
Create or delete a configurable service	**mqsicreateconfigurableservice** **mqsideleteconfigurableservice**	• Member of mqbrkrs.
List brokers	**mqsilist**	• Member of mqbrkrs.

Task	Command	Authorization
Show broker properties	**mqsireportbroker** **mqsireportproperties** **mqsireportflowmonitoring** **mqsireportflowstats** **mqsireportflowuserexits** **mqsireportresourcestats**	• Member of mqbrkrs.
Change properties	**mqsichangeproperties** **mqsichangeflowmonitoring** **mqsichangeflowstats** **mqsichangeflowuserexits** **mqsichangeresourcestats**	• Member of mqbrkrs.
Set and update passwords	**mqsisetdbparms**	• Member of mqbrkrs.
Report or update a broker mode	**mqsimode**	• Member of mqbrkrs.
Deploy an object to a broker	**mqsideploy**	• Member of mqbrkrs.
Reload a broker, execution groups or security	**mqsireload** **mqsireloadsecurity**	• Member of mqbrkrs.
Trace a broker	**mqsichangetrace** **mqsireporttrace** **mqsireadlog** **mqsiformatlog**	• Member of mqbrkrs.
Set up symbolic links needed for coordinated transactions	**mqsimanagexalinks**	• Root user.
Add the mqbrkrs group	**mqsisetsecurity**	• Root user.

User is...[1]	Command Used	Local domain (WORKSTATION)
Running a broker (WebSphere MQ non-trusted application) (login ID).	• Not applicable	• Member of mqbrkrs. • The broker runs under the login ID that started it.
Running a broker (WebSphere MQ trusted application) (login ID).	• Not applicable	• Login ID must be mqm. • mqm must be a member of mqbrkrs.

Ensure that mqbrkrs has access to all user-defined queues that you have defined for use by your message flows. You can use the **setmqaut** command to set permissions.

- Set the following permissions on all input queues:

```
setmqaut -m MB7BROKER -n TEST_INPUT -t queue -g mqbrkrs  +get +inq
```

- Set the following permissions on all output queues:
  `setmqaut -m MB7BROKER -n TEST_OUTPUT -t queue -g mqbrkrs +put +inq +setall`
- You might also need to add **+passid +passall +setid +setall**, depending on your requirements.

Related tasks:

"Broker component security" on page 497
You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

Security requirements for Windows systems

Security requirements depend on the administrative task that you want to perform.

The following tables summarize the requirements for administrative tasks. They show what group membership is required if you are using a local security domain defined on your local system.

Note: If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Domain users in a multi-workstation domain, or from domains that are in a Windows transitive trust relationship with the local domain, can also perform these administrative tasks. They need to fulfill the group membership requirements specified in the tables. One way to set up this group membership is by adding the domain user to a domain group which in turn is a member of the local group. For an example of how to set up security by using domain groups, see "Security in a Windows domain environment" on page 249.

Task	Command	Authorization
Create, delete or migrate a broker	**mqsicreatebroker** **mqsideletebroker** **mqsimigratecomponents**	• Must be a user ID defined in WORKSTATION. • Member of Administrators. • On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be run from a command prompt with elevated privileges. For more information, see "**mqsicommandconsole** command" on page 3830. • Using LDAP: Ensure that the registry is appropriately secured to prevent unauthorized access. The setting of **LdapPrincipal** and **LdapCredentials** parameters on **mqsichangebroker** is not required for correct operation of the broker. The password is not stored in clear text in the file system.

Task	Command	Authorization
Change a broker	**mqsichangebroker**	• Must be a user ID defined in WORKSTATION. • Member of mqbrkrs. • If you specify the **-s** parameter to activate broker administration security, the user ID used to run this command must be a member of the mqm group, because several queues are created for use by the broker. • Using LDAP: Ensure that the registry is appropriately secured to prevent unauthorized access. The setting of **LdapPrincipal** and **LdapCredentials** parameters on **mqsichangebroker** is not required for correct operation of the broker. The password is not stored in clear text in the file system.
Add or remove a broker instance	**mqsiaddbrokerinstance** **mqsiremovebrokerinstance**	• Must be a user ID defined in WORKSTATION. Member of Administrators. • On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be run from a command prompt with elevated privileges. For more information, see "**mqsicommandconsole** command" on page 3830.
Backup or restore a broker	**mqsibackupbroker** **mqsirestorebroker**	• Member of mqbrkrs.
Start a broker, or verify a broker	**mqsistart** **mqsicvp**	• Member of mqbrkrs. • Member of mqm if the queue manager is not already running.
Stop a broker	**mqsistop**	• Member of mqbrkrs. • Member of mqm if **-q** is specified.
Create or delete an execution group	**mqsicreateexecutiongroup** **mqsideleteexecutiongroup**	Member of mqbrkrs. • If broker administration security is active, the user ID that runs this command must be a member of the group mqm. If you do not want your broker to run with mqm authority, you must work with your WebSphere MQ administrator to create or delete the appropriate authority queue when you create or delete an execution group.
Start or stop a message flow	**mqsistartmsgflow** **mqsistopmsgflow**	• Member of mqbrkrs.
Create or delete a configurable service	**mqsicreateconfigurableservice** **mqsideleteconfigurableservice**	Member of mqbrkrs.

Task	Command	Authorization
List brokers	**mqsilist**	• Must be a user ID defined in WORKSTATION. • Member of mqbrkrs or mqm to run the command with broker and execution group specified: **mqsilist** *broker_name execution_group_name*
Show broker properties	**mqsireportbroker** **mqsireportproperties** **mqsireportflowmonitoring** **mqsireportflowstats** **mqsireportflowuserexits** **mqsireportresourcestats**	• Member of mqbrkrs.
Change properties	**mqsichangeproperties** **mqsichangeflowmonitoring** **mqsichangeflowstats** **mqsichangeflowuserexits** **mqsichangeresourcestats**	• Member of mqbrkrs.
Set and update passwords	**mqsisetdbparms**	• Member of mqbrkrs.
Report or update a broker mode	**mqsimode**	• Member of mqbrkrs.
Deploy an object to a broker	**mqsideploy**	• Member of mqbrkrs.
Reload a broker, execution groups or security	**mqsireload** **mqsireloadsecurity**	• Member of mqbrkrs.
Trace a broker	**mqsichangetrace** **mqsireporttrace** **mqsireadlog** **mqsiformatlog**	• Must be a user ID defined in WORKSTATION. • Member of mqbrkrs.
Add the mqbrkrs group	**mqsisetsecurity**	• Must be a user ID defined in WORKSTATION. • Member of Administrators. • On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be run from a command prompt with elevated privileges. For more information, see “**mqsicommandconsole** command” on page 3830.

Task	Command	Authorization
Run commands that require elevated privileges	**mqsicommandconsole**	• Member of Administrators. • On Windows 7 and Windows Server 2008 systems, the user ID used to run this command must be run from a command prompt with elevated privileges. For more information, see "**mqsicommandconsole** command" on page 3830.

User is...[1]	Command Used	Local domain (WORKSTATION)
Running a broker (WebSphere MQ fast path off) (service user ID)[2]	• Not applicable	• Must be a user ID defined in WORKSTATION • Member of mqbrkrs • Must have the *Logon as a service* privilege in the Windows Local Security Policy. This privilege is added when **mqsicreatebroker** is run, if necessary.
Running a broker (WebSphere MQ fast path on) (service user ID)[2]	• Not applicable	• Must be a user ID defined in WORKSTATION • Member of mqbrkrs • Member of mqm • Must have the *Logon as a service* privilege in the Windows Local Security Policy. This privilege is added when **mqsicreatebroker** is run, if necessary.
Running a WebSphere Message Broker Toolkit[3]	• Start WebSphere Message Broker Toolkit from the **Start** menu	• Must be a user ID defined in WORKSTATION. For example, WORKSTATION\User1 is valid, PRIMARY\User2 and TRUSTED\User3 are not.

Notes:

1. By default when a broker is created, the service user ID is given the required permissions to access to relevant directories of the product directory tree; for example, write access to the logs directory.

   This happens even if you set a location that is not the default, with the *–w* flag on the **mqsicreatebroker** command, or use the *–e* flag on the **mqsicreatebroker** command to create a multi-instance broker. If these permissions are changed manually, you must always ensure that the mqbrkrs group has appropriate access to these locations.
2. Ensure that mqbrkrs has access to all user-defined queues that you have defined for use by your message flows. You can use the **setmqaut** command to set permissions.
   - Set the following permissions on all input queues:

     ```
     setmqaut -m MB7BROKER -n TEST_INPUT -t queue -g mqbrkrs  +get +inq
     ```
   - Set the following permissions on all output queues:

     ```
     setmqaut -m MB7BROKER -n TEST_OUTPUT -t queue -g mqbrkrs +put +inq +setall
     ```
   - You might also need to add **+passid +passall +setid +setall**, depending on your requirements.

3. All WebSphere Message Broker Toolkit users need read access to the WebSphere MQ Java `\lib` subdirectory of the WebSphere MQ home directory (the default location is `X:\Program Files\WebSphere MQ`, where X: is the operating system disk). This access is restricted to users in the local group mqm by WebSphere MQ. WebSphere Message Broker installation overrides this restriction and gives read access for this subdirectory to all users.

Broker security requirements on Windows

On all Windows platforms, there is no longer any requirement for the service user ID to be a member of the Administrators group.

The only requirement is that the service user ID is a member of the mqbrkrs group. In addition, the `LocalSystem` account can be used as the service user ID by specifying `LocalSystem` for the *–i* parameter on the **mqsicreatebroker** command.

In this case you must enter the *–a* (password) parameter on the command line, but the value entered is ignored.

You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

Security requirements for z/OS

View a summary of the authorizations in a z/OS environment.

The following table summarizes the UNIX System Services file access authorizations in a z/OS environment.

Note: If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Task	Command	Authorization
Create, delete or migrate a broker	**mqsicreatebroker** **mqsideletebroker** **mqsimigratecomponents**	• *READ* and *WRITE* access to the component directory by the z/OS user ID running the command. • The broker runs under its z/OS assigned started task user ID.
Change a broker	**mqsichangebroker**	• *READ* and *WRITE* access to the component directory by the z/OS user ID running the command. • The broker runs under its z/OS assigned started task user ID.
Backup or restore a broker	**mqsibackupbroker** **mqsirestorebroker**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Start or stop a broker	Console commands	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID. • **UPDATE** authority in class **OPERCMDS** to the `MVS.START.STC.message_broker_component_started_ta` resource.

Task	Command	Authorization
Create or delete an execution group	**mqsicreateexecutiongroup** **mqsideleteexecutiongroup**	*READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Start or stop a message flow	**mqsistartmsgflow** **mqsistopmsgflow**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Create or delete a configurable service	**mqsicreateconfigurableservice** **mqsideleteconfigurableservice**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
List brokers	**mqsilist**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Show broker properties	**mqsireportbroker** **mqsireportproperties** **mqsireportflowmonitoring** **mqsireportflowstats** **mqsireportflowuserexits** **mqsireportresourcestats**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Change properties	**mqsichangeproperties** **mqsichangeflowmonitoring** **mqsichangeflowstats** **mqsichangeflowuserexits** **mqsichangeresourcestats**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Set and update passwords	**mqsisetdbparms**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Deploy an object to a broker	**mqsideploy**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Reload a broker, execution groups or security	**mqsireload** **mqsireloadsecurity**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Trace a broker	**mqsichangetrace** **mqsireporttrace** **mqsireadlog** **mqsiformatlog**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.
Report or update a broker mode	**mqsimode**	• *READ* and *WRITE* access to the component directory by the z/OS assigned started task user ID.

Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

"Developing applications that use the Administration API" on page 956
Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

Restrictions that apply in each operation mode

The operation mode in which your broker is working defines how many execution groups you can use, and which nodes are available.

Trial Edition mode

All features are enabled, but you can use the product for only 90 days after installation.

Starter Edition mode

All features are enabled. You can create one execution group, but the number of message flows that you can deploy is unlimited.

Not all samples work in Starter Edition mode because the sample import and deploy wizards create one or more execution groups, and the number of execution groups is limited in this mode.

You can run a sample in Starter Edition mode if the default execution group is deleted after you have run the Default Configuration wizard, but before you install the sample. For example, to run the Pager sample:

1. Run the Default Configuration wizard.
2. Delete the default execution group on the MB7BROKER that is created by the wizard.
3. To import and deploy the Pager sample, click Set up the Pager samples.
4. Follow the documented steps to run the Pager samples.

If you want to run samples to explore and understand the features of the product, you can install them on your development and unit test computers; see "Development and unit test" on page 50.

Entry Edition mode

In `entry` mode, the broker operates with a limited set of nodes available for deployed flows. You are also limited to one execution group. If you attempt to exceed the limits of this mode, the deployment is rejected. Use this edition for simple use cases only.

The functions that are enabled and the number of execution groups that you can create are limited. Therefore, not all samples work in Entry Edition mode.

The following message flow nodes can be used in `entry` mode. Plug-in nodes are also supported in `entry` mode.

• Check node • Database node • EmailOutput node • FileInput node • FileOutput node • FlowOrder node • HTTPHeader node • HTTPInput node • HTTPReply node • HTTPRequest node • Input node • JavaCompute node • JMSHeader node • JMSInput node • JMSMQTransform node • JMSOutput node • JMSReply node	• Label node • Mapping node • MQGet node • MQHeader node • MQInput node • MQJMSTransform node • MQOutput node • MQReply node • Output node • Passthrough node • PHPCompute node • Publication node • ResetContentDescriptor node • RouteToLabel node • SOAPAsyncRequest node • SOAPAsyncResponse node • SOAPEnvelope node	• SOAPExtract node • SOAPInput node • SOAPReply node • SOAPRequest node • TCPIPClientInput node • TCPIPClientOutput node • TCPIPClientReceive node • TCPIPServerInput node • TCPIPServerOutput node • TCPIPServerReceive node • Throw node • Trace node • TryCatch node • Validate node • XSLTransform node

Remote Adapter Deployment mode

Only adapter-related features are enabled, and the types of node that you can use, and the number of execution groups that you can create, are limited. You can create up to two execution groups, with no limit on the number of deployed message flows in each of these execution groups.

Not all samples work in this mode. If you want to run samples to explore and understand the features of the product, you can install them on your development and unit test computers; see "Development and unit test" on page 50.

The following message flow nodes can be used in `adapter` mode. Plug-in nodes are also supported in `adapter` mode.

• CDInput node • CDOutput node • CICSRequest node • CORBARequest node • DatabaseInput node • EmailInput node • EndpointLookup node • FileInput node • FileOutput node • FTEInput node • FTEOutput node • HTTPInput node • HTTPReply node • HTTPRequest node • IMSRequest node • Input node • JavaCompute node • JDEdwardsInput node • JDEdwardsRequest node	• JMSInput node • JMSOutput node • MQGet node • MQInput node • MQOutput node • Output node • PeopleSoftInput node • PeopleSoftRequest node • PHPCompute node • Real-timeInput node • Real-timeOptimizedFlow node • RegistryLookup node • SAPInput node • SAPReply node • SAPRequest node • SCAAsyncRequest node • SCAAsyncResponse node	• SCAInput node • SCAReply node • SCARequest node • SecurityPEP node • SiebelInput node • SiebelRequest node • SOAPInput node • SOAPReply node • SOAPRequest node • TCPIPClientInput node • TCPIPClientOutput node • TCPIPClientReceive node • TCPIPServerInput node • TCPIPServerOutput node • TCPIPServerReceive node • TimeoutControl node • TimeoutNotification node

Enterprise mode

All features are enabled and no restrictions or limits are imposed.

On UNIX and Linux systems, you can check that the ODBC environment is configured correctly by running the **mqsicvp** command. This command also validates the connection to all data sources that are listed in the `odbc.ini` file that have been associated with a broker by using the **mqsisetdbparms** command. For more information, see "**mqsicvp** command" on page 3857.

Related tasks:

"Connecting to a database from Linux and UNIX systems using the DataDirect drivers" on page 674
To enable a broker to connect to a database, define the ODBC data source name (DSN) for the database.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"Sample WebSphere Message Broker ODBC Database Extender (IE02) configuration files" on page 3596
How you use WebSphere Message Broker ODBC Database Extender (IE02) to load the correct data source driver.

Support for Unicode and DBCS data in databases

You can manipulate Unicode Standard version 3.0 data, in suitably configured databases, using ESQL, in nodes that access databases by ODBC. The broker does not support DBCS-only columns in tables that are defined in databases.

The broker does not, therefore, support certain data types, including the following types:

- NCHAR, NVARCHAR, NVARCHAR2, NCLOB (on Oracle)
- NCHAR, NVARCHAR, NTEXT, UNICHAR, UNIVARCHAR (on Sybase)
- NCHAR, NVARCHAR (on Informix)

For WebSphere Message Broker 7.0.0.4 and later, GRAPHIC, VARGRAPHIC, LONGVARGRAPHIC, and DBCLOB data type support on DB2 is provided for the broker with the following limitations:

- Due to issues related to the z/OS Unicode support when calling stored procedures by using PASSTHRU, you must not use this method of calling stored procedures. For more information, see "PASSTHRU statement" on page 5147.
- Using the DB2 string functions with Unicode data can return unexpected results. For more information, see "Unicode string functions in DB2" on page 3670.

Support for Unicode is available only for the generally-supported versions of the following database managers:

- IBM DB2 for Windows, Linux, UNIX, and z/OS operating systems.
- Oracle
- Microsoft SQL server
- Sybase Adaptive Server Enterprise (ASE)

For information about the versions of databases supported, see WebSphere Message Broker Requirements.

Support for the manipulation of Unicode data is not available for nodes that access databases that use JDBC; for example, DatabaseRetrieve and DatabaseRoute.

The following instructions apply to both 32-bit and 64-bit applications.

If you are using DB2:

- On Windows, Linux, and UNIX operating systems, your database must be created with code set `utf-8`.
- On z/OS, set the variable MQSI_DB2_CONVERSION in the broker environment to the value `UNICODE`. In the ODBC definition add the statement `CURRENTAPPENSCH=UNICODE` to the `[COMMON]` stanza.
- On all platforms, DB2 returns the lengths of strings in bytes, rather than characters; this response has implications for the behavior of string length-related ESQL functions.

  Some functions might fail, or function differently, when processed by the database. See "Unicode string functions in DB2" on page 3670 for further information.

If you are using Oracle:

- Your database must be created with NLS_CHARACTERSET of AL32UTF8.
- Your ODBC data source definition must include the setting `ColumnSizeAsCharacter=1`.

  On UNIX and Linux platforms, this setting must be included in the appropriate stanza in the ODBC ini files.

  On Windows platforms, this string value must be added to the ODBC data source key in the registry.

  See "Enabling ODBC connections to the databases" on page 668 for further information.
- For 32-bit connections, you must set the variable NLS_LANG in the broker environment to the value `<yourlanguage>_<yourterritory>.AL32UTF8`.

if you are using Microsoft SQL server:

- You must use NCHAR, NVARCHAR, and NTEXT data types for your column definitions.
- For brokers on UNIX and Linux platforms, your ODBC data source definition must include the setting `ColumnSizeAsCharacter=1`; this setting must be included in the appropriate stanza in the ODBC `.ini` files.

If you are using Sybase ASE:

- The default character set of your ASE server must be `UTF-8`.
- Your ODBC data source definition must include the settings `ColumnSizeAsCharacter=1` and `CharSet=UTF8`.

  On UNIX and Linux platforms, this setting must be included in the appropriate stanza in the ODBC `.ini` files.

  On Windows platforms, this string value must be added to the ODBC data source key in the registry.

  See "Enabling ODBC connections to the databases" on page 668 for further information.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"User database connections" on page 2110
User databases contain business data that is written and accessed by deployed message flows. You must create connections from the broker to the user database by using ODBC or JDBC.

Related tasks:

"Accessing databases from message flows" on page 2112
Create and configure message flows to access user databases.

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

Unicode string functions in DB2:

When you use string functions in ESQL expressions, certain parameters refer to character positions or counts.

For example, with the SUBSTRING function, coding:

```
SUBSTRING('Hello World!' FROM 7 FOR 4)
```

results in the string `Worl` because `7` refers to the seventh character position, and `4` refers to four characters.

If the string `Hello World!` is represented in an ASCII code page, the seventh *byte* of that representation is the seventh character. However, in other code pages or encoding schemes (for example, some Unicode representations) the seventh character could start at byte 13, and 4 characters can occupy 8 bytes.

WebSphere Message Broker correctly handles this situation; that is, the numeric parameters and results of these string functions always refer to *characters* and not the bytes used to represent them.

In some situations, WebSphere Message Broker delegates expressions to a database engine for processing. For example, if there is a WHERE clause, in a SELECT function, applied to a database data source, the database is passed the WHERE clause if it can interpret all the functions in the expression.

If there are functions that are not supported by the database, WebSphere Message Broker passes only those parts of the expression that can be interpreted, retrieves an unfiltered record set, and performs the remaining filtering itself.

DB2 string functions use *byte* indexing and not *character* indexing. Therefore, for Unicode data, the meaning of certain functions differs from the WebSphere Message Broker functions, even though they can be ‘interpreted'.

Characters in Unicode UTF8 representation, for example, can occupy from 1-4 bytes, so that the seventh character can start anywhere from byte 7 to byte 25.

The following string functions are affected:

- INSERT function
- LEFT function
- LENGTH function
- OVERLAY function
- POSITION function
- RIGHT function
- SPACE function
- SUBSTRING function

These functions either take numeric parameters, or return numeric results that refer to indexes, or counts, of characters in a string.

When expressions involving these functions are passed to the DB2 database, and Unicode string data is manipulated in the database, the results can be unexpected, or an error might occur.

This error might also occur if, for example, an expression of this type is passed directly to the database by using the PASSTHRU function. In this situation, you could modify each expression yourself, as necessary, for the target database.

It is not possible to systematically modify expressions to avoid this problem and WebSphere Message Broker does not attempt to do so.

If the Unicode strings do not use any characters that, in UTF8 representation, occupy more than 1 byte each, the functions perform correctly.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Accessing databases from message flows" on page 2112
Create and configure message flows to access user databases.

Related reference:

"Support for Unicode and DBCS data in databases" on page 3668
You can manipulate Unicode Standard version 3.0 data, in suitably configured databases, using ESQL, in nodes that access databases by ODBC. The broker does not support DBCS-only columns in tables that are defined in databases.

Administration API

Use the Administration API for WebSphere Message Broker (CMP API) Java classes and methods to develop CMP applications.

Full details of the Java classes and methods are provided in the CMP API Javadoc information.

You must adhere to a few rules when you provide names or identifiers for the components and resources in your broker environment.

"Rules for using commands" on page 3681
Observe the following rules when using the WebSphere Message Broker commands on distributed systems.

Syntax diagrams

The syntax for commands and ESQL statements and functions is presented in the form of a railroad diagram. The diagram tells you what you can do with the command, statement, or function and indicates relationships between different options and, sometimes, different values of an option.

For details about how to read a railroad diagram, see "How to read railroad diagrams."

Related reference:

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

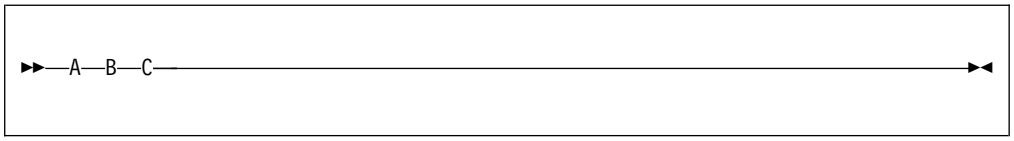
How to read railroad diagrams:

Understand the syntax used in railroad diagrams that show syntax.

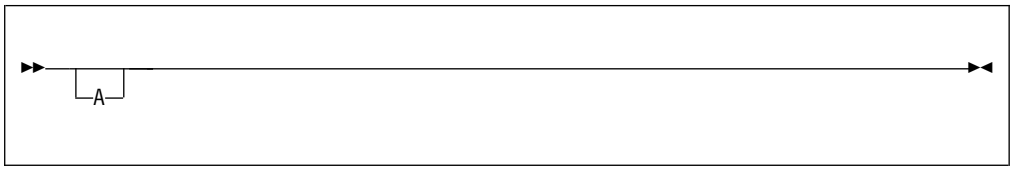
Each railroad diagram begins with a double right arrow and ends with a right and left arrow pair. Lines that begin with a single right arrow are continuation lines. You read a railroad diagram from left to right and from top to bottom, following the direction of the arrows.

The following examples show other conventions used in railroad diagrams.

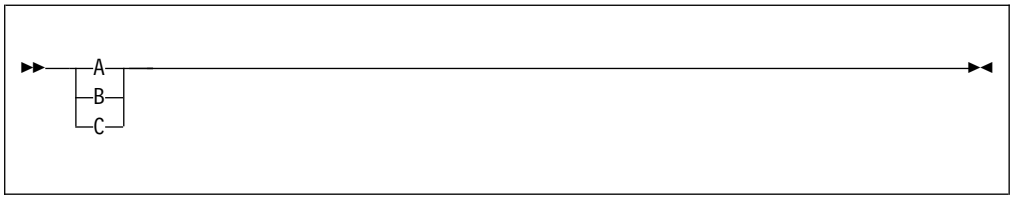
This example shows that you must specify values `A`, `B`, and `C`. Required values are shown on the main line of a railroad diagram:



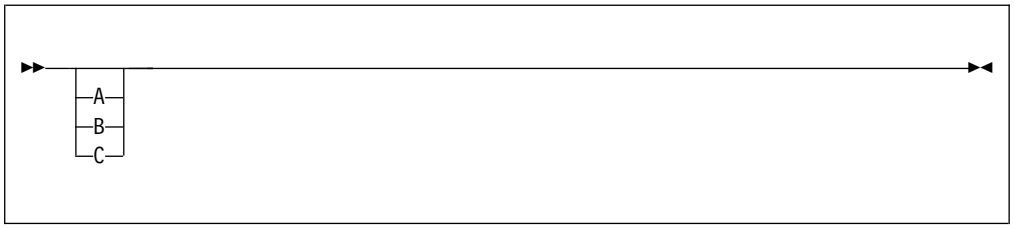
This shows that you can specify value `A`. Optional values are shown below the main line of a railroad diagram:



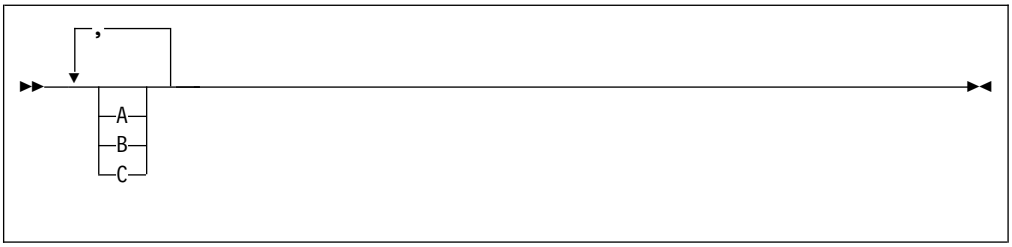
The next example specifies that values `A`, `B`, and `C` are options, one of which you must specify:



Values `A`, `B`, and `C` are options in this example, one of which you can specify:

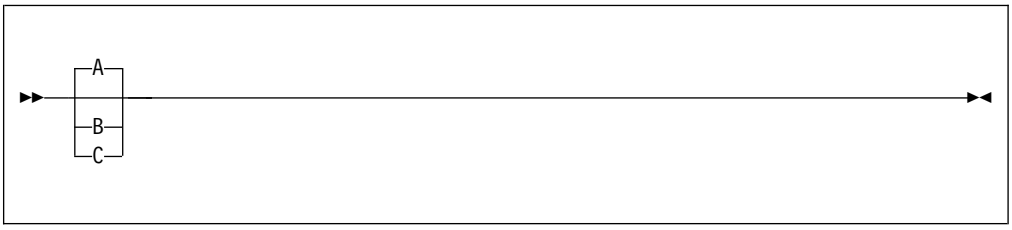


The next example shows that you can specify one or more of the values `A`, `B`, and `C`. Any required separator for multiple or repeated values (in this example, the comma (,)) is shown on the arrow:



In this example, you can specify value A multiple times. The separator in this example is optional:

Values A, B, and C are alternatives in the next example, one of which you can specify. If you specify none of the values shown, the default A (the value shown above the main line) is used:



The last example shows the use of a syntax fragment Name, which is shown separately from the main railroad diagram. This technique is used to simplify the diagram, or help fit it into the page of text. The fragment can be used multiple times in the railroad diagram:

Punctuation and uppercase values must be specified exactly as shown.

Lowercase values (for example, *name*) indicate where to type your own text in place of the *name* variable.

Related reference:

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

Characters allowed in commands

You must adhere to a few rules when you provide names or identifiers for the components and resources in your broker environment.

The character set that you can use to name brokers, execution groups, and message identifiers is as follows:

- Uppercase alphabetic characters A-Z
- Lowercase alphabetic characters a-z
- Numeric characters 0-9
- All special characters supported by the underlying file system:
  - The following special characters are accepted on Windows platforms:

$	%	' (apostrophe)	" (quotation mark)
- (dash)	_ (underscore)	@	~ (tilde)
!	(	)	{
}	[	]	&
#	&	+	, (comma)
;	=	(space)	

  - The following special characters, except for a space, are accepted on Linux and UNIX platforms:

. (dot)	%	- (dash)	_ (underscore)
@	~ (tilde)	!	{
}	[	]	&
#	, (comma)	=	(space)
+			

In general, you can use characters **A** through **Z**, **a** through **z**, and **0** through **9**.

If you expect to trace the operation of an execution group, restrict the name of the execution group to include only the valid alphabetic and numeric characters listed. The trace commands do not support the use of special characters for an execution group name.

If you intend to use WebSphere MQ File Transfer Edition for managed file transfers, see "Preparing the environment for WebSphere MQ File Transfer Edition nodes" on page 740 for information about naming execution groups.

The acceptable character set for configurable service names is identical to the character set for directory names on the file system of the target broker. The names of deployable resources (such as message flows, dictionaries, and JAR files) must consist only of characters that are acceptable in file names on the file systems of both the WebSphere Message Broker Toolkit and the target broker.

On Windows platforms, broker names are not case-sensitive. For example, broker names `Broker1` and `BROKER1` refer to the same broker.

On Linux and UNIX systems, broker names are case sensitive, and the previous examples refer to different brokers.

On z/OS systems, you must enclose mixed-case names in quotation marks.

Additional rules are enforced for naming message service folders in the MQRFH2 header.

Related reference:

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"Syntax diagrams" on page 3677

"Message service folders" on page 6401
A number of folders are defined for use by WebSphere MQ products.

Rules for using commands

Observe the following rules when using the WebSphere Message Broker commands on distributed systems.

If you are using commands on z/OS, refer to the section on z/OS commands in "Commands" on page 3672.

- Each command must be issued on the system on which the resource to which it relates is defined (or is to be created).
- Each command starts with a primary keyword (the executable command name) followed by one or more blanks.
- Following the primary keyword, flags (parameters) can occur in any order.
- Flags are shown in this book in the form **-t**, for example. In all cases, the character **/** can be substituted for the **-** character.
- If a flag has a corresponding value, its value must follow the flag to which it relates. A flag can be followed by its value directly or can be separated by any number of blanks.
- Flags can be concatenated if they do not have corresponding values, although the last flag in a concatenated group *can* have a value associated with it. For example, the command:

  ```
  mqsireadlog MB7BROKER -u -e default -o trace.xml -f
  ```

  can be entered as:

  ```
  mqsireadlog MB7BROKER -ufedefault -o trace.xml
  ```

  where the name of the execution group, `default`, relates to the **-e** flag. For clarity, all examples given in this documentation are shown with separate flags and with a space before any associated value.
- Repeated flags are not allowed.
- Strings that contain blanks or special characters must be enclosed in double quotation marks. For example:

  ```
  mqsireadlog "My Broker" -u -e default -o trace.xml -f
  ```

  Additionally, you can specify a null, or empty, string with a pair of quotation marks with nothing between: "".
- z/OS If you are running a command by submitting one of the JCL utilities (see "Contents of the broker PDSE" on page 3991), and an argument to one of the parameters contains a blank character, you must replace the blank with the mnemonic ` ` before you submit the JCL. For example, if you are using **BIPDPLY** to run the **mqsideploy** command to delete a deployed `.jar` file that is named `my jar.jar` from the execution group *default*, then modify the JCL to contain the following sample:

```
mqsideploy MB7BROKER -e default -d my jar.jar
```

- The case sensitivity of primary keywords and parameters depends on the underlying operating system. On Windows platforms, keywords are not case sensitive; **mqsistart**, mqsiSTART, and MQSISTART are all acceptable. On Linux and UNIX platforms, you must use lowercase; only **mqsistart** is acceptable.

All WebSphere Message Broker commands have dependencies on WebSphere MQ function. You must ensure that WebSphere MQ is available before issuing these commands.

Related reference:

"Characters allowed in commands" on page 3680
You must adhere to a few rules when you provide names or identifiers for the components and resources in your broker environment.

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"Responses to commands"
Responses are issued to the commands as messages. Messages that are returned to several commands are listed here; messages that are specific to a command, or have a specific meaning, are listed with the command.

Responses to commands

Responses are issued to the commands as messages. Messages that are returned to several commands are listed here; messages that are specific to a command, or have a specific meaning, are listed with the command.

If a command is successful, it returns a return code of zero, and a message with the number BIP8071I (command successful).

Warning and error responses are listed in the command descriptions. If the command is unsuccessful and returns, for example, the message BIP8083, it has an exit code, in this case, of 83.

The following responses are returned by many commands, and are not listed with each individual command:

- BIP8001 Unknown flag selected
- BIP8002 Selected flags are not valid
- BIP8003 Duplicate flag
- BIP8004 Invalid flags or arguments specified
- BIP8005 Flag or argument missing
- BIP8006 Mandatory flag missing
- BIP8007 Mandatory argument missing
- BIP8009 Program name not valid
- BIP8010 Component name not supplied
- BIP8013 Component does not exist
- BIP8071 Successful command completion
- BIP8073 Not a valid component
- BIP8081 Error generated by command processing
- BIP8083 Invalid component name
- BIP8087 Component exists and cannot be created

- BIP8092 Cannot locate return code in message catalog
- BIP8093 and BIP8094 Unable to access the WebSphere MQ queue manager
- BIP8099 The supplied parameters are not valid

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"Rules for using commands" on page 3681
Observe the following rules when using the WebSphere Message Broker commands on distributed systems.

Runtime and WebSphere Message Broker Toolkit commands (common)

Some commands are common to both runtime and WebSphere Message Broker Toolkit environments.

The following commands are available on workstations that have either the runtime, the WebSphere Message Broker Toolkit, or both components installed:

- "**mqsiapplybaroverride** command" on page 3684
- "**mqsireadbar** command" on page 3697

If either of these commands is run on a workstation that has both the runtime and WebSphere Message Broker Toolkit components installed, the version of the command that is used is determined by the relative locations of the WebSphere Message Broker Toolkit and runtime directories in the PATH variable of the workstation. The directory that appears earlier in the PATH takes precedence.

In most cases the WebSphere Message Broker Toolkit and runtime versions of the command are identical. However, if different levels of service pack have been applied to the WebSphere Message Broker Toolkit and runtime components, the updated commands might differ. For this reason, when either command is run, the first line of the output describes which version of the command is being used. For example:

```
BIP1138I: Overriding BAR File using runtime mqsiapplybaroverride.
```

on distributed systems.

"Syntax diagrams" on page 3677

"Runtime commands" on page 3715
The topics in this section describe the WebSphere Message Broker runtime commands.

"WebSphere Message Broker Toolkit commands" on page 3699
Several commands are provided as part of the WebSphere Message Broker Toolkit.

mqsiapplybaroverride command:

Use the **mqsiapplybaroverride** command to replace configurable values in the broker archive (BAR) deployment descriptor with new values that you specify in a properties file.

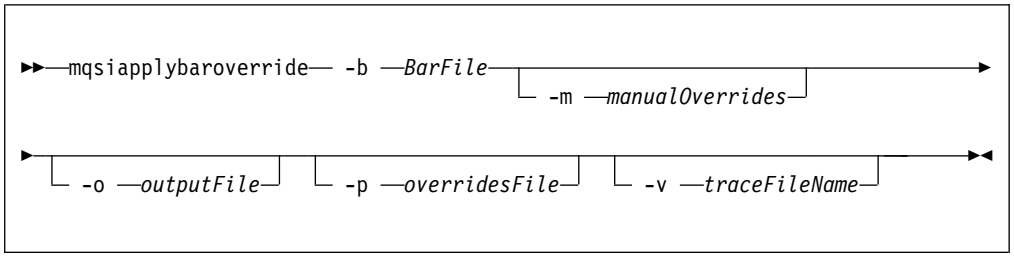
Supported operating systems:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPOBAR.

Purpose:
Use the **mqsireadbar** command to see which properties you can configure by using the **mqsiapplybaroverride** command.

Write scripts to create BAR files and apply different override values in the broker deployment descriptor archive file by using the **mqsiapplybaroverride** command, together with the **mqsicreatebar** command. For a list of message flow node properties and the corresponding properties of the **mqsiapplybaroverride** command, see "Configurable properties" on page 3687. The **mqsiapplybaroverride** command properties are also listed in the tables of properties in the reference topic for each affected node.

Syntax:



Parameters:

-b *BarFile*
(Required) The path to the BAR file (in compressed format) to which the override values apply. The path can be absolute or relative to the executable command.

-m *manualOverrides*
(Optional) A list of the `property-name=override` pairs, `current-property-value=override` pairs, or a combination of them, to be applied to the BAR file. The pairs in the list are separated by commas (,). On Windows, you must enclose the list in quotation marks (" "). If used with the overridesFile (**-p**)

parameter, overrides specified by the manualOverrides (**–m**) parameter are performed after any overrides specified the **–p** parameter have been made.

-o *outputFile*
(Optional) The name of the output BAR file to which the BAR file changes are to be made. If an output file is not specified, the input file is overwritten.

-p *overridesFile*
(Optional) The path to one of the following resources:

- A BAR file that contains the deployment descriptor that is used to apply overrides to the BAR file.

  You can use XML for the deployment descriptor file. If you use an XML property file written in EBCDIC onz/OS, ensure that you remove any `encoding="UTF-8"` from the XML header; for example, change:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  ```

  to

  ```
  <?xml version="1.0"?>
  ```

- A properties file in which each line contains a `property-name=override` or `current-property-value=new-property-value` pair.
- A deployment descriptor that is used to apply overrides to the BAR file.

-v *traceFileName*
(Optional) Specifies that the internal trace is to be sent to the named file.

In all cases, any existing deployment descriptor in the BAR file is renamed to `META-INF\broker.xml.old`, replacing any existing file of that name.

Each override that is specified in a **–p** overrides file or a **–m** overrides list must conform to one of the following syntaxes:

- `FlowName#NodeName.PropertyName=NewPropertyValue` (or `FlowName#PropertyName=NewPropertyValue` for message flow properties) where:
  - *FlowName* is the name of the message flow without the `.cmf` extension (for example, Flow1).
  - *NodeName* is the optional name of the node whose property is overridden (for example, InputNode).
  - *PropertyName* is the name of the property to be overridden (for example, queueName).
  - *NewPropertyValue* is the value to assign to that property (for example, PRODUCTION_QUEUE_NAME).
- `OldPropertyValue=NewPropertyValue`. This syntax does a global search and replace on the property value `OldPropertyValue`. It overrides the value fields of `OldPropertyValue` in the deployment descriptor with `NewPropertyValue`.
- `FlowName#NodeName.PropertyName` (or `FlowName#PropertyName` for message flow properties). This syntax removes any override that is applied to the property of the supplied name.

Variables and comments are not allowed in property files.

When the **mqsiapplybaroverride** command runs, it displays the version of the command that is being used (either runtime environment or WebSphere Message Broker Toolkit) before it does anything else. For example:

```
BIP1138I: Overriding BAR File using runtime mqsiapplybaroverride
```

Authorization:
On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be started from an environment that has **Run as Administrator** authority.

If you do not run the command from a privileged environment, you are asked to confirm that you want to continue. When you click **OK**, a new privileged command console is created and the command completed, but all responses are written to the privileged environment and are lost when that console closes when the command completes.

On all operating systems, the user ID used to invoke this command must have write authority to the BAR file on the local system.

Responses:
This command returns the following responses:

0 The command completed successfully.

99 One or more of the parameters that you specified is invalid.

Windows This command is supplied as a batch file. If you run the command in an automation system or from a script, use the Windows CALL command, to ensure that the correct ERRORLEVEL is returned:

```
...
CALL mqsiapplybaroverride
...
```

Examples:
Open the BAR file `myflow.bar`, and replace configurable values in its deployment descriptor (typically `broker.xml`) with the values that are specified in the properties file `mychanges.properties`:

```
mqsiapplybaroverride -b myflow.bar -p mychanges.properties
```

Override the deployment descriptor in `c:\test.bar` by using the key=value pairs specified in `c:\my.properties`:

```
mqsiapplybaroverride -b c:\test.bar -p c:\my.properties
```

Override the deployment descriptor in `c:\test.bar` by using the deployment descriptor contained in `c:\previous.bar`:

```
mqsiapplybaroverride –b c:\test.bar –p c:\previous.bar
```

Override the deployment descriptor in `c:\test.bar` by using the deployment descriptor contained in `c:\broker.xml`:

```
mqsiapplybaroverride –b c:\test.bar –p c:\broker.xml
```

Override any properties with values set to OLDA and OLDB in `c:\test.bar` with the values NEWA and NEWB:

```
mqsiapplybaroverride –b c:\test.bar –m OLDA=NEWA,OLDB=NEWB
```

Override the value of the property name **sampleFlow#MQInput.queueName** to NEWC:

```
mqsiapplybaroverride –b c:\test.bar –m sampleFlow#MQInput.queueName=NEWC
```

For an example of the details that are contained in a properties file, see "Editing configurable properties" on page 3227.

Configurable properties:

Some properties of message flow nodes are configurable and can be changed by using the **mqsiapplybaroverride** command. The following table maps the message flow node properties to the corresponding properties of the **mqsiapplybaroverride** command.

The **mqsiapplybaroverride** command properties are also listed in the tables of properties in the reference topic for each affected node.

Node	Configurable node property	mqsiapplybaroverride command property

Related concepts:

"Configurable properties of a broker archive" on page 3217
System objects that are defined in message flows can have properties that you can update in the broker archive (BAR) file before deployment.

Related tasks:

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Related reference:

"**mqsiapplybaroverride** command" on page 3684
Use the **mqsiapplybaroverride** command to replace configurable values in the broker archive (BAR) deployment descriptor with new values that you specify in a properties file.

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

mqsireadbar command:

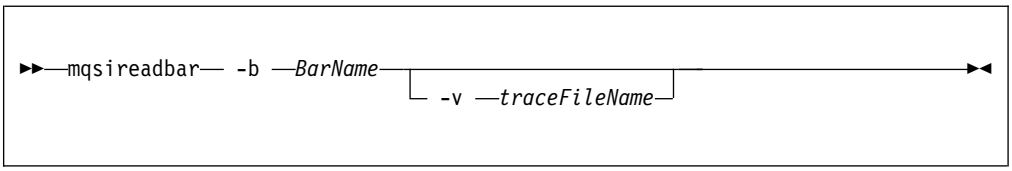
Use the **mqsireadbar** command to read a deployable BAR file and identify its defined keywords.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPRBAR.

Purpose:
The **mqsireadbar** command returns the keywords defined for each deployable file in a deployable broker archive file.

Syntax:



Parameters:

-b *BarName*
(Required) The name of the BAR archive file to be read. The BAR file is in compressed format.

-v *traceFileName*
(Optional) The name of the file to which the command trace is sent. This option activates an internal debug trace; specify this option only at the request of an IBM service representative.

Authorization:
On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be started from an environment that has **Run as Administrator** authority.

If you do not run the command from a privileged environment, you are asked to confirm that you want to continue. When you click **OK**, a new privileged command console is created and the command completed, but all responses are written to the privileged environment and are lost when that console closes when the command completes.

On all platforms, the user ID that is used to start this command must have the authority to read the BAR file on the local system.

Responses:
This command returns the following responses:

0 The command completed successfully.

99 One or more of the parameters that you specified is invalid.

The command displays the version of the command that is being run (either WebSphere Message Broker Toolkit or runtime environment), before all other response data:

```
BIP1052I: Reading BAR File using runtime mqsireadbar
```

The command then displays a list of the deployable files, together with their keywords. For example:

```
C:\test.bar
     BAR Entry: simpleflow.cmf (07/10/07 10:43:44)
          Author = Matt
          VERSION = v1.1
          Information = This flow simply removes messages from IN.Q
```

It also displays deployment descriptors and the list of any properties in the BAR file that can be overridden, together with the new values of any overrides that are currently applied. For example:

```
Deployment descriptor:
    simpleflow#additionalInstances
    simpleflow#commitCount
    simpleflow#commitInterval
    simpleflow#coordinatedTransaction
    simpleflow#MQInput.topicProperty
    simpleflow#MQInput.validateMaster
    simpleflow#MQInput.queueName = OVERRIDDEN.Q
    simpleflow#MQInput.serializationToken
```

Windows This command is supplied as a batch file. If you run the command in an automation system or from a script, use the Windows CALL command to ensure that the correct ERRORLEVEL is returned:

```
...
CALL mqsireadbar
...
```

Examples:
The following example reads the file `my_bar_file.bar` and returns defined keywords within the given file:

```
mqsireadbar -b my_bar_file.bar
```

Related concepts:

"Broker archive" on page 3216
The unit of deployment to the broker is the *broker archive* or *BAR* file.

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"Syntax diagrams" on page 3677

mqsicreatebar command:

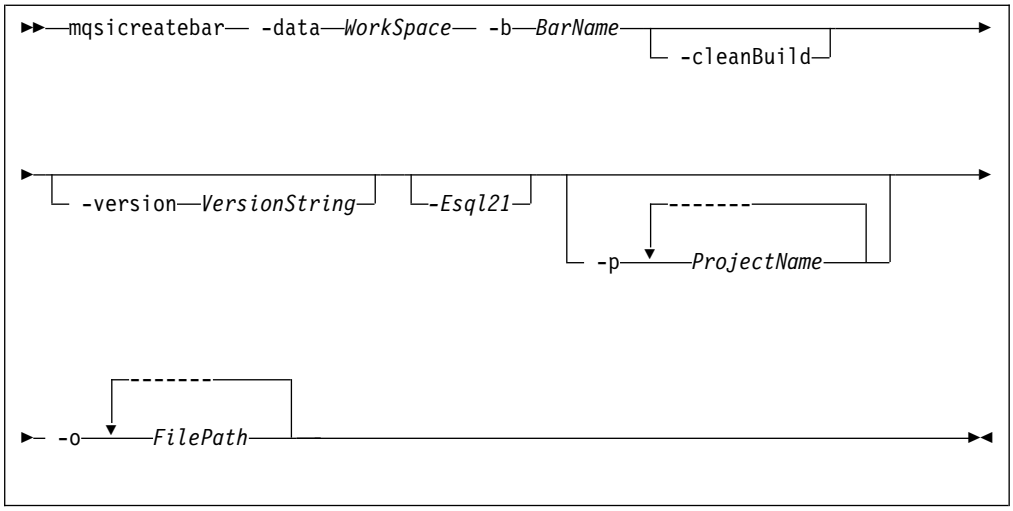
Use the **mqsicreatebar** command to create deployable broker archive (BAR) files containing message flows and dictionaries.

Supported platforms:

- Windows
- Linux on x86

Purpose:
If you use a repository to store your message flows and dictionaries, you can write scripts that use the **mqsicreatebar** command and the repository's command-line tools to deploy your message flow applications.

Syntax:



Parameters:

-data *WorkSpace*
(Required) The path of the workspace in which your projects are created.

The workspace location is also the default location for projects. Relative paths are interpreted as being relative to the directory from which the command was started.

-b *BarName*
(Required) The name of the BAR (compressed file format) archive file where the result is stored. The BAR file is replaced if it already exists and the `META-INF/broker.xml` file is created.

-cleanBuild
(Optional) Refreshes the projects in the workspace and then invokes a clean build before new items are added to the BAR file.

Use the **-cleanBuild** parameter to refresh all the projects in the BAR file and run a clean build if amendments have been made to BAR file resources by using external tools.

-version *VersionString*
(Optional) Appends the _ (underscore) character and the value of *VersionString* to the names of the compiled versions of the message flows (`.cmf`) files added to the BAR file, before the file extension.

-Esql21
(Optional) Compile ESQL for brokers at Version 2.1 of the product.

-p *ProjectName*
(Optional) Projects containing files to include in the BAR file in a new workspace. A new workspace is a system folder without the `.metadata` folder.

The projects defined must already exist in the folder defined in the -data parameter, and must include all projects and their reference projects that a deployable resource, defined in the -o parameter, needs.

The -p parameter is optional with an existing workspace, but you should use -p, together with a new workspace, in a build environment.

If a project that you specify is part of your workspace but is currently closed, the command opens and builds the project so that the files in the project can be included in the BAR file.

-o *FilePath*
(Required) The workspace relative path (including the project) of a deployable file to add to the BAR file; for example, a `msgflow` or `messageSet.mset` file.

You can add more than one deployable file to this command by using the following format: `-o FilePath1 FilePath2 .... FilePath'n'`

Authorization:
On Windows XP and Windows Server 2003 systems, the user ID used to run this command must be a member of the group Administrators on the local system.

On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be started from an environment that has **Run as Administrator** authority.

If you do not run the command from a privileged environment, you are asked to confirm that you want to continue. When you click **OK**, a new privileged command console is created and the command completed, but all responses are written to the privileged environment and are lost when that console closes when the command completes.

On Linux on x86, the user ID must have write access to the **-data** (workspace) and **-b** (BAR file location) directories.

Responses:
This command returns the following responses:

- BIP0956 Unable to start **mqsicreatebar**
- BIP0957 Incorrect arguments supplied to **mqsicreatebar**
- BIP0958 Nothing to do in **mqsicreatebar**
- BIP0959 Incorrect arguments supplied to **mqsicreatebar** (Project name)
- BIP0960 Incorrect arguments supplied to **mqsicreatebar** (Project directory)
- BIP0961 Error opening workspace in **mqsicreatebar** (Project could not be created)
- BIP0962 Error opening workspace in **mqsicreatebar** (Project could not be opened)
- BIP0963 Error saving file in **mqsicreatebar**
- BIP0964 Incorrect "-o" argument supplied to **mqsicreatebar**
- BIP0965 Error compiling files in **mqsicreatebar**

Examples:
You can run the **mqsicreatebar** command from a window opened anywhere in the file structure as long as the PATH environment variable specifies the correct path to the `WMB toolkit` directory.

- On Windows 32-bit editions, the default location of the `WMB toolkit` directory is `C:\Program Files\IBM\WMBT700`
- On Windows 64-bit editions, the default is `C:\Program Files (x86)\IBM\WMBT700`, and
- On Linux on x86, the default is `/opt/IBM/WMBT700`.

Your installation might differ from the default.

The -b parameter specifies the name of the BAR file and an optional alternative path for BAR file generation. When a path is not specified as part of the -b parameter, the location in the file structure where the **mqsicreatebar** command runs specifies where the BAR file is created. For example, if you are currently in C:\> and run the **mqsicreatebar** command, the BAR file is created on C:\. However, if you run the **mqsicreatebar** with -b c:\myfiles\myflow.bar specified, the BAR file is created in the myfiles directory.

The following example creates a BAR file called myflow.bar in the directory where the command is issued. The Test.msgflow message flow from the TestFlowProject is added to the BAR file as a compiled message flow (.cmf) file.

```
mqsicreatebar -data C:\Workspace -b myflow.bar -p TestFlowProject -o TestFlowProject\TestFlow\Test.msgflow
```

The following example creates a BAR file called mySet.bar. The messageSet.mset message set from the TestSetProject is added to the BAR file.

```
mqsicreatebar -data C:\Workspace -b mySet.bar -o TestSetProject\TestSet\messageSet.mset
```

The following example creates a BAR file called mySet.bar. The messageSet.mset message set from the TestSetProject and Test.msgflow message flow from the TestFlowProject are added to the BAR file. The message flow is added as a compiled message flow (.cmf) file.

```
mqsicreatebar -data C:\Workspace -b mySet.bar -o TestFlowProject\TestFlow\Test.msgflow
TestSetProject\TestSet\messageSet.mset
```

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Related reference:

"Syntax diagrams" on page 3677

"**mqsiapplybaroverride** command" on page 3684
Use the **mqsiapplybaroverride** command to replace configurable values in the broker archive (BAR) deployment descriptor with new values that you specify in a properties file.

mqsicreatemsgdefs command:

Use the **mqsicreatemsgdefs** command to create message definition files.

Supported platforms:

- Windows
- Linux on x86

Purpose:
The **mqsicreatemsgdefs** command generates message definition files (*.mxsd), according to a set of import options that are specified in an option file. The generated files are placed in the specified message set folder.

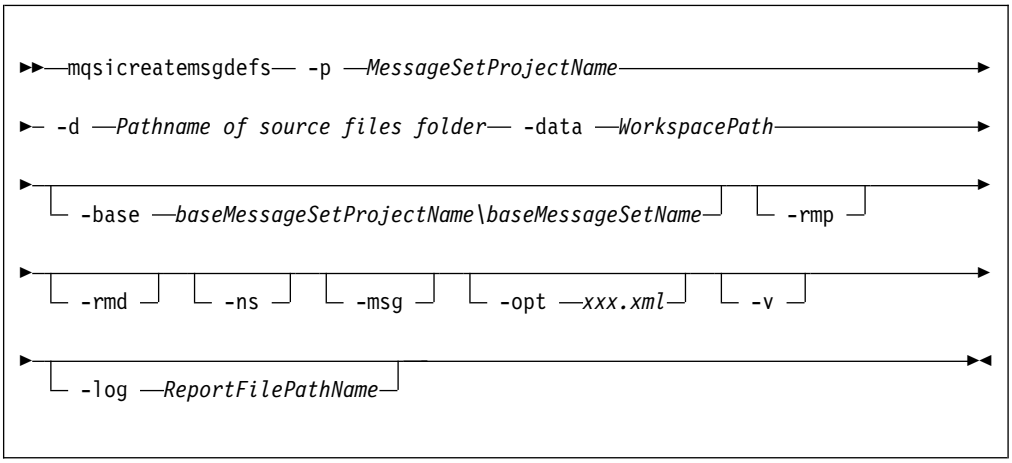
The command takes as a parameter a directory where source files of various types, for example, C and COBOL source files, are located (in addition to various other parameters), and starts the appropriate operation based on the extensions to the files.

1. Ensure that only the files that are required for the command to run exist in the directory and subdirectory structure that you specify. One of the actions that

the **mqsicreatemsgdefs** command performs is to copy all the files in the directory and subdirectories into the workspace, before creating the message definition. The **mqsicreatemsgdefs** command copies the source files into the import files folder of the messageSet project. Therefore the source directory should not be, or contain the message set project folder. Files that are not related to the message definitions that you are trying to create might also be copied.

2. You must specify the **-data** *WorkspacePath* parameter to specify the target workspace.

Syntax:



Parameters:

-p *MessageSetProjectName*
(Required) The name of the message set project. If the project does not exist, a new message set project is created.

-d *Pathname of source files folder*
(Required) The absolute or relative path name of the directory of definition files (source files).

All relevant files that are located in any sub-folders under the source files folder are scanned and imported.

-data *WorkspacePath*
(Required) The path of the workspace in which your projects are created.

The workspace location is also the default location for projects. Relative paths are interpreted as being relative to the directory from which the command was started.

-base *baseMessageSetProjectName\baseMessageSetName*
(Optional) If a new message set is to be created, specifies the existing message set project and message set, on which it is based.

-rmp
(Optional) Replaces the existing project of the same name.

-rmd
(Optional) Replaces an existing message definition file of the same name.

1. If you omit this flag, and a message definition file of the same name exists, a warning is returned.

2. The location of the generated message definition file in the message set is determined by the target namespace.

-ns
(Optional) If a new message set is to be created, the message set is enabled for namespace support.

-msg
(Optional) Creates messages from complex imported structures.

-opt *xxx.xml*
(Optional) The absolute or relative path name of the options file. The options file can be one of the following types:

- **C language** - "C options file for the **mqsicreatemsgdefs** command" on page 3705
- **COBOL language** - "COBOL options file for the **mqsicreatemsgdefs** command" on page 3707
- **XSD_NO_NS** - "XSD options file for the **mqsicreatemsgdefs** command" on page 3709

If you do not specify an option, the default options file (`mqsicreatemsgdefs.xml`) is used; see "Default options file for the **mqsicreatemsgdefs** command" on page 3710.

You can copy the default options file, and customize it, to create an options file for your environment.

-v
(Optional) Verbose report.

-log *ReportFilePathname*
(Optional) Absolute or relative path name of the report file. If you omit this option, the report is written to the default log file (`mqsicreatemsgdefs.report.txt`) in the Eclipse current directory.

If you specify *-log* without the report file path name, or with a path name that is not valid, the command issues an error message and stops.

Authorization:
On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be started from an environment that has **Run as Administrator** authority.

If you do not run the command from a privileged environment, you are asked to confirm that you want to continue. When you click **OK**, a new privileged command console is created and the command completed, but all responses are written to the privileged environment and are lost when that console closes when the command completes.

On other platforms, no specific authority is required to run this command.

Examples:
The following example creates or uses the message set project `newproject` in the source file `c:\myproject\source` and replaces the existing message project and message definition files of the same name.

```
mqsicreatemsgdefs -p newproject -d c:\myproject\source -rmp -rmd
```

C options file for the **mqsicreatemsgdefs** *command:*

Specify the options for the **mqsicreatemsgdefs** command when you import a C header file.

The following table lists the elements in the C language section of the options file. The following restrictions apply:

- You must specify, in an XML file, a valid value for the options listed, unless otherwise specified. See "Default options file for the **mqsicreatemsgdefs** command" on page 3710 for details of the syntax.
- Values of options are case-sensitive.
- If you do not specify the *-opt* parameter on the **mqsicreatemsgdefs** command, the default options file called `mqsicreatemsgdefs.xml` is used; see "Default options file for the **mqsicreatemsgdefs** command" on page 3710.

For further information on using these options, see "Importing from C" on page 2934.

<C> element	**Possible values**
COMPILER_NAME[1]	• Msvc (Default) • Icc • AIXgcc • AIXxlc • OS390
CODEPAGE	• SO8859-1 • Cp037 • Cp1252 (Default)
FLOATING_POINT_FORMAT	• IEEE Extended INTEL (Default) • IEEE Extended AIX • IEEE Extended OS/390® • IEEE Non-Extended • IBM 390 Hexadecimal
INCLUDE_PATH[2]	Absolute path names of other header files, or an empty string (this is the default value).
BYTE_ORDER	• Little Endian (Default) • Big Endian
ADDRESS_SIZE	• 32 (Default) • 64

<C> element	Possible values
SIZE_OF_LONG_DOUBLE	• 64 (Default) • 128 (Not supported)
PACK_LEVEL[1]	• 1 • 2 • 4 • 8 (Default) • 16
SIZE_OF_ENUM	• 1 • 2 • 4 • 5 (Default)
PRESERVE_CASE_IN_VARIABLE_NAMES	• True (Default) • False
STRING_ENCODING	• SPACE - Fixed-length strings (Default) • NULL - Null-terminated strings
STRING_PADDING_CHARACTER	• SPACE (Default) • NUL • 'c' • "c" • 0xYY • YY • U+xxxx
SCHEMA_TARGET_NAMESPACE_URI	A valid namespace URI, or empty (default)
MESSAGE_PREFIX[3]	A string with which to prefix created messages, or empty. Default is `msg_`.
PRE_PROCESSING_OPTION	• none (default) • ale_idoc • file_idoc

Notes:

1. If COMPILER_NAME is set to AIXxlc, the value of PACK_LEVEL is not used.
2. In INCLUDE_PATH, separate paths by the system-dependent path separator character.
3. MESSAGE_PREFIX is ignored if PRE_PROCESSING_OPTION is ale_idoc or file_idoc.

Options for the **mqsicreatemsgdefs** command take default values if you do not specify an options file.

COBOL options file for the **mqsicreatemsgdefs** *command:*

Specify the options for the **mqsicreatemsgdefs** command when you import a COBOL copybook.

The following table lists the elements in the COBOL language section of the options file. The following restrictions apply:

- You must specify in an XML file a valid value for the options listed, unless otherwise specified. See "Default options file for the **mqsicreatemsgdefs** command" on page 3710 for details of the syntax.
- Options values are case-sensitive.
- If you do not specify the *-opt* parameter on the **mqsicreatemsgdefs** command, the default options file (`mqsicreatemsgdefs.xml`) is used; see "Default options file for the **mqsicreatemsgdefs** command" on page 3710.

For further information about using these options, see "Importing from COBOL copybooks" on page 2937. For more information about COBOL parameters, see Compiler Options

<COBOL> element	**Possible values**
PLATFORM_SELECTION	Operating system that your enterprise uses: • 0 (Win32) (Default) • 1 (AIX) • 2 (z/OS)
CODEPAGE	Indicates the numeric identifier of the code page associated with a language. • ISO8859_1 (Default) • 037
FLOATING_POINT_FORMAT	Indicates how floating point numbers are encoded. • IEEE Non-Extended (Default) • IBM 390 Hexadecimal
ENDIAN	Indicates whether the most significant byte is first (big endian) or last (little endian). • Big • Little (Default)
EXT_DECIMAL_SIGN	Indicates the physical type of the sign numeric element. For more information, see "CWF properties for compound element decimal types" on page 6107. • ASCII (Default) • EBCDIC • EBCDIC Custom
TRUNC	Specifies how arithmetic fields are truncated. • STD (Default) • OPT • BIN

<COBOL> element	Possible values
NSYMBOL	Indicates whether to use the National or double-byte character sets. • DBCS • NATIONAL (Default)
QUOTE	Indicates whether single or double quotes are used. • SINGLE • DOUBLE (Default)
CREATE_DEFAULT_VALUES FROM_INITIAL_VALUES	Indicates whether initial values are used as defaults. • True • False (Default)
CREATE_FACETS_FROM LEVEL_88_VALUE_CLAUSES	Indicates whether to create XSD facets from level-88 values. • True • False (Default)
PRESERVE_CASE_IN VARIABLE_NAMES	Indicates whether upper- and lowercase are kept when using names of variables. • True (Default) • False
CREATE_NULL_VALUES_FOR_FIELDS	Indicates whether fields should be set up with null values. • True • False (Default)
NULL_CHARACTER	Indicates which character is to be used as the null character. • SPACE (Default) • NUL • 'c' • "c" • 0xYY • YY • U+xxxx
STRING_PADDING_CHARACTER	Indicates which character is to be used as the padding character for strings. • SPACE (Default) • NUL • 'c' • "c" • 0xYY • YY • U+xxxx
SCHEMA_TARGET_NAMESPACE_URI	A valid namespace URI, or empty (default)
MESSAGE_PREFIX	A string with which to prefix created messages, or empty. Default is `msg_`.

Specify the options for the **mqsicreatemsgdefs** command when you import an XML Schema file.

mqsicreatemsgdefsfromwsdl command:

Use the **mqsicreatemsgdefsfromwsdl** command to import a single WSDL definition.

Supported platforms:

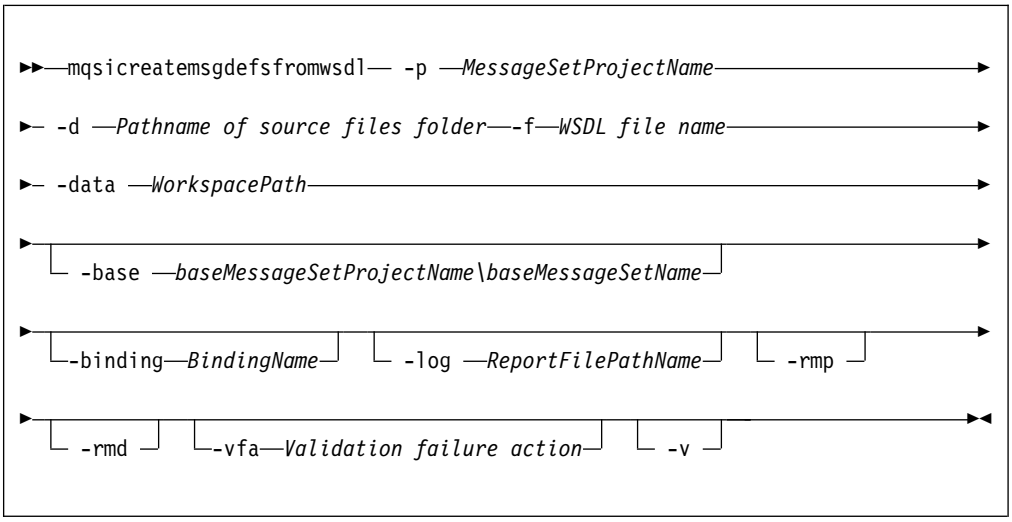
- Windows
- Linux on x86

Purpose:
If the WSDL is split into multiple files then the file specified must contain the WSDL service definition or binding definition. The WS-I validator can be run automatically on the imported WSDL under the control of the -vfa flag.

1. Ensure that only the files that are required for the WSDL definition you are importing exist in the directory and subdirectory structure. One of the actions the **mqsicreatemsgdefsfromwsdl** command performs is to copy all the files in the directory and subdirectories into the workspace prior to creating the message definition. Files that are not associated to that WSDL definition but exist in the directory are also copied.

2. If the WSDL definition uses a relative path that includes files outside of the directory or subdirectory structure specified, you must import these files into the workspace before you run the command. Make sure that the relative paths are still valid after importing these files into the workspace.
3. Message sets that are created are namespace enabled.
4. Existing message sets must be namespace enabled and have an XML physical format.
5. If you are creating a new message set for runtime parsing, you should base it on an existing message set which has an XML physical format.

Syntax:



Parameters:

-p *MessageSetProjectName*
(Required) The name of the message set project. If the project exists, it must be namespace-enabled. If the project does not exist, a new namespace-enabled project is created.

-base *baseMessageSetProjectName\baseMessageSetName*
(Optional) If a new message set is to be created, specify the existing message set project and message set on which it is based

-binding *BindingName*
(Optional) The name of a binding to be imported. This parameter is mandatory if the WSDL definition includes more than one binding, but optional if the WSDL definition includes a single binding

-d *Pathname of source files folder*
(Required) The absolute or relative path name of the directory where the top-level WSDL file is located. The top-level WSDL file can contain the entire WSDL definition, or it can be the top of a hierarchy of files, each of which can import further files via import elements. An import element specifies the location of the resource to import with a location attribute

The importer attempts to resolve all relative import locations relative to the specified directory; the importer also attempts to resolve any absolute import locations that it encounters. However, avoid using absolute import locations, because any further imports in the hierarchy must use absolute locations after the first time you specify an absolute location.

-data *WorkspacePath*
(Required) The path of the workspace in which your projects are created.

The workspace location is also the default location for projects. Relative paths are interpreted as being relative to the directory from which the command was started.

-f *<WSDL file name>*
(Required) The file name of the top-level WSDL file to be imported.

Where a path is required to fully identify the filename, the path should be specified using the **-d** parameter.

-log *ReportFilePathName*
(Optional) Absolute or relative path name of the report file; if omitted, the report is written to the default log file and is named *Wsdl-file-name*.wsdl.report.txt. *Wsdl-file-name* is the name of the WSDL definition you are importing and it is placed in the directory from which the command is invoked.

-rmd
(Optional) Replaces an existing message definition file of the same name.

Note:

1. If you omit this flag, and a message definition file of the same name exists, a warning is returned.
2. The location of the generated message definition file in the message set is determined by the target namespace.

-rmp
(Optional) Replaces the existing project of the same name.

-v
(Optional) Verbose report.

-vfa
(Optional) Validation failure action. Specifies the required action if WS-I compliance checking detects a problem in the WSDL to be imported. The default is set to fail. Select from:

- fail: If the WSDL definition is not WS-I compliant, the import process stops, and errors are written to the log file.
- warn: If the WSDL definition is not WS-I compliant, the import process writes warning errors to the log file.
- ignore: If the WSDL definition is not WS-I compliant, the import process ignores them and informational messages of how this WSDL definition is not compliant to the WS-I profile are written to the logfile.

Authorization:
On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be started from an environment that has **Run as Administrator** authority.

If you do not run the command from a privileged environment, you are asked to confirm that you want to continue. When you click **OK**, a new privileged

command console is created and the command completed, but all responses are written to the privileged environment and are lost when that console closes when the command completes.

On other platforms, no specific authority is required to run this command.

Examples:
In the following example, the WSDL document `service.wsdl` which exists in the directory `wsdlfiles`, is to be imported into the project myProject and overwrite the project if it exists.

```
mqsicreatemsgdefsfromwsdl -p myProject -d .\wsdlfiles -f service.wsdl -rmd -data .\wsdlfilewspc
```

In the following example, the WSDL document `service.wsdl` which exists in the directory `wsdlfiles`, is to be imported to create a new message set project (newProj) based on an existing project (existingProj).

```
mqsicreatemsgdefsfromwsdl -p newProj -base existingProj -d .\wsdlfiles -f service.wsdl -data .\wsdlfilewspc
```

Related concepts:

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

Related tasks:

"Creating a message definition file" on page 2865
Creating an empty message definition file to contain your message model objects.

"Importing from WSDL" on page 2946
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

"Importing WSDL definitions from the command line" on page 2948
WSDL definitions can be imported using the (**mqsicreatemsgdefsfromwsdl**) command.

Runtime commands

The topics in this section describe the WebSphere Message Broker runtime commands.

These commands are available on all computers on which you have installed the broker.

See "Commands" on page 3672 for a list of all the WebSphere Message Broker commands.

Related reference:

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

"Syntax diagrams" on page 3677

mqsiaddbrokerinstance command:

Use the **mqsiaddbrokerinstance** command to create a multi-instance broker on a server where WebSphere Message Broker has been installed.

Supported platforms:

- Windows

- Linux and UNIX systems

Purpose:
Use the **mqsiaddbrokerinstance** command to add a broker instance to any additional server on which you require multi-instance support. You must first create a multi-instance enabled broker on one server by using the **mqsicreatebroker** command.

If you add a broker instance with the **mqsiaddbrokerinstance** command, you cannot use this command to start and stop a multi-instance broker as a WebSphere MQ service; you must use the "**mqsichangebroker** command" on page 3723 instead.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsiaddbrokerinstance** command - Linux and UNIX systems" on page 3717
- "**mqsiaddbrokerinstance** command - Windows platforms" on page 3718

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

On all Windows platforms, you must install WebSphere MQ on a domain server, and create a user to own WebSphere MQ resources. The user must either be a member of domain group `mqm` or a member of another global domain group which is directly or indirectly a member of `mqm`. Make this user the owner of the shared queue manager and log files. The `sid` of the user who owns the queue manager and log files is then the same as the `sid` of the user that runs instances of the queue manager.

On Linux and UNIX systems, the user ID used to run this command must be a member of both the mqbrkrs group and the mqm group. Additionally, you need to make the `uid` and `gid` for this user ID the same on all the systems, and the user ID needs to be the same one that created the first instance of the multi-instance broker, using the **mqsicreatebroker** command.

You might need to edit the `/etc/passwd` file on each system to set a common `uid` and `gid` for the user ID being used to create and add broker instances; then reboot your systems.

You should change the `uid` and `gid` in the Linux and UNIX environments with caution, as it affects the permission levels of files on the system.

Changing a `uid` or `gid` causes the ownership of all the files previously owned by that user or group to change to the actual integer of the previous owner of the file. Therefore, you must ensure that your system administrator manually restores the ownerships of the affected files and directories.

"Syntax diagrams" on page 3677

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

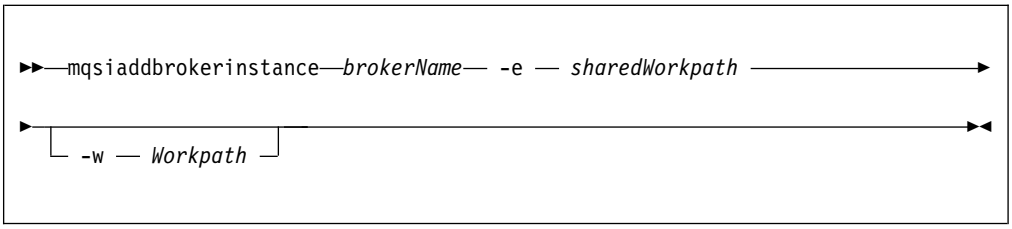
"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsiremovebrokerinstance** command" on page 3918
Use the **mqsiremovebrokerinstance** command to remove a multi-instance broker from a server where WebSphere Message Broker has been installed.

mqsiaddbrokerinstance *command - Linux and UNIX systems:*

Use the **mqsiaddbrokerinstance** command to add a multi-instance broker on Linux and UNIX systems.

Syntax:



Parameters:

brokerName
(Required) The name of the broker instance that you are adding. You must specify the name as the first parameter and the name is case-sensitive. The broker instance name must match that of a multi-instance enabled broker previously created using the **mqsicreatebroker** command.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-e ***sharedWorkpath***
(Required) The value represents the directory in which globally accessible working files for this broker are located in shared network storage (NFS or NAS).

You must ensure the broker has access to this network storage location before you start the broker, and that the queue manager for the broker has been configured as a WebSphere MQ multi-instance queue manager.

The information stored in this shared directory includes:

- The broker registry
- Component directories
- Internal broker tables and files for deployed message flows
- Configurable service properties.

-w ***Workpath***
(Optional) The directory in which working files specific to this broker instance are stored locally on the server where the broker instance is going to run. If you do not specify this parameter, files are stored in the default Work path,

which is the one you specified when the product was installed. If you specify this parameter, you must create this directory before you start the broker.

This directory is also used for trace records that are created when tracing is active. These records are written to a subdirectory, `log`, which you must create before you start the broker.
Error logs that are written by the broker when a process ends abnormally are stored in this directory.
The error log is unbounded and continues to grow. Check this directory periodically and clear out old error information.
You cannot change this parameter using the **mqsichangebroker** command. To specify or change the work path, delete and re-create the broker.
Specifying this parameter creates a separate working directory for the broker. This working directory is a subset of the default working directory structure that contains fewer subdirectories and no `common\profiles` subdirectory.

Examples:
The following example adds a broker instance on broker `Mybroker` using queue manager `MyQmgr` on the shared work path `MyNetworkSharedWorkpath`:

```
mqsiaddbrokerinstance MyBroker –e /MyNetworkSharedWorkpath
```

Related reference:

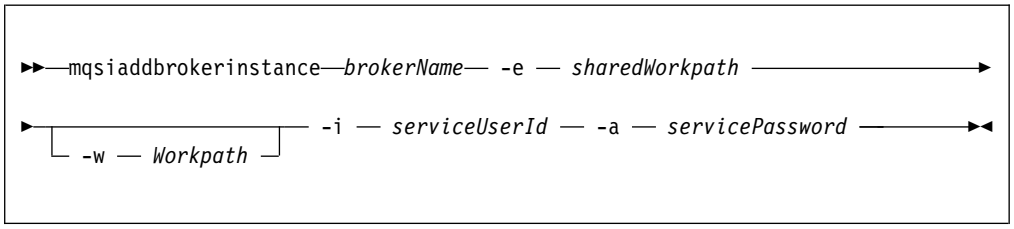
mqsiaddbrokerinstance *command - Windows platforms:*

Use the **mqsiaddbrokerinstance** command to add a multi-instance broker on Windows platforms.

Syntax:



Parameters:

brokerName
(Required) The name of the broker instance that you are adding. You must

specify the name as the first parameter and the name is case-sensitive. The broker instance name must match that of a multi-instance enabled broker previously created using the **mqsicreatebroker** command.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-e ***sharedWorkpath***
(Required) The value represents the directory in which globally accessible working files for this broker are located in shared network storage (NFS or NAS).

You must ensure the broker has access to this network storage location before you start the broker, and that the queue manager for the broker has been configured as a WebSphere MQ multi-instance queue manager.

The information stored in this shared directory includes:

- The broker registry
- Component directories
- Internal broker tables and files for deployed message flows
- Configurable service properties.

-w ***Workpath***
(Optional) The directory in which working files specific to this broker instance are stored locally on the server where the broker instance is going to run. If you do not specify this parameter, files are stored in the default Work path, which is the one you specified when the product was installed. If you specify this parameter, you must create this directory before you start the broker.

This directory is also used for trace records that are created when tracing is active. These records are written to a subdirectory, `log`, which you must create before you start the broker.
Error logs that are written by the broker when a process ends abnormally are stored in this directory.
The error log is unbounded and continues to grow. Check this directory periodically and clear out old error information.
You cannot change this parameter using the **mqsichangebroker** command. To specify or change the work path, delete and re-create the broker.
Specifying this parameter creates a separate working directory for the broker. This working directory is a subset of the default working directory structure that contains fewer subdirectories and no `common\profiles` subdirectory.

-i *serviceUserId*
(Required) The user ID under which the broker runs.

You can specify the *serviceUserId* in any valid user name syntax:

- `\\server\username`
- `.\username`
- `username`

Do not use a domain name as part of the *serviceUserId* parameter.
If you use the unqualified form for this user ID (`username`), the operating system searches for the user ID throughout its domain, starting with the local system. This search might take some time to complete.
The *serviceUserId* that you specify must be a direct or indirect member of the mqbrkrs local group. The *serviceUserId* must also be authorized to access the home directory (where WebSphere Message Broker has been installed), and the working directory (if specified by the **-w** parameter).
If you specify that the broker is to run as a WebSphere MQ trusted application

(**-t** parameter), you must also add the service user ID to the mqm group. The security requirements for the *serviceUserId* are described in "Security requirements for Windows systems" on page 3651.

-a *servicePassword*
(Required) The password for the *serviceUserId*.

For compatibility with existing systems, you can specify `<password>`. However, if you do not specify a password with this parameter when you run the command, you are prompted to enter a password. You must enter the password a second time to verify that you have entered it correctly.

Examples:
The following example adds a broker instance on broker `Mybroker` on the shared work path `MyNetworkSharedWorkpath`:

```
mqsiaddbrokerinstance MyBroker –e /MyNetworkSharedWorkpath -i Fred -a Test
```

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsiremovebrokerinstance** command" on page 3918
Use the **mqsiremovebrokerinstance** command to remove a multi-instance broker from a server where WebSphere Message Broker has been installed.

mqsibackupbroker command:

Use the **mqsibackupbroker** command to back up the current configuration of a broker.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting `BIPBUBK`; see "Contents of the broker PDSE" on page 3991.

Purpose:
The **mqsibackupbroker** command creates a record of the current configuration of a broker in a file, in compressed file format. You can use the file to restore the broker at a later time, if required.

Usage notes:
The command backs up of the following persistent configuration data associated with the broker:

- Deployed resources; message flows, dictionaries, JAR files, and other runtime resources that you have previously deployed in a BAR file.
- Execution groups.

- Broker configuration; for example, configurable services.

The command does not back up the following resources:

- Transient information; for example, inflight aggregations or collections.
- Executable code, including resources that are associated with user-defined extensions (nodes, parsers, and exits).
- Resources required by message flows to function correctly; for example, WebSphere MQ queues and data stored in user databases.

Use the backup file to restore a broker on a computer that has an identical configuration; the operating system must be at the same level, and the broker and queue manager names must be identical.

You can run this command for a broker that is active. However, you must not take a backup while the broker is processing configuration changes and deployments; the backup file created might contain incomplete information. If the file contains partial records, you cannot use it to restore the broker at a later time.

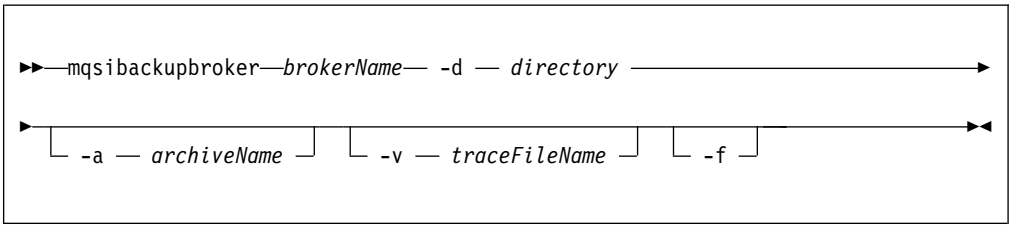
To ensure that the backup is complete and correct, either take a backup when the broker is not processing a configuration change (such as a deployment or change property) or when the broker is stopped.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Syntax:



Parameters:

brokerName
(Required) The name of the broker that you want to back up. You must specify the name as the first parameter.

-d *directory*
(Required) The directory in which the backup file is created. You must specify a directory that is on a file system that can be accessed by the computer on which you run this command.

-a *archiveName*
(Optional) The name of the backup (archive) file. The file is created in compressed file format. If you do not specify this parameter, the default name *brokerName_yyMMdd_HHmmss*.zip is used.

-v *traceFileName*
(Optional) The location of a trace file that records details of the actions taken by the command.

-f
(Optional) Force incomplete backup files to be created if one or more parts of the broker configuration cannot be read.

The command creates a backup file that contains all available information; if it cannot access some configuration detail, that subset of data is not saved. For example, if a message flow required exclusive access to a deployed resource, and the message flow is running, the deployed resource might not be included in the backup file.

If you do not specify this option, the command fails if it cannot create complete backup file.

Specify this option only if directed to do so by your IBM service representative.

Examples:
The following example backs up broker MB7BROKER on Windows:

```
mqsibackupbroker MB7BROKER -d C:\MQSI\BACKUP -v C:\MQSI\BACKUP\trace.log
```

Related tasks:

Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsirestorebroker** command" on page 3952
Use the **mqsirestorebroker** command to restore the broker configuration from a backup file.

"Sample BIPBUBK file" on page 4004
The sample BIPBUBK file that is shipped with WebSphere Message Broker is

included here for your reference.

mqsichangebroker command:

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Note: You can use the **mqsireportbroker** command to report the current values of the configuration parameters of the broker before you change anything, and to confirm any changes that you made. See "**mqsireportbroker** command" on page 3919 for more information.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command either as a console command, or by customizing and submitting BIPCHBK; see "Contents of the broker PDSE" on page 3991

Purpose:
You can modify the value of many, but not all, of the parameters that you set when you created the broker. For example, after you change a password, you must run the **mqsichangebroker** command. You can also use this command to set the **UserExitPath** property or to enable administrative authority.

You can use the **mqsichangebroker** command with the **-c** parameter on WebSphere Message Broker Version 7.0 in the same way that you did for WebSphere Message Broker .

However, the converter file name must follow the WebSphere Message Broker Version 7.0 form, and the location given must specify the path up to, but not including, the *icudt38b* component; see "Generating a new code page converter" on page 824 for further information.

You must stop the broker before you issue this command, and restart the broker for the changes to take effect:

- On Windows, Linux, and UNIX systems, use the **mqsistop** and **mqsistart** commands to stop and restart the broker.
- On z/OS, you must have started the original broker control process by using the `/S` option. You must stop the broker components using the `/F broker,PC` option and start the broker components again using the `/F broker,SC` option.

On Windows systems, Linux, and UNIX systems, use this command to specify whether the broker can start and stop as a WebSphere MQ service.

Use the **-f** (`function level`) parameter to specify functions that become available in WebSphere Message Broker fix packs. See the version of the command that is applicable to your enterprise for more information.

For details of this command on the operating system that your enterprise uses, see the appropriate topic:

- "**mqsichangebroker** command - Linux and UNIX systems" on page 3724
- "**mqsichangebroker** command - Windows systems" on page 3729
- "**mqsichangebroker** command - z/OS" on page 3733

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

"START and STOP commands on z/OS" on page 3981

mqsichangebroker *command - Linux and UNIX systems:*

Use the **mqsichangebroker** command on Linux and UNIX systems to modify your broker.

Syntax:

Parameters:

BrokerName

(Required) This parameter must be the first parameter. Specify the name of the broker to modify.

-t (Optional) The broker runs as a WebSphere MQ trusted application.

For more details about using WebSphere MQ trusted applications, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

-n

(Optional) The broker ceases to run as a WebSphere MQ trusted application.

-l *userLilPath*

(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

On Linux and UNIX systems, directory names are case sensitive. You must include the names in single quotation marks if they contain mixed case characters.
Do not include environment variables in the path; the broker ignores them.

Create your own directory for storing your `.lil` or `.jar` files. Do not save them in the WebSphere Message Broker installation directory.
If you specify more than one additional directory, each directory must be separated by the default platform-specific path separator.

-g *configurationChangeTimeout*
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k *internalConfigurationTimeout*
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-P *httpListenerPort*
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-v *statisticsMajorInterval*
(Optional) The time interval (in minutes) at which statistics and accounting archive records are written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

-y *ldapPrincipal*
(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *ldapCredentials*
(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *ICU converter path*
(Optional) A set of directories to search for additional code page converters, delimited by a colon (:).

The code page converters must be either of the form *codepagename*.cnv, or in an ICU data package called icudt38.dat. The code page converters must be located in a sub-directory named icudt38_<*platform_suffix*> of the specified directory where <*platform_suffix*> is one of the following values:

- l for little-endian ASCII platforms
- b for big-endian ASCII platforms
- e for EBCDIC platforms

-x ***userExitPath***
(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (PATH,LIBPATH,LD_LIBRARY_PATH,SHLIBPATH) for the execution group process only.

-e ***activeUserExits***
(Optional) Active user exits. By default, user exits are inactive. Adding a *userExit* name to this colon-separated list changes its default state to active for this broker. You can use the **mqsichangeflowuserexits** command to override the default state at the execution group or message flow level. If you specify a user exit name, and no library is found to provide that user exit when the execution group starts, a BIP2314 message is written to the system log. The execution group fails to start.

-o *operationMode*
(Optional) Use this parameter to set the mode of your broker; see "Operation modes" on page 48. Valid values that you can set are enterprise (the full package, enterprise mode), entry (Entry Edition mode), starter (Starter Edition mode), and adapter (Remote Adapter Deployment mode). The default is enterprise unless you have the Trial Edition, when the default is trial. If no **-o** parameter is set, the default is set automatically.

-f *function level*
(Optional) Use this parameter to enable function that becomes available in WebSphere Message Broker fix packs. Valid values that you can set are all, which enables all functions, or a version string of the form V.R.M.F (for example, 7.0.0.7), which indicates the maximum level of feature function to enable. You can use this parameter to revert to a previous fix pack level, but you must first remove any flows that are using the new functions.

This command does not disable all new features, and it is not possible to use this flag to run the broker at a different major version.

-s ***security_status***
(Optional) Specify this parameter to change the administrative security status of the broker.

- If you specify active, administrative security is enabled for the broker. The command creates authorization queues that are required, if they do not exist.
- If you specify inactive, administrative security is disabled for the broker. The command does not delete or clear the security queues that are associated with this broker and its execution groups.

If you omit this parameter, the security status is unchanged.

For further information about using security, see "Broker administration security overview" on page 362 and "Authorizing users for broker administration" on page 371.

-d (Optional) Enables a broker to be started and stopped as a WebSphere MQ service when the queue manager starts and stops.

This option is an alternative to starting a multi-instance broker in standby mode using the **mqsistart** command.

If you specify **-d defined**, the WebSphere MQ service is defined to the queue manager and the broker starts and stops when the queue manager starts and stops.

If you specify **-d undefined**, the WebSphere MQ service is not defined to the queue manager and the broker does not start and stop when the queue manager starts and stops. This is the default setting.

To change other broker properties, first delete and re-create the broker, and then use the WebSphere Message Broker Toolkit to redeploy the broker configuration. If you want to update the user ID credentials that the broker uses to access one or more databases from deployed message flows, use the **mqsisetdbparms** command. For more information, see "Accessing databases from message flows" on page 2112.

Examples:
Define the path to user-defined exits:

```
mqsichangebroker MB7BROKER -x /opt/3rdparty/wmbexit
```

Enable the new function that is supplied in WebSphere Message Broker Version 7.0.0.7:

```
mqsichangebroker MB7BROKER -f 7.0.0.7
```

Set the broker's security status to `active`, so that the broker checks that the user has the correct authority to complete actions that are requested after this change.

```
mqsichangebroker MB7BROKER -s active
```

Set the WebSphere MQ status of the broker to `defined`, so that the broker starts and stops when its associated queue manager starts and stops.

```
mqsichangebroker MB7BROKER -d defined
```

Set the WebSphere MQ service status to `undefined`, so that the broker no longer starts and stops when its associated queue manager starts and stops. The broker starts only when using the **mqsistart** command.

```
mqsichangebroker MB7BROKER -d undefined
```

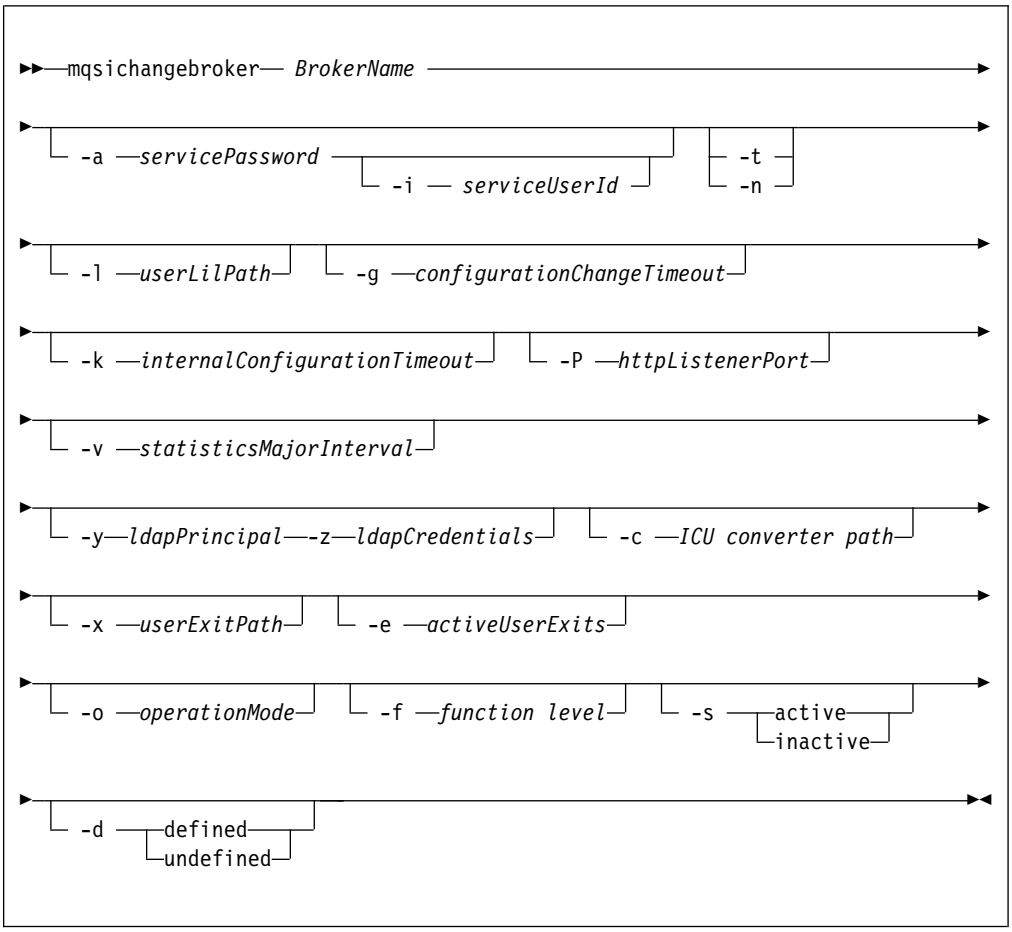
Use the **mqsicreatebroker** command to create a broker and its associated resources.

mqsichangebroker *command - Windows systems:*

Use the **mqsichangebroker** command on Windows systems to modify your broker.

Syntax:



Parameters:

BrokerName

(Required) This parameter must be the first parameter. Specify the name of the broker to modify.

-a *servicePassword*
(Optional) The password for the *serviceUserId*.

-i *serviceUserId*
(Optional) The user ID under which the broker runs. You must also change the password (**-a**) if you change this value.

You can specify the *serviceUserId* in any valid user name syntax:

- `\\server\username`
- `.\username`
- `username`

Do not use a domain name as part of the *serviceUserId* parameter.
If you use the unqualified form for this user ID (`username`), the operating system searches for the user ID throughout its domain, starting with the local

system. This search might take some time to complete.
The *serviceUserId* that you specify must be a direct or indirect member of the mqbrkrs local group. The *serviceUserId* must also be authorized to access the home directory (where WebSphere Message Broker has been installed), and the working directory (if specified by the **-w** parameter).
If you specify that the broker is to run as a WebSphere MQ trusted application (**-t** parameter), you must also add the service user ID to the mqm group.
The security requirements for the *serviceUserId* are described in "Security requirements for Windows systems" on page 3651.

-t (Optional) The broker runs as a WebSphere MQ trusted application.

For more details about using WebSphere MQ trusted applications, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

-n

(Optional) The broker ceases to run as a WebSphere MQ trusted application.

-l *userLilPath*
(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

Create your own directory for storing your `.lil` or `.jar` files. Do not save them in the WebSphere Message Broker installation directory.
If you specify more than one additional directory, each directory must be separated by the default platform-specific path separator.

-g *configurationChangeTimeout*
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k *internalConfigurationTimeout*
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-P *httpListenerPort*
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-v *statisticsMajorInterval*
(Optional) The time interval (in minutes) at which statistics and accounting archive records are written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

-y *ldapPrincipal*
(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *ldapCredentials*
(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *ICU converter path*
(Optional) A set of directories to search for additional code page converters, delimited by a semicolon (;).

The code page converters must be either of the form *codepagename*`.cnv`, or in an ICU data package called `icudt38.dat`. The code page converters must be located in a sub-directory named `icudt38_`*<platform_suffix>* of the specified directory where *<platform_suffix>* is one of the following values:

- l for little-endian ASCII platforms
- b for big-endian ASCII platforms
- e for EBCDIC platforms

-x *userExitPath*
(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (`PATH`,`LIBPATH`,`LD_LIBRARY_PATH`,`SHLIBPATH`) for the execution group process only.

-e *activeUserExits*
(Optional) Active user exits. By default, user exits are inactive. Adding a *userExit* name to this colon-separated list changes its default state to active for this broker. You can use the **mqsichangeflowuserexits** command to override the default state at the execution group or message flow level. If you specify a user exit name, and no library is found to provide that user exit when the execution group starts, a BIP2314 message is written to the system log. The execution group fails to start.

Note you can use double quotation marks to remove all the user exits from the active list:

```
mqsichangebroker <brokername> ""
```

-o *operationMode*
(Optional) Use this parameter to set the mode of your broker; see “Operation modes” on page 48. Valid values that you can set are `enterprise` (the full package, enterprise mode), `entry` (Entry Edition mode), `starter` (Starter Edition mode), and `adapter` (Remote Adapter Deployment mode). The default

value is `enterprise`, unless you have the Trial Edition, when the default value is `trial`. If you do not set the **-o** parameter, the default value is used automatically.

-f *function level*
(Optional) Use this parameter to enable function that becomes available in WebSphere Message Broker fix packs. Valid values that you can set are `all`, which enables all functions, or a version string of the form V.R.M.F (for example, `7.0.0.7`), which indicates the maximum level of feature function to enable. You can use this parameter to revert to a previous fix pack level, but you must first remove any flows that are using the new functions.

This command does not disable all new features, and it is not possible to use this flag to run the broker at a different major version.

-s ***security_status***
(Optional) Specify this parameter to change the administrative security status of the broker.

- If you specify `active`, administrative security is enabled for the broker. The command creates authorization queues that are required, if they do not exist.
- If you specify `inactive`, administrative security is disabled for the broker. The command does not delete or clear the security queues that are associated with this broker and its execution groups.

If you omit this parameter, the security status is unchanged.

For further information about using security, see "Broker administration security overview" on page 362 and "Authorizing users for broker administration" on page 371.

-d (Optional) Enables a broker to be started and stopped as a WebSphere MQ service when the queue manager starts and stops.

This option is an alternative to starting a multi-instance broker in standby mode using the **mqsistart** command.

If you specify **-d defined**, the WebSphere MQ service is defined to the queue manager and the broker starts and stops when the queue manager starts and stops.

If you specify **-d undefined**, the WebSphere MQ service is not defined to the queue manager and the broker does not start and stop when the queue manager starts and stops. This is the default setting.

To change other broker properties, first delete and re-create the broker, and then use the WebSphere Message Broker Toolkit to redeploy the broker configuration. If you want to update the user ID credentials that the broker uses to access one or more databases from deployed message flows, use the **mqsisetdbparms** command. For more information, see "Accessing databases from message flows" on page 2112.

Examples:
Define the path to user-defined exits:

```
mqsichangebroker MB7BROKER -x /opt/3rdparty/wmbexit
```

Enable the new function that is supplied in WebSphere Message Broker Version 7.0.0.7:

```
mqsichangebroker MB7BROKER -f 7.0.0.7
```

Set the broker's security status to `active`, so that the broker checks that the user has the correct authority to complete actions that are requested after this change.

```
mqsichangebroker MB7BROKER -s active
```

Set the broker's WebSphere MQ status to `defined`, so that the broker starts and stops when its associated queue manager starts and stops.

```
mqsichangebroker MB7BROKER -d defined
```

Set the WebSphere MQ service status to `undefined`, so that the broker no longer starts and stops when its associated queue manager starts and stops. The broker starts only when using the **mqsistart** command.

```
mqsichangebroker MB7BROKER -d undefined
```

Use the **mqsicreatebroker** command to create a broker and its associated resources.

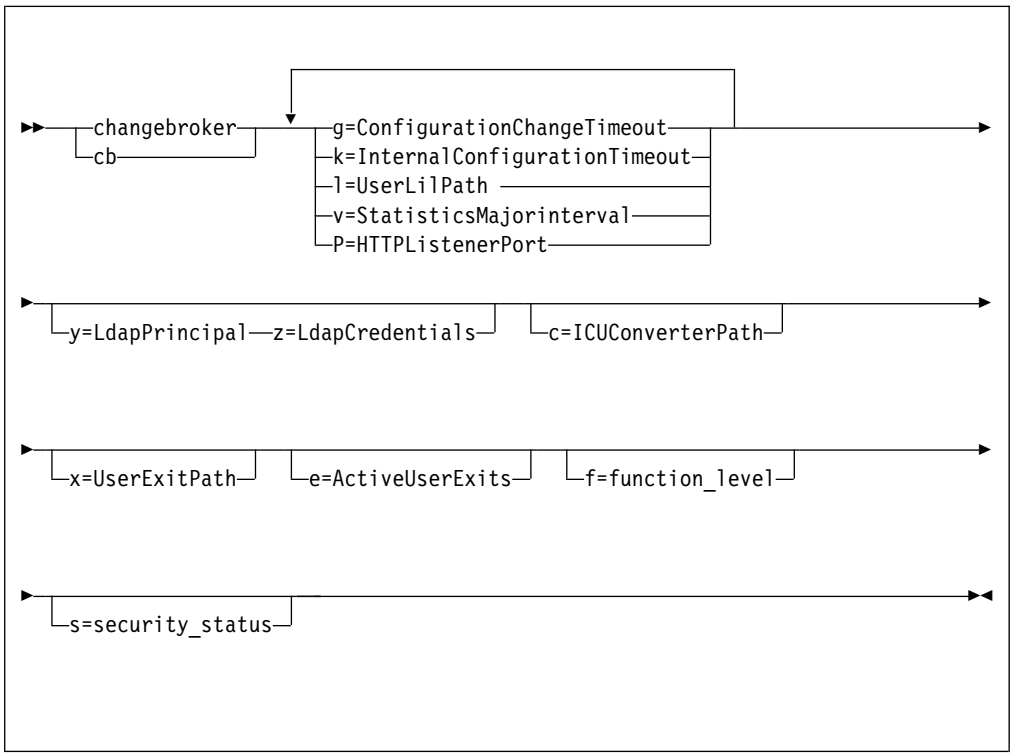
mqsichangebroker *command - z/OS:*

Use the **mqsichangebroker** command on z/OS to modify your broker.

Syntax:

z/OS command - BIPCHBK:

z/OS console command:
Synonym: cb



Parameters:

BrokerName
(Required) This parameter must be the first parameter. Specify the name of the broker to modify.

This parameter is implied in the console form of the command.

-l ***UserLilPath***
(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

This name is case sensitive; enclose the names in single quotation marks if they are in mixed case.
Do not include environment variables in this path; WebSphere Message Broker ignores them.

Create your own directory for storing your `.lil` or `.jar` files. Do not save them in the WebSphere Message Broker installation directory.
If you specify more than one additional directory, each directory must be separated by the default platform-specific path separator.

-g ***ConfigurationChangeTimeout***
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k ***InternalConfigurationTimeout***
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-P ***HTTPListenerPort***
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-v *StatisticsMajorInterval*
(Optional) Specify the interval (in minutes) at which statistics and accounting archive records are to be written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

An interval of zero minutes indicates that the operating system has an external method of notification (the ENF timer), and is not using an internal timer within WebSphere Message Broker.

-y *LdapPrincipal*
(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *LdapCredentials*
(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *ICUConverterPath*
(Optional) A delimited set of directories to search for additional code page converters; the delimiter is a period (.).

The code page converters must be either of the form *codepagename*`.cnv`, or in an ICU data package called `icudt38.dat`. The code page converters must be located in a sub-directory named `icudt38_`*<platform_suffix>* of the specified directory where *<platform_suffix>* is one of the following values:

- l for little-endian ASCII platforms
- b for big-endian ASCII platforms
- e for EBCDIC platforms

Do not use this parameter to set the converter path if you are using a converter that matches one of the built-in converters that are provided with Version 6.0, and that converter is the local code page for the broker. Use the **ICU_DATA** environment variable instead.

-x *UserExitPath*
(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (`PATH,LIBPATH,LD_LIBRARY_PATH,SHLIBPATH`) for the execution group process only.

-e *ActiveUserExits*
(Optional) Active user exits. By default, user exits are inactive. Adding a *userExit* name to this colon-separated list changes its default state to active for this broker. You can use the **mqsichangeflowuserexits** command to override the default state at the execution group or message flow level. If you specify a user exit name, and no library is found to provide that user exit when the execution group starts, a BIP2314 message is written to the system log. The execution group fails to start.

-f *function level*
(Optional) Use this parameter to enable function that becomes available in WebSphere Message Broker fix packs. Valid values that you can set are `all`, which enables all functions, or a version string of the form V.R.M.F (for example, `7.0.0.7`), which indicates the maximum level of feature function to enable. You can use this parameter to revert to a previous fix pack level, but you must first remove any flows that are using the new functions.

This command does not disable all new features, and it is not possible to use this flag to run the broker at a different major version.

-s ***security_status***
(Optional) Specify this parameter to change the administrative security status of the broker.

- If you specify `active`, administrative security is enabled for the broker. The command creates authorization queues that are required, if they do not exist.
- If you specify `inactive`, administrative security is disabled for the broker. The command does not delete or clear the security queues that are associated with this broker and its execution groups.

If you omit this parameter, the security status is unchanged.

For further information about using security, see "Broker administration security overview" on page 362 and "Authorizing users for broker administration" on page 371.

To change other broker properties, first delete and re-create the broker, and then use the WebSphere Message Broker Toolkit to redeploy the broker configuration. If you want to update the user ID credentials that the broker uses to access one or more databases from deployed message flows, use the **mqsisetdbparms** command. For more information, see "Accessing databases from message flows" on page 2112.

Examples:
When you run the console command, you must use a comma between each command option, as shown in these examples.

Change the configuration timeout parameters:

```
F MQP1BRK,cb g=100,k=200
```

Specify both the **x** and **e** parameters to set the user exit path and set an exit to active state:

```
/f MA05BRK,cb x='/u/test/wbi/MsgFlowTrackingUserExit/zOS',e='MqsiStrUserExit02:MqsiStrUserExit03'
```

Enable the new function that is supplied in WebSphere Message Broker Version 7.0.0.7:

```
F MQP1BRK,cb f=7.0.0.7
```

Set the broker's security status to `active`, so that the broker checks that the user has the correct authority to complete actions that are requested after this change.

```
mqsichangebroker MB7BROKER -s active
```

mqsichangeflowmonitoring command:

Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

Supported operating systems:

- Windows
- Linux and UNIX systems
- z/OS: Run this command either as a console command, or by customizing and submitting BIPCHME; see "Contents of the broker PDSE" on page 3991.

Purpose:
Use the **mqsichangeflowmonitoring** command to carry out the following tasks:

- Activate or deactivate monitoring for a message flow
- Enable or disable an event source within a message flow
- Associate a configurable service with a message flow by setting its `monitoringProfile` property.

This facility can be used to change the state (enabled or disabled) of any event in the message flow, whether it was configured using the node's monitoring properties, or a monitoring profile configurable service. The new state takes effect immediately (but safely).

The state change persists, and so it survives a restart of the message flow or execution group. For an event configured using the node's monitoring properties, the state change is lost if the message flow is redeployed, unless the node property is also changed.

Select the appropriate link for details of the **mqsichangeflowmonitoring** command on the platform that your enterprise uses:

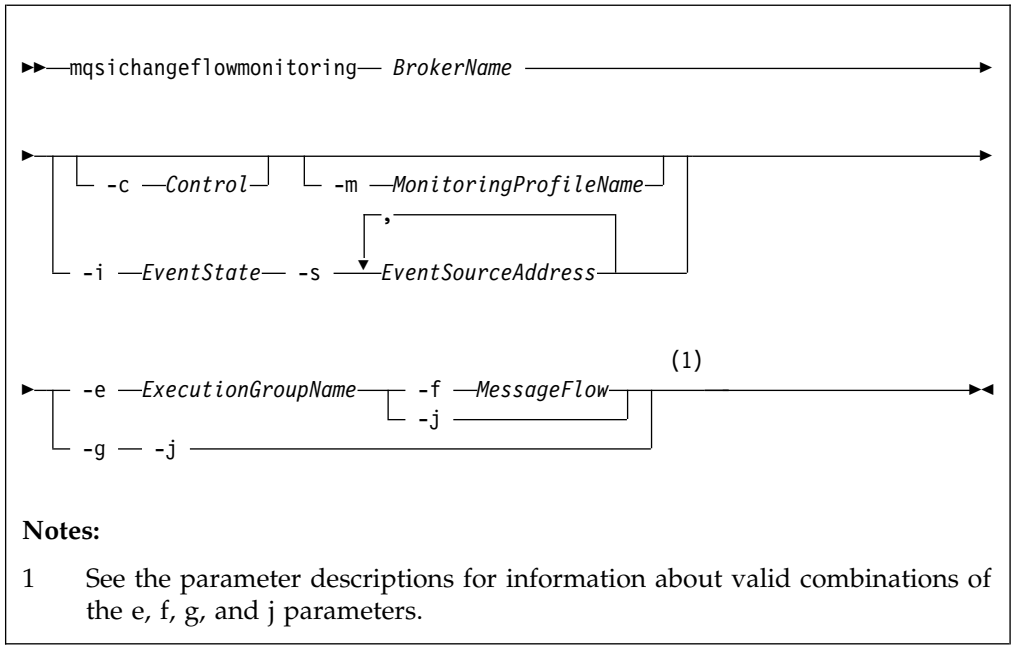
Security requirements depend on the administrative task that you want to perform.

mqsichangeflowmonitoring *command - Windows, Linux and UNIX systems:*

Use the **mqsichangeflowmonitoring** command on Windows, Linux and UNIX systems to enable monitoring of message flows.

Syntax:



Notes:

1 See the parameter descriptions for information about valid combinations of the e, f, g, and j parameters.

Parameters:

BrokerName
(Required) Specify the label of the broker to which the message flows that you want to be monitored are deployed.

-c *Control*
(Optional) Specify the string value that controls monitoring for the specified message flows. Possible values are:

`active` - activate monitoring

`inactive` - deactivate monitoring

-f *MessageFlow*
(Required) Specify the label for the message flow, for which the monitoring options are to be activated or updated.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

-g

(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

-i EventState

(Optional) Specify the string value that controls monitoring for the specified event source. Valid only when used with the -e and -f parameters. Possible values are:

`enable` - enable monitoring for the specified event sources.

`disable` - disable monitoring for the specified event sources.

-j

(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-m *MonitoringProfileName*

(Optional) Specify the name of the monitoring profile which the specified message flows should use.

If there is no monitoring profile with the specified name on the specified broker, the command completes successfully, and the message flows attempt to use the specified monitoring profile. Each message flow logs a warning in the User Trace to indicate that it was instructed to use a nonexistent monitoring profile. No event message is created. If a monitoring profile with the specified name is later deployed to the broker, the message flows do not immediately begin to use it. A refresh of the monitoring state can be triggered by issuing the command again with the –c option to activate or reactivate monitoring.

-s EventSourceAddress

(Optional) Comma-separated list of the event sources to be enabled or disabled. Valid only when used with the -e and -f parameters. This value takes the form <*node name*>.<*event source*>, where <*event source*> is one of the following values:

`'terminal.`<*terminal name*>'

`'transaction.Start'`

`'transaction.End'`

`'transaction.Rollback'`

If a message flow contains two or more nodes with identical names, the event sources on those nodes cannot be accurately addressed. If this is attempted, behavior is undefined.

<*node name*> is the label of the node as known by the broker runtime components. If the node is in a subflow, the label reflects this. For example, flow A contains an instance of flow B as a subflow that is labeled 'myB'. Flow B contains an instance of a Compute node that is labeled 'myCompute'. The <*node name*> for the Compute node is 'myB.myCompute'.

If you issue this command with a comma separated list to enable or disable individual event sources, and you have not already issued the command with the **-c** parameter, monitoring is not activated for these event sources. To enable monitoring, reissue the command with the **-c** parameter set to `active`.

Examples:
Assign *monitoringProfile1* to *messageFlow1* in execution group *default*:

```
mqsichangeflowmonitoring WBRK_BROKER -e default
     -f messageFlow1 -m monitoringProfile1
```

Activate monitoring for all message flows in all execution groups:

```
mqsichangeflowmonitoring WBRK_BROKER -c active -g -j
```

Enable individual event sources:

```
mqsichangeflowmonitoring WBRK_BROKER
     -e default
     -f myMessageFlow
     -s "SOAP Input1.terminal.out,MQOutput1.terminal.in"
     -i enable
```

Related tasks:

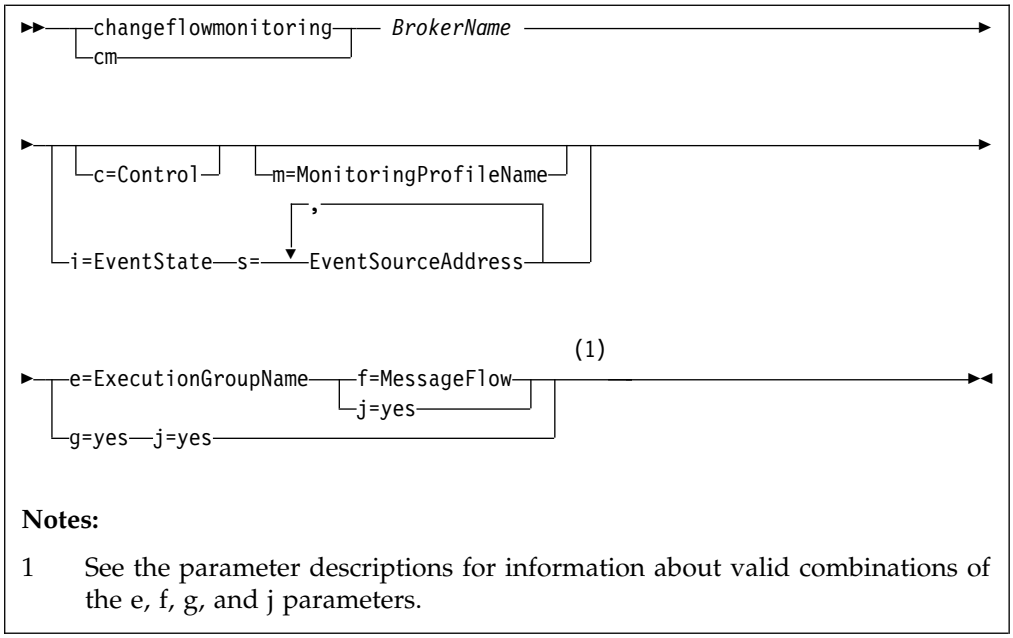
mqsichangeflowmonitoring *command - z/OS:*

Use the **mqsichangeflowmonitoring** command on z/OS to enable monitoring of message flows.

Syntax:

z/OS console command:
Synonym: cm



Notes:

1 See the parameter descriptions for information about valid combinations of the e, f, g, and j parameters.

Parameters:

BrokerName
(Required) Specify the label of the broker to which the message flows that you want to be monitored are deployed.

This parameter is implied on the console form of the command.

c=Control
(Optional) Specify the string value that controls monitoring for the specified message flows. Possible values are:

`active` - activate monitoring

`inactive` - deactivate monitoring

e=ExecutionGroupName
(Required) Specify the name for the execution group to which the message flows that you want to be monitored are deployed.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

f=MessageFlow
(Required) Specify the label for the message flow, for which the monitoring options are to be activated or updated.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

g (Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

i=EventState
(Optional) Specify the string value that controls monitoring for the specified event source. Valid only when used with the -e and -f parameters. Possible values are:

`enable` - enable monitoring for the specified event sources.

`disable` - disable monitoring for the specified event sources.

j (Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

m=MonitoringProfileName
(Optional) Specify the name of the monitoring profile which the specified message flows should use.

If there is no monitoring profile with the specified name on the specified broker, the command completes successfully, and the message flows attempt to use the specified monitoring profile. Each message flow logs a warning in the User Trace to indicate that it was instructed to use a nonexistent monitoring profile. No event message is created. If a monitoring profile with the specified name is later deployed to the broker, the message flows do not immediately begin to use it. A refresh of the monitoring state can be triggered by issuing the command again with the –c option to activate or reactivate monitoring.

s=EventSourceAddress
(Optional) Comma-separated list of the event sources to be enabled or disabled. Valid only when used with the -e and -f parameters. This value takes the form <*node name*>.<*event source*>, where <*event source*> is one of the following values:

`'terminal.`<*terminal name*>'

`'transaction.Start'`

`'transaction.End'`

`'transaction.Rollback'`

If a message flow contains two or more nodes with identical names, the event sources on those nodes cannot be accurately addressed. If this is attempted, behavior is undefined.

<*node name*> is the label of the node as known by the broker runtime components. If the node is in a subflow, the label reflects this. For example, flow A contains an instance of flow B as a subflow that is labeled 'myB'. Flow B contains an instance of a Compute node that is labeled 'myCompute'. The <*node name*> for the Compute node is 'myB.myCompute'.

If you issue this command with a comma separated list to enable or disable individual event sources, and you have not already issued the command with the **-c** parameter, monitoring is not activated for these event sources. To enable monitoring, reissue the command with the **-c** parameter set to `active`.

Example:
Activate monitoring on all message flows in all execution groups:

```
F MI10BRK,cm c=active,g=yes,j=yes
```

Related tasks:

“Business-level monitoring” on page 3319
You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

mqsichangeflowstats command:

Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

Supported Platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting BIPCHMS; see "Contents of the broker PDSE" on page 3991

Purpose:
Use the **mqsichangeflowstats** command to:

- Turn on or off accounting and statistics snapshot publication, or archive record output.
- Specify that the command is applied to a specific flow message flow, or all flows in an execution group, or all execution groups belonging to a broker.
- Modify the granularity of the data collected in addition to the standard message flow accounting and statistics. This extra data can include thread related data, node related data, node terminal related data, or a mixture of this data.

The options set using this command remain active until modified by a subsequent **mqsichangeflowstats** command, or until affected by a subsequent deploy.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "mqsichangeflowstats command - Windows, Linux and UNIX systems" on page 3745
- "mqsichangeflowstats command - z/OS" on page 3748

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an

input message is received.

Related tasks:

"Optimizing message flow throughput" on page 587
Each message flow that you design must provide a complete set of processing for messages received from a certain source. This design might result in very complex message flows that include large numbers of nodes that can cause a performance overhead, and might create potential bottlenecks. You can increase the number of message flows that process your messages to provide the opportunity for parallel processing and therefore improved throughput.

"Optimizing message flow response times" on page 3264
You can use different solutions to improve message flow response times.

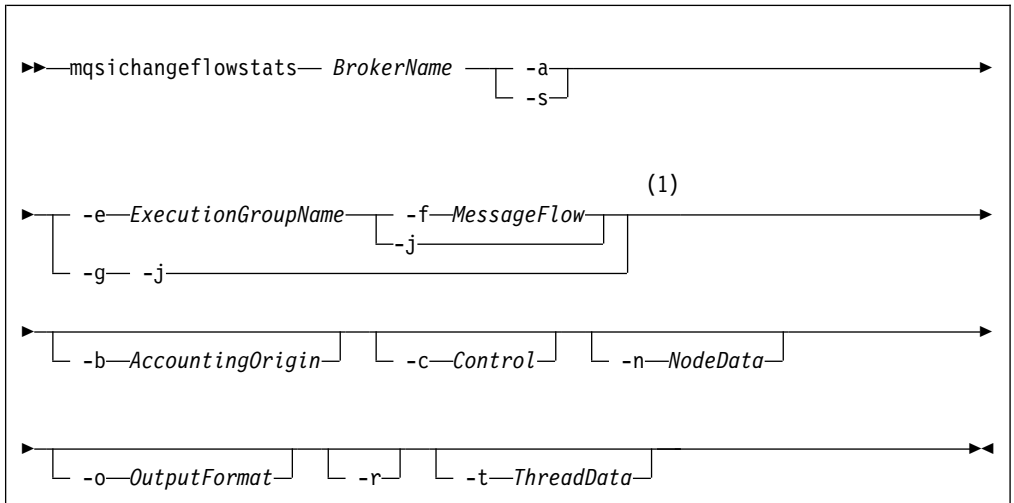
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsireportflowstats** command" on page 3929
Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

mqsichangeflowstats command - Windows, Linux and UNIX systems:

Use the **mqsichangeflowstats** command on Windows, Linux and UNIX systems to control the accumulation of statistics about message flow operation.

Syntax:



Notes:

1 See the parameter descriptions for information on valid combinations of the e, f, g, and j parameters.

Parameters:

BrokerName
(Required) Specify the label of the broker for which accounting and statistics are to be changed.

-a (Required) Specify that the command modifies archive accounting and statistics collection.

You must specify either **-a** or **-s**. If you do not specify one of these arguments you receive a warning message.

-b *AccountingOrigin*
(Optional) Specifies that the environment tree path *Broker.Accounting.Origin* is used to partition the collected statistics into distinct outputs. Possible values are:

- none - do not partition statistics according to accounting origin data
- basic - partition statistics according to accounting origin data

-c *Control*
(Optional) Specify the string value that controls the level of the action to be applied to accounting and statistics collection for snapshot or archiving. Possible values are:

- active - turn on snapshot or archiving
- inactive - turn off snapshot or archiving.

-e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which accounting and statistics options are to be changed.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-f *MessageFlow*
(Required) Specify the label for the message flow, for which accounting and statistics options are to be changed.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

-g
(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-j
(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-n *NodeData*
(Optional) Specify a string value to modify the collection of node statistics data for a message flow. Possible values are:

- none - exclude node related data in the statistics
- basic - include node related statistics in the statistics
- advanced - include node related and terminal related data in the statistics

-o *OutputFormat*
(Optional) Specify the output destination for the statistics reports. Possible values are:

- usertrace - this is the default and writes "bip" messages to usertrace, which can be post processed in the normal way using the **mqsireadlog** and **mqsiformatlog** commands
- xml - the statistics reports are generated as XML documents and published by the broker running the message flow.

  The topic on which the data is published has the following structure:

  ```
  $SYS/Broker/<brokerName>/StatisticsAccounting/<recordType>
  /<executionGroupLabel>/<messageFlowLabel>
  ```

  where recordType is set to Snapshot or Archive, and broker, execution group, and message flow names are specified according to the subscriber's requirements.

-r (Optional) This parameter applies only to archive data and specifies that archive data is to be reset.

This results in the clearing out of accounting and statistics data accumulated so far for this interval, and restarts collection from this point. All archive data for all flows in the execution group, or groups, is reset.

The archive interval timer is only reset if the **-v** option (*statistics archive interval*) of **mqsicreatebroker** or **mqsichangebroker** is non zero.

That is, the interval timer is set only if the internal interval notification mechanism is being used, and not an external method.

-s (Required) Specify that the command modifies snapshot accounting and statistics collection.

You must specify either **-a** or **-s**. If you do not specify one of these arguments you receive a warning message.

-t *ThreadData*
(Optional) Specify a string value to modify the collection of thread statistics data for a message flow Possible values are:

- none - exclude thread related data from the statistics
- basic - include thread related data in the statistics

Examples:
Turn on snapshot statistics for the message flow "myFlow1" in all execution groups of BrokerA and specify that the statistics are not to be partitioned according to accounting origin data:

```
mqsichangeflowstats BrokerA -s -g -j -b none -c active
```

Turn off the collection of archive statistics for message flow "MyFlow1" in execution group "EGRP2" for BrokerA, and at the same time modify the granularity of data that is to be collected (when next activated) to include thread related data.

```
mqsichangeflowstats BrokerA -a -e EGRP2 -f MyFlow1 -c inactive -t basic
```

Turn off snapshot data for all message flows in all execution groups for Broker A.

```
mqsichangeflowstats BrokerA -s -g -j -c inactive
```

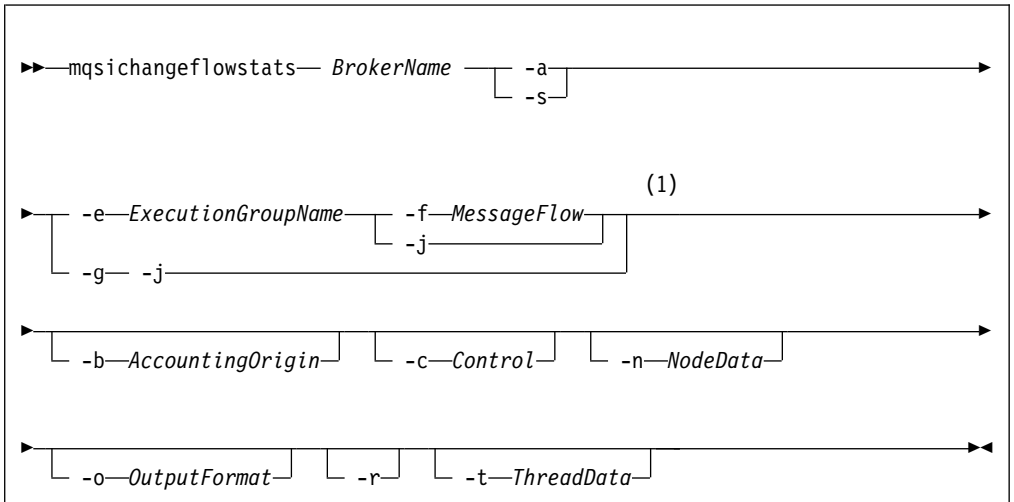
"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

mqsichangeflowstats command - z/OS:

Use the **mqsichangeflowstats** command on z/OS to control the accumulation of statistics about message flow operation.

Syntax:

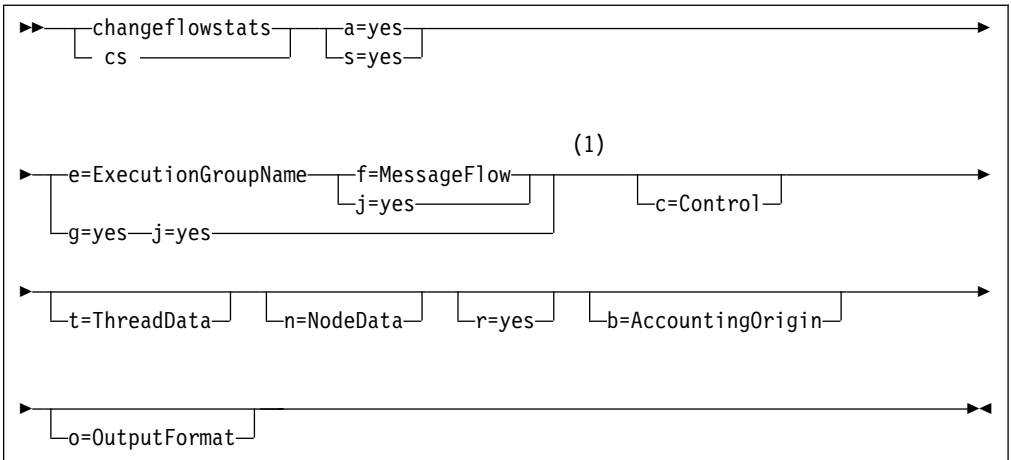
z/OS command - BIPCHMS:



Notes:

1 See the parameter descriptions for information on valid combinations of the e, f, g, and j parameters.

z/OS console command:
Synonym: cs



Notes:

1 See the parameter descriptions for information on valid combinations of the e,f, g, and j parameters.

Parameters:

BrokerName
(Required) Specify the label of the broker for which accounting and statistics are to be changed.

This parameter is implied on the console form of the command.

-a (Required) Specify that the command modifies archive accounting and statistics collection.

You must specify either **-a** or **-s**. If you do not specify one of these arguments you receive a warning message.

-b *AccountingOrigin*
(Optional) Specifies that the environment tree path *Broker.Accounting.Origin* is used to partition the collected statistics into distinct outputs. Possible values are:

- none - do not partition statistics according to accounting origin data
- basic - partition statistics according to accounting origin data

-c *Control*
(Optional) Specify the string value that controls the level of the action to be applied to accounting and statistics collection for snapshot or archiving. Possible values are:

- active - turn on snapshot or archiving
- inactive - turn off snapshot or archiving.

-e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which accounting and statistics options are to be changed.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-f *MessageFlow*
(Required) Specify the label for the message flow, for which accounting and statistics options are to be changed.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

-g
(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-j
(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-n *NodeData*
(Optional) Specify a string value to modify the collection of node statistics data for a message flow. Possible values are:

- none - exclude node related data in the statistics
- basic - include node related statistics in the statistics
- advanced - include node related and terminal related data in the statistics

-o *OutputFormat*
(Optional) Specify the output destination for the statistics reports. Possible values are:

- usertrace - this is the default and writes "bip" messages to usertrace, which can be post processed in the normal way using the **mqsireadlog** and **mqsiformatlog** commands
- xml - the statistics reports are generated as XML documents and published by the broker running the message flow.

  The topic on which the data is published has the following structure:

  ```
  $SYS/Broker/<brokerName>/StatisticsAccounting/<recordType>
  /<executionGroupLabel>/<messageFlowLabel>
  ```

  where recordType is set to Snapshot or Archive, and broker, execution group, and message flow names are specified according to the subscriber's requirements.
- smf - statistics reports are output as SMF type 117 records.

-r (Optional) This parameter applies only to archive data and specifies that archive data is to be reset.

This results in the clearing out of accounting and statistics data accumulated so far for this interval, and restarts collection from this point. All archive data for all flows in the execution group, or groups, is reset.

The archive interval timer is only reset if the **-v** option (*statistics archive interval*) of **mqsicreatebroker** or **mqsichangebroker** is non zero.

That is, the interval timer is set only if the internal interval notification mechanism is being used, and not an external method.

-s (Required) Specify that the command modifies snapshot accounting and statistics collection.

You must specify either **-a** or **-s**. If you do not specify one of these arguments you receive a warning message.

-t *ThreadData*
(Optional) Specify a string value to modify the collection of thread statistics data for a message flow Possible values are:

- none - exclude thread related data from the statistics
- basic - include thread related data in the statistics

Examples:
Using the command BIPCHMS:

- Turn on snapshot statistics for the message flow "myFlow1" in all execution groups and specify that the statistics are not to be partitioned according to accounting origin data:

  ```
  mqsichangeflowstats BrokerA -s -g -j -b none
  ```

- Turn off the collection of archive statistics for message flow "MyFlow1" in execution group "EGRP2" , and at the same time modify the granularity of data that is to be collected (when next activated) to include thread related data.

  ```
  mqsichangeflowstats BrokerA -a -e "EGRP2" -f MyFlow1 -c inactive -t basic
  ```

The following example uses the console form of the command. Turn on archive accounting for all the message flows in all the execution groups that belong to the broker and output the report as SMF records.

```
F VCP2BRK,CS A=YES,G=YES,J=YES,C=ACTIVE,O=SMF
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

mqsichangeflowuserexits command:

Use the **mqsichangeflowuserexits** command to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

Supported operating systems:

- Windows
- Linux and UNIX systems
- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting the BIPCHUE utility; see "Contents of the broker PDSE" on page 3991

Purpose:
The order of precedence is message flow, execution group, then broker default. The active list takes precedence over the inactive list in the message flow and execution group settings.

If the state for a given user exit is not set for the message flow, its state is taken from the execution group setting. If its state is not set for the message flow or

execution group, it takes the default state which is implicitly inactive, or can be explicitly defined as active by the broker property *activeUserExits*, through the **mqsichangebroker** command.

If a particular user exit name is present in both the active and inactive lists for a message flow or execution group, the active list takes precedence and the user exit is active for that level. Therefore, if you want to change a user exit from active to inactive you must specify it as part of the inactive list, by using the **-i** flag and also remove it from the active list by re-specifying the new active list by using the **-a** flag.

When multiple exits are active for a given flow, they are invoked in a defined order. Those exits in the message flow's active list are invoked first in the order in which they were specified on the **-a** flag.

After those have been invoked, the exits in the execution group's active list (which were in neither the message flow's active nor inactive list) are invoked. These exits are invoked in the order in which they were specified on the **-a** flag.

Note, that to clear the user exit lists, double quotation marks must be used as an argument with the **-i** or **-a** flag, depending on which user exit list is to be cleared.

All user exits that are not mentioned in the execution group's or message flow's active or inactive list, but are in the broker's active list, are invoked in the order in which they were specified when the broker property *activeUserExits* was set.

If any of the user exits specified in either the active or inactive list are not registered for the target execution group, the command fails with a BIP8858 error.

After successful command completion, if a user exit becomes invalid, the following action is taken, depending on which list the user exit appeared in:

- If the user exit was specified in the message flow's active or inactive list, the flow fails to start and a BIP2315 message is written to system log.
- If the user exit was specified in the execution group's active or inactive list, the execution group fails to start and a BIP2314 message is written to system log.

A user exit might become invalid for one of the following reasons:

- The broker or execution group is restarted after you change the MQSI_USER_EXIT_PATH variable by removing the directory containing the user exit library.
- The broker or execution group is restarted after you change the *userExitPath* broker property by removing the directory containing the user exit library.
- The user exit library (or one of its dependencies) is removed, or the broker is unable to load it.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- “mqsichangeflowuserexits command - Windows, Linux, and UNIX systems” on page 3753
- “mqsichangeflowuserexits command - z/OS” on page 3754

Authorization:
For information about platform-specific authorizations, see the following topics:

- “Security requirements for Linux and UNIX platforms” on page 3648

- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Develop a user exit by declaring it, implementing its behavior, then compiling it.

"Deploying a user exit" on page 3116
Deploy your user exit to the broker.

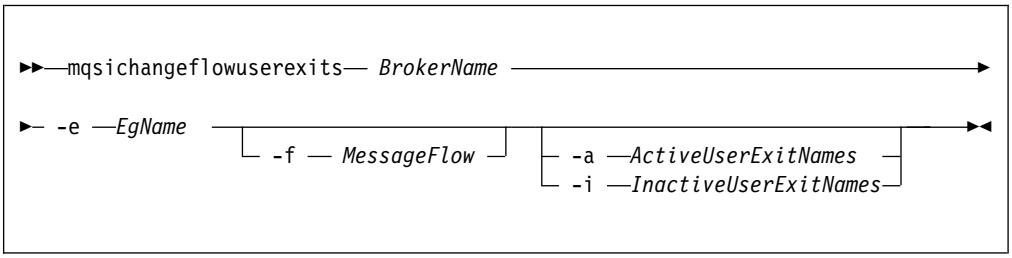
Related reference:

"**mqsireportflowuserexits** command" on page 3933
Use the **mqsireportflowuserexits** command to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

mqsichangeflowuserexits command - Windows, Linux, and UNIX systems:

Use the **mqsichangeflowuserexits** command on Windows, Linux, and UNIX systems to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

Syntax:



Parameters:

BrokerName
(Required). The name of the broker.

-a *ActiveUserExitNames*
(Optional). A list of the names, separated by colons, of the active user exits. These are the names registered by the user exits when they were loaded. If any of the user exits listed are not registered for the target execution group, then the command fails with a BIP8858 error.

-e *EgName*
(Required). The name of the execution group.

-f *MessageFlow*
(Optional). The name of the message flow.

If you supply this value, the user exit is changed for that message flow; if you do not, the user exit is set at the execution group level.

-i *InactiveUserExitNames*
(Optional). A list of the names, separated by colons, of the inactive user exits. These are the names registered by the user exits when they were loaded. If any of the user exits listed are not registered for the target execution group, then the command fails with a BIP8858 error.

Examples:
Setting active exits at flow level

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -a exit2
```

Setting inactive exits at flow level

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -i exit1
```

Setting active exits at execution group level:

```
mqsichangeflowuserexits MB7BROKER -e default -a exit3,exit1
```

Setting inactive exits at execution group level:

```
mqsichangeflowuserexits MB7BROKER -e default -1 exit2
```

Changing exit1 to inactive and leaving exit2 active at flow level (A command had previously been issued with "-a exit1:exit2" to set them both active):

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -i exit1 -a exit2
```

Clearing the active user exit list at flow level:

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -a ""
```

Related reference:

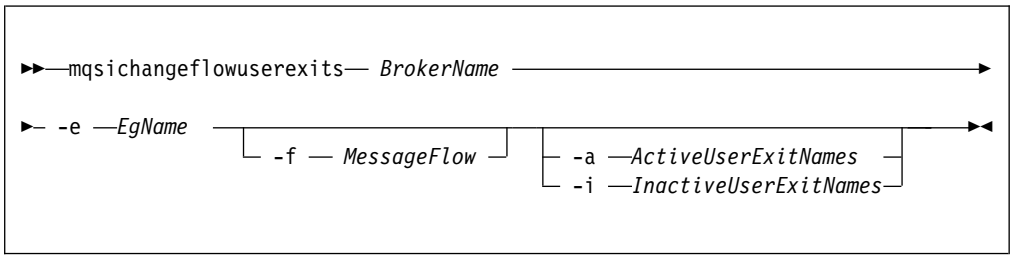
Use the **mqsichangeflowuserexits** command to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

mqsichangeflowuserexits command - z/OS:

Use the **mqsichangeflowuserexits** command on z/OS to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

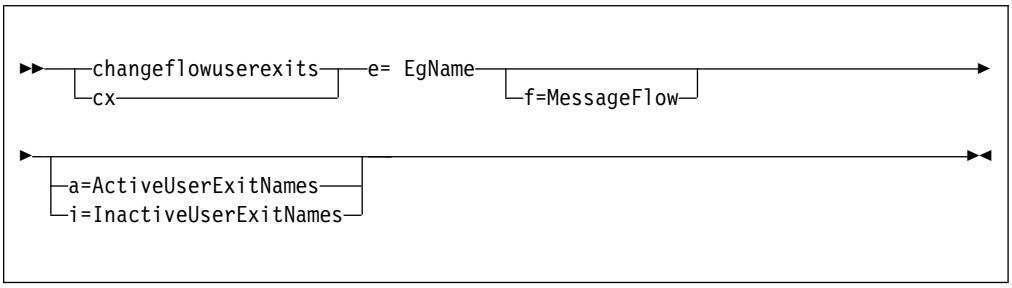
Syntax:

z/OS command - BIPCHUE:



z/OS console command:

Synonym: cx



Parameters:

BrokerName
(Required). The name of the broker.

-a *ActiveUserExitNames*
(Optional). A list of the names, separated by colons, of the active user exits. These are the names registered by the user exits when they were loaded. If any of the user exits listed are not registered for the target execution group, then the command fails with a BIP8858 error.

-e *EgName*
(Required). The name of the execution group.

-f *MessageFlow*
(Optional). The name of the message flow.

If you supply this value, the user exit is changed for that message flow; if you do not, the user exit is set at the execution group level.

-i *InactiveUserExitNames*
(Optional). A list of the names, separated by colons, of the inactive user exits. These are the names registered by the user exits when they were loaded. If any of the user exits listed are not registered for the target execution group, then the command fails with a BIP8858 error.

Examples:
Setting active exits at flow level

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -a exit2
```

Setting inactive exits at flow level

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -i exit1
```

Setting active exits at execution group level

```
mqsichangeflowuserexits MB7BROKER -e default -a exit3,exit1
```

Setting inactive exits at execution group level

```
mqsichangeflowuserexits MB7BROKER -e default -1 exit2
```

Changing exit1 to inactive and leaving exit2 active at flow level (A command had previously been issued with "-a exit1:exit2" to set them both active)

```
mqsichangeflowuserexits MB7BROKER -e default -f myFlow -i exit1 -a exit2
```

Related reference:
"Syntax diagrams" on page 3677

"**mqsichangeflowuserexits** command" on page 3751
Use the **mqsichangeflowuserexits** command to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

mqsichangeproperties command:

Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

Supported platforms:

- Windows systems.
- Linux and UNIX systems.
- z/OS. Run this command by customizing and submitting the BIPCHPR utility; see "Contents of the broker PDSE" on page 3991.

Purpose:
Use the **mqsichangeproperties** command to change properties that are associated with a broker:

- Properties that affect the whole broker; for example, an HTTP listener or Service Federation Management
- Properties that affect one or more execution groups; for example, the broker registry
- Properties that affect a configurable service; for example, a JMS provider

You can also use the WebSphere Message Broker Explorer or the Administration API for WebSphere Message Broker (also known as the CMP API) to change properties.

Use the **mqsireportproperties** command to view properties that are associated with a broker.

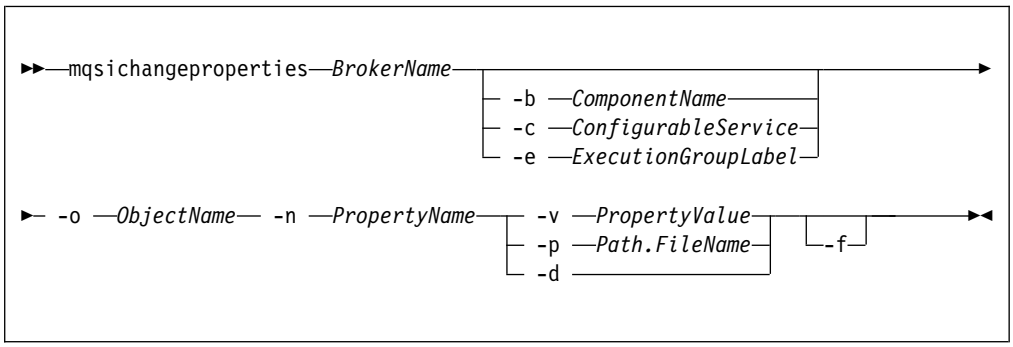
Usage notes:

Before you run the **mqsichangeproperties** command, ensure that the broker is running.

If you change one or more values, stop and start the broker again for the change to take effect.

When a message flow that includes HTTP nodes is started, the broker starts the HTTP and HTTPS listeners, unless this listener has been disabled.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker to modify. This parameter must be the first parameter.

-b *ComponentName*
(Optional) The name of the component. Valid values are *httplistener*, *securitycache*, and *servicefederation*. The properties associated with these components affect the whole broker.

-c *ConfigurableService*
(Optional) The type of configurable service. The type is predefined; for example, JMSProviders. You can define additional services of all defined types by using the WebSphere Message Broker Explorer or the **mqsicreateconfigurableservice** command.

The valid resource types are listed in "Configurable services properties" on page 3766.

-e *ExecutionGroupLabel*
(Optional) The label of the execution group for which you want to change properties.

-o *ObjectName*
(Required) The name of the broker resource for which you want to change the properties.

You must also specify **-b**, **-e**, or **-c** with **-o**, except if you specify the object name `BrokerRegistry`, or the object name `ComIbmJVMManager` to change a property related to the heap size.

For compatibility with previous versions, you can also specify the value `ComIbmXmlParserFactory` for the **ObjectName**.

-n *PropertyName*
(Required) The name of the property to be changed. The available property names differ according to the component or configurable service that you have specified. All property names start with a lowercase character.

The property names for predefined configurable services are described in "Configurable services properties" on page 3766.

If you specify a Configurable Service of type UserDefined, the PropertyName specified is created if it does not exist.

-v *PropertyValue*
(Required) The value that is assigned to the property that is specified by the **-n** parameter.

You can specify more than one property name together with a corresponding value, by using commas as separators, if you use a valid value for the corresponding property; for example, `-n Name1,Name2 -v Value1,Value2`.

Do not leave a space after each comma in the list of names and corresponding values. Use "" to specify an empty *PropertyValue* string.

If the property value contains a comma, enclose the value with escaped double quotation marks (\" and \"); for example, `-n Name1,Name2 -v Value1,\"Value21,Value22\"`.

UNIX On UNIX, if the **-v** parameter contains a semicolon (;), enclose the entire string in quotation marks, as shown in the following example:

```
mqsichangeproperties MB7BROKER -c JDBCProviders -o DB2EXTRA -n connectionUrlFormat
-v "jdbc:db2://[serverName]:[portNumber]/[databaseName]:user=[user];password=[password];"
```

If you set the **-c** parameter to `EISProviders` or `JMSProviders`, and the **-n** parameter to `jarsURL`, the expected value is a URL that specifies the file location of the EIS or JMS provider JAR files, but omits the `file://` part of the URL. (On Windows, the file location cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a Storage Area Network (SAN) disk.)

-p *Path.FileName*
(Optional) The location and name of a file from which the command reads the property value. Use this command as an alternative to **-v** where the value of the property is complex and is defined in a file, such as an XML file.

The following conditions apply to the use of this parameter:

- **-p** can be used to set a single property only. Therefore, the **-n** parameter must have a single property name, not a comma-separated list.
- White space characters (including line feed, carriage return, and end of file characters) read from the file are preserved by the command.

Use this parameter for policy sets and bindings.

Use this parameter for monitoring profiles; the XML file must conform to the monitoring profile schema.

-d (Optional) This parameter is valid only if you specify a configurable service of type UserDefined. If the property that you specify on the **-n** parameter exists, it is deleted.

If you specify this parameter for other configurable services or components, an error is generated.

-f (Optional) This parameter is valid only if you specify a property of an execution group level object. If the property that you specify on the **-n** parameter exists, its value is changed to the *PropertyValue* specified by the **-v** parameter.

You can use this parameter only when the execution group is in the stopped state. You are advised to use this parameter only under the direction of IBM support to recover from execution group startup failures.

If you specify this parameter for other configurable services or components, an error is generated.

For detailed information about valid components, configurable services, object names, properties, and values, select the appropriate topic:

- "Broker registry object parameter values" on page 3765
- "Configurable services properties" on page 3766
- "Content based filtering component parameter values" on page 3805
- "Execution group HTTP listener parameters (SOAP and HTTP nodes)" on page 3805
- "Broker-wide HTTP listener parameters" on page 3809
- "JVM parameter values" on page 3813
- "Parameter values for the securitycache component" on page 3815
- "Parameter values for the servicefederation component" on page 3816

- "ServiceFederationManager object property values" on page 3818

Authorization:
For information about platform-specific authorizations, see the following topics:
- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Examples:
Always enter the command on a single line; in some examples, line breaks have been added to enhance readability.

Changes to broker components

The following examples specify the **-b** parameter to identify a particular broker component.

- Disable the broker-wide HTTP listener:

```
mqsichangeproperties MB7BROKER -b httplistener -o HTTPListener
   -n startListener -v false
```

- Enable the broker-wide HTTP listener:

```
mqsichangeproperties MB7BROKER -b httplistener -o HTTPListener
   -n startListener -v true
```

- Enable the HTTPSConnector for the HTTP nodes deployed to the specified broker that use the broker-wide listener:

```
 mqsichangeproperties MB7BROKER -b httplistener -o HTTPListener
   -n enableSSLConnector -v true
```

- Change the default SSL protocol from SSLv3 to TLS for the HTTP nodes that are deployed to the specified broker:

```
mqsichangeproperties MB7BROKER  -b httplistener -o HTTPSConnector
   -n sslProtocol -v TLS
```

- Change the securitycache timeout to 200 seconds:

```
mqsichangeproperties MB7BROKER -b securitycache -o SecurityCache
   -n cacheTimeout -v 200
```

- Enable Service Federation Management (SFM) and specify a host name and contact name:

```
mqsichangeproperties MB7BROKER -b servicefederation -o scmp
-n enabled,hostname,contactName -v true,mbhost.ibm.com,John.Smith
```

- Change the JVM heap size for the broker:

```
mqsichangeproperties MB7BROKER -o ComIbmJVMManager
-n jvmMaxHeapSize -v size_in_bytes
```

Changes to properties that are associated with execution groups

The following examples include the **-e** parameter to specify the execution group to change.

- Configure the execution group so that all deployed HTTP nodes use the embedded listener:

```
mqsichangeproperties MB7BROKER -e exgroup1 -o ExecutionGroup
 -n httpNodesUseEmbeddedListener -v true
```

If you disable the broker-wide listener (as shown in a previous example), you do not have to change the execution group configuration as shown in this command; if the broker-wide listener is not active, all execution groups use the embedded listener by default for all HTTP message handling.

- Configure the execution group properties so that deployed HTTP nodes do not use the embedded listener:

```
mqsichangeproperties MB7BROKER -e exgroup1 -o ExecutionGroup
 -n httpNodesUseEmbeddedListener -v false
```

- Set the port number when changing properties for execution groups:

```
mqsichangeproperties MB7BROKER -e exgroup1 -o HTTPSConnector
  -n explicitlySetPortNumber -v 7777
```

- Set the list of ciphers allowed by the HTTPS listener of the execution group:

```
mqsichangeproperties MB7BROKER -e default
-o HTTPSConnector -n ciphers
-v \"SSL_RSA_WITH_RC4_128_MD5,SSL_RSA_WITH_RC4_128_SHA\"
```

  On distributed systems, if the property value contains a comma, enclose the value with escaped double quotation marks (\" and \"); for example:

```
-v \"SSL_RSA_WITH_RC4_128_MD5,SSL_RSA_WITH_RC4_128_SHA\"
```

  On z/OS, if the property value contains a comma, enclose the value with double quotation marks (" and "); for example:

```
-v "SSL_RSA_WITH_RC4_128_MD5,SSL_RSA_WITH_RC4_128_SHA"
```

- Set the JVM port number to activate message flow debugging:

```
mqsichangeproperties MB7BROKER -e exgroup1 -o ComIbmJVMManager
 -n jvmDebugPort -v 8018
```

- Change the JVM heap size for the execution group:

```
mqsichangeproperties MB7BROKER -e exgroup1 -o ComIbmJVMManager
-n jvmMaxHeapSize -v size_in_bytes
```

- Set the type of server keystore:

```
mqsichangeproperties MB7BROKER -e AddressSampleProvider
 -o ComIbmJVMManager
 -n keystoreType -v JKS
```

- Set a host name and port to be used in the endpoint address of SFM proxies created in an execution group that is to be used as an SFM Connectivity Provider:

```
mqsichangeproperties MB7BROKER -e exgroup1
 -o ServiceFederationManager
 -n proxyURLHostName,port,securePort -v mbhost.ibm.com,8811,8844
```

- Set the coordination queue manager to *QM2* for execution group myExecutionGroup in broker MB7BROKER:

```
mqsichangeproperties MB7BROKER -e myExecutionGroup
-o FTEAgent -n coordinationQMgr -v QM2
```

  Note: After running this command, you must reload the execution group for the change to take effect.

- Configure the expiry compensation to prevent messages from immediately expiring when put:

```
mqsichangeproperties MB7BROKER -e default
-o ComIbmMQConnectionManager -n expiryCompensation -v option
```

  where *option* specifies if the expiry compensation is active or not:

  – *false* This option is the default value. No adjustment is applied to the expiry

– *true* This option causes the expiry to be reduced by the amount of time that the message has spent in the flow at the time that the MQPUT call is made by the MQOutput Node.

Changes to the BrokerRegistry object

- Set the HTTPConnector Port Range in the broker registry:

```
mqsichangeproperties MB7BROKER -o BrokerRegistry
 -n httpConnectorPortRange -v 7777-8888
```

Changes to configurable services

The following examples include the **-c** parameter to specify the type of configurable service to change.

- Change an Aggregation configurable service:

```
mqsichangeproperties MB7BROKER -c Aggregation
 -o myAggregationService
 -n timeoutSeconds -v 120
```

  This command changes all nodes that are configured to use the myAggregationService configurable service by setting the timeout of an aggregation to 120 seconds.

- Change a CICSConnection configurable service:

```
mqsichangeproperties MB7BROKER -c CICSConnection -o myCICSConnectionService
 -n connectionTimeoutSecs -v 120
```

  This command changes the CICSRequest node that is configured to use the myCICSConnectionService configurable service by setting the Connection timeout to 120 seconds.

- Change a Collector configurable service:

```
mqsichangeproperties MB7BROKER -c Collector
 -o myCollectorService
 -n collectionExpirySeconds -v 120
```

  This command changes all nodes that are configured to use the myCollectorService configurable service by setting the expiry time of collections to 120 seconds.

- Change the location of the object reference for all nodes that are configured to use the myCORBAService configurable service. After you run this command, all nodes look for the object reference name "Europe.region/Market.object" in the naming service on the local host on port 2809.

```
mqsichangeproperties MB7BROKER -c CORBA -o myCORBAService -n namingService,objectReferenceName
```

- Change an EmailServer configurable service:

```
mqsichangeproperties MB7BROKER -c EmailServer -o
myEmailConfigurableServiceName -n securityIdentity -v
myNewSecurityIdentityObjectName
```

  This command changes the EmailInput node that is configured to use the myEmailConfigurableServiceName configurable service by renaming the securityIdentity object to myNewSecurityIdentityObjectName.

- Change the *myCDServer* configurable service to use a specific staging directory `-/tmp/cdtransfer`.

  Note that you can use any string for the -o *Objectname* parameter.

```
mqsichangeproperties MB7BROKER -c CDServer -o myCDServer -n brokerPathToStagingDir
 -v /tmp/cdtransfer
```

- Make the JAR files and shared libraries available to the WebSphere Adapter for SAP:

```
mqsichangeproperties MB7BROKER -c EISProviders -o SAP
 -n jarsURL,nativeLibs
      -v c:\sapjco\jars,c:\sapjco\bin
```

- For the FtpServer configurable service called TEST1, change the protocol to SFTP and change the server name to winlnx58:

```
mqsichangeproperties MB7BROKER -c FtpServer -o TEST1
-n protocol,serverName,scanDelay,remoteDirectory,securityIdentity,
cipher,compression,strictHostKeyChecking
-v  SFTP,winlnx58,30,.,chbatey,blowfish-cbc,9,no
```

- Change all the nodes that are configured to use the *myIMSConnectService* configurable service. After you run this command, all nodes connect to the production system (`production.ims.ibm.com`) instead of the test system (`test.ims.ibm.com`).

```
mqsichangeproperties MB7BROKER -c IMSConnect
 -o myIMSConnectService
 -n Hostname -v production.ims.ibm.com
```

- Update the security identity for the JDBCProvider service for Oracle:

```
mqsichangeproperties MB7BROKER -c JDBCProviders -o Oracle

 -n securityIdentity -v OracleDSN
```

  OracleDSN is the DSN with which you have associated a user ID and password using the **mqsisetdbparms** command.

- Change the location of the JAR files for the IBM WebSphere MQ JMS client:

```
mqsichangeproperties MB7BROKER -c JMSProviders -o WebSphere_MQ
      -n jarsURL -v file://D:\SIBClient\Java
```

- Change the value of the properties `proprietaryAPIAttr2` and `proprietaryAPIAttr3` for a user-defined JMS provider configurable service definition called BEA_Weblogic, where the properties represent the URL of the BEA WebLogic bindings and the DNS name of the JMS server:

```
mqsichangeproperties MB7BROKER -c JMSProviders -o BEA_Weblogic
      -n proprietaryAPIAttr2, proprietaryAPIAttr3
      -v t3://9.20.94.16:7001,BEAServerName
```

- Change the value of the `jndiEnvironmentParms` property in the definition of a user-defined JMS provider configurable service called *myJMSprovider*:

```
mqsichangeproperties MB7BROKER -c JMSProviders -o myJMSprovider
      -n jndiEnvironmentParms
      -v domainName=myDomain;timeout=6000
```

- Set the properties of monitoring profile 'mp1' by using the contents of file `mp1.xml`:

```
mqsichangeproperties MB7BROKER -c MonitoringProfiles -o mp1
-n profileProperties -p mp1.xml
```

- Change all connections that are used by the adapter *myPeopleSoftAdapter.outadapter*. After you run this command, all adapters connect to the production system (`my.peoplesoft.production.com`) instead of the test system (`my.peoplesoft.qa.com`).

```
mqsichangeproperties MB7BROKER -c PeopleSoftConnection

 -o myPeopleSoftAdapter.outadapter -n hostName
 -v "my.peoplesoft.production.com"
```

- When you create a policy set, its properties are always set to default values. Use this command to change the property values.

  Import a policy set to a broker from a file:

```
mqsichangeproperties MB7BROKER -c PolicySets -o Policy_2
      -n ws-security -p policyset.xml
```

This command reads file policyset.xml and sets its contents as Policy_2 in broker MB7BROKER. The command is used to move policy sets between brokers, or to restore from a backup.

- Import a policy set bindings to a broker from a file:

```
mqsichangeproperties MB7BROKER -c PolicySetBindings -o Bindings_2
      -n ws-security -p bindings.xml
```

This command reads file bindings.xml and sets its contents as Bindings_2 in broker MB7BROKER. The command is used to move policy set bindings between brokers, or to restore from a backup.

- Change a Resequence configurable service:

```
mqsichangeproperties MB7BROKER -c Resequence -o myResequenceService
 -n missingMessageTimeoutSeconds -v 120
```

This command changes all nodes that are configured to use the myResequenceService configurable service, by setting them to propagate message sequences that have missing messages after waiting for 120 seconds.

- Change all connections that are used by the adapter *mySAPAdapter.outadapter*. After you run this command, all adapters connect to the production system (production.sap.ibm.com) instead of the test system (test.sap.ibm.com).

```
mqsichangeproperties MB7BROKER -c SAPConnection -o mySAPAdapter
-n applicationServerHost -v production.sap.ibm.com
```

- Change a SecurityProfiles configurable service to enable identity mapping using the WS-Trust v1.3 STS provider interface to Tivoli Federated Identity Manager (TFIM) V6.2:

```
mqsichangeproperties MB7BROKER -c SecurityProfiles
  -o TFIMv62MapSecProfile
  -n mapping,mappingConfig
  -v "WS-Trust v1.3 STS",
   http://wstrusthost1.ibm.com:9080/TrustServerWST13/services/RequestSecurityToken
```

- Change the connection timeout for queries issued by the WebSphere Service Registry and Repository nodes to 180 seconds:

```
mqsichangeproperties MB7BROKER -c ServiceRegistries -o DefaultWSRR
      -n connectionTimeout -v 180
```

- Change the connection that is used by the adapter *myAdapter.outadapter*. After you run this command, all message flows in all execution groups that use this adapter connect to the production system (my.siebel.production.com) instead of the test system (my.siebel.qa.com). If you are using different adapters in the message flow, run the **mqsichangeproperties** command for each named adapter.

```
mqsichangeproperties MB7BROKER -c SiebelConnection
 -o mySiebelAdapter.outadapter
 -n connectString
 -v "siebel://my.siebel.production.com/SBA_80/SSEObjMgr_enu"
```

- Update the TCPIPClient configurable service so that it does not create client connections until they are required:

```
mqsichangeproperties MB7BROKER -c TCPIPClient
 -o ClientPort1452HostnameJsmith
      -n MinimumConnections -v 0
```

- Change the connection expiry time on TCPIPServer connections to 30 seconds:

```
mqsichangeproperties MB7BROKER -c TCPIPServer -o ServerPort1452
      -n ExpireConnectionSec -v 30
```

- Change the TCPIPClient configurable service to use alternative addresses:

```
mqsichangeproperties MB7BROKER -c TCPIPClient -o MyTCPIPClient
      -n AlternativeAddresses -v smith6:1111;jones7
```

- Change the TCPIPClient configurable service to use a connection pool other than the main pool:

```
mqsichangeproperties MB7BROKER -c TCPIPClient -o MyTCPIPClient
      -n UseUniqueConnectionPool -v true
```

- Change a TCPIPClient or TCPIPServer configurable service to use SSL:

  "Configuring TCP/IP client nodes to use SSL" on page 551

  "Configuring TCP/IP server nodes to use SSL" on page 553

- Change a Timer configurable service:

```
mqsichangeproperties MB7BROKER -c Timer -o myTimerService
 -n timeoutIntervalSeconds -v 1
```

  This command changes all TimeoutNotification nodes that are configured to use the myTimerService configurable service, by configuring them to generate events every second if the node is configured in Automatic mode.

- Select content based filtering on the default execution group:

```
mqsichangeproperties MB7BROKER -e default -o ContentBasedFiltering
  -n cbfEnabled -v true
```

- Select content based filtering on the default execution group and increase the number of evaluation threads to five:

```
mqsichangeproperties MB7BROKER -e default -o ContentBasedFiltering
  -n validationThreads -v 5
```

- Change a JavaClassLoader service:

```
mqsichangeproperties MB7BROKER -c JavaClassLoader
  -o myJavaClassLoader
  -n sharedJarPath
  -v /var/app2/jars
```

- Add a property to a configurable service of type UserDefined:

```
mqsichangeproperties MB7BROKER -c UserDefined
  -o MyService1 -n VerifyRequestTimeout -v 60
```

- Delete a property of a configurable service of type UserDefined:

```
mqsichangeproperties MB7BROKER -c UserDefined
  -o HTTP_Timeout -n VerifyRequestTimeout -d
```

Related concepts:

"Using the WebSphere Message Broker Explorer to work with configurable services" on page 644
Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services.

"HTTP listeners" on page 1589
You can choose between broker-wide listeners and execution group (embedded) listeners to manage HTTP messages in your HTTP flows. Learn about the two types of listener, how ports are assigned to them, and how you can switch from one to the other for individual execution groups.

Related tasks:

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

"Setting up a JDBC provider for type 4 connections" on page 684
Use the **mqsicreateconfigurableservice** or the **mqsichangeproperties** command to configure a JDBC provider service.

Administration API for WebSphere Message Broker (CMP API)

Broker registry object parameter values:

Select the names of the properties and values that you want to change for the broker registry object.

To change these properties, you must specify the broker name and the **ObjectName** `BrokerRegistry`. You do not have to specify **-b**, **-c**, or **-e** to change properties associated with this object.

The following properties and values are valid:

-n brokerKeystorePass
: The password used to access the server certificate from the specified keystore file.

  Set the password by using **mqsisetdbparms** when the broker is stopped.

  - Value type - string
  - Initial value - brokerKeystore::password

-n brokerKeystoreFile
: The path to the keystore file where the server certificate, which is to be loaded, has been stored. The HTTP listener expects a file with the default name `.keystore` in the home directory of the user who started the broker.

  - Value type - string
  - Initial value - *default value* (described previously)

-n brokerKeystoreType
: The type of keystore file to be used for the server certificate.

  - Value type - string
  - Initial value - `JKS`

-n brokerTruststorePass
: The password used to access the server certificate from the specified keystore file.

  Set the password by using **mqsisetdbparms** when the broker is stopped.

  - Value type - string
  - Initial value - brokerKeystore::password

-n brokerTruststoreFile
The path to the keystore file where the server certificate, which is to be loaded, has been stored. The HTTP listener expects a file with the default name `.keystore` in the home directory of the user who started the broker.

- Value type - string
- Initial value - *default value* (described previously)

-n brokerTruststoreType
The type of keystore file to be used for the server certificate.

- Value type - string
- Initial value - `JKS`

-n httpConnectorPortRange
The numeric range of ports available to the HTTPConnector object that is associated with SOAP nodes.

- Value type - integer
- Initial value - `7800-7842`

-n httpsConnectorPortRange
The numeric range of ports available to the HTTPSConnector object that is associated with SOAP nodes.

- Value type - integer
- Initial value - `7843-7884`

See the "**mqsichangeproperties** command" on page 3756 for examples of how to change `BrokerRegistry` parameters. Other examples are provided for particular tasks:

"Viewing and setting keystore and truststore runtime properties at broker level" on page 780

"Accessing a secure WSRR repository" on page 1884

Related tasks:

"Viewing and setting keystore and truststore runtime properties at broker level" on page 780
Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"Execution group HTTP listener parameters (SOAP and HTTP nodes)" on page 3805
Select the resources and properties associated with the HTTPInput, HTTPReply, SOAPInput, SOAPReply, and SOAPAsyncResponse nodes that you want to change.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

Configurable services properties:

The supplied configurable services, and the configurable services that you create, are defined by their names and properties. You can use the supplied services.

Use the WebSphere Message Broker Explorer to view, create, and modify configurable services. You can also delete custom-named configurable services; however, you cannot delete IBM-defined configurable services. For more information, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

You can create your own configurable services by using the **mqsicreateconfigurableservice** command. For examples of how to use this command to create each configurable service, see "**mqsicreateconfigurableservice** command" on page 3849. You can also delete services that you have created by using the **mqsideleteconfigurableservice** command. For examples of how to use this command to delete each configurable service, see "**mqsideleteconfigurableservice** command" on page 3866.

If you want to change the properties for a configurable service, use the **mqsichangeproperties** command and specify the broker name and **-c** *ConfigurableService*. Set the **ObjectName** to the name of the service for which you want to change properties; the name can be a predefined name (one of the names shown for the service type in the following tables), or the name of a configurable service that you have created yourself. For examples of how to use this command, see "**mqsichangeproperties** command" on page 3756.

To display one or more of the defined configurable services, use the **mqsireportproperties** command. The following example displays all configurable services that are available for a single broker:

```
mqsireportproperties brokerName -c AllTypes -o AllReportableEntityNames -r
```

Specify the appropriate parameters from those parameters shown in the following tables on the **mqsichangeproperties** and **mqsireportproperties** commands:

- Specify **-c** to identify the configurable service type.
- Specify **-o** to identify the name of the configurable service object.
- Specify **-n** to identify the properties of the service.
- Specify **-v** to identify the values of the properties specified.

Follow the link to the configurable service that you want to use to view the available properties:

Aggregation configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	queuePrefix	The queue prefix used to specify the storage queues that are generated for use by the aggregation nodes. This property is optional. Five queues are required: • SYSTEM.BROKER.AGGR.*QueuePrefix*.CONTROL • SYSTEM.BROKER.AGGR.*QueuePrefix*.REPLY • SYSTEM.BROKER.AGGR.*QueuePrefix*.REQUEST • SYSTEM.BROKER.AGGR.*QueuePrefix*.UNKNOWN • SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT The prefix can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET.1` is valid, but `.SET1` and `SET1.` are invalid. Multiple configurable services can use the same queue prefix. If no queue prefix is specified, the aggregation nodes use the default queues that are generated when the broker is created: • SYSTEM.BROKER.AGGR.CONTROL • SYSTEM.BROKER.AGGR.REPLY • SYSTEM.BROKER.AGGR.REQUEST • SYSTEM.BROKER.AGGR.UNKNOWN • SYSTEM.BROKER.AGGR.TIMEOUT
	timeoutSeconds	The timeout value used by the AggregateControl node to set the expiry time (in seconds) of an aggregation. The value can be any positive integer. This property is optional; if it is not set, the value set on the node is used. The value of this property overrides the value set on the node, but it can be overridden by a value in the local environment.
	timeoutThreads	The number of threads used by the AggregateReply node to process expired messages. The value can be any positive integer. This property is optional. When the property is set, a unique `queuePrefix` property must be set on the Aggregation configurable service, and this Aggregation configurable service must be used only in a single execution group. If the property is not set, a single thread is used to process expired messages.

CICSConnection configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	cicsServer	The value that is used by the CICSRequest node to determine the connection to CICS Transaction Server for z/OS. One of the following connection methods can be specified: **A direct connection to CICS (two-tier):** If making a direct connection from WebSphere Message Broker to CICS, the `cicsServer` property must contain the URL of the CICS Transaction Server for z/OS region where the program exists. The URL allows you to specify a protocol, host name, and port number, which is the minimum information you need to connect to the CICS target region. The URL must be made up of the following structure: *protocol*`://`*hostname*`:`*port* Where: • *protocol* can be `tcp` or `ssl`. • *hostname* is the Internet Protocol version 4 (IPv4) TCP/IP address or DNS-resolvable host name of the CICS host. • *port* is the port number of the TCPIPSERVICE listener in CICS that is listening for IP InterCommunications (IPIC) protocol requests over TCP/IP or Secure Sockets Layer (SSL) protocol. You can enter an integer in the range 1 - 65535. For example: `tcp://mycicsregion.com:12345` or `ssl://mycicsregion.com:56789`. You can obtain the *hostname* and *port* values from the IPIC TCPIPSERVICE definition in the CICS target region. **A connection to CICS through a CICS Transaction Gateway (three-tier):** If you make connections to CICS through a Transaction Gateway (CICS TG), • The `gatewayURL` property must contain the URL for the CICS TG to use for the connection, and • The `cicsServer` property must contain the *CICS server definition* that you have specified in the CICS TG (`.INI`) initialization file. For example, the property can specify the particular CICS region that you want the transaction gateway to connect to. For more information about the two-tier and three-tier connection models, see “CICS Transaction Server for z/OS overview” on page 2173 for a high-level overview, or “CICS Transaction Server for z/OS two-tier connectivity” on page 2177 and “CICS Transaction Server for z/OS three-tier connectivity” on page 2181 for detailed conceptual information.
	clientApplid	The APPLID by which WebSphere Message Broker is known to the CICS region. This is not the APPLID of the CICS region. You can enter a maximum of 8 characters. This property is optional.
	clientQualifier	The APPLID qualifier by which WebSphere Message Broker is known to the CICS region. You can enter a maximum of 8 characters. This property is optional.
	securityIdentity	The name of the security identity object that is created and

Collector configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	queuePrefix	The queue prefix used to specify the storage queues that are generated for use by the Collector node. This property is optional. Two queues are required: • SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS • SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS The prefix can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET.1` is valid, but `.SET1` and `SET1.` are invalid. Multiple configurable services can use the same queue prefix. If no queue prefix is specified, the Collector node uses the default queues that are generated when the broker is created: • SYSTEM.BROKER.EDA.EVENTS • SYSTEM.BROKER.EDA.COLLECTIONS These default queues are also used by the Resequence node.
	collectionExpirySeconds	The value used by the Collector node to set the expiry time (in seconds) of a collection. The value can be any positive integer. This property is optional; if it is not set, the value set on the node is used. The value of this property (if it is set) overrides the value set on the node.

CDServer configurable service

For information about FtpServer configurable service properties, see "*CDServer* configurable service properties" on page 3798.

CORBA configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	namingService	The host name of the naming service from which to get the object reference. The format of this value is host:port, where port is optional. For example, localhost:2809. You can obtain this value from the administrator of the CORBA application that you are calling.
	objectReferenceName	The name of the reference to the object in the naming service. You can obtain this value from the CORBA server that you are calling. For more information about how to specify the object reference name, see "CORBA naming service" on page 2154.

EmailServer configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	serverName	The URL of the email server where the email messages exist for retrieving. The URL allows you to specify a protocol, host name, and port number, which is the minimum information you need to connect to the email server. The URL must be made up of the following structure: *protocol*://*hostname*:*port* Where: • *protocol* can be pop3 or imap. • *hostname* is the Internet Protocol version 4 (IPv4) TCP/IP address or DNS-resolvable host name of the email host. • *port* is the port number that the email server is listening on for connections over Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP). You can enter an integer in the range 1 - 65535. For example: pop3://myemailserver.com:12345 or imap://myemailserver.com:56789. There is no default value for this property, however this property is mandatory, and therefore must be configured with a URL. You can obtain the *hostname* and *port* values from the email server or email server administrator.
	securityIdentity	The name of the security identity object that is created and configured by the **mqsisetdbparms** command, which contains the user ID and password to be used by the broker to authenticate the connection to the email server. Use the **mqsisetdbparms** command to set the security identity user ID and password to be accessed by the broker. This property is optional. There is no default value for this property. If a value is not entered, the security identity object is taken from the Security identity property value that is configured on the EmailInput node. For more information about email server security identity support, see "**mqsisetdbparms** command" on page 3954.

EISProviders configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
PeopleSoft SAP Siebel Twineball	jarsURL	A URL that specifies the file location of the EIS provider JAR files. Omit `file://` from the URL. On Windows, the file location cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a storage area network (SAN) disk. If you do not set the **-n** parameter on the **mqsicreateconfigurableservice** command, the default location for the EIS provider JAR files is the broker shared-classes directories.
	nativeLibs	The file location of any libraries that the EIS provider owns. If you do not set the **-n** parameter on the **mqsicreateconfigurableservice** command, the default location for any libraries that the EIS provider owns, is the broker LILPATH.
Siebel	siebelPropertiesURL	A URL that specifies the file location of a `siebel.properties` file. To connect to a Siebel server in a clustered environment, use the `siebel.conmgr.virtualhosts` property in the `siebel.properties` file to list the Siebel servers in the cluster. The `siebel.conmgr.virtualhosts` property is used to list groups of servers with the same function. Servers are listed by using a comma-separated list in the format *hostname:port*. The only property in the `siebel.properties` file that WebSphere Message Broker supports is `siebel.conmgr.virtualhosts`. Information message BIP3427 indicates if a `siebel.properties` file is being used, and error message BIP3428 indicates if a problem occurs when attempting to access the `siebel.properties` file.

FtpServer configurable service

For more information about FtpServer configurable service properties, see "FtpServer configurable service properties" on page 3794.

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	accountInfo	Some FTP servers require an account name during the FTP logon procedure. If this property is specified, its value is the account name that is supplied when it is requested during FTP logon. If this property is not specified, and the server requests an account name, the FTP transfer fails.
	cipher	This property identifies the cipher that is used for encryption. This property takes the form of one or more of the following values, separated by plus signs (+): • `blowfish-cbc` • `3des-cbc` • `aes128-cbc` The cipher that you use for encryption depends on your SSH implementation. List the values in order of preference. This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored. If no value is specified, the following default is used: `blowfish-cbc+3des-cbc+aes128-cbc`
	compression	This property specifies the level of compression to be used. Valid values are integers in the range 0 - 9, where 0 specifies no compression and 9 specifies maximum compression. This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored. If no value is specified, the default value of 0 is used.
	connectionType	This property identifies the FTP data socket connection. Valid values are ACTIVE or PASSIVE. This property is valid only when FTP is specified as the protocol. If SFTP is specified, this property is ignored.
	knownHostsFile	This property specifies the location of the known hosts file. The value must be the fully qualified path to a valid known hosts file. The host information is stored in a `known_hosts` file in the standard OpenSSH format. This property is mandatory if the `strictHostKeyChecking` property is set to Yes. If the `strictHostKeyChecking` property is set to No, this property is ignored. This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.
	mac	This property specifies the Message Authentication Code. This property takes the form of one or more of the following values, separated by plus signs (+): • `hmac-md5` • `hmac-sha1` The MAC that you use depends on your SSH implementation. List the values in order of preference. This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored. If no value is specified, the following default is used: `hmac-md5+hmac-sha1`
	preserveRemoteFileDate	This property specifies whether files that are retrieved from a remote server by the FileInput node retain the last modified date on the server.

IMSConnect configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	Hostname	The host name of the computer on which the IMS Connect instance is running. This property is mandatory; if you leave it blank, the node cannot connect to IMS Connect.
	PortNumber	The port number on which the IMS Connect instance is listening. This value must be a positive integer. This property is mandatory; if you leave it blank, the node cannot connect to IMS Connect.
	DataStoreName	The data store name against which the IMS Connect instance is running. This property is not mandatory, but if you do not set it, an exception is issued by any node that attempts to use this configurable service.
	SocketTimeoutSec	The socket timeout is the maximum amount of time that the IMS Connector for Java waits for a response from IMS Connect before it disconnects the socket and returns an exception to the broker. If network problems or routing failures occur, this property prevents the client that is using the IMS Resource Adapter from waiting indefinitely for a response from IMS Connect. This property is based on the TCP/IP sockets that IMS Connect and the IMS Resource Adapter use to communicate; therefore, it is not applicable with the Local option. This property is optional, and the default value is 0 (zero), indicating that the socket never times out. You can enter an integer in the range 0 - 2147483. You set the socket timeout independently of the execution timeout on the configurable service. The socket timeout is used to respond to network problems (such as a loss of connection), while the execution timeout is used to recover from a non-responsive IMS program. The socket timeout is typically longer than the execution timeout.
	ExecutionTimeoutSec	The execution timeout is the maximum amount of time that the IMS Connector for Java waits for a response from a transaction. This property is not mandatory, and the default value is 60, indicating that the IMS Connector for Java waits for 60 seconds. You can enter an integer in the range 1 - 2147483.
	ConnectionIdleTimeoutSec	The connection idle timeout is the maximum amount of time, in seconds, that a connection can be idle before it expires. This property is not mandatory, and the default value is 0 (zero), indicating that the connection never times out. You can enter an integer in the range 0 - 2147483. Any IMS connection that is idle for more than the value specified by this property is not reused, and it is removed from the connection pool.
	UseSSL	The value that defines whether the TCP/IP connection to IMS Connect uses Secure Sockets Layer (SSL) encryption. Valid values are `True` or `False`. Both values are not case-sensitive. If no value is specified, the default value of `False` is used.
	SSLEncryptionType	The value of the cipher that is used for encryption. This value takes effect only when property `UseSSL` is set to `True`. Valid encryption values are `Strong`, `Weak`, or `ENULL`. These values are case-sensitive. Value definition, where: • *ENULL* allows for authentication during the SSL handshaking process. When the handshaking process for a socket has completed including authentication as required, all messages then flow in plain text over that authenticated socket. This

JavaClassLoader configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	includedDeployedJars	The JAR files that are loaded by the classloader. The JAR files must have been deployed to the execution group. Specify one of the following values: • `none` if no deployed JAR files are to be loaded. • `automatic` if only the JAR file that contains the class that implements a JavaCompute node is to be loaded. • a semicolon separated list of JAR file names that are to be loaded. The JAR file names must end with `.jar`. No wildcard characters are supported. You can include `automatic` in the list to also load the JAR file that contains the class required by a JavaCompute node. The default value is `automatic`. Java classes in the JAR files in `includedDeployedJars` are searched and loaded before classes in the JAR files in the `sharedJarPath`.
	sharedJarPath	The fully qualified file path of a single additional directory to be searched by the classloader. The directory must not be in the broker file path or work path, as defined by the `MQSI_FILEPATH` and `MQSI_WORKPATH` environment variables. If the directory is specified, it is used to resolve additional classes. If the directory is not specified, the broker `shared-classes` directories are used to resolve additional classes. Java classes in the JAR files in `includedDeployedJars` are searched and loaded before classes in the JAR files in the `sharedJarPath`.

JDBCProviders configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
DB2 Informix Informix_With_Date_Format Microsoft_SQL_Server Oracle Sybase_JConnect6_05	connectionUrlFormat	A pattern that represents the connection URL definition, which is specific to a particular database type. For example, the pattern for DB2 is defined with the following fixed content: `jdbc:db2://[serverName]:[portNumber]/[databaseName] :user=[user];password=[password];` Do not use the **mqsichangeproperties** command to change the pattern itself; changes made to the pattern might cause unpredictable results.
	connectionUrlFormatAttr1 connectionUrlFormatAttr2 connectionUrlFormatAttr3 connectionUrlFormatAttr4 connectionUrlFormatAttr5	If the specified URL format contains non-standard JDBC data source properties, such as a server identifier, specify one of five general-purpose connection attributes to define these additional properties. For example, if `connectionURLFormat = jdbc:oracle:thin:[user]/[password]@[serverName]:[portNumber]:[connectionUrlFormatAttr1]`, connectionUrlFormatAttr1 must contain an Oracle server identifier, which you must supply by defining the value for the property connectionUrlFormatAttr1 on the **mqsicreateconfigurableservice** or **mqsichangeproperties** command. The broker can then substitute all the required values into the required pattern.
	databaseName	The name of the database to which the data source entry enables connections; for example, employees.
	databaseType	The database type, for example, DB2.
	databaseVersion	The database version; for example, 9.1.
	description	An optional property to describe the data source definition.
	environmentParms	DB2 only. An optional property specifying a list of data source properties of the form `name=value` each separated by a semicolon.
	jarsURL	The local directory path on the system on which the broker is running, where the JAR file that contains the type 4 driver class is located.
	portNumber	The port number on which the database server is listening; for example, 50000.
	securityIdentity	A unique security key to perform a second broker registry lookup to find an entry under the broker DSN entries, which store the encrypted password for the user on their associated host system; for example, `jdbc::mysecurityIdentity`. Use the **mqsisetdbparms** command to create a DSN entry, as described in "Securing a JDBC type 4 connection" on page 689.
	serverName	The name of the server; for example, `host1`.
	type4DatasourceClassName	The name of the JDBC type 4 data source class name that is used to establish a type 4 connection to a remote database and for coordinated transaction support; for example, `com.ibm.db2.jcc.DB2XADataSource`.
	type4DriverClassName	The name of the JDBC driver class name that is used to establish a connection; for example, `com.ibm.db2.jcc.DB2Driver`.
	jdbcProviderXASupport	This property is optional. Setting this property to true, indicates that the selected JDBC provider supports XA coordinated transactions, and the database server is enabled to use the XA transaction protocol. Setting this property to false, indicates that the selected JDBC provider either does not support XA coordinated transactions, or the database server is not enabled to use the XA transaction protocol. The default value for this property is true.

JDEdwardsConnection configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	assuredOnceDelivery	Specifies whether to provide assured once-only delivery for inbound events. This property applies only to `.inadapter` files. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` file.
	Environment	The JD Edwards EnterpriseOne environment to which to connect. A JD Edwards EnterpriseOne environment is a user-defined pointer that indicates the location of data and objects on a JD Edwards EnterpriseOne server. Users can be authorized to use multiple JD Edwards EnterpriseOne environments on a single JD Edwards EnterpriseOne server.
	Role	The role that is applicable to the JD Edwards connection. Roles define what authority users have. Users can have multiple roles. A user's access to applications, forms, table columns, data sources, and so on, is based on one or more roles to which the user is assigned. Roles are created and named by the JD Edwards EnterpriseOne administrator.

JMSProviders configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
ActiveMQ BEA_Weblogic FioranoMQ Generic_File Generic_LDAP JBoss JOnAS Joram OpenJMS Oracle_OEMS SeeBeyond SonicMQ SwiftMQ Tibco_EMS WebSphere_MQ WebSphere_WAS_Client	clientAckBatchSize	This property is optional. Set this property to configure JMS message flows to send a batch acknowledgment of non-transactional messages that have been received. The value of this property is an integer that represents the threshold number of messages received before the batch acknowledgment is sent. This property can be used in combination with the **clientAckBatchTime** property. If both properties are set, and the time interval set on **clientAckBatchTime** has expired, the batch acknowledgment is sent even if the **clientAckBatchSize** threshold for the number of received messages has not been reached. A batch acknowledgment is also sent when: • there are no more input messages on the JMS server • an error occurs during message processing • the message flow stops. The minimum non-zero value is 2. To disable batch acknowledgment, set **clientAckBatchSize** to 0 and ensure that **clientAckBatchTime** is set to 0.
	clientAckBatchTime	This property is optional. Set this property to configure JMS message flows to send a batch acknowledgment of non-transactional messages that have been received. The value of this property is an integer that represents the length, in milliseconds, of a repeating interval. At the end of each interval a batch acknowledgment is sent for all unacknowledged non-transactional JMS messages that were received during the preceding interval. This property can be used in combination with the **clientAckBatchSize** property. If both properties are set, and the threshold set on **clientAckBatchSize** is reached, the batch acknowledgment is sent even if the time interval specified by **clientAckBatchTime** has not yet expired. A batch acknowledgment is also sent when: • there are no more input messages on the JMS server • an error occurs during message processing • the message flow stops. To disable batch acknowledgment, set **clientAckBatchTime** to 0 and ensure that **clientAckBatchSize** is set to 0.
	initialContextFactory	This property is optional. The fully qualified class name of the class used to perform JNDI lookups. If set it overrides the property set on a node that uses this JMS Provider.
	jarsURL	A URL that specifies the file location of the JMS provider JAR files. Omit `file://` from the URL. If you do not set the **-n** parameter on the **mqsicreateconfigurableservice** command, the default location for the JMS provider JAR files is the broker shared-classes directories. To connect to different versions of the same JMS provider (for example, JBoss), create a JMSProviders configurable service for each version of the JMS provider, then set the **jarsURL** property to a unique path.
	jmsAsyncExceptionHandling	This property is optional. If you set this property to true, the broker registers an exception listener on the JMS connection when the connection is created, and handles connection exceptions

MonitoringProfiles configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
DefaultMonitoringProfile	profileProperties	The name of the monitoring profile. The monitoring options defined by the monitoring profile can be configured with an XML file that conforms to the monitoring profile schema.
	useParserNameInMonitoringPayload	When a payload is included in a monitoring message, setting this property to TRUE forces the **wmb:applicationData/wmb:complexContent/wmb:elementName** attribute to contain the name of the input node parser if present. This property is optional. Valid values are TRUE and FALSE. The default value is FALSE, which means that the **wmb:applicationData/wmb:complexContent/wmb:elementName** attribute contains the MessageType property value. Setting this property on the default monitoring profile affects the behavior for all nodes that are not explicitly using configurable services.

PeopleSoftConnection configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	hostName	Identifies, either by name or IP address, the server that hosts PeopleSoft Enterprise. This property is mandatory. By default, the value of this property is an empty string, therefore you must set a valid host name or IP address.
	port	The port number that the adapter uses to access the PeopleSoft Enterprise server. This property is mandatory. By default, the value of this property is an empty string, therefore you must set a valid port number.
	connectionIdleTimeout	The number of seconds for which a connection can be idle before it is closed by WebSphere Message Broker to effectively maintain the connection pool. The default value for this property is 0 (zero) seconds, indicating that no timeout occurs.

PolicySets configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
WSS10Default	config	Reserved for future use.
	ws-security	The content of the policy set. The content is edited with the Policy Sets and Policy Set Bindings editor and can be backed up and restored by using the **-p** parameter on the **mqsireportproperties** and **mqsichangeproperties** commands.

PolicySet Bindings configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
WSS10Default	associatedPolicySet	The name of the policy set configurable service with which this policy set binding is associated. This value is set by the Policy Set editor when an association is defined. If you are restoring a policy set and binding by using the **mqsichangeproperties** command, ensure that this command refers to the correct associated policy set.
	config	Reserved for future use.
	ws-security	The content of the policy set binding. The content is edited with the Policy Sets and Policy Set Bindings editor and can be backed up and restored by using the **-p** parameter on the **mqsireportproperties** and **mqsichangeproperties** commands.

Resequence configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	queuePrefix	The queue prefix used to specify the storage queues that are generated for use by the Resequence node. This property is optional. Two queues are required: • SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS • SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS The prefix can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET.1` is valid, but `.SET1` and `SET1.` are invalid. Multiple configurable services can use the same queue prefix. If no queue prefix is specified, the Resequence node uses the default queues that are generated when the broker is created: • SYSTEM.BROKER.EDA.EVENTS • SYSTEM.BROKER.EDA.COLLECTIONS These default queues are also used by the Collector node.
	missingMessageTimeoutSeconds	The value used by the Resequence node to specify how long the node waits for the next message in a sequence before it is propagated. The value can be any integer that is greater than 1. The value of this property (if it is set) overrides the value set on the node. This property is optional; if it is not set, the value set on the node is used.
	startSequenceSeconds	The value used by the Resequence node to specify how long the node waits before calculating the start number in a sequence of messages. The value can be any positive integer. This value is used only if the `Start of sequence` property of the Resequence node is set to `Automatic`. The value of this property (if it is set) overrides the value set on the node. This property is optional; if it is not set, the value set on the node is used.
	endSequenceSeconds	The value used by the Resequence node to specify how long the node waits for the next message in the sequence to arrive before it closes the sequence. The value can be any positive integer. The value of this property (if it is set) overrides the value set on the node. This property is optional; if it is not set, the value set on the node is used.

SAPConnection configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	applicationServerHost	Specifies the IP address or the name of the application server host to which the adapter logs on. This property applies to `.inadapter` and `.outadapter` files. This property is mandatory; you must set the value to a valid SAP server host name or IP address. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file.
	assuredOnceDelivery	Specifies whether to provide assured once-only delivery for inbound events. This property applies only to `.inadapter` files. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` file.
	client	The client number of the SAP system to which the adapter connects. This property applies to `.inadapter` and `.outadapter` files. Set this property to the required SAP client number, which is a three-digit integer in the range 000 - 999. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file.
	connectionIdleTimeout	The number of seconds for which a connection can be idle before it is closed by WebSphere Message Broker to effectively maintain the connection pool. The default value for this property is 0 (zero) seconds, indicating that no timeout occurs. New connections to SAP are opened with different user IDs, therefore do not set this property to zero if you are using identity propagation.
	gatewayHost	The host name of the SAP gateway. This property applies to `.inadapter` and `.outadapter` files. This property is not mandatory. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file.
	gatewayService	The identifier of the gateway on the gateway host that carries out the RFC services. This property applies to `.inadapter` and `.outadapter` files. This property is not mandatory. The default value is an empty string, which indicates that behavior is controlled by the `.inadapter` or `.outadapter` file. The property controls the port number that the broker uses when establishing a TCP/IP connection to the SAP server. Set the property to either of the following values: • The name of the service, which must be defined in the services (`/etc/services` or `C:\Windows\System32\drivers\etc\services`) with the port number that corresponds to the port on which the SAP gateway is listening • The port number The name of the gatewayService property and its corresponding port number typically depend on the system number. The gateway

SecurityProfiles configurable service

For more information about SecurityProfiles configurable services, see "SecurityProfiles configurable service properties" on page 3801.

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
Default_Propagation	authentication	The type of authentication that is performed on the source identity. Valid values are: • NONE • LDAP • TFIM • WS-Trust V1.3 STS • A user-defined value If you are using TFIM V6.1, specify `TFIM`. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.
	authenticationConfig	The information that the broker needs to connect to the provider, specific to the provider. It is a provider-specific configuration string.
	authorization	The types of authorization checks that are performed on the mapped or source identity. Valid values are: • NONE • LDAP • TFIM • WS-Trust V1.3 STS • A user-defined value If you are using TFIM V6.1, specify `TFIM`. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.
	authorizationConfig	How the broker connects to the provider, specific to the provider. It is a provider-specific configuration string.
	mapping	The type of mapping that is performed. Valid values are: • NONE • TFIM • WS-Trust V1.3 STS • A user-defined value If you are using TFIM V6.1, specify `TFIM`. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.
	mappingConfig	How the broker connects to the provider, specific to the provider. It is a provider-specific configuration string.
	passwordValue	How passwords are treated when they enter a message flow. Valid values are: • PLAIN • MASK • OBFUSCATE
	propagation	Indicates whether identity propagation is performed on output and request nodes. Valid values are: • TRUE • FALSE

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
	rejectBlankpassword	Indicates whether the security manager rejects authentication of a username that has an empty password token, without passing it to LDAP. Valid values are: • TRUE • FALSE Default is FALSE.

Service Registries configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
DefaultWSRR	connectionFactoryName	The name of the WSRR WebSphere Application Server JMS provider JMS connection factory for Cache Notifications. The default value is jms/SRConnectionFactory.
	connectionTimeout	The WSRR connection timeout period in seconds. The default value is 180 seconds (3 minutes).
	enableCacheNotification	The default value is False. Select True to enable WebSphere Message Broker WSRR Cache Notification.
	endpointAddress	The location or endpoint of the WSRR server. The default value for all versions of WSRR is `http://fill.in.your.host.here:9080/WSRRCoreSDO/services/WSRRCoreSDOPort` For information about the specific levels of WSRR that are supported with WebSphere Message Broker, see WebSphere Message Broker Requirements.
	initialContextFactory	The name of the WSRR WebSphere Application Server JMS provider JMS context factory for Cache Notifications. The default value is `com.ibm.websphere.naming.WsnIitialContextFactory`
	locationJNDIBinding	The URL to the WebSphere Application Server JMS provider JNDI bindings. The default value is `iiop://`*`host_name`*`:2809/`
	needCache	The default value is True, indicating that the WebSphere Message Broker WSRR cache is enabled.
	predefinedCacheQueries	A list of semicolon-separated WSRR XPath query expressions with which to initialize the WebSphere Message Broker WSRR cache at start-up. These WSRR XPath query expressions are defined by the WSRR SOAP interface query expression language, and might include an optional depth specifier extension.
	refreshQueriesAfter Notification	When a notification is received from WSRR, if refreshQueriesAfterNotification is set to True, the Cache is updated with the new version of the object immediately; if it is set to False, the Cache is updated on the next request. The default value is True.
	subscriptionTopic	The topic name that is used to receive WebSphere Application Server JMS provider Cache Notifications. The default value is jms/SuccessTopic.
	timeout	The cache expiry time in milliseconds. The default value is 10000000, which is approximately 166 minutes.

SiebelConnection configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties

None	connectString	The connection URL that is needed to connect to the Siebel server.
		
		This property is mandatory. By default, the value of this property is an empty string, therefore you must set a valid URL. The URL has the following format:
		`Protocol://machinename:port/enterprisename/object manager/server name`
		
		For example:
		• For Siebel 7.0.5 to 7.5x:
		`siebel://IP_ADDRESS/siebel/SSEObjMgr_ENU/sebldev1`
		• For Siebel 7.8:
		`siebel://IP_ADDRESS:2321/Sieb78/SSEObjMgr_enu`
		• For Siebel 8:
		`siebel://IP_ADDRESS:2321/SBA_80/SSEObjMgr_enu`
		
		The default port number is 2320, but in these examples, for Siebel version 7.8 and 8, the port has been set to 2321.

	connectionIdleTimeout	The number of seconds for which a connection can be idle before it is closed by WebSphere Message Broker to effectively maintain the connection pool. The default value for this property is 0 (zero) seconds, indicating that no timeout occurs.

SMTP configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	serverName	The name of the server; for example, `host1`.
	securityIdentity	The name of a security identity that is defined using the **mqsisetdbparms** command.

TCPIPClient configurable service

Applying TCPIP configurable service changes implies restarting the TCPIP connection managers, so all flows which use configurable services to specify TCPIP parameters can be expected to pick up new TCPIP connections.

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
Default	Hostname	The host name of the remote system to which to connect with a client connection. A valid value is any IP address or computer name. You cannot change this value if there is already a configurable service with this name using the same port (unless the port is set to 0 (zero)).
	Port	The port number to be used for this configurable service. The default is 0 (zero), which means no port number. By default, the configurable service is disabled and the value of the port provided on the node is used instead. A port number can be assigned to only one configurable service at a time; if you try to assign a port number to more than one configurable service, an error occurs.
	AlternativeAddresses	The list of secondary host names and ports to be tried if the main remote address fails. If no addresses are specified, only the main remote address is used. Addresses must be in the format *hostname:port*. If no port is specified, the main port number is used. Multiple addresses must be separated with semicolons; for example: `jones6:1111;edwards`
	CloseWithUnprocessedData	The default value is false. When the value is set to true, the Broker reads ahead up to 1 MB on the stream to look for TCP/IP close events from the steam. If a close event is encountered, then the connection is allowed to close if it is not owned by an input node. This process allows flows that contain connections that are owned by receive nodes to respond to TCP/IP close events, even if execution never proceeds to another Receive node (for example if the flow's input node is idle when the close occurs).
	MinimumConnections	The minimum number of client connections made by the broker. The broker attempts to establish this number of connections even if no flows are using the connections. The default value is 0 (zero), which means that the broker does not make any client connections until they are required.
	MaximumConnections	The maximum number of client connections that can be made on this port. The default value is 100, which means that, by default, the broker accepts up to 100 server connections.
	MaxReceiveRecordBytes	The maximum size a record can reach before an exception is thrown. The default value is 104857600, which means that, by default, the broker accepts messages with a maximum size of 100 MB. The record size is taken to be the size of the data including all delimiters.
	ExpireConnectionSec	The length of time (in seconds) that a connection is kept open without being used. The value can be any integer. A value of 0 (zero) causes the connection to be closed immediately, and a value of -1 causes the connection to remain open indefinitely (no expiry).
	UseUniqueConnectionPool	Specifies whether the connection pool corresponding to the configurable service is the main connection pool for the specified host name and port. You can have two connection pools for the same remote address, and you can use the UseUniqueConnectionPool property to specify whether the connection pool corresponding to this configurable service is the main connection pool. The nodes in a message flow specify which pool to use by specifying the appropriate configurable service.

TCPIPServer configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
Default	CloseWithUnprocessedData	The default value is false. When the value is set to true, the Broker reads ahead up to 1 MB on the stream to look for TCP/IP close events from the steam. If a close event is encountered, then the connection is allowed to close if it is not owned by an input node. This process allows flows that contain connections that are owned by receive nodes to respond to TCP/IP close events, even if execution never proceeds to another Receive node (for example if the flow's input node is idle when the close occurs).
	Port	The port number to be used for this configurable service. The default is 0 (zero), which means no port number. By default, the configurable service is disabled and the value of the port provided on the node is used instead. A port number can be assigned to only one configurable service at a time; if you try to assign a port number to more than one configurable service, an error occurs.
	MaximumConnections	The maximum number of server connections that can be made on this port. The default value is 100.
	MaxReceiveRecordBytes	The maximum size a record can reach before an exception is thrown. The default value is 104857600, which means that, by default, the broker accepts messages with a maximum size of 100 MB. The record size is taken to be the size of the data including any delimiters.
	ExpireConnectionSec	The length of time (in seconds) that a connection is kept open without being used. The value can be any integer. A value of 0 (zero) causes the connection to be closed immediately, and a value of -1 causes the connection to remain open indefinitely (no expiry).
	SO_RCVBUF	The size (in bytes) of the SO_RCVBUF property on the socket. Valid values vary according to the operating system that you are using. This property is a standard TCP/IP property. The default value is 0 (zero), which sets the size of the SO_RCVBUF property to the operating system default.
	SO_SNDBUF	The size (in bytes) of the SO_SNDBUF property on the socket. Valid values vary according to the operating system that you are using. This property is a standard TCP/IP property. The default value is 0 (zero), which sets the size of the SO_SNDBUF property to the operating system default.
	SO_KEEPALIVE	The value of the KEEPALIVE property on the socket. If the value is set to True, the socket checks that it is still connected after a specified time. The length of time depends on the TCP/IP implementation on the operating system, but is typically two hours. Keep alive processing works only if the underlying operating system supports SO_KEEPALIVE. This property is a standard TCP/IP property. The default value is False, which means that no keep alive processing is performed.
	TCP_NODELAY	The value of the TCP_NODELAY property on the socket. If the value is set to True, the socket sends data as soon as it is sent to its buffer. The default value is False.
	TrafficClass	The traffic class on any connection that is established. Valid values are positive integers. The default value is -1, which leaves the TrafficClass set to the platform default.
	SO_LINGER	The SO_LINGER property on any connection that is established.

Timer configurable service

Supplied configurable services that are created for each broker	Properties for each configurable service that is defined	Description of properties
None	queuePrefix	The queue prefix used to specify the storage queue that is generated for use by the Timer nodes. This property is optional. The following queue is required: • SYSTEM.BROKER.TIMEOUT.*QueuePrefix*.QUEUE The prefix can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET.1` is valid, but `.SET1` and `SET1.` are invalid. Multiple configurable services can use the same queue prefix. If no queue prefix is specified, the Timer nodes use the default queue that is generated when the broker is created: • SYSTEM.BROKER.TIMEOUT.QUEUE
	timeoutIntervalSeconds	The value used by the TimeoutNotification node to set the timeout interval (in seconds) when running in automatic mode. The value can be any integer that is greater than 1. This property is optional; if it is not set, the value set on the node is used. The value of this property overrides the value set on the node, but it is ignored if the node is not running in automatic mode.

UserDefined configurable service

A UserDefined configurable service has no predefined properties. You can create, modify, and delete properties for your own purposes; for more information, see "UserDefined configurable service properties" on page 3804.

Related concepts:

"Caching artifacts from the WebSphere Service Registry and Repository" on page 1888
WebSphere Message Broker saves the data it retrieves from the WebSphere Service Registry and Repository (WSRR) in a local cache.

"Using the WebSphere Message Broker Explorer to work with configurable services" on page 644
Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services.

Related tasks:

"Creating a security profile" on page 433
You can create a security profile for use with Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2. Support is also provided for TFIM V6.1, for compatibility with previous versions of WebSphere Message Broker. You can create the security profile by using either the **mqsicreateconfigurableservice**

command or an editor in the WebSphere Message Broker Explorer.

"Setting up a JDBC provider for type 4 connections" on page 684
Use the **mqsicreateconfigurableservice** or the **mqsichangeproperties** command to configure a JDBC provider service.

"Business-level monitoring" on page 3319
You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

FtpServer configurable service properties:

Select the properties and values that you want to change for an existing FtpServer configurable service or to create a new service.

To change these properties, you must specify the broker name and **-c FtpServer**.

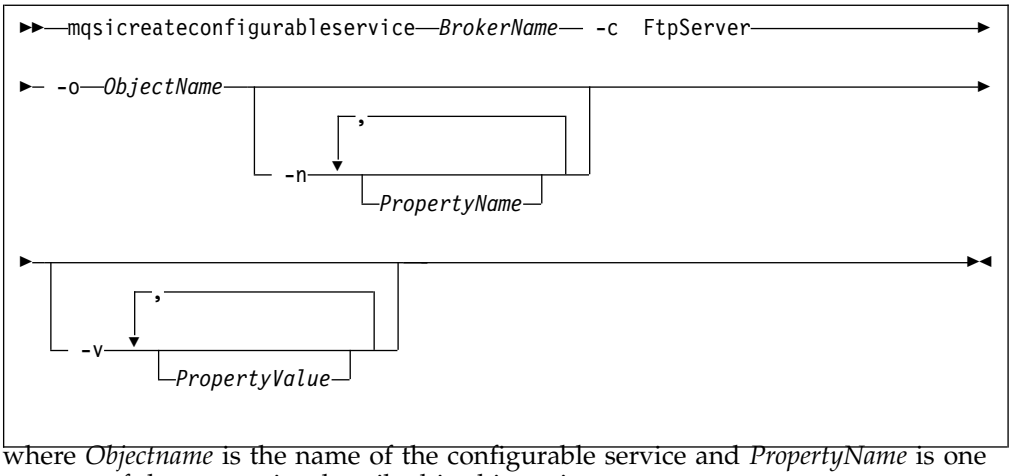
You must also set the **ObjectName** to the name of the configurable service that you have previously created.

See the "**mqsichangeproperties** command" on page 3756 for examples of its use.

49

If you define an FtpServer configurable service by using the **mqsicreateconfigurableservice** command, you can then specify the name of this configurable service in the `Remote server and port` property on the **FTP** tab of the FileInput and FileOutput nodes.

To create an FtpServer configurable service, the command has the following syntax:



where *Objectname* is the name of the configurable service and *PropertyName* is one or more of the properties described in this topic.

If you define an FtpServer configurable service, you **must** specify a value for its serverName property. All the other properties are optional.

serverName
The IP address and, optionally, port number for the remote FTP or SFTP server. The syntax for the property is identical to the syntax that is permitted for the `Remote server and port` property of the FileInput and FileOutput nodes (except that it cannot be the name of an FtpServer configurable service).

accountInfo
Some FTP servers require an account name during the FTP logon procedure. If this property is specified, its value is the account name supplied when requested during FTP logon. If this property is not specified and the server requests an account name, the FTP transfer fails.

cipher
The cipher used for encryption. This property takes the form of a list of one or more of the following values, separated by plus signs (+):
- blowfish-cbc
- 3des-cbc
- aes128-cbc

The cipher that you use for encryption depends on your SSH implementation. List the values in order of preference.

This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.

If no value is specified, the following default is used: blowfish-cbc+3des-cbc+aes128-cbc

compression
Specifies the level of compression to be used. Valid values are integers in the range 0 - 9, where 0 specifies no compression and 9 specifies maximum compression.

This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.

If no value is specified, the default value of 0 is used.

connectionType
The FTP data socket connection. It is either `ACTIVE` or `PASSIVE`.

This property is valid only when FTP is specified as the protocol. If SFTP is specified, this property is ignored.

knownHostsFile
The location of the known hosts file. The value must be the fully qualified path to a valid known hosts file.

The host information is stored in a `known_hosts` file in the standard OpenSSH format.

This property is mandatory if the `strictHostKeyChecking` property is set to Yes. If the `strictHostKeyChecking` property is set to No, this property is ignored.

This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.

mac
Message Authentication Code. This property takes the form of a list of one or more of the following values, separated by plus signs (+):
- hmac-md5
- hmac-sha1

The MAC that you use depends on your SSH implementation. List the values in order of preference.

This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.

If no value is specified, the following default is used: hmac-md5+hmac-sha1

preserveRemoteFileDate
This property specifies whether files that are retrieved from a remote server by the FileInput node retain the last modified date on the server.

The default value is No. If you select Yes, the FileInput node completes appropriate parsing to determine the remote file date during processing. The MDTM command is used where it is supported by the remote server. Where the MDTM command is not supported, the listing text is used.

When parsing from listing text, the precision is limited to the information that is available in the specific listing format used by the remote server. If the listing format is ambiguous, the FileInput node bases parsing on the locale settings of the broker. If the date cannot be determined reliably from the remote server, an exception is issued and the message is not processed.

protocol
The remote transfer protocol to use. Valid values are FTP or SFTP. If no protocol is specified in the configurable service, the value specified in the node is used.

remoteDirectory
The relative or absolute directory name on the remote FTP server. If set, this property overrides the `Server directory` on the **FTP** tab of the FileInput or FileOutput node that uses this service.

scanDelay
The length of time, in seconds, to wait after a scan of the directory has resulted in no files having been identified for processing. The default is 60 seconds. If set, this property overrides the `Scan delay` on the **FTP** tab of the FileInput node that uses this service.

securityIdentity
The name of a security identity defined using the **mqsisetdbparms** command. If

set, this property overrides `Security identity` on the **FTP** tab of the FileInput or FileOutput node that uses this service. If the value of this property is secId, define the security identity using the following command:

- If you are using FTP:

  ```
  mqsisetdbparms MB7BROKER -n ftp::secId -u userName -p password
  ```

- If you are using SFTP:

  ```
  mqsisetdbparms MB7BROKER -n sftp::secId -u userName -p password
  ```

  or

  ```
  mqsisetdbparms MB7BROKER -n sftp::secId -u userName -i SSHIdentityFile
  -r Passphrase
  ```

strictHostKeyChecking
Specifies how host keys are checked during the connection and authentication phase. Valid values are:

No Specifies that the following action is performed:

- If the connection is to a new host, connect and accept the host's key, and store it
- If the connection is to a host that has been connected to previously, and the host key has changed, issue an exception (FileOutput node).

If you select No, a default known hosts file (managed by the broker) is used.

Yes Connect only to known hosts with valid keys; otherwise issue an exception.

If you select Yes, you must specify your own known hosts file using the `knownHostsFile` property.

The default value is No.

The host information is stored in a `known_hosts` file in the standard OpenSSH format.

This property is valid only when SFTP is specified as the protocol. If FTP is used, this property is ignored.

timeoutSec
The timeout value in seconds to establish a connection to the remote FTP or SFTP server. You can set any valid integer as the `timeoutSec` property value. A timeout of 0 is interpreted as an infinite timeout. If you are using FTP, the default value is 5 seconds. If you are using SFTP, the default value is 20 seconds.

transferMode
The transfer mode of the FTP connection. This value is either `BINARY` or `ASCII`. The default is `BINARY`. If set, this property overrides `Transfer mode` on the **FTP** tab of the FileInput or FileOutput node that uses this service.

This property is valid only when FTP is specified as the protocol. If SFTP is specified, this property is ignored.

By default, none of these properties in the FtpServer configurable service definition is set. The only mandatory property when you define an FtpServer configurable service is serverName.

The following example of a **mqsicreateconfigurableservice** command shows how to create an FtpServer configurable service:

```
mqsicreateconfigurableservice MB7BROKERR -c FtpServer -o Server01
-n serverName,scanDelay,transferMode,connectionType,securityIdentity
-v one.hursley.abc.com:123,20,BINARY,ACTIVE,secId
```

Values set in properties in the FtpServer configurable service definition override the values set in the corresponding properties in the FileInput and FileOutput nodes.

If you set the accountInfo property, it is used during the login protocol when connecting to the FtpServer configurable service after supplying the user identifier and password. This information is sometimes required by FTP servers and requested as part of the login protocol. This setting allows the FileInput and FileOutput nodes to respond appropriately during login.

If you set the connectionType property, it alters the type of data socket that is used to transfer files to or from the FTP server. If you set this property to `ACTIVE`, this refers to a socket that is established by the remote server to the client (the broker message flow). If you set this property to `PASSIVE`, it refers to a socket that is established by the client to the remote server (as is the login or control socket). The default is `PASSIVE`, which is more likely to be tolerated by most types of firewall protection that allow the client to log in. You can set this property to `ACTIVE` if either the FTP server does not support `PASSIVE` connections, or there are special arrangements that your configuration must meet.

CDServer configurable service properties:

Select the objects and properties that you want to change for the *CDServer* configurable service.

You can use configurable services if, for example, you have different CDOutput nodes addressing more than one Connect:Direct server.

To change the *CDServer* configurable service properties, you must specify the broker name and **-c CDServer**.

The **-o** parameter is set to the name of the configurable service you are using.

You can edit the predefined configurable service, named `Default`, to alter the default behavior of the CDInput and CDOutput nodes.

Alternatively, you can create your own configurable service, name it (for example, **-o myCDServer**), and reference this configurable service in the `CDServer configurable service` property of the CDInput or CDOutput node; for more information, see "CDInput node" on page 4305 and "CDOutput node" on page 4312.

The *hostname* and *port* properties are mandatory; all the other properties are optional.

-n hostname
The host name of the Connect:Direct server

- Value type - string
- Initial value - localhost
- Other valid value:
  - Host name of the machine running the Connect:Direct server.

-n port
The API port of the Connect:Direct server.

- Value type - string
- Initial value - 1363
- Other valid value:
  - API port on which the Connect:Direct server is listening.

-n brokerPathToStagingDir
The high level path used by the CDOutput node for staging files to transfer. The CDOutput node creates directories and files under this path.

The path given is used by the broker on the machine running the WebSphere Message Broker. The Connect:Direct server must have access to these files and if it is on a different machine, the directory must be mounted on the remote machine.

If the remote path to the mounted directory is different on the IBM Sterling Connect:Direct machine, the *cdPathToStagingDir* must be set to the correct value.

- Value type - string
- Initial value - ""

  If not set, the broker uses the following default location: `$MQSI_WORKPATH/common/CD/Tranfers`
- Other valid value:
  - Any path on the brokers machine to which the broker user has both read and write access.

-n cdPathToStagingDir
The high level path used by the Connect:Direct server node for accessing files staged by the CDOutput node. The CDOutput node creates directories

and files under this path which the Connect:Direct server must have access to. The path given is used by the Connect:Direct server on the machine running the Connect:Direct server.

- Value type - string
- Initial value - ""

  If not set, the value uses the default location set in *brokerPathToStagingDir*
- Other valid value:
  - The path on the Connect:Direct server machine that allows access to the files staged by the CDOutput node.

-n cdPathToInputDir

The directory, including all subdirectories, on the Connect:Direct server machine that contains the files transferred by CD in which this configurable service is interested. Transfers to any other directory are ignored.

For WebSphere Message Broker to be able to process the files transferred to this directory, this directory must be accessible toWebSphere Message Broker.

If the directory is remote, the directory must be mounted to the WebSphere Message Broker machine. If the mounted file system has a different path on the WebSphere Message Broker machine, the *brokerPathToInputDir* must be set to the correct value.

- Value type - string
- Initial value - ""

  The CDInput node uses the file path sent by the Connect:Direct server.
- Other valid value:
  - A path to a directory structure on the Connect:Direct server machine.

-n brokerPathToInputDir

The file path to reach files transferred to *cdPathToInputDir* from the WebSphere Message Broker machine.

- Value type - string
- Initial value - ""

  The CDInput node uses the file path sent by the Connect:Direct server.
- Other valid value:
  - A path to a directory structure on the WebSphere Message Broker machine.

-n queuePrefix

A queue prefix for use when WebSphere Message Broker stores data on WebSphere MQ about this Connect:Direct server. Two queues are used to store state:

- SYSTEM.BROKER.CD.STATS
- SYSTEM.BROKER.CD.TRANSFERS

If you give a prefix, use the following queue name formats:

- SYSTEM.BROKER.CD.<queuePrefix>.STATS
- SYSTEM.BROKER.CD.<queuePrefix>.TRANSFERS
- Value type - string
- Initial value - ""

The SYSTEM.BROKER.CD.STATS queue and SYSTEM.BROKER.CD.TRANSFERS queue are used.

- Other valid value:
  - The queues are created and used with the <queuePrefix> inserted. The <queuePrefix> must:

    Be a maximum length of 16 characters

    Be a valid value for a queue name

    Not begin or end in a period.

-n securityIdentity

A security identity used to connect to the Connect:Direct server.

- Value type - string
- Initial value - `default`

  The default security identity is used.
- Other valid value:
  - Any valid security identity that is defined on the broker. You must define the identity by using the syntax `cd::<name>`.

See the "**mqsichangeproperties** command" on page 3756 for examples of its use.

SecurityProfiles configurable service properties:

Select the objects and properties that you want to change for the SecurityProfiles configurable service.

To change these properties, you must specify the broker name and **-c SecurityProfiles**.

You must also set the **ObjectName** to either `Default_Propagation` or the name of a SecurityProfiles configurable service that you have defined by using the **mqsicreateconfigurableservice**. The properties and values are the same for all services.

This configurable service is independent of the securitycache component.

-n authentication
The type of authentication that is performed on the source identity.

- Value type - enum
- Initial value - NONE
- Other valid values:
  - LDAP
  - TFIM
  - WS-Trust V1.3 STS
  - A user-defined value

  `TFIM` applies to TFIM V6.1 only. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.

-n authenticationConfig
The information that the broker needs to connect to the provider, specific to the provider.

- Value type - string
- Initial value - None

-n authorization
The types of authorization checks that are performed on the mapped or source identity.

- Value type - enum
- Initial value - NONE
- Other valid values:
  - LDAP
  - TFIM
  - WS-Trust V1.3 STS
  - A user-defined value

  `TFIM` applies to TFIM V6.1 only. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.

-n authorizationConfig
How the broker connects to the provider, specific to the provider.

- Value type - string
- Initial value - None

-n mapping
The type of mapping that is performed.

- Value type - enum
- Initial value - NONE
- Other valid values:
  - TFIM
  - WS-Trust V1.3 STS
  - A user-defined value

`TFIM` applies to TFIM V6.1 only. If you are using TFIM V6.2, specify `WS-Trust V1.3 STS`.

-n mappingConfig
How the broker connects to the provider, specific to the provider.
- Value type - string
- Initial value - None

-n passwordValue
How passwords are treated when they enter a message flow.
- Value type - enum
- Initial value - PLAIN
- Other valid values:
  - MASK
  - OBFUSCATE

-n propagation
Indicates whether identity propagation is performed on output and request nodes.
- Value type - Boolean
- Initial value - TRUE

-n rejectBlankpassword
Indicates whether the security manager rejects a username that has an empty password token, without passing it to LDAP.
- Value type - Boolean
- Initial value - FALSE

See the "**mqsichangeproperties** command" on page 3756 for examples of its use.

Related concepts:

"Security profiles" on page 387
A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

UserDefined configurable service properties:

A UserDefined configurable service has no predefined properties; you can create, change, view, and delete your own values.

To change these properties, you must specify the broker name and **-c UserDefined**.

You must also set the **ObjectName** to the name of a UserDefined configurable service that you have defined by using the **mqsicreateconfigurableservice** command.

Use a UserDefined configurable service to define properties that you can access in your message flows. The properties that you can define are unlimited; you can create properties to serve any purpose that you can think of. Possible uses include:

- Set timeout values for HTTP message processing.
- Set timeouts that are associated with by message category for HTTP messages.

A UserDefined configurable service is accessible by the JavaCompute Node node only, and cannot be accessed by ESQL.

See the "**mqsichangeproperties** command" on page 3756 for examples of its use with a UserDefined configurable service.

Related concepts:

"Security profiles" on page 387
A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

Content based filtering component parameter values:

Select the objects and properties associated with the content based filtering component that you want to change.

To change these properties, you must specify the broker name and **-e ExecutionGroupLabel**. You must also set the **ObjectName** to `ContentBasedFiltering`.

-n cbfEnabled
Whether content-based filtering is enabled.
- Value type - Boolean
- Initial value - false

-n evaluationThreads
The number of evaluation threads available.
- Value type - integer
- Initial value - 1
- Other valid values: positive integer in the range 2 - 32.

-n validationThreads
The number of validation threads available.
- Value type - integer
- Initial value - 1
- Other valid values: positive integer in the range 2 - 32.

Note, that if `cbfEnabled` = true and you set either of the thread settings to zero, the value of that thread setting is changed to one automatically.

See the "**mqsichangeproperties** command" on page 3756 for examples of its use.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

Execution group HTTP listener parameters (SOAP and HTTP nodes):

Select the resources and properties associated with the HTTPInput, HTTPReply, SOAPInput, SOAPReply, and SOAPAsyncResponse nodes that you want to change.

To change these properties, you must specify the broker name and **-e** followed by the name of a single execution group, and **-o** to specify the execution group object. If you specify **-o ExecutionGroup**, you can omit **-e** to change a property that applies to all execution groups on the specified broker.

Because you define all of these properties at the execution group level, they apply to all HTTPInput, HTTPReply, SOAPInput, SOAPReply, and SOAPAsyncResponse nodes that you deploy to the specified execution group.

By default, the HTTP nodes that you deploy to the broker all use the single broker-wide listener. If you prefer, you can change the configuration of the broker so that all execution groups use the embedded execution group. You can also use the broker-wide listener for some execution groups, and the embedded listener in other execution groups. For more information about these options, see "HTTP listeners" on page 1589.

If you want HTTP nodes to use the broker-wide listener, see "Broker-wide HTTP listener parameters" on page 3809 for further information about setting this configuration.

You must restart the execution group for all changes to be implemented.

Choose the **ObjectName** from the following options:
- `ExecutionGroup` for controlling common properties
- `HTTPConnector` for controlling HTTP communication.
- `HTTPSConnector` for controlling HTTPS communication.

The following combinations are valid:

-o ExecutionGroup
The following properties and values are valid:

-n httpNodesUseEmbeddedListener
A value of false, the default value, indicates that all HTTPInput and HTTPReply nodes use the broker-wide HTTP listener. If you set this property to true, all HTTPInput and HTTPReply nodes that are deployed to the specified execution group use the embedded execution group listener.

If you have disabled the broker-wide HTTP listener, all HTTPInput, HTTPReply nodes use the embedded listener regardless of the value of this property.
- Value type - Boolean
- Initial value - False

-o HTTPConnector
The following properties and values are valid for HTTPConnector and HTTPSConnector:

-n address
For servers with more than one IP address, this value specifies which address is used for listening on the specified port. By default, this port is used on all IP addresses associated with the server. If specified, only one address can be used.
- Value type - string
- Initial value - null

-n explicitlySetPortNumber
The TCP/IP port number on which this Connector creates a server socket and awaits incoming connections.

Setting this value disconnects the automatic port-finding capability of the connector; this port is the only one allowed, and the connector fails to start if another program has already used this port.
- Value type - integer
- Initial value - `7800-7842`
- Other valid values - any integer in the range 0-65536.

You must use the **explicitlySetPortNumber** attribute, because the **port** attribute no longer works.

When you set the value to zero, the system enables the automatic port-finding capability again, starting with the last used port, which was saved by the execution group. You can change the default port used when port-scanning starts by explicitly setting a value in the range 7800-7842, then specifying the port number as zero.

The default initial value for HTTPS is 7843 within the range 7843-7884.

-n autoRespondHTTPHEADRequests

Specifies if the connector handles HEAD requests for HTTP traffic in the same way that it does for SOAP traffic. When the value is `True`, if the request is for a URI associated with a flow, the connector returns an HTTP 200 OK response. If not, the connector returns an HTTP 404 Not Found response.

When the value is `False` or left unchanged from the initial value, if the request is for a URI associated with a message flow, the request causes the message flow to be invoked. Otherwise, the connector returns an HTTP 404 Not Found response.

- Value type - boolean
- Initial value - `False`

serverName

Set the value that is set in the "Server" header for all HTTP responses sent by this server.

- Value type - string
- Initial value - Apache-Coyote/1.1

-o HTTPSConnector

The properties listed for object name **HTTPConnector** (`address`, `explicitlySetPortNumber`, `autoRespondHTTPHEADRequests`, and `autoRespondHTTPHEADRequests`) are also valid for this object name. See HTTPConnector for more information.

The following additional properties and values are valid:

Tip: The valid values for `keystoreType`, `sslProtocol`, `sslSessionTimeout`, and `ciphers` are JSSE-implementation specific. These values are in the JSSE provider documentation. For a list of the platforms that use IBM Java, see Appendix A of the IBM JSSE2 Guide, at: http://www.ibm.com/developerworks/java/jdk/security/60/secguides/jsse2Docs/JSSE2RefGuide.html.

-n algorithm

The certificate encoding algorithm to be used.

- Value type - string
- Initial value -
  - Solaris HP-UX SunX509 on Solaris and HP-UX
  - AIX z/OS Linux Windows IbmX509 on other systems (AIX, Linux, Windows, z/OS)

-n ciphers

A comma-separated list of the encryption ciphers that can be used. If not specified (the default), any available cipher can be used. The

client sends a list of ciphers in priority order. The server selects the first acceptable cipher in the list. If none of the ciphers in the list are suitable, the server returns a handshake failure alert and closes the connection.
- Value type - string
- Initial value - null

-n clientAuth
Set to true if the SSL stack requires a valid certificate chain from the client before accepting a connection. A false value (which is the default) does not require a certificate chain.
- Value type - string
- Initial value - false

-n keyAlias
The alias that is used for the server certificate in the keystore. If not specified, the first key that is read in the keystore is used.
- Value type - string
- Initial value - null

-n keystoreFile
The path to the keystore file where the server certificate, which is to be loaded, is stored. By default the HTTP listener expects a file called `.keystore` in the home directory of the user who started the broker.
- Value type - string
- Initial value - *default value* (described previously)

-n keystorePass
The password used to access the server certificate from the specified keystore file.
- Value type - string
- Initial value - changeit

-n keystoreType
The type of keystore file to be used for the server certificate.
- Value type - string
- Initial value - `JKS`

-n sslProtocol

Specifies the version of the SSL protocol to use.
- Value type - string
- Initial value - `TLS`
- Other valid values - `SSL`, `SSLv3`

-n sslSessionTimeout
Specifies the timeout value in seconds, and is set on the SSLSessionContext for SSLSessions created by the **`HTTPConnector`**.
- Value type - integer
- Initial value - 86400 (24 hours)
- Other valid values - any positive integer, 0 means no timeout

See the "**`mqsichangeproperties`** command" on page 3756 for examples of its use.

Related concepts:

"HTTP listeners" on page 1589
You can choose between broker-wide listeners and execution group (embedded) listeners to manage HTTP messages in your HTTP flows. Learn about the two types of listener, how ports are assigned to them, and how you can switch from

one to the other for individual execution groups.

Related reference:

"Broker registry object parameter values" on page 3765
Select the names of the properties and values that you want to change for the broker registry object.

"Broker-wide HTTP listener parameters"
Select the resources and properties associated with the broker-wide HTTP listener that you want to change.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"HTTPInput node" on page 4474
Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

"HTTPReply node" on page 4484
Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

"SOAPReply node" on page 4819
Use the SOAPReply node to send SOAP messages from the broker to the originating client in response to a message received by a SOAPInput node.

Broker-wide HTTP listener parameters:

Select the resources and properties associated with the broker-wide HTTP listener that you want to change.

To change these properties, you must specify the broker name and **-b httplistener**.

The httplistener component defines properties for the broker that are used for all the HTTPInput and HTTPReply nodes that you deploy to that broker. These properties include the broker-wide listener for all HTTP nodes; if you prefer, you can disable this option so that the HTTP nodes use the listener that is embedded within each execution group.

You must restart the broker for all changes to be implemented.

Choose the **ObjectName** from the following options:

- `HTTPListener` for controlling the HTTPListener process

  You can use the following values with `HTTPListener`:

```
uuid='HTTPListener'
  enableSSLConnector='false'
  threadPoolSize=''
  traceOverrideLevel=''
  traceOverrideSize=''
```

```
  traceLevel='none'
  traceSize='102400 KB'
  javaDebugPort=''
  startListener='true'
```

- `HTTPConnector` for controlling HTTP communication.

  You can use the following values with `HTTPConnector`:

```
 uuid='HTTPConnector'
  address=''
  port='7080'
  allowTrace=''
  maxPostSize=''
  acceptCount=''
  bufferSize=''
  compressableMimeTypes=''
  compression=''
  connectionLinger=''
  connectionTimeout=''
  maxHttpHeaderSize=''
  maxKeepAliveRequests=''
  maxSpareThreads=''
  maxThreads='20'
  minSpareThreads=''
  noCompressionUserAgents=''
  restrictedUserAgents=''
  socketBuffer=''
  tcpNoDelay=''
  enableLookups='false'
```

- `HTTPSConnector` for controlling HTTPS communication.

  You can use the following values with `HTTPSConnector`:

```
uuid='HTTPSConnector'
  algorithm='Platform Default'
  clientAuth='Platform Default'
  keystoreFile='Platform Default'
  keystorePass='********'
  keystoreType='Platform Default'
  sslProtocol='Platform Default'
  ciphers='Platform Default'
  keyAlias=''
  keypass='********'
  address=''
  port=''
  allowTrace=''
  maxPostSize=''
  acceptCount=''
  bufferSize=''
  compressableMimeTypes=''
  compression=''
  connectionLinger=''
  connectionTimeout=''
  maxHttpHeaderSize=''
  maxKeepAliveRequests=''
  maxSpareThreads=''
  maxThreads=''
  minSpareThreads=''
  noCompressionUserAgents=''
  restrictedUserAgents=''
  socketBuffer=''
  tcpNoDelay=''
  enableLookups='false'
```

The following combinations are valid for the httplistener component:

-o HTTPListener
: The following properties and values are valid:

enableSSLConnector

A Boolean value which can be used to enable or disable the HTTPS (SSL) connector. You must set this value to TRUE to start the HTTP listener listening for inbound SSL connections.

- Value type - Boolean
- Initial value - FALSE

-n maxKeepAliveRequests

The value is the maximum number of HTTP requests that can be pipelined until the connection is closed by the server. Setting the attribute to 1 disables HTTP/1.0 keep-alive, as well as HTTP/1.1 keep-alive and pipelining. Setting the value to `-1` allows an unlimited amount of pipelined or keep-alive HTTP requests.

- Value type - integer
- Initial value `-100`

-n maxThreads

The value is the maximum number of request processing threads to be created by this Connector. This value, therefore, determines the maximum number of simultaneous requests that can be handled.

- Value type - integer
- Initial value - `200`

-n startListener

The broker-wide listener that is used by deployed HTTP nodes is started by default. Use this parameter to change its status between active and inactive.

If this listener is active, all HTTP nodes in all execution groups use this listener, unless you have activated the embedded listener in the execution group by using the **mqsichangeproperties** command for that execution group. For information about configuring an execution group so that HTTP nodes can use the embedded listener, see "Execution group HTTP listener parameters (SOAP and HTTP nodes)" on page 3805.

If this listener is disabled, all execution groups use the embedded listener for all nodes.

- Value type - Boolean
- Initial value `-TRUE`

-o HTTPConnector

The following properties and values are valid:

address

For servers with more than one IP address, this value specifies which address is used for listening on the specified port. By default, this port is used on all IP addresses associated with the server. If specified, only one address can be used.

- Value type - string
- Initial value - null

port The TCP port number on which this HTTPConnector creates a server socket and awaits incoming connections.

- Value type - integer
- Initial value - `7080`

serverName

Set the value that is set in the "Server" header for all HTTP responses sent by this server.

- Value type - string
- Initial value - Apache-Coyote/1.1

-o HTTPSConnector

The properties listed for object name **HTTPConnector** are also valid for this object name. The following additional properties and values are valid:

algorithm

The certificate encoding algorithm to be used.

- Value type - string
- Initial value -
  - Solaris HP-UX SunX509 on Solaris and HP-UX
  - AIX z/OS Linux Windows IbmX509 on other systems (AIX, Linux, Windows, z/OS)

ciphers

A comma-separated list of the encryption ciphers that can be used. If not specified (the default), any available cipher can be used.

- Value type - string
- Initial value - null

clientAuth

Set to true if the SSL stack requires a valid certificate chain from the client before accepting a connection. A false value (which is the default) does not require a certificate chain unless the client requests a resource protected by a security constraint that uses CLIENT-CERT authentication.

- Value type - string
- Initial value - false

keyAlias

The alias that is used for the server certificate in the keystore. If not specified, the first key that is read in the keystore is used.

- Value type - string
- Initial value - null

keystoreFile

The path to the keystore file where the server certificate, which is to be loaded, has been stored. By default, the HTTP listener expects a file called `.keystore` in the home directory of the user who started the broker.

- Value type - string
- Initial value - *default value* (described previously)

keystorePass

The password used to access the server certificate from the specified keystore file.

- Value type - string
- Initial value - changeit

keystoreType

The type of keystore file to be used for the server certificate.

- Value type - string
- Initial value - `JKS`

sslProtocol

The version of the SSL protocol to use.

- Value type - string
- Initial value - SSLv3

-n sessionCacheSize

Set the value to the maximum number of sessions that you allow in the SSL Session Cache. These cached sessions are available for SSL session renegotiation.

- Value type - integer
- Initial value - 100

The properties listed for object name **HTTPConnector** are also valid for this object name. The valid values for keystoreType, sslProtocol, and ciphers are JSSE-implementation-specific, and these values are in the JSSE provider documentation.

See the "**mqsichangeproperties** command" on page 3756 for examples of how to change parameters for the httplistener component.

Related concepts:

"HTTPReply node" on page 4484
Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

JVM parameter values:

Select the objects and properties associated with the Java Virtual Machine (JVM) that you want to change.

To change these properties, you must specify the broker name, and set the **ObjectName** to ComIbmJVMManager. If you are setting a debug port number, you must also include **-e** and specify the name of the execution group which will use the port.

-n jvmMinHeapSize
The minimum size of the storage available to the JVM, specified in bytes.

- Value type: integer
- Initial value: -1, which represents 33554432 bytes (32MB)

-n jvmMaxHeapSize
The maximum size of the storage available to the JVM, specified in bytes. If you have configured a publish/subscribe domain, when execution groups retain publications, you might need to increase this value. If you have included the XSLTransform node in one or more message flows, and the node is processing very large XML messages, you might also have to change this parameter.

- Value type: integer
- Initial value: -1, which represents 268435456 bytes (256 MB)

-n jvmDebugPort
The port on which the execution group is listening. You must set a port number to activate debug in the execution group.

- Value type: integer
- Initial value: 0

-n jvmNativeStackSize
The maximum stack size for Java threads.

- Value type: integer
- Initial value: -1, which represents 1048576 bytes (1 MB) on Solaris and Linux platforms, otherwise the value is JVM dependent

-n jvmJavaOSStackSize
The default stack size for Java Operating System threads. If you have a message flow with large number of nodes between two nodes written in Java (for example, JavaCompute nodes or Java user-defined nodes), you might have to increase the size of this parameter.

- Value type: integer
- Initial value: JVM dependent

-n jvmSystemProperty
The value of this property defines Java system properties for an execution group that can be used by JavaCompute nodes. The format is in the form -Dname1=value1. You can set multiple properties in the following way:

```
-v"-Dname1=value1 -Dname2=value2"
```

- Value type: integer
- Initial value: JVM dependent

-n jvmVerboseOption
The value of this property identifies the type of Java verbose information that is displayed for an execution group.

- Value type: string
- Initial value: none
- Other valid values:
  - class: display information about each class loaded

- `jni`: display information about use of native methods and other Java Native Interface activity
- `gc`: display information about each garbage collection event
- `all`: display information for all of the verbose options

See the "**mqsichangeproperties** command" on page 3756 for examples of how to change parameters for the JVM. Other examples are provided for particular tasks:

"Using the Test Client in trace and debug mode" on page 3155

"Attaching the flow debugger to an execution group for debugging" on page 3160

"XSLTransform node" on page 4968
Use the XSLTransform node to transform an XML message to another form of message, according to the rules provided by an XSL (Extensible Stylesheet Language) style sheet, and to set the `Message domain`, `Message set`, `Message type`, and `Message format` for the generated message.

Parameter values for the securitycache component:

Select the objects and properties associated with the securitycache component that you want to change.

To change these properties, you must specify the broker name and **-b securitycache**. You must also set the **ObjectName** to `SecurityCache`.

-n cacheTimeout

The timeout value for marking entries in the cache as invalid. The time is specified in seconds.

- Value type - integer
- Initial value - 60
- Other valid values: any positive integer.

The **cacheSweepInterval** property, which is displayed when you report the properties of the *securitycache* component, is ignored and has no effect.

See the "**mqsichangeproperties** command" on page 3756 for examples of its use.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"**mqsireloadsecurity** command" on page 3911
Use the **mqsireloadsecurity** command to force the immediate expiry of some or all the entries in the security cache.

Parameter values for the servicefederation component:

Select the objects and properties associated with the servicefederation component that you want to change.

To change these properties, you must specify the broker name and **-b servicefederation**. Choose the **ObjectName** from the following options:

- `HTTPConnector` for controlling the properties of the HTTP port that processes Service Control Management Protocol (SCMP) Atom requests. Property values and usage are the same as for the properties available on the `HTTPConnector` option on the httplistener component and are described in "Broker-wide HTTP listener parameters" on page 3809. The default HTTP port used for SCMP Atom requests is 7088.
- `HTTPSConnector` for controlling the properties of the secure HTTPS port that processes SCMP Atom requests. Property values and usage are the same as for the properties available on the `HTTPSConnector` option on the httplistener component and are described in "Broker-wide HTTP listener parameters" on page 3809. The default HTTPS port used for SCMP Atom requests is 7089.
- `scmp` for controlling the properties that relate to the implementation of Service Federation Management (SFM) support in WebSphere Message Broker.

You can select these properties when you specify `scmp` as the **ObjectName**:

enabled
A Boolean value to establish whether the broker is to start Service Federation SCMP Atom support so that an SFM console can connect to the broker. You must set this value to true if you want WebSphere Message Broker to start Service Federation and accept a connection from the SFM console.

- Value type - Boolean
- Initial value - false

enableSSL
A Boolean value to establish whether the SFM console needs to use HTTPS to the SCMP Atom port. You must set this value to true if you need to use HTTPS. You must set this value to false if you need to use HTTP. If you specify a value of true, you must configure the `HTTPSConnector` option, ensuring that you set appropriate values in the keystore-related properties. If you specify a value of false, you must configure the `HTTPConnector` option.

- Value type - Boolean
- Initial value - true

hostname
The host name that the SFM console should use to reach the Broker host.

The SFM console might run in a separate network domain so ensure that you specify a fully qualified domain name, for example `brkhost01.location.ibm.com`. If you do not set a value, the value that is supplied is, on many systems, the dot-separated IP address of the host; this address is subject to change should the network be re-configured.

- Value type - string
- Initial value - null

contextRoot
A valid URI path to define the context root of all URIs for SCMP Atom requests.

- Value type - string
- Initial value - /scmp

contactName
The contact property presented in the connectivity provider Atom entry for all execution groups in the broker. This value of the property might, typically, be the contact details of the broker administrator.

- Value type - string
- Initial value - null

locationName
The location property presented in the connectivity provider Atom entry for all execution groups in the broker. This value of the property might, typically, be the location details of the broker.

- Value type - string
- Initial value - null

-n organizationName
This value specifies the organization property presented in the connectivity provider Atom entry for all execution groups in the broker. This value of the property might, typically, be the organization details of the services hosted by the broker.

- Value type - string
- Initial value - null

Related concepts:

"Working with Service Federation Management (SFM)" on page 911
You can use a broker as a connectivity server that can be administered by a Service Federation Management (SFM) console provided with WebSphere Service Registry and Repository (WSRR) V7.0. The SFM console can then configure SFM proxies in the broker.

Related reference:

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

"Broker-wide HTTP listener parameters" on page 3809
Select the resources and properties associated with the broker-wide HTTP listener that you want to change.

"ServiceFederationManager object property values" on page 3818
Select the properties associated with the ServiceFederationManager component that you want to change.

ServiceFederationManager object property values:

Select the properties associated with the ServiceFederationManager component that you want to change.

To change these properties, you must specify the execution group name and **-o ServiceFederationManager**.

port The insecure HTTP port that Service Federation Management (SFM) proxy input endpoints that are created in this connectivity provider are to use. You might select a particular port value to make that port available through a firewall, for example. If you do not specify a value or if you specify a value of 0, the broker selects the first unused port in the range 8810 - 8842.

- Value type - integer
- Initial value - 0

securePort
The secure HTTPS port that SFM proxy input endpoints that are created in this connectivity provider are to use. You might select a particular port value to make that port available through a firewall, for example. If you do not specify a value or if you specify a value of 0, the broker selects the first unused port in the range 8843 - 8872.

- Value type - integer
- Initial value - 0

maxWaitTime
The maximum time, in seconds, that an SFM proxy is to wait for the target service to respond to a request that it has sent. If this time is exceeded, the proxy returns a SOAP fault to the calling client.

- Value type - integer
- Initial value - 180

proxyURLHostName
The host name that is to appear in the input endpoint URL for an SFM proxy created in this connectivity provider. You might, typically, set this to a domain name that the service consumer should use to address the proxy, given that the service consumer might be accessing it from a remote network domain. An example is `myhost.location.ibm.com`.

- Value type - string
- Initial value - null

ProxyPathPrefix
The fixed path prefix that is to be appended with unique digits and prefixed to the input endpoint URL for an SFM proxy created in this connectivity provider. If set to null, no prefix is used in the proxy input path and the remainder of the proxy path becomes the target service path. For example, if a proxy is created for a service which has the endpoint URL `http:://host:7080/service` and the initial value `proxy` is used, the proxy URL that is created would be similar to `http:://myhost:8810/proxy1/service`.

- Value type - string
- Initial value - proxy

Select the objects and properties associated with the servicefederation component that you want to change.

mqsichangeresourcestats command:

Use the **mqsichangeresourcestats** command to control statistics gathering for resources in the broker.

Supported platforms:

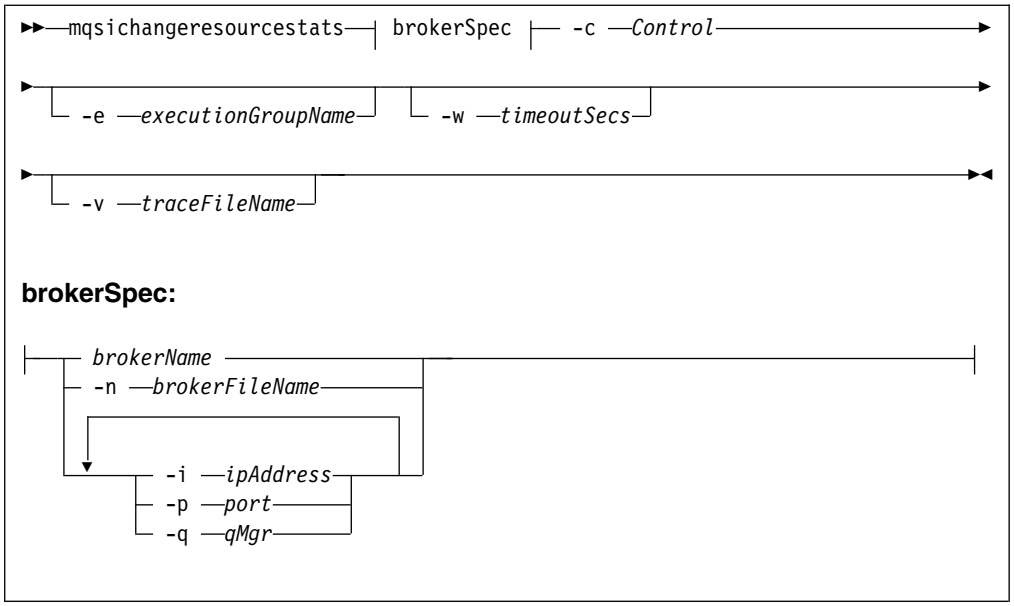
- Windows systems
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPCHRS; see "Contents of the broker PDSE" on page 3991

Purpose:
Use this command to start or stop statistics collection for the resource types listed in "Resource statistics data" on page 6745.

You can run this command only if the broker is running. If you start statistics collection, then stop and restart the broker, you do not have to rerun this command; the active status is maintained when the broker starts again.

If you start statistics collection for all execution groups on a broker, you can stop collection on all execution groups or on individual execution groups. If you start statistics collection for individual execution groups, you can stop collection for those specific execution groups or for all execution groups.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3971.

-c *Control*
(Required) The value to define the action to be applied to resource statistics collection:

- Specify `active` to start resource statistics collection
- Specify `inactive` to stop resource statistics collection

-e *executionGroupName*
(Optional) The name of the execution group for which resource statistics collection is started or stopped.

If you do not specify **-e**, resource statistics collection is started or stopped for all execution groups on the broker.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Start resource statistics collection for all execution groups on `BrokerA`:

```
mqsichangeresourcestats BrokerA -c active
```

Stop resource statistics collection for the execution group `default` on broker `BrokerA`:

```
mqsichangeresourcestats BrokerA -c inactive -e default
```

:

This example message shows an XML publication that contains resource statistics data.

mqsichangetrace command:

Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS - as a console command

Purpose:
This command is valid for:

- User trace. Specify the **-u** option.
- Service trace. Specify the **-t** option. Use this option only if directed to do so by the action described in a BIPxxxx message, or by your IBM Support Center.
- Trace nodes. Specify the **-n** option to switch Trace nodes on or off. You can significantly improve the performance of a flow by switching Trace nodes off.

You can initiate, modify, or end user (or service) tracing for a broker.

You can switch Trace nodes for a broker on and off, but you cannot use this command to initiate service tracing for the WebSphere Message Broker Toolkit.

If you specify a broker, or any of its resources (execution group or message flow), you must have deployed them before you can start trace. If you want to use the **mqsichangetrace** command to start or stop user trace, you must ensure the broker is running. But for service trace, you can also use the **mqsichangetrace** command to enable or disable trace when the broker is in a shutdown state. This allows you to trace the startup of the broker components.

The output for service and user trace generated by these commands is written to trace files in the `log` subdirectory. When you have completed the work you want to trace, use the **mqsireadlog** command to retrieve the log as an XML format file. Use either the **mqsiformatlog** command (to produce a formatted file), or an XML browser to view the XML records.

When you set tracing on, you cause additional processing to be executed for every activity in the broker that you are tracing. Expect performance to be affected when trace is active.

If you want to trace the command processes themselves, set the environment variables `MQSI_UTILITY_TRACE` and `MQSI_UTILITY_TRACESIZE` before you initiate trace.

You can set `MQSI_UTILITY_TRACE` to `normal` or `debug`, depending whether you want normal or debug tracing, and you should set `MQSI_UTILITY_TRACESIZE` to the maximum size of the trace file that you require in kilobytes (KB), the default being 102400 (100MB).

Ensure that you reset these variables when tracing for the selected command is complete. If you do not do so, all subsequent commands are also traced, and their performance degraded. For more information about MQSI_UTILITY_TRACE and MQSI_UTILITY_TRACESIZE, see "Starting service trace" on page 3534.

You can also start and stop tracing activity for execution groups and message flows using the facilities of the WebSphere Message Broker Toolkit. See "User trace" on page 6873 for more information.

If you want to view the tracing options that are currently in effect, use the **mqsireporttrace** command.

To enable service trace of your CMP applications, take one of the following steps:

- Call the method BrokerProxy.enableAdministrationAPITracing(String filename).
- Before running your CMP application, set the environment variable MQSI_CMP_TRACE to the name of the file to which trace is sent.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsichangetrace** command - Windows, Linux, and UNIX systems" on page 3824
- "**mqsichangetrace** command - z/OS" on page 3827

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648

- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

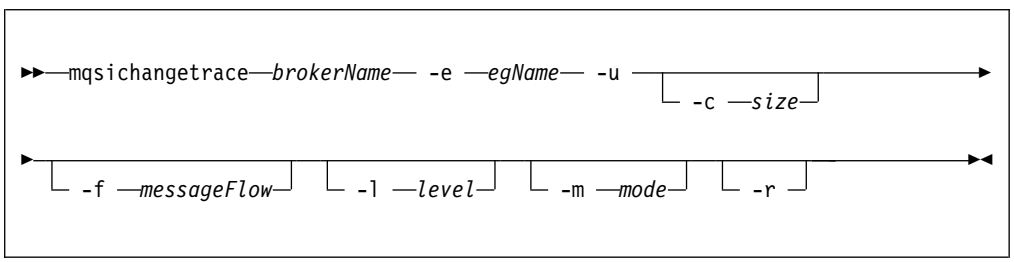
"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

mqsichangetrace *command - Windows, Linux, and UNIX systems:*

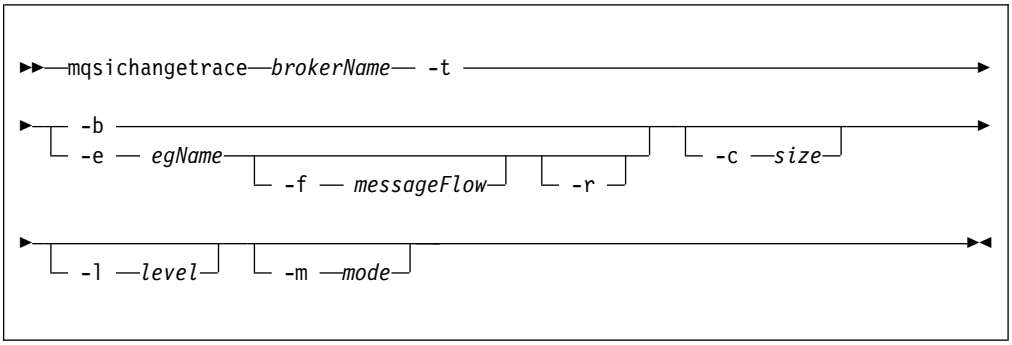
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Syntax:

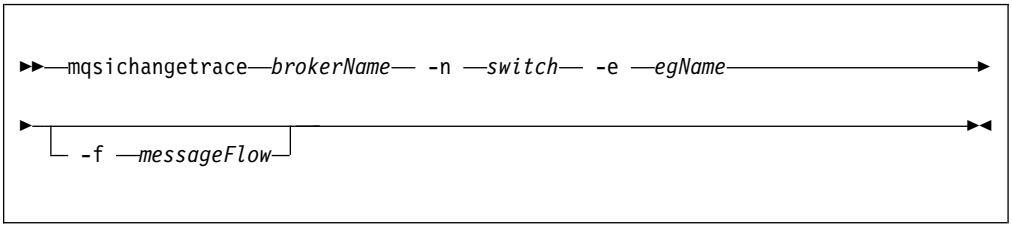
User trace:



Service trace:



Trace nodes:



Parameters:

brokerName
(Required) Specify the name of the broker that you want to trace.. All names are case sensitive on Linux and UNIX systems.

Key words `WebSphere Message Broker Toolkit` and `utility` are reserved, and must not be used as a broker name.

-c *size*

(Optional) The size of the trace file in KB (kilobytes). If you do not specify this parameter, the current value is left unchanged.

Each broker starts with a default value of 102400 KB. Specify this option to reset the value. The maximum value you can specify depends on how you subsequently intend to read the log, by using the **mqsireadlog** command;

- If you use this command with the **-f** option set, the log file is read directly from the file system. In this case, the maximum value that you can specify is 2097151, which allows a trace file up to 2 GB (gigabyte) to be created.
- If you use this command without setting the **-f** option, a WebSphere MQ message is sent to the broker to retrieve the log. In this case, do not allow the trace file to exceed 70 MB (megabytes). The maximum value that you can set is 70000.

On HP-UX, set the *size* value below 500 MB.

However you intend to retrieve the trace file, you might want to keep its size small, either by using a low value for this parameter, or by using the reset (**-r**) option on this command to clear the trace log. The benefit of adopting this approach is that the formatting process (**mqsiformatlog**) is much faster and requires less resource to carry out its task.

If you change this value, it affects tracing for the execution group (if you have specified one), or for the agent component (if you have not specified an execution group).

-e *egName*

(Required for user trace; required for service trace if you do not specify the -b flag)

Identifies the execution group for which trace options are to be modified (for example, started or stopped).

-f *messageFlow*

(Optional) Identifies the message flow for which trace options are to be modified. This option is valid only if you have specified an execution group (flag **-e**).

-l *level*

(Optional) Set the level of the trace. The following options are supported:

- `normal`. This option provides a basic level of trace information.
- `none`. This option switches tracing off.
- `debug`. This option provides a more comprehensive trace.

Each broker is created with a default value of `none`. If you do not specify this parameter, the current value is unchanged. When you have successfully changed this value, it is persistent.

-m *mode*

(Optional) Indicate the way trace information is to be buffered:

- `safe`. This mode causes trace entries to be written to file when they are generated.
- `fast`. This mode causes trace entries to be buffered, and written to file in batches.

Each broker starts with a default value of `safe`. If you do not specify this parameter, the current value is unchanged.

If you change this value, it affects tracing for the execution group (if you have specified one), or for the agent component (if you have not specified an execution group).

-r

(Optional) This option requests that the trace log is reset: that is, all current records are discarded. Use this option when you start a new trace to ensure that all records in the log are unique to the new trace.

This option is valid only if you have specified an execution group (flag **-e**).

-u (Required for user trace)

Specifies that user trace options are to be modified.

Additional parameters exclusive to service trace:
Use these options only when directed to do so by your IBM Support Center, or by a BIPxxxx message.

-b

(Required) Specifies that service trace options for the `agent` subcomponent of the broker specified are to be modified (for example, started or stopped). You can specify this flag only if **-t** is also specified.

You must specify the -b flag or the -e flag, but not both.

-m *mode*

(Optional) In addition to the `safe` and `fast` modes available for user trace, there is a third `temp` mode available with execution group service trace only:

- `temp`. This mode is the same as safe mode but trace is automatically switched off when the component restarts. You cannot specify a mode of `temp` if **-f** is also specified.

-t

(Required) Specifies that service trace options are to be modified.

Additional parameters exclusive to Trace nodes:

-n *switch*
(Required) Specifies the mode for trace flow. Valid values are `on` and `off`.

Examples:
To collect and process a user trace for the default execution group use the command:

```
mqsichangetrace MB7BROKER -u -e default -l normal -c 5000
```

To collect and process a service trace for flow f1 in the default execution group use the command:

```
mqsichangetrace MB7BROKER -t -e default -m fast
```

To collect and process a service trace for an agent use the command:

```
mqsichangetrace MB7BROKER -t -b -m -l normal
```

To switch off Trace nodes in the default execution group, use the command:

```
mqsichangetrace MB7BROKER –n off -e default
```

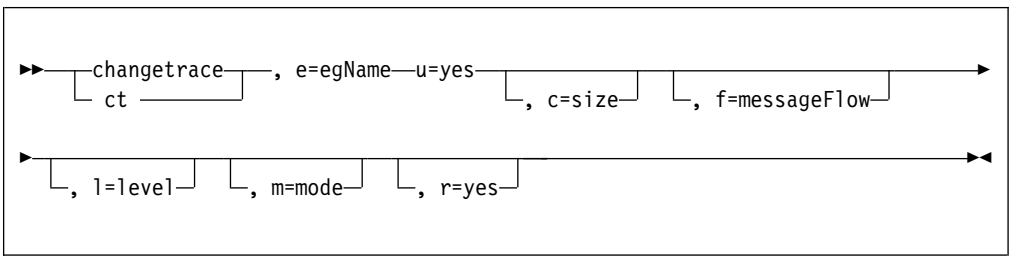
mqsichangetrace *command - z/OS:*

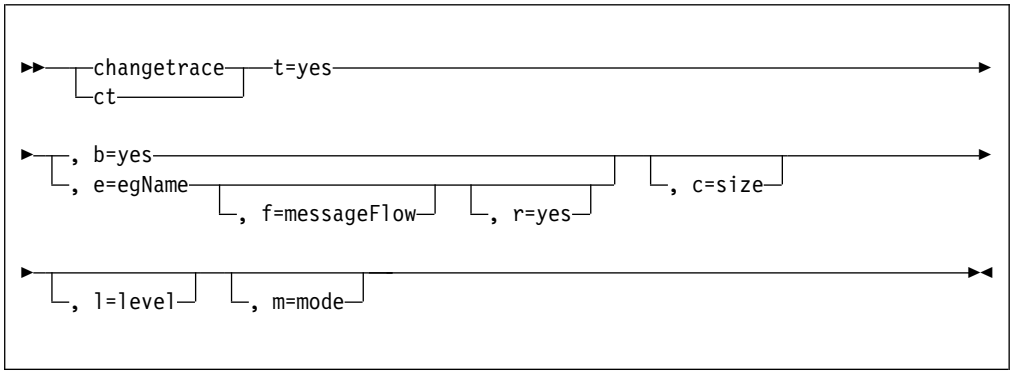
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Syntax:

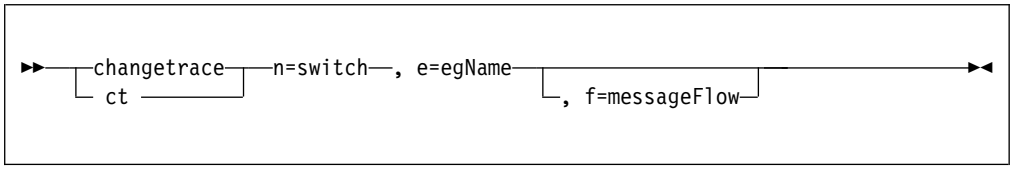
z/OS console command:
User trace



Service trace



Trace nodes:



Parameters:

-c *size*

(Optional) The size of the trace file in KB (kilobytes). If you do not specify this parameter, the current value is left unchanged.

Each broker starts with a default value of 102400 KB. Specify this option to reset the value. The maximum value you can specify depends on how you subsequently intend to read the log, by using the **mqsireadlog** command;

- If you use this command with the **-f** option set, the log file is read directly from the file system. In this case, the maximum value that you can specify is 2097151, which allows a trace file up to 2 GB (gigabyte) to be created.
- If you use this command without setting the **-f** option, a WebSphere MQ message is sent to the broker to retrieve the log. In this case, do not allow the trace file to exceed 70 MB (megabytes). The maximum value that you can set is 70000.

However you intend to retrieve the trace file, you might want to keep its size small, either by using a low value for this parameter, or by using the reset (**-r**) option on this command to clear the trace log. The benefit of adopting this approach is that the formatting process (**mqsiformatlog**) is much faster and requires less resource to carry out its task.

If you change this value, it affects tracing for the execution group (if you have specified one), or for the agent component (if you have not specified an execution group).

-e *egName*

(Required for user trace; optional for service trace)

Identifies the execution group for which trace options are to be modified (for example, started or stopped).

This name is case sensitive; you must include names in single quotes if they contains mixed case characters.

-f *messageFlow*

(Optional) Identifies the message flow for which trace options are to be modified. This option is valid only if you have specified an execution group (flag **-e**).

This name is case sensitive; you must include names in single quotes if they contain mixed case characters.

-l *level*

(Optional) Set the level of the trace. The following options are supported:

- `normal`. This option provides a basic level of trace information.
- `none`. This option switches tracing off.
- `debug`. This option provides a more comprehensive trace.

Each broker is created with a default value of `none`. If you do not specify this parameter, the current value is unchanged. When you have successfully changed this value, it is persistent.

-m *mode*

(Optional) Indicate the way trace information is to be buffered:

- `safe`. This mode causes trace entries to be written to file when they are generated.
- `fast`. This mode causes trace entries to be buffered, and written to file in batches.

Each broker starts with a default value of `safe`. If you do not specify this parameter, the current value is unchanged.

If you change this value, it affects tracing for the execution group (if you have specified one), or for the agent component (if you have not specified an execution group).

-r

(Optional) This option requests that the trace log is reset: that is, all current records are discarded. Use this option when you start a new trace to ensure that all records in the log are unique to the new trace.

This option is valid only if you have specified an execution group (flag **-e**).

-u (Required for user trace)

Specifies that user trace options are to be modified.

Additional parameters exclusive to service trace:
Use these options only when directed to do so by your IBM Support Center, or by a BIPxxxx message.

-b

(Required) Specifies that service trace options for the `agent` subcomponent of the broker specified are to be modified (for example, started or stopped). You can specify this flag only if **-t** is also specified.

-m *mode*

(Optional) In addition to the `safe` and `fast` modes available for user trace, there is a third `temp` mode available with execution group service trace only:

- `temp`. This mode is the same as safe mode but trace is automatically switched off when the component restarts. You cannot specify a mode of `temp` if **-f** is also specified.

-t

(Required) Specifies that service trace options are to be modified.

Additional parameters exclusive to Trace nodes:

n=*switch*

(Required) Specifies the mode for trace flow. Valid values are `on` and `off`.

Examples:
To collect and process a user trace for the default execution group use the command:

```
F MQP1BRK,ct U=YES, E='default', L=NORMAL, C=5000
```

and in the PDSE member BIPRELG, set the option for **mqsireadlog** to

```
-u -e default -f
```

To collect and process a service trace for flow f1 in the default execution group use the command:

```
F MQP1BRK,ct T=YES, E='default', F='F1', M=FAST, L=DEBUG
```

and in the PDSE member BIPRELG, set the option for **mqsireadlog** to

```
 -t -e default -f
```

To collect and process a service trace for an agent use the command:

```
F MQP1BRK,ct T=YES, B=YES, M=FAST, L=DEBUG
```

and in the PDSE member BIPRELG, set the option for **mqsireadlog** to

```
-t -b agent -f
```

To switch off Trace nodes for the default execution group, use the command:

```
F MQP1BRK,ct n='off', e='default'
```

Related tasks:

"Switching Trace nodes on and off" on page 3555
Use the **mqsichangetrace** command or the WebSphere Message Broker Explorer to switch Trace nodes on and off.

Related reference:

"Syntax diagrams" on page 3677

Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

mqsicommandconsole command:

Use the **mqsicommandconsole** command to launch an elevated command console from which commands that require elevation on Windows can be run.

Supported platforms:

- Windows

Purpose:
The **mqsicommandconsole** command is required for the following commands:

- **mqsiaddbrokerinstance**
- **mqsicreatebroker**
- **mqsimigratecomponents**

- **mqsisetsecurity**
- **mqsimanagexalinks**

Syntax:

Parameters:
None

Authorization:
On Windows XP and Windows Server 2003 systems, the user ID used to run this command must be a member of the group Administrators on the local system.

On Windows 7, Windows Vista, and Windows Server 2008 systems, the user ID used to run this command must be running with elevated privileges on the local system:

- The user ID must be a member of the group Administrators.
- The command must be run from an elevated command prompt. To obtain an elevated command prompt, run the mqsicommandconsole command and follow the Windows prompt to launch a new elevated command console.

  This console starts with the correct mqsiprofile environment from which commands that require elevation can be run.

If you do not run the command from within a privileged command console, the command will not process successfully.

Related concepts:

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

Related reference:

"Syntax diagrams" on page 3677

"Security requirements for Windows systems" on page 3651
Security requirements depend on the administrative task that you want to perform.

mqsicreatebroker command:

Use the **mqsicreatebroker** command to create a broker and its associated resources.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPCRBK; see "Contents of the broker PDSE" on page 3991

Purpose:
The **mqsicreatebroker** command completes the following tasks.

1. The command checks whether the specified WebSphere MQ queue manager exists:
   - If the queue manager does not exist, the following behavior occurs.
     - If you run this command on z/OS, the action fails and an error is issued.
     - If you run this command on Linux, UNIX, or Windows, a queue manager is created.

       If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel auth security is automatically disabled.

       The queues that are created include a dead letter queue (DLQ), SYSTEM.DEAD.LETTER.QUEUE. The security settings are the same as for other broker-specific WebSphere MQ queues.

       If a message received by a message flow cannot be processed, it is typically backed out onto the input queue. If it cannot be backed out, or the message flow is not configured to back out messages, or to complete alternative error processing, the broker puts the message to the DLQ.

       The **mqsideletebroker** command does not delete the default DLQ (unless the queue manager is deleted).
   - If the queue manager does exist, check that the queue manager has a DLQ defined; the queue is not created by this command on an existing queue manager, but is required because the broker puts messages that cannot be processed to the DLQ.

     If you use WebSphere MQ clusters in your domain, define the queue manager before you run this command, and configure the queue manager in the cluster to benefit from reduced administration and increased availability.
     - If you run this command on Linux, UNIX, or Windows and the existing queue manager is WebSphere MQ Version 7.1, or later, it is assumed that the user has applied the appropriate security configuration to meet their requirements, and therefore channel auth security is not disabled.
2. The command starts the WebSphere MQ queue manager, if it is not already running, except on z/OS.

   If the command creates the queue manager on Windows, the queue manager is not started as a service. If you log off, the queue manager stops. Therefore, you must either remain logged on, or change the startup status of the queue manager service. If you lock your workstation, the WebSphere MQ queue manager does not stop.
3. The command connects to the associated queue manager.
4. The command creates the WebSphere MQ queues that are required by the broker, if they do not exist.

   If you enable administrative security, the queues required for this support are also created by this command.
5. On Windows only, the command installs a service under which the broker runs.
6. The command creates the broker in one of the available modes. If the full package is installed, the default mode is `enterprise`. If the trial package is installed, the default mode is `trial`. For more information, see "Operation modes" on page 48.
7. The command creates a record for the component in the registry.
8. On Windows systems, Linux, and UNIX systems, the command allows you to specify, when the broker is created, whether the broker can be started and stopped as a WebSphere MQ service.

Brokers can access only local queue managers, so you cannot create a broker on a queue manager that is on a remote system.

Usage notes:
If you have migrated from Version 6.1 or Version 6.0, the following restrictions apply.

In previous versions of WebSphere Message Broker, parameters that you specified on this command were used by the broker to provide default authorization for database access: either the database user ID and password (if specified) or the service user ID and password. Because the Version 7.0 broker does not use a database for its own purposes, the database user ID and password parameters have been deprecated. The broker service ID and password parameters have also been deprecated, except on Windows.

If you migrate a broker from a previous release, the associated values are stored and used for default user database access as though you had entered these values by using the **mqsisetdbparms** command.

When you create a Version 7.0 broker, you must use the **mqsisetdbparms** command to set up database access authorization.

When you create a multi-instance broker, the resources are stored on a shared file system. The user that issues the **mqsicreatebroker** command must have the correct permissions on the shared file system to create these resources.

For details of this command on the operating system that your enterprise uses, see the appropriate topic.

- "**mqsicreatebroker** command - Linux and UNIX systems" on page 3835
- "**mqsicreatebroker** command - Windows systems" on page 3840
- "**mqsicreatebroker** command - z/OS" on page 3845

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

WebSphere MQ queues created:

- SYSTEM.BROKER.ADAPTER.FAILED
- SYSTEM.BROKER.ADAPTER.INPROGRESS
- SYSTEM.BROKER.ADAPTER.NEW
- SYSTEM.BROKER.ADAPTER.PROCESSED
- SYSTEM.BROKER.ADAPTER.UNKNOWN
- SYSTEM.BROKER.ADMIN.QUEUE
- SYSTEM.BROKER.ADMIN.REPLYTODM
- SYSTEM.BROKER.AGGR.CONTROL
- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST
- SYSTEM.BROKER.AGGR.TIMEOUT
- SYSTEM.BROKER.AGGR.UNKNOWN

- SYSTEM.BROKER.AUTH
- SYSTEM.BROKER.CONTROL.QUEUE
- SYSTEM.BROKER.DEPLOY.QUEUE
- SYSTEM.BROKER.DEPLOY.REPLY
- SYSTEM.BROKER.EDA.COLLECTIONS
- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EXECUTIONGROUP.QUEUE
- SYSTEM.BROKER.EXECUTIONGROUP.REPLY
- SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS
- SYSTEM.BROKER.MODEL.QUEUE
- SYSTEM.BROKER.TIMEOUT.QUEUE
- SYSTEM.BROKER.WS.ACK
- SYSTEM.BROKER.WS.INPUT
- SYSTEM.BROKER.WS.REPLY

Access authority is granted for the WebSphere Message Broker group mqbrkrs to all these queues. If the DLQ is enabled, it also has the same authority.

Responses:
If you run the **mqsicreatebroker** command and it fails, resolve the problem that caused the failure:

- Check responses; see "Responses to commands" on page 3682.
- Check the error logs; see "Local error logs" on page 6867.
- Check the error messages in the error log; you can search for error messages in the information center.

When you run the same command again, you might receive a series of messages specifying items that cannot be created. Receiving these messages does not indicate a problem with the **mqsicreatebroker** command itself.

Related concepts:

"Operation modes" on page 48
The operation mode that you use for your broker is determined by the license that you purchase.

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

"Logs" on page 6864
If an error is reported by a WebSphere Message Broker component, start your investigations into its causes by looking at the product and systems logs to which information is written during component operation.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

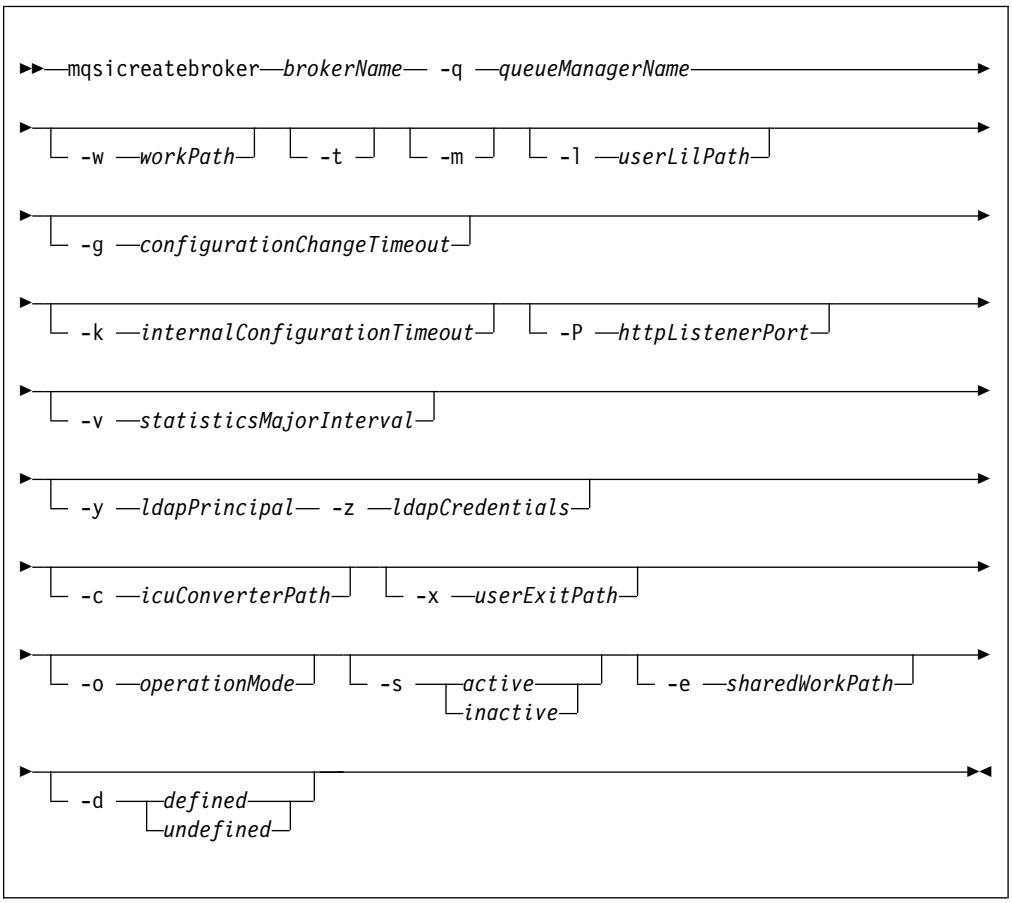
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

mqsicreatebroker *command - Linux and UNIX systems:*

Use the **mqsicreatebroker** command to create a broker on a Linux or UNIX systems.

Syntax:



Parameters:

brokerName
(Required) The name of the broker that you are creating. This parameter must be the first parameter, and it is case sensitive.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-q *queueManagerName*
(Required) The name of the queue manager, (or multi-instance queue manager

if creating a multi instance broker) that is associated with this broker instance. Use the same name for your broker and the queue manager to simplify the organization and administration of your network. Queue manager names are limited to 48 characters in length, and they are case sensitive.

The default behavior is to create a queue manager using the default `mqm` path, if the queue manager does not already exist on the same server.

When creating a multi-instance broker where the queue manager does not exist on the server, a multi-instance queue manager is created beneath the multi-instance broker shared work path using the WebSphere MQ **crtmqm** command as follows:

```
crtmqm –md /<broker sharedWorkPath>/mqm/qmdata
       -ld //<broker sharedWorkPath>/mqm/qmlog queueManagerName
```

If this shared queue manager path is not appropriate, create the multi-instance queue manager on the server before you run this command.

The queue manager attribute `MAXMSGLEN` (the maximum length of messages that can be put to queues) is updated to 100 MB. This attribute is updated regardless of whether the queue manager is created by this command.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-w *workPath*
(Optional) The directory in which working files for this broker are stored. If you do not specify this parameter, files are stored in the default work path, which was specified when the product was installed. If you specify this parameter, you must create this directory before you start the broker.

When a broker has been enabled for multi-instance mode using the –e flag, the broker `workPath` is divided between data that is specific to this broker instance, and that which is shared between this broker and any of its instances created using the **mqsiaddbrokerinstance** command. Data specific to the multi-instance enabled broker is stored in the `workPath` directory on the local server, whereas the shared data is held in a directory on network storage at the location specified using the –e flag.

This directory is also used for trace records that are created when tracing is active. These records are written to a subdirectory, `log`, which you must create before you start the broker.
Error logs that are written by the broker when a process ends abnormally are stored in this directory.
The error log is unbounded and continues to grow. Check this directory periodically and clear out old error information.
You cannot change this parameter using the **mqsichangebroker** command. To specify or change the work path, delete and re-create the broker.
Specifying this parameter creates a separate working directory for the broker. This working directory is a subset of the default working directory structure that contains fewer subdirectories and no `common\profiles` subdirectory.

-t (Optional) The broker runs as a WebSphere MQ trusted application.

If you specify this parameter on HP-UX and Solaris, specify the *serviceUserId* as `mqm`.

For more details about using WebSphere MQ trusted applications, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

-l *userLilPath*
(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

Directory names are case sensitive, and you must include the names in single quotation marks if they contain mixed case characters.
Do not include environment variables in the path; the broker ignores them.

Create your own directory for storing your `.lil` or `.jar` files. Do not save them in the WebSphere Message Broker installation directory.
If you specify more than one directory, separate directories by using a colon (`:`).

-g *configurationChangeTimeout*
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k *internalConfigurationTimeout*
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-P *httpListenerPort*
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-v *statisticsMajorInterval*
(Optional) Specify the interval (in minutes) at which statistics and accounting archive records are to be written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

-y *ldapPrincipal*
(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *ldapCredentials*
(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *icuConverterPath*
(Optional) A set of directories to search for additional code page converters, delimited by a colon (:).

Do not use this parameter to set the converter path if you are using a converter that matches one of the built-in converters that are provided, and that converter is the local code page for the broker. Use the **ICU_DATA** environment variable instead.

-x *userExitPath*
(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (`PATH,LIBPATH,LD_LIBRARY_PATH,SHLIBPATH`) for the execution group process only.

-o *operationMode*
(Optional) Use this parameter to set the mode of your broker; for more information, see "Operation modes" on page 48. Valid values are `enterprise` (the full package, enterprise mode), `starter` (Starter Edition mode), `entry` (Entry Edition mode), and `adapter` (Remote Adapter Deployment mode). The default value is `enterprise`, unless you have the Trial Edition, in which case the default value is `trial`. If you do not set the **-o** parameter, the default value is used automatically.

-s (Optional) Specify the administrative security status for the broker.

If you specify **-s active**, administration security is enabled. Only user IDs that you authorize are permitted to complete actions on the broker. Read, write, and execute authority is always granted on the security queue SYSTEM.BROKER.AUTH to all user IDs that belong to the security group mqbrkrs. When the broker has been created, you can add further user ID authorizations to this queue.

When you create an execution group on a broker for which administrative security is enabled, the queue SYSTEM.BROKER,AUTH.*egroup_name* is created. Populate the queue with the appropriate user authorization.

If you specify **-s inactive**, or omit this parameter, broker administration security is not enabled. All users are able to complete all actions against the broker and all execution groups.

For further information about using security, see "Broker administration security overview" on page 362 and "Authorizing users for broker administration" on page 371.

-e *sharedWorkPath*
(Optional) Setting this value enables the broker for the multi-instance mode of operation.

You must ensure the broker has access to this network storage location before you start the broker, and that the queue manager for the broker has been configured as a WebSphere MQ multi-instance queue manager. The information stored in this shared directory includes:

- The broker registry
- Component directories
- Internal broker tables and files for deployed message flows
- Configurable service properties.

-d (Optional) Specify whether you enable a broker to be started and stopped as a WebSphere MQ service when the queue manager starts and stops.

This option is an alternative to starting a multi-instance broker in standby mode using the **mqsistart** command.

If you specify **-d defined**, the WebSphere MQ service is defined to the queue manager and the broker starts and stops when the queue manager starts and stops.

If you specify **-d undefined**, the WebSphere MQ service is not defined to the queue manager and the broker does not start and stop when the queue manager starts and stops. This is the default setting.

-i *serviceUserId*
(Deprecated) This parameter is included for compatibility with earlier versions.

-a *servicePassword*
(Deprecated) This parameter is included for compatibility with earlier versions.

Examples:
Create a broker to run as a trusted application:

```
mqsicreatebroker MB7BROKER
 -q MB7QMGR -t
```

Create a broker that references user exits:

```
mqsicreatebroker MB7BROKER
 -q MB7QMGR -x /opt/3rdparty/wmbexits
```

Create a broker with administrative security enabled:

```
mqsicreatebroker MB7BROKER
 -q MB7QMGR -s active
```

Create a broker, by using the multi-instance queue manager `MyQMGR` and the shared work path `MyNetworkSharedWorkpath`, where the broker starts as a WebSphere MQ service:

```
mqsicreatebroker MB7BROKER
 -q MyQmgr -e MyNetworkSharedWorkpath -d defined
```

Use the **mqsiaddbrokerinstance** command to create a multi-instance broker on a server where WebSphere Message Broker has been installed.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

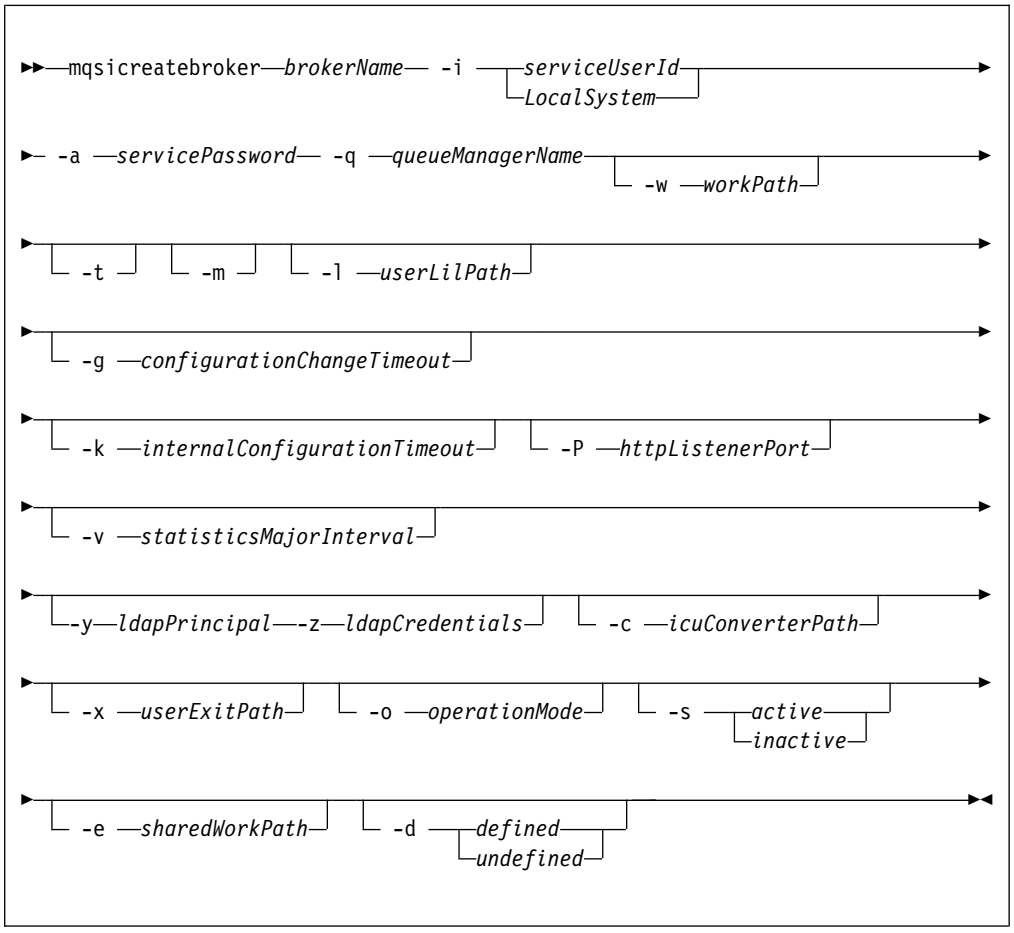
"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

mqsicreatebroker *command - Windows systems:*

Use the **mqsicreatebroker** command to create a broker on a Windows system.

Syntax:



Parameters:

brokerName
(Required) The name of the broker that you are creating. This parameter must be the first parameter. If you create a broker with an uppercase name, you must also specify the name in uppercase in the WebSphere Message Broker Toolkit.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-i *serviceUserId*
(Optional) The user ID under which the broker runs.

You can specify the *serviceUserId* in any valid user name syntax:

- `\\server\username`
- `.\username`
- `username`

Do not use a domain name as part of the *serviceUserId* parameter.
If you use the unqualified form for this user ID (`username`), the operating system searches for the user ID throughout its domain, starting with the local system. This search might take some time to complete.
The *serviceUserId* that you specify must be a direct or indirect member of the mqbrkrs local group. The *serviceUserId* must also be authorized to access the home directory (where WebSphere Message Broker has been installed), and the working directory (if specified by the **-w** parameter).
If you specify that the broker is to run as a WebSphere MQ trusted application (**-t** parameter), you must also add the service user ID to the mqm group.
The security requirements for the *serviceUserId* are described in "Security requirements for Windows systems" on page 3651.

-i *LocalSystem*
(Optional) You can specify *LocalSystem* instead of *serviceUserId*.

If you specify *LocalSystem*, you must use the *servicePassword* parameter, however, the value of the *servicePassword* parameter is ignored.

If you specify the **-e** parameter, *LocalSystem* should not be used. When specifying the **-e** parameter, you must use a real userid for the **-i** option.

For Windows, only the **-i** *LocalSystem* option is available. If you specify the **-e** parameter for a multi-instance broker, the system issues an error (BIP8022E: Invalid service userid and password combination supplied).

Note: Either the *Localsystem* or *serviceUserId* option must be specified for the **-i** parameter.

-a *servicePassword*
(Required) The password for the *serviceUserId*.

For compatibility with existing systems, you can specify `<password>`. However, if you do not specify a password with this parameter when you run the command, you are prompted to enter a password. You must enter the password a second time to verify that you have entered it correctly.

-q *queueManagerName*
(Required) The name of the queue manager, (or multi-instance queue manager if creating a multi instance broker) that is associated with this broker instance. Use the same name for your broker and the queue manager to simplify the organization and administration of your network. Queue manager names are limited to 48 characters in length, and they are case sensitive.

The default behavior is to create a queue manager using the default `mqm` path, if the queue manager does not already exist on the same server.

When creating a multi-instance broker where the queue manager does not exist on the server, a multi-instance queue manager is created beneath the multi-instance broker shared work path using the WebSphere MQ **crtmqm** command as follows:

```
crtmqm –md /<broker sharedWorkPath>/mqm/qmdata
       -ld //<broker sharedWorkPath>/mqm/qmlog queueManagerName
```

If this shared queue manager path is not appropriate, create the multi-instance queue manager on the server before you run this command.

The queue manager attribute `MAXMSGLEN` (the maximum length of messages that can be put to queues) is updated to 100 MB. This attribute is updated regardless of whether the queue manager is created by this command.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-w *workPath*
(Optional) The directory in which working files for this broker are stored. If you do not specify this parameter, files are stored in the default work path, which was specified when the product was installed. If you specify this parameter, you must create this directory before you start the broker.

When a broker has been enabled for multi-instance mode using the –e flag, the broker `workPath` is divided between data that is specific to this broker instance, and that which is shared between this broker and any of its instances created using the **mqsiaddbrokerinstance** command. Data specific to the multi-instance enabled broker is stored in the `workPath` directory on the local server, whereas the shared data is held in a directory on network storage at the location specified using the –e flag.

This directory is also used for trace records that are created when tracing is active. These records are written to a subdirectory, `log`, which you must create before you start the broker.
Error logs that are written by the broker when a process ends abnormally are stored in this directory.
The error log is unbounded and continues to grow. Check this directory periodically and clear out old error information.
You cannot change this parameter using the **mqsichangebroker** command. To specify or change the work path, delete and re-create the broker.
Specifying this parameter creates a separate working directory for the broker. This working directory is a subset of the default working directory structure that contains fewer subdirectories and no `common\profiles` subdirectory.

-t (Optional) The broker runs as a WebSphere MQ trusted application.

If you specify this parameter, add the *serviceUserId* (identified by the **-i** parameter) to the mqm group.

For more details about using WebSphere MQ trusted applications, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

-l *userLilPath*
(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

Do not include environment variables in the path; the broker ignores them.

Create your own directory for storing your `.lil` or `.jar` files. Do not save them in the WebSphere Message Broker installation directory.
If you specify more than one directory, separate directories by using a semicolon (`;`).

-g *configurationChangeTimeout*
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k *internalConfigurationTimeout*
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-P *httpListenerPort*
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-v *statisticsMajorInterval*
(Optional) Specify the interval (in minutes) at which statistics and accounting archive records are to be written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

-y *ldapPrincipal*
(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *ldapCredentials*
(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *icuConverterPath*
(Optional) A delimited set of directories to search for additional code page converters. On Windows systems, the delimiter is a semicolon (;). On UNIX and Linux systems, the delimiter is a colon (:).

Do not use this parameter to set the converter path if you are using a converter that matches one of the built-in converters that are provided, and that converter is the local code page for the broker. Use the **ICU_DATA** environment variable instead.

-x *userExitPath*
(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (`PATH,LIBPATH,LD_LIBRARY_PATH,SHLIBPATH`) for the execution group process only.

-o *operationMode*
(Optional) Use this parameter to set the mode of your broker; see "Operation modes" on page 48. Valid values that you can set are `enterprise` (the full package, enterprise mode), `entry` (Entry Edition mode), `starter` (Starter Edition mode), and `adapter` (Remote Adapter Deployment mode). The default value is `enterprise`, unless you have the Trial Edition, in which case the default value is `trial`. If you do not set the **-o** parameter, the default value is used automatically.

-s (Optional) Specify the administrative security status for the broker.

If you specify **-s active**, administration security is enabled. Only user IDs that you authorize are permitted to complete actions on the broker. Read, write, and execute authority is always granted on the security queue SYSTEM.BROKER.AUTH to all user IDs that belong to the security group mqbrkrs. When the broker has been created, you can add further user ID authorizations to this queue.

When you create an execution group on a broker for which administrative security is enabled, the queue SYSTEM.BROKER,AUTH.*egroup_name* is created. Populate the queue with the appropriate user authorization.

If you specify **-s inactive**, or omit this parameter, broker administration security is not enabled. All users are able to complete all actions against the broker and all execution groups.

For further information about using security, see "Broker administration security overview" on page 362 and "Authorizing users for broker administration" on page 371.

-e *sharedWorkPath*
(Optional) Setting this value enables the broker for the multi-instance mode of operation.

You must ensure the broker has access to this network storage location before you start the broker, and that the queue manager for the broker has been configured as a WebSphere MQ multi-instance queue manager. The information stored in this shared directory includes:

- The broker registry
- Component directories
- Internal broker tables and files for deployed message flows
- Configurable service properties.

-d (Optional) Specify whether you enable a broker to be started and stopped as a WebSphere MQ service when the queue manager starts and stops.

This option is an alternative to starting a multi-instance broker in standby mode using the **mqsistart** command.

If you specify **-d defined**, the WebSphere MQ service is defined to the queue manager and the broker starts and stops when the queue manager starts and stops.

If you specify **-d undefined**, the WebSphere MQ service is not defined to the queue manager and the broker does not start and stop when the queue manager starts and stops. This is the default setting.

Examples:
Create a broker to run as a trusted application:

```
mqsicreatebroker MB7BROKER -i wbrkuid -a wbrkpw -q MB7QMGR -t
```

Create a broker that references user exits:

```
mqsicreatebroker MB7BROKER -i wbrkuid -a wbrkpw
 -q MB7QMGR -x /opt/3rdparty/wmbexits
```

Create a broker with administrative security enabled:

```
mqsicreatebrokerMB7BROKER -q MB7QMGR -s active
```

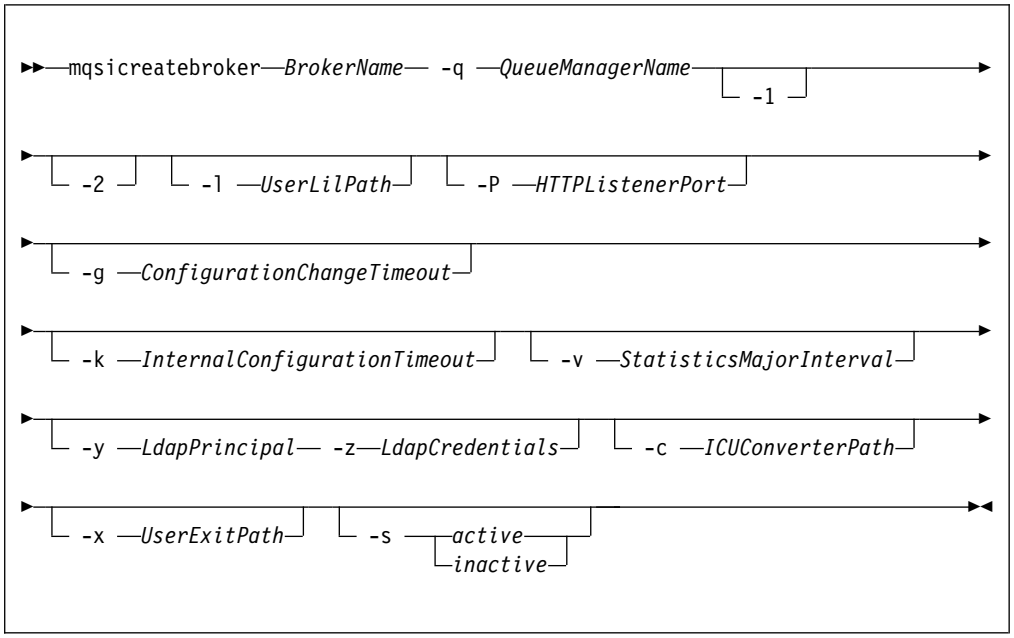
mqsicreatebroker *command - z/OS:*

Use the **mqsicreatebroker** command to create a broker on a z/OS system.

Syntax:
z/OS command - BIPCRBK



Parameters:

BrokerName
(Required) The name of the broker that you are creating. This parameter must be the first parameter. If you create a broker with an uppercase name, you must also specify the name in uppercase in the WebSphere Message Broker Toolkit.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-q *QueueManagerName*
(Required) The name of the queue manager, (or multi-instance queue manager if creating a multi instance broker) that is associated with this broker instance. Use the same name for your broker and the queue manager to simplify the organization and administration of your network. Queue manager names are limited to 48 characters in length, and they are case sensitive.

The default behavior is to create a queue manager using the default `mqm` path, if the queue manager does not already exist on the same server.

When creating a multi-instance broker where the queue manager does not exist on the server, a multi-instance queue manager is created beneath the multi-instance broker shared work path using the WebSphere MQ **crtmqm** command as follows:

```
crtmqm –md /<broker sharedWorkPath>/mqm/qmdata
       -ld //<broker sharedWorkPath>/mqm/qmlog queueManagerName
```

If this shared queue manager path is not appropriate, create the multi-instance queue manager on the server before you run this command.

The queue manager attribute `MAXMSGLEN` (the maximum length of messages that can be put to queues) is updated to 100 MB. This attribute is updated regardless of whether the queue manager is created by this command.

For restrictions on the character set that you can use, see "Characters allowed in commands" on page 3680.

-l *UserLilPath*
(Optional) A list of paths (directories) from which the broker loads Loadable implementation libraries (LIL files) for user-defined message processing nodes.

This name is case sensitive; enclose the names in single quotation marks if they are in mixed case.
Do not include environment variables in this path; WebSphere Message Broker ignores them.

You must create your own directory for storing your `.lil` or `.jar` files. Do not save these files in the WebSphere Message Broker install directory.

-P *HTTPListenerPort*
(Optional) Enter the number of the port on which the Web services support is listening.

The broker starts this listener when a message flow that includes HTTP nodes or Web services support is started; the default is 7080.

Ensure that the port that you specify has not been specified for any other purpose.

-g *ConfigurationChangeTimeout*
(Optional) The maximum time (in seconds) that is allowed for a user configuration request to be processed. It defines the length of time taken within the broker to apply to an execution group a configuration change that you have initiated. For example, if you deploy a configuration from the WebSphere Message Broker Toolkit, the broker must respond to the Configuration Manager within this time.

A message flow cannot respond to a configuration change while it is processing an application message. An execution group returns a negative response to the deployed configuration message if any one of its message flows does not finish processing an application message and apply the configuration change within this timeout.

Specify the value in seconds, in the range 10 - 3600. The default is 300.

For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-k *InternalConfigurationTimeout*
(Optional) The maximum time (in seconds) that is allowed for an internal configuration change to be processed. For example, it defines the length of time taken within the broker to start an execution group.

The response time of each execution group differs according to system load and the load of its own processes. The value must reflect the longest response time that any execution group takes to respond. If the value is too low, the broker returns a negative response, and might issue error messages to the local error log.
Specify the value in seconds, in the range 10 - 3600. The default is 60.
For information about how to set the value for this timeout, see "Setting configuration timeout values" on page 3258.

-v *StatisticsMajorInterval*
(Optional) Specify the interval (in minutes) at which statistics and accounting archive records are to be written. The valid range is from 1 minute to 43200 minutes; the default value is 60.

An interval of zero minutes indicates that the operating system has an external method of notification (the ENF timer), and is not using an internal timer within WebSphere Message Broker.

-1

(Optional) The registry pass, which creates only the broker registry.

You must run the command with option **1** before you run the command with option **2**, otherwise the command fails.

-2

(Optional) The WebSphere MQ pass, which creates only the broker WebSphere MQ queues.

-y *LdapPrincipal*

(Optional, but mandatory when *ldapCredentials* is provided.) The user principal for access to an optional LDAP directory that holds the JNDI administered Initial Context for the JMS provider.

-z *LdapCredentials*

(Optional, but mandatory when *ldapPrincipal* is provided.) The user password for access to LDAP.

-c *ICUConverterPath*

(Optional) A delimited set of directories to search for additional code page converters.

The code page converters must be either of the form *codepagename*`.cnv`, or in an ICU data package called `icudt38.dat`. The code page converters must be located in a sub-directory named `icudt38_`*<platform_suffix>* of the specified directory where <*platform_suffix*> is one of the following values:

- l for little-endian ASCII platforms
- b for big-endian ASCII platforms
- e for EBCDIC platforms

Do not use this parameter to set the converter path if you are using a converter that matches one of the built-in converters that are provided with Version 6.0, and that converter is the local code page for the broker. Use the **ICU_DATA** environment variable instead.

-x *UserExitPath*

(Optional) The path that contains the location of all user exits to be loaded for execution groups in this broker. This path is added to the system library search path (`PATH,LIBPATH,LD_LIBRARY_PATH,SHLIBPATH`) for the execution group process only.

-s (Optional) Specify the administrative security status for the broker.

If you specify **-s active**, administration security is enabled. Only user IDs that you authorize are permitted to complete actions on the broker. Read, write, and execute authority is always granted on the security queue SYSTEM.BROKER.AUTH to all user IDs that belong to the security group mqbrkrs. When the broker has been created, you can add further user ID authorizations to this queue.

When you create an execution group on a broker for which administrative security is enabled, the queue SYSTEM.BROKER,AUTH.*egroup_name* is created. Populate the queue with the appropriate user authorization.

If you specify **-s inactive**, or omit this parameter, broker administration security is not enabled. All users are able to complete all actions against the broker and all execution groups.

For further information about using security, see “Broker administration security overview” on page 362 and “Authorizing users for broker administration” on page 371.

Examples:
Create a broker on z/OS by using a single command:

```
mqsicreatebroker CSQ1BRK -q CSQ1
```

Create a broker with administrative security enabled:

```
mqsicreatebroker MB7BROKER -q MB7QMGR -s active
```

Related tasks:

“Setting configuration timeout values” on page 3258
Change timeout values that affect configuration tasks in the broker.

Related reference:

“Syntax diagrams” on page 3677

“**mqsichangebroker** command” on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

“**mqsicreatebroker** command” on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

“**mqsideletebroker** command” on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

mqsicreateconfigurableservice command:

Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

You can also use the WebSphere Message Broker Explorer to create configurable services. For more information, see “Using the WebSphere Message Broker Explorer to work with configurable services” on page 644.

Supported platforms:

- Windows.
- Linux and UNIX systems.
- z/OS. Run this command by customizing and submitting BIPCRCS. For more information, see “Contents of the broker PDSE” on page 3991.

Purpose:
For configurable services that you add by using the **mqsicreateconfigurableservice** command:

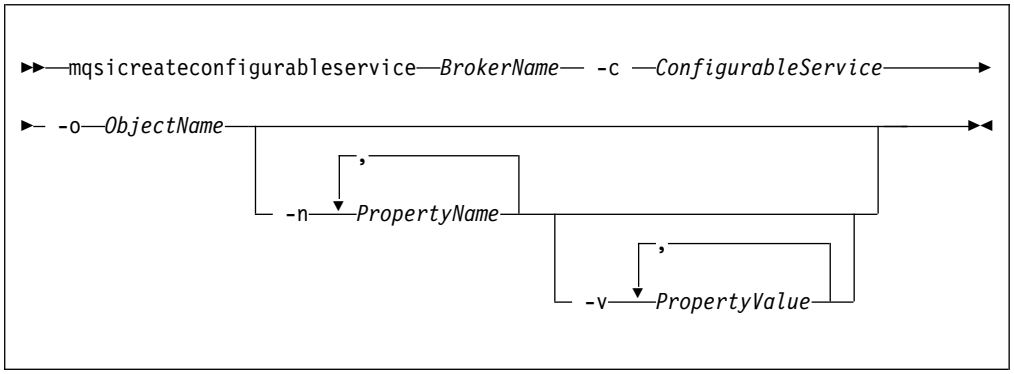
- Use the **mqsireportproperties** command to view the configurable services.
- Use the **mqsichangeproperties** command to modify the configurable services.
- Use the **mqsideleteconfigurableservice** command to delete configurable services.

You do not have to use the **mqsicreateconfigurableservice** command to create EIS providers, because definitions are supplied for you. Use the **mqsichangeproperties** command to modify EIS providers.

Usage notes:

- Before you run this command, ensure that the broker is running.
- Stop and restart the broker before you use any new broker resources and properties.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker to modify. This parameter must be the first parameter.

-c *ConfigurableService*
(Required) The type of external resource (configurable service). Use the **mqsireportproperties** command to view the list of valid values.

The valid resource types are listed in "Configurable services properties" on page 3766.

-o *ObjectName*
(Required) The name of the object whose properties you want to change.

For example, if the **-c** parameter is set to JDBCProviders, the expected object name is either an IBM-defined JDBC provider name, or a user-defined JDBC provider name. Default services are provided for the supported databases to which you can connect over JDBC type 4 connections. Use the supplied services as a template when you create a service by using this command. Use the **mqsireportproperties** command to view the list of default provider names.

-n *PropertyName*
(Optional) The name of the property that is being changed.

The valid property names are listed in "Configurable services properties" on page 3766.

-v *PropertyValue*
(Optional, but required if the **-n** parameter is specified) The value that is assigned to the property that is specified by the **-n** parameter. You can specify more than one property name and corresponding value by using commas as separators; for example, `-n Name1,Name2 -v Value1,Value2`.

If the property value contains a comma, enclose the value with escaped double quotation marks (\" and \"); for example, `-n Name1,Name2 -v Value1,\"Value21,Value22\"`.

UNIX On UNIX systems, if the **-v** parameter contains a semi-colon (;), enclose the entire string in quotation marks, as shown in the following example:

```
mqsicreateconfigurableservice MB7BROKER -c JDBCProviders -o DB2EXTRA -n connectionUrlFormat
-v "jdbc:db2://[serverName]:[portNumber]/[databaseName]:user=[user];password=[password];"
```

The property values are described in "Configurable services properties" on page 3766.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

- BIP8011 Unable to create configuration data
- BIP8012 Unable to connect to system components
- BIP8014 Component cannot be created
- BIP8073 Invalid broker name
- BIP8983 Configurable service already exists
- BIP8984 Configurable service was not found

Examples:
Create an Aggregation configurable service that uses a set of queues that is prefixed with SYSTEM.BROKER.AGGR.SET1, and with a timeout of 60 seconds:

```
mqsicreateconfigurableservice MB7BROKER -c Aggregation -o myAggregationService
-n queuePrefix,timeoutSeconds -v SET1,60
```

Create a CICSConnection configurable service for the CICS instance that is running at `tcp://test.cics.ibm.com` port 12345. The broker is identified by APPLID *BRKApp* and qualifier *BRKQual*. The connection timeout is 10 seconds and the request timeout is 5 seconds in this example:

```
mqsicreateconfigurableservice MB7BROKER -c CICSConnection -o myCICSConnectionService
-n cicsServer,clientApplid,clientQualifier,connectionTimeoutSecs,
requestTimeoutSecs -v tcp://test.cics.ibm.com:12345,BRKApp,BRKQual,10,5
```

Create a Collector configurable service that uses queues that are prefixed with SYSTEM.BROKER.EDA.SET1, and with a collection expiry of 60 seconds:

```
mqsicreateconfigurableservice MB7BROKER -c Collector -o myCollectorService
-n queuePrefix,collectionExpirySeconds -v SET1,60
```

Create a Connect:Direct server configurable service on object `test`, with a host name of `9.122.17.58` and port number `1369`:

```
mqsicreateconfigurableservice MB7BROKER -c CDServer -o test
-n Hostname,Port -v 9.122.17.58,1369
```

Create a CORBA configurable service that specifies the location of the object reference:

```
mqsicreateconfigurableservice MB7BROKER -c CORBA -o myCORBAService
-n namingService,objectReferenceName -v localhost:2809,Europe.region/Market.object
```

Create an EmailServer configurable service to which the EmailInput node or message flow can refer at run time to connect to an email server. The server is running at pop3://test.email.server.ibm.com on port 12345. In this example, the security identity is identified by *mySecurityIdentityObjectName*.

```
mqsicreateconfigurableservice MB7BROKER -c EmailServer -o myEmailConfigurableServiceName
-n serverName,securityIdentity -v pop3://test.email.server.ibm.com
:12345,mySecurityIdentityObjectName
```

Create an FtpServer configurable service:

```
mqsicreateconfigurableservice MB7BROKER -c FtpServer -o Server01
-n serverName,scanDelay,transferMode,connectionType,securityIdentity
-v one.hursley.abc.com:123,20,Binary,ACTIVE,secId
```

Create an FtpServer configurable service to use SFTP without strict host key checking:

```
mqsicreateconfigurableservice MB7BROKER -c FtpServer -o TEST1
-n protocol,serverName,scanDelay,remoteDirectory,securityIdentity,cipher,compression,strictHostKeyChecking
-v  SFTP,winlnx58,30,.,chbatey,blowfish-cbc,9,no
```

Create an IMSConnect configurable service for the IMS instance IMSA that is running on test.ims.ibm.com port 9999:

```
mqsicreateconfigurableservice MB7BROKER -c IMSConnect -o myIMSConnectService
-n Hostname,PortNumber,DataStoreName -v test.ims.ibm.com,9999,IMSA
```

Create a JavaClassLoader service:

```
mqsicreateconfigurableservice MB7BROKER -c JavaClassLoader
-o myJavaClassLoader
-n includedDeployedJars,sharedJarPath
-v "jcnapp1.jar","/var/app1/jars"
```

Add a JMS provider that is called "MyProviderXYZ":

```
mqsicreateconfigurableservice MB7BROKER -c JMSProviders -o JMS_MyProviderXYZ
```

Add a JMS provider that is called "ProviderABC", with default values for the resource properties:

```
mqsicreateconfigurableservice MB7BROKER -c JMSProviders -o JMS_ProviderABC
```

Add a JMS provider that is called "BEAV91", specifying the name of an IBM supplied Java class that is called com.ibm.broker.apihandler.BEAWebLogicAPIHandler to handle vendor-specific API calls:

```
mqsicreateconfigurableservice MB7BROKER -c JMSProviders -o BEAV91
-n proprietaryAPIHandler,proprietaryAPIAttr1,proprietaryAPIAttr2,proprietaryAPIAttr3
–v com.ibm.broker.apihandler.BEAWebLogicAPIHandler,weblogic.jndi.WLInitialContextFactory,
t3://19.21.194.126:7001,BEAServerName
```

Create a monitoring profile with the name 'mp1' to broker MB7BROKER:

```
mqsicreateconfigurableservice MB7BROKER -c MonitoringProfiles -o mp1
```

Create a PeopleSoftConnection configurable service for the PeopleSoft instance that is running on *my.peoplesoft.qa.com*:

```
mqsicreateconfigurableservice MB7BROKER -c PeopleSoftConnection
-o myPeopleSoftAdapter.outadapter -n hostName,port -v "my.peoplesoft.qa.com",9000
```

Create a Resequence configurable service that uses a set of queues that are prefixed with SYSTEM.BROKER.EDA.SET1, and with a missing message timeout of 60 seconds:

```
mqsicreateconfigurableservice MB7BROKER -c Resequence -o myResequenceService
-n queuePrefix,missingMessageTimeoutSeconds -v SET1,60
```

Create a SAPConnection configurable service for the SAP adapter *mySAPAdapter.outadapter* that connects to the SAP host `test.sap.ibm.com`, and uses client *001* for the connections into that server:

```
mqsicreateconfigurableservice MB7BROKER -c SAPConnection -o mySAPAdapter.outadapter
-n applicationServerHost,client -v test.sap.ibm.com,001
```

You can set the user name and password for an SAP adapter by using the **mqsisetdbparms** command.

Create a security profile for a WS-Trust V1.3 STS provider by using Tivoli Federated Identity Manager (TFIM) V6.2:

```
mqsicreateconfigurableservice MB7BROKER -c SecurityProfiles -o myWSTrustTFIMv62Profile
-n authentication,mapping,authorization,propagation,mappingConfig
-v "WS-Trust v1.3 STS","WS-Trust v1.3 STS","WS-Trust v1.3 STS",TRUE,
http://wstrusthost1.ibm.com:9080/TrustServerWST13/services/RequestSecurityToken
```

The Default Propagation profile is a predefined profile that requests only identity propagation. For more information about creating a security profile for a WS-Trust V1.3 STS provider, LDAP, or TFIM V6.1, see "Creating a security profile" on page 433.

Create a SiebelConnection configurable service for the Siebel adapter *mySiebelAdapter.outadapter* that connects to the Siebel server *"siebel://my.siebel.qa.com/SBA_80/SSEObjMgr_enu"*.

```
mqsicreateconfigurableservice MB7BROKER -c SiebelConnection -o mySiebelAdapter.outadapter
-n connectString -v "siebel://my.siebel.qa.com/SBA_80/SSEObjMgr_enu"
```

You can set the user name and password for a Siebel adapter by using the **mqsisetdbparms** command.

Create a TCPIPServer configurable service:

```
mqsicreateconfigurableservice MB7BROKER -c TCPIPServer -o ServerPort1452
-n Port,MaximumConnections,ExpireConnectionSec -v 1452,1000,15
```

Create a TCPIPClient configurable service:

```
mqsicreateconfigurableservice MB7BROKER -c TCPIPClient
-o ClientPort1452HostnameJsmith
-n Port,Hostname,AlternativeAddresses,MinimumConnections,MaximumConnections
-v 1452,jsmith.hursley.ibm.com,jones:1111;edwards,5,10
```

Create a TCP/IP configurable service that uses SSL:

"Configuring TCP/IP client nodes to use SSL" on page 551

"Configuring TCP/IP server nodes to use SSL" on page 553

Create a Timer configurable service that uses a queue that is prefixed with SYSTEM.BROKER.TIMEOUT.SET1, and has a timeout of 5 seconds:

```
mqsicreateconfigurableservice MB7BROKER -c Timer -o myTimerService
-n queuePrefix,timeoutIntervalSeconds -v SET1,5
```

Create a UserDefined service:

```
mqsicreateconfigurableservice MB7BROKER -c UserDefined
-o HTTP_Timeout -n VerifyRequestTimeout -v 60
```

Related concepts:

"Using the WebSphere Message Broker Explorer to work with configurable services" on page 644
Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services.

Select the properties and values that you want to change for an existing FtpServer configurable service or to create a new service.

mqsicreateexecutiongroup command:

Use the **mqsicreateexecutiongroup** command to add a new execution group to a broker.

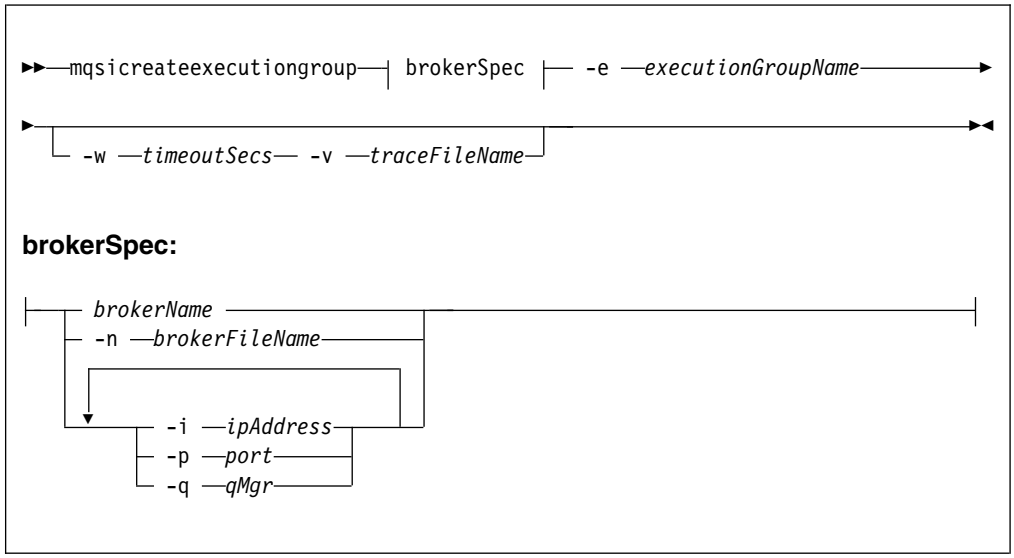
Supported platforms:

- Windows
- Linux and UNIX systems

- z/OS. Run this command by customizing and submitting BIPCREG; see "Contents of the broker PDSE" on page 3991

Purpose:
You must start the broker before you run the **mqsicreateexecutiongroup** command.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note."

-e *executionGroupName*
(Required) The name of the execution group to create.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to

process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Create an execution group called `EG1` on the broker that is hosted by the queue manager `QMGR`, which is listening on `fred.abc.com:1414`.

```
mqsicreateexecutiongroup -i fred.abc.com -p 1414 -q QMGR –e EG1
```

Create an execution group called `EG2` on the broker that is defined by the connection parameters in file `BROKER.broker`

```
mqsicreateexecutiongroup –n BROKER.broker –e EG2
```

Create an execution group `EG3` on the broker that is defined by the connection parameters in file `FRED.broker`. Wait 5 minutes for the broker to respond, and send output to `trace.txt`.

```
mqsicreateexecutiongroup –n FRED.broker –e EG3 –w 300 –v trace.txt
```

Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"Syntax diagrams" on page 3677

mqsicvp command:

Use the **mqsicvp** command to perform verification tests on a broker, or to verify ODBC connections.

Supported platforms:

- Windows
- Linux and UNIX systems

When you start a broker by using the **mqsistart** command, this command is run automatically to verify the component.

On z/OS, the same verification procedures are run automatically when you start a broker.

You can run this command against a broker that is running, or is not running. If the broker is not running, the verification tests are performed, but the broker is not started.

Purpose:
The **mqsicvp** command completes the following actions:

- The command checks that the broker environment is set up correctly; for example, that the installed level of Java is supported.
- The command verifies that the WebSphere MQ queues are defined and accessible.
- Linux UNIX On Linux and UNIX systems, the command verifies that the ODBC environment (if specified) is configured correctly.

  If the ODBCINI environment variable is set, the **mqsicvp** command writes warning messages to the syslog in the following situation:
  - If the file to which the ODBCINI environment variable points does not exist, or the broker does not have access to read it or write to it

  If the environment variable ODBCUOINI is set, the **mqsicvp** command writes warning messages to the syslog in the following situations:
  - If the file that is referenced by the ODBCUOINI environment variable does not exist, or the broker does not have access to read or write to the file
  - If ODBCSYSINI is not set
  - If the directory that is referenced by the ODBCSYSINI environment variable does not contain a file called `odbcinst.ini`, or the broker does not have access to read or write to this file
  - If the IE02_PATH environment variable is not set
- Linux UNIX On Linux and UNIX systems, if the ODBC environment check is successful, the command connects to all data sources that are listed in the `odbc.ini` files, and that were associated with the broker by using the **mqsisetdbparms** command.

Use of the command to provide information about user data sources:
Extra invocations of the **mqsicvp** command have been added to provide ODBC Test Tool function. This function provides useful information and diagnostics about a user data source, or Compares two user data sources for equivalence. These invocations are discrete from the existing invocation of the **mqsicvp** command, and are not run at broker startup.

When you use the **mqsicvp** command as an ODBC Test Tool, the command issues an informational message on successful connection, providing the name of the datasource, database type, and version. If a secondary datasource is supplied, the **mqsicvp** command issues a second informational message on successful connection to that datasource, with the same information concerning the secondary datasource, and informing you that a comparison will be made.

When the tool is run against one data source, it completes several checks against the ODBC interface to determine which data types and functions are supported, together with information on the names and sizes of those data types. If any data types or functions are not supported, they are summarized in a final informational message.

When these tests are run against two data sources, they are run against both data sources, and both results are shown. A final informational message states whether

the two data sources are equivalent and eligible to be used within the same message processing node; for more information, see “Accessing databases from ESQL” on page 2115.

Syntax:

Invocation to verify the broker

When you run the **mqsicvp** command with only the broker name, and no other parameters, the command completes the following checks:

- Checks that the broker environment is set up correctly (for example, the installed level of Java is supported).
- Verifies that the WebSphere MQ queues are defined and accessible.
- Linux UNIX On Linux and UNIX systems only, the command verifies that the ODBC environment (if specified) is configured correctly. If the ODBCINI environment variable is not set, ODBC environment verification is skipped. If the ODBC environment check is completed successfully, the command then tries to connect to all data sources that are listed in the `odbc.ini` files where the **mqsisetdbparms** command was used to associate the data source with the broker.

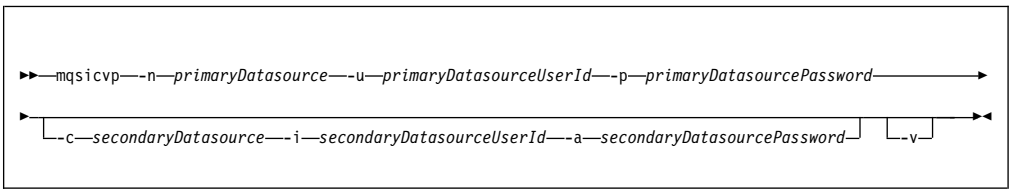
Syntax:

Invocation where data source names have not been associated with the broker

When you run the **mqsicvp** command with parameters shown in the following syntax diagram, the command provides ODBC test tool function. You can use the command to display useful information about a user data source, or compare two user data sources. On Linux and UNIX systems only, invocations of the command that use these parameters also verify that the ODBC environment (if specified) is configured correctly. In these cases, the command checks that the ODBCINI, ODBCSYSINI, ODBCUOINI, and IE02_PATH variables are set.

Each data source name (DSN) is fully specified with a user name and password.

This invocation does not rely on an association between the broker and the data source, and returns information about the data source even when there is no association with a broker.



Syntax:

Invocation where data source names were associated with the broker

This invocation requires an association between the broker and the data source name (DSN). In order to successfully use this invocation, you must first run the **mqsisetdbparms** command to identify a specific user ID and password for the broker to use when connecting to the data source. The output from this invocation is the same as the output from the invocation where data source names have not been associated with the broker.

When using the **mqsisetdbparms** command, you can either specify the data source name directly, or add one of the following prefixes:

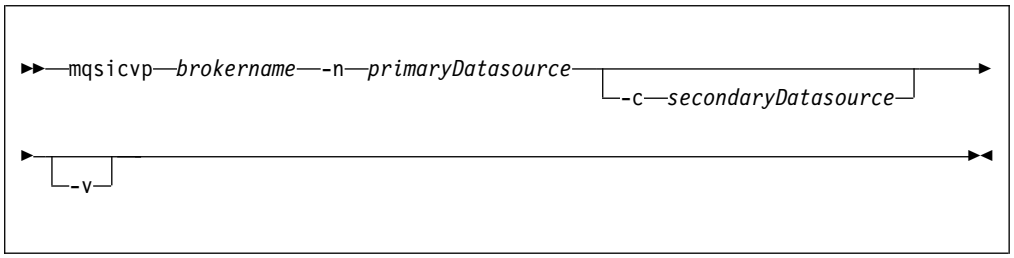
- `dsn::`
- `odbc::`

These prefixes identify the type of identity being created in **mqsisetdbparms**, and must be omitted when using this identity as the data source in **mqsicvp**. For example:

- `mqsisetdbparms MB7BROKER -n dsn::myDsn -u username -p password`
- `mqsicvp MB7BROKER -n myDsn`

If you use **mqsisetdbparms** to set an execution group level identity for a data source, the identity cannot be used in **mqsicvp**. Additionally, **mqsicvp** cannot use a default user ID and password that has been set for all data sources.

Linux UNIX On Linux and UNIX systems only, invocations of the command that use the parameters in the following syntax diagram also verify that the ODBC environment (if specified) is configured correctly. In these cases, the command checks that the ODBCINI, ODBCSYSINI, ODBCUOINI, and IE02_PATH variables are set.



Parameters:

brokername
(Required - if you are using an invocation containing *brokername*) Specify a broker name to verify, or the broker name with which the `primaryDatasource` is associated.

Linux UNIX All names are case sensitive on Linux and UNIX systems.

-n *primaryDatasource*
(Required if you are using an invocation containing *primaryDatasource*) Name of the ODBC connection to verify.

-u *primaryDatasourceUserId*
(Required if you have not previously associated the data source name with the broker) User name with which to connect to the *primaryDatasource*.

-p *primaryDatasourcePassword*
(Required if you have not previously associated the data source name with the broker) Password used with the *primaryDatasourceUserId*.

-c *secondaryDatasource*
(Optional) If two data sources are being compared for equivalence, this is the second ODBC connection name.

-i *secondaryDatasourceUserId*
(Optional) User name with which to connect to the *secondaryDatasource*.

-a *secondaryDatasourcePassword*
(Optional) Password used with the *secondaryDatasourceUserId*.

-v (Optional) Causes extra, untranslated, diagnostics related to supported CASTS to be output by the command.

Authorization:
For information about authorizations that are specific to operating systems, see the following topics:

- Linux UNIX "Security requirements for Linux and UNIX platforms" on page 3648
- Windows "Security requirements for Windows systems" on page 3651

If you enabled broker administration security, you must also set up the authority that is described in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
- BIP8040W: No database access (unable to connect).
- BIP8267W: Warning, there might be issues using this data source. See the preceding messages for more information.
- BIP8268I: The two data sources supplied are compatible, and can be used in the same Compute node.
- BIP8269W: The two data sources supplied are not compatible, and must not be used in the same Compute node.
- BIP8270I: Connected to datasource <..multiple inserts..>
- BIP8271I: Connected to second datasource <..multiple inserts..> for comparison.
- BIP8272W: Datasource specified has not been associated with the broker.
- BIP8273I: The following datatypes and functions are not natively supported by datasource '&1': <..multiple inserts..>
- BIP8274W: The following datatypes and functions might cause problems when using datasource '&1' with WebSphere Message Broker: <..multiple inserts..>
- BIP8288W: Unable to read ODBCINI file '*file_name*'. Check that this file exists, and that the broker user ID has permission to read and write the file.
- BIP8289W: Unable to read ODBCSYSINI file in specified directory '*directory_name*'. Check that this file exists, and that the broker user ID has permission to read and write the file.
- BIP8290I: Verification passed for the ODBC environment.
- BIP8291W: The IE02_PATH environment variable is not set.
- BIP8292I: '*insert1*' user data sources were not verified because they do not have **mqsisetdbparms** credentials.
- BIP8293W: Unable to read ODBCUOINI file '*file_name*'. Check that this file exists, and that the broker user ID has permission to read and write to the file.

- BIP8294I: ODBC environment verification was skipped because both the ODBCINI and ODBCUOINI environment variables are not set.
- BIP8295E: ODBCINI environment variables have not been set, or are invalid.
- BIP8296W: The ODBCSYSINI environment variable is not set.
- BIP8297W: '*environment_variable_name*' file '*file_name*' is empty.
- BIP8873I: Starting the component verification for broker '*broker_name*'.
- BIP8874I: The component verification for '*broker_name*' has finished successfully.
- BIP8875W: The component verification for '*broker_name*' has finished, but one or more checks failed.
- BIP8876I: Starting the environment verification for broker '*broker_name*'.
- BIP8877W: The environment verification for broker '*broker_name*' has finished, but one or more checks failed.
- BIP8878I: The environment verification for broker '*broker_name*' has finished successfully.
- BIP8882I: Starting the WebSphere MQ verification for broker '*broker_name*'.
- BIP8883W: The WebSphere MQ verification for broker '*broker_name*' has finished, but one or more checks failed.
- BIP8884I: The WebSphere MQ verification for broker '*broker_name*' has finished successfully.
- BIP8885E: Verification failed. Failed to connect to queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
- BIP8886I: Verification passed for queue '*queue_name*' on queue manager '*queue_manager_name*'.
- BIP8887E: Verification failed for queue '*queue_name*' on queue manager '*queue_manager_name*' while issuing '*operation*'. MQRC: *return_code* MQCC: *completion_code*
- BIP8888E: Verification failed. Failed to disconnect from queue manager '*queue_manager_name*'. MQRC: *return_code* MQCC: *completion_code*
- BIP8892E: Verification failed. The installed Java level '*level_installed*' does not meet the required Java level '*level_supported*'.
- BIP8893E: Verification failed for environment variable '*variable_name*'. Unable to access file '*file_name*' with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*.
- BIP8894I: Verification passed for '*broker_name*'.
- BIP8895E: Verification failed. Environment variable '*variable_name*' is incorrect or missing.
- BIP8896E: Verification failed. Unable to access the registry with user ID '*user_ID*'. Additional information for IBM support: *data1 data2*
- BIP8897E: Verification failed. Environment variable '*variable_name*' does not match the broker name '*broker_name*'.
- BIP8900I: APF Authorization check successful for file '*file_name*'.
- BIP8903E: Verification failed. The APF Authorization check failed for file '*file_name*'.
- BIP8904E: Verification failed. Failed to stat file '*file_name*1' with return code '*return_code*' and errno '*error_number*'.

Examples:
Run verification checks on the broker named MB7BROKER:

```
mqsicvp MB7BROKER
```

Data Source Name (DSN) MyDB is associated with the broker MB7BROKER using the **mqsisetdbparms** command:

```
mqsicvp MB7BROKER -n MyDB
```

DSNMyDB is compared against a secondary DSN MyDB2 associated with the broker MB7BROKER using the **mqsisetdbparms** command:

```
mqsicvp MB7BROKER -n MyDB -c MyDB2
```

The fully qualified DSN MyDB is compared against a secondary fully qualified DSN MyDB2 using the primary and secondary user IDs and passwords:

```
mqsicvp –n MyDB –u username –p password –c MyDB2 –i username2 –a password2
```

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsideletebroker command:

Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPDLBK; see "Contents of the broker PDSE" on page 3991

Purpose:
The **mqsideletebroker** command:

- On Windows platforms, stops the service that runs the broker.
- Stops and deletes the WebSphere MQ queue manager for the broker, if requested.
- Deletes the administrative security queues that are associated with the broker, if requested.
- Removes the record for the component in the registry.

If you delete a broker that has WebSphere MQ publish/subscribe broker neighbors, you must also run the **clrmqbrk** on each of these neighbors. You must identify the broker that you are deleting on this command.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsideletebroker** command - Windows, Linux, and UNIX systems"
- "**mqsideletebroker** command - z/OS" on page 3865

Usage notes:
If you run the command against a component that does not exist (for example, the component has already been deleted, or you have mistyped the component name), the command returns with a successful completion message. The command does not inform you that the component does not exist.

You cannot delete a broker to which you have an open connection; the command fails. For example, if your WebSphere Message Broker Explorer session is currently connected to a broker, you cannot delete that broker until you disconnect it.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related tasks:

"Deleting a broker" on page 930
Delete a broker using the command line on the system where the broker component is installed.

Related reference:

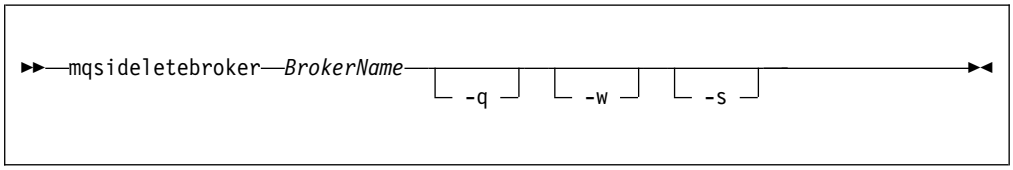
"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

mqsideletebroker *command - Windows, Linux, and UNIX systems:*

Use the **mqsideletebroker** command to delete a broker on Linux, UNIX, or Windows systems.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker that you want to delete. You must specify this parameter first.

-q (Optional) Specifies that the broker's queue manager should be deleted. If you do not specify this parameter, only the WebSphere MQ queues and broker's data are deleted.

-w (Optional) Deletes all files related to this broker from the work path.

-s (Optional) Specify this option to delete all administrative security queues for this broker when the broker is deleted. The queue SYSTEM.BROKER.AUTH and the queue for every defined execution group (SYSTEM.BROKER.AUTH.*egroup_name*) are deleted.

If you do not specify this option, the security queues are retained and can be reused if you re-create the broker.

This parameter is ignored if you specify **-q**, which deletes the queue manager and all its queues.

Examples:
Delete the broker and its associated queue manager:

```
mqsideletebroker MB7BROKER -q
```

Delete the broker and all its security queues that are defined on the associated queue manager:

```
mqsideletebroker MB7BROKER -s
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

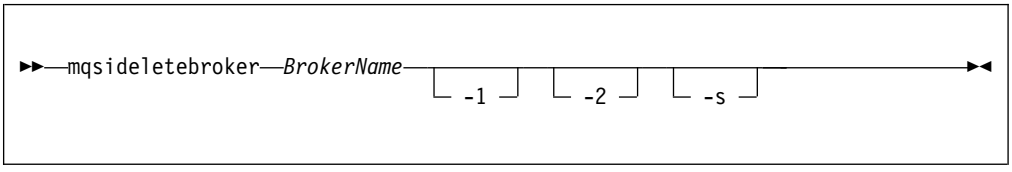
"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

mqsideletebroker *command - z/OS:*

Use the **mqsideletebroker** command to delete a broker on a z/OS system.

Syntax:

z/OS command - BIPDLBK:



Parameters:

BrokerName
(Required) The name of the broker that you want to delete. You must specify this parameter first.

-1
(Optional) Deletes only the broker registry.

-2
(Optional) Deletes only the broker WebSphere MQ queues.

-s (Optional) Specify this option to delete all administrative security queues for this broker when the broker is deleted. The queue SYSTEM.BROKER.AUTH and the queue for every defined execution group (SYSTEM.BROKER.AUTH.*egroup_name*) are deleted.

If you do not specify this option, the security queues are retained and can be reused if you re-create the broker.

Examples:
Delete the broker registry for the broker `CSQ1BRK` on z/OS:

```
mqsideletebroker CSQ1BRK -1
```

Delete the broker `CSQ2BRK` and all its associated resources:

```
mqsideletebroker CSQ2BRK
```

Delete the broker and all its security queues that are defined on the associated queue manager:

```
mqsideletebroker CSQ1BRK -s
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

mqsideleteconfigurableservice command:

Use the **mqsideleteconfigurableservice** command to delete a configurable service, such as a JMS provider, JDBC provider, or FTP server, that you have created by using the **mqsicreateconfigurableservice** command.

You can also use the WebSphere Message Broker Explorer to delete custom-named configurable services; however, you cannot delete IBM-defined configurable services. See "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information.

Supported platforms:
- Windows systems
- Linux and UNIX systems

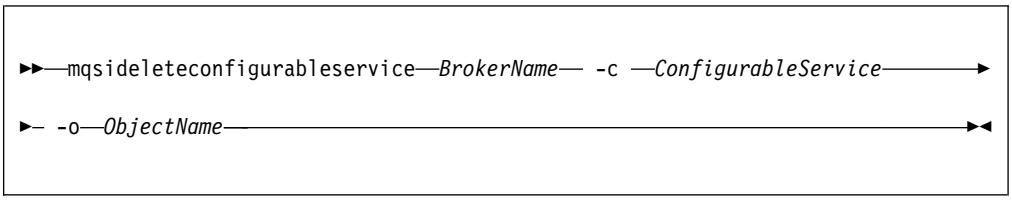
- z/OS. Run this command by customizing and submitting BIPDLCS; see "Contents of the broker PDSE" on page 3991

Purpose:
Use this command to delete a configurable service. Use the **mqsireportproperties** command to view the configurable services that are defined.

Usage notes:

- Before you run this command, ensure that the broker is running.
- After you have run this command, stop and restart the broker to ensure that deleted broker resources and properties are not being used.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker to modify. This parameter must be the first parameter.

-c *ConfigurableService*
(Required) The type of configurable service. Use the **mqsireportproperties** command to view the list of all defined services.

For a list of supplied configurable services, and their properties and values, see "Configurable services properties" on page 3766.

-o *ObjectName*
(Required) The name of the object for which you want to delete the properties. Use the **mqsireportproperties** command to view the list of properties that you can delete.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses

- BIP8012 Unable to connect to system components
- BIP8014 Component cannot be created
- BIP8073 Invalid broker name
- BIP8984 Configurable service was not found

Examples:
Delete a CICSConnection configurable service for broker MB7BROKER:

```
mqsideleteconfigurableservice MB7BROKER -c CICSConnection
-o myCICSConnectionService
```

Delete a CORBA configurable service for broker MB7BROKER:

```
mqsideleteconfigurableservice MB7BROKER -c CORBA -o myCORBAService
```

Delete an EmailServer configurable service for broker MB7BROKER called *myEmailConfigurableServiceName* that the EmailInput node or message flow is referring to at runtime:

```
mqsideleteconfigurableservice MB7BROKER -c EmailServer
-o myEmailConfigurableServiceName
```

Delete an FtpServer configurable service for broker MB7BROKER:

```
mqsideleteconfigurableservice MB7BROKER -c FtpServer -o Server01
```

Delete an IMS configurable service called *myIMSconnectService*:

```
mqsideleteconfigurableservice MB7BROKER -c IMSConnect
-o myIMSconnectService
```

Delete a JavaClassLoader configurable service:

```
mqsideleteconfigurableservice MB7BROKER -c JavaClassLoader -o myJavaClassLoader
```

Delete a JMS provider configurable service called *MyProviderXYZ*:

```
mqsideleteconfigurableservice MB7BROKER -c JMSProviders -o JMS_MyProviderXYZ
```

Delete a monitoring profile:

```
mqsideleteconfigurableservice MB7BROKER -c MonitoringProfiles -o myMonitoringProfile
```

Delete the PeopleSoftConnection configurable service that is associated with *myPeopleSoftAdapter.outadapter*:

```
mqsideleteconfigurableservice MB7BROKER -c PeopleSoftConnection
-o myPeopleSoftAdapter.outadapter
```

Delete a security profile for LDAP use:

```
mqsideleteconfigurableservice MB7BROKER -c SecurityProfiles -o MyLDAPProfile
```

Delete the SiebelConnection configurable service that is associated with *mySiebelAdapter.outadapter*:

```
mqsideleteconfigurableservice MB7BROKER -c SiebelConnection -o mySiebelAdapter.outadapter
```

Delete a TCPIPClient configurable service:

```
mqsideleteconfigurableservice MB7BROKER -c TCPIPClient
-o ClientPort1452HostnameJsmith
```

Delete a TCPIPServer configurable service:

```
mqsideleteconfigurableservice MB7BROKER -c TCPIPServer -o ServerPort1452
```

Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

"**mqsireportproperties** command" on page 3937
Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

mqsideleteexecutiongroup command:

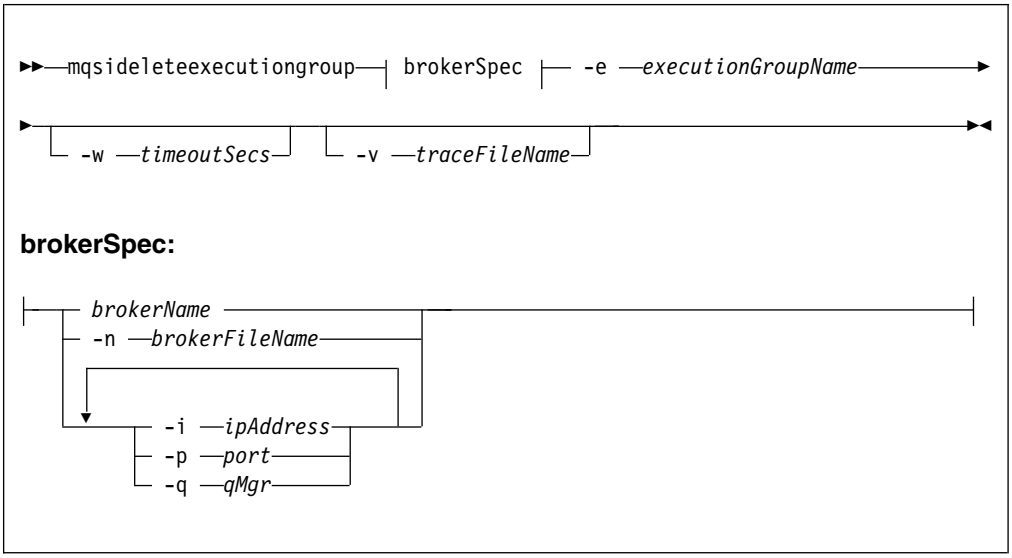
Use the **mqsideleteexecutiongroup** command to remove an execution group from a broker.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPDLEG; see "Contents of the broker PDSE" on page 3991

Purpose:
You must start the broker before you can issue this command.

Syntax:



Parameters:

brokerSpec

(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName

This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*

This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*

These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3871.

-e *executionGroupName*

(Required) The name of the execution group to delete.

-w *timeoutSecs*

(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Delete an execution group called `EG1` on the broker defined by connection parameters specified by the file `BKR1.broker`.

```
mqsideleteexecutiongroup –n BKR1.broker –e EG1
```

Delete an execution group `EG2` on the broker specified by the file `FRED.broker`. Wait 5 minutes for the broker to tidy up related resources, and send output to `trace.txt`.

```
mqsideleteexecutiongroup –n FRED.broker –e EG2 –w 300 –v trace.txt
```

Delete the execution group `EG3` on the locally defined broker **MYBROKER**.

```
mqsideleteexecutiongroup MYBROKER –e EG3
```

mqsideploy command:

Use the **mqsideploy** command to make a deployment request to the broker.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting BIPDPLY; see "Contents of the broker PDSE" on page 3991

Purpose:
Use the **mqsideploy** command to make deployment requests of all types from a batch command script, without the need for manual interaction.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsideploy** command - Windows, Linux, and UNIX systems" on page 3873
- "**mqsideploy** command - z/OS" on page 3876

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

Related tasks:

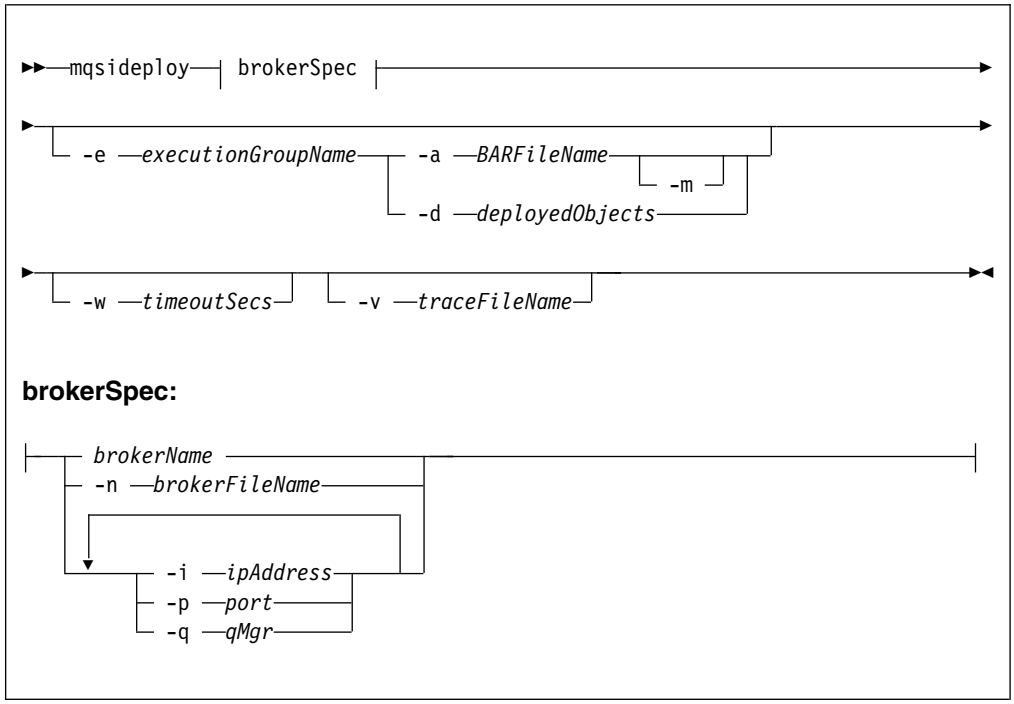
"Enabling broker administration security" on page 368
Enable broker administration security on a broker to control which users can complete specific tasks against that broker and its resources.

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

mqsideploy *command - Windows, Linux, and UNIX systems:*

Use the **mqsideploy** command on Windows, Linux, and UNIX systems to make a deployment request to the broker.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

-a *BARFileName*
(Optional) This parameter specifies the name of the broker archive (BAR) file that is to be used for deployment of the message flow and other resources. You must also specify the **-e** parameter with this option.

-d *deployedObjects*
(Optional) This parameter describes the set of objects that you want to remove from the execution group. You can specify multiple files to delete by separating the filenames with a colon (:).

You can specify objects of all types, but if you specify an ambiguous object name (for example, "top", when both "top.dictionary" and "top.cmf" are deployed to the same execution group), the entire command fails with the message BIP1089. In these circumstances, you must specify the fully qualified name of the objects to remove; for example, "top.dictionary:top.cmf".

-e *executionGroupName*
(Optional) This parameter specifies the name of the execution group to which to deploy. You must also specify the **-a** parameter with this option.

-m
(Optional) This parameter specifies deployment of complete information:

The default operation is a delta or incremental deployment. Use the **-m** parameter to override the default operation and run a complete deployment.

- For a *BAR file deployment*, **-m** removes all currently-deployed message flows and message sets from the execution group as part of the deployment. If you do not set **-m**, the contents of the BAR file are deployed in addition to what is already deployed to the execution group. Any deployed objects with the same name as an item inside the BAR file are replaced by the version inside the BAR file.
- For a *remove message flow or message set operation*, the **-m** parameter is ignored.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the maximum time in seconds that the command waits for the broker to complete the request before returning.

You can set this parameter to a value in the range 1 - 2 145 336 164. If you do not provide a *timeoutValue* value, or you set a value less than 1 or greater than 2 145 336 164 is specified, an error is returned.

Set this parameter to a value greater than the sum of the configuration timeout parameters **ConfigurationChangeTimeout** and **InternalConfigurationTimeout** that you specified for the broker, if you want to ensure that a response is received within the *timeoutValue* period. If you set a smaller value, the response returned might indicate that the state of the deploy request is unknown.

Examples:
The following examples show the use of the **-n** parameter to define the connection parameters for the broker; if you prefer, you can specify the **i**, **p**, and **q** parameters. If the broker is on the local computer, you can specify it by name.

Deploy a BAR file to the broker identified by the connection parameters in the file `b1.broker`, and remove all currently-deployed message flows and message sets from the execution group as part of the deployment. Allow 10 minutes for the broker to reply.

```
mqsideploy -n b1.broker -e default -a mybar.bar -m -w 600
```

Remove the message flow `top` and the dictionary `bar` from the execution group `default` on the broker identified by the connection parameters in the file `b1.broker`.

```
mqsideploy –n b1.broker –e default –d top.cmf:bar.dictionary
```

For information about using this command with SSL protected channels, see You want to run a command that uses SSL to administer a remote broker over a secured channel

Related concepts:

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are

packaged in broker archive (BAR) files for deployment.

“Syntax diagrams” on page 3677

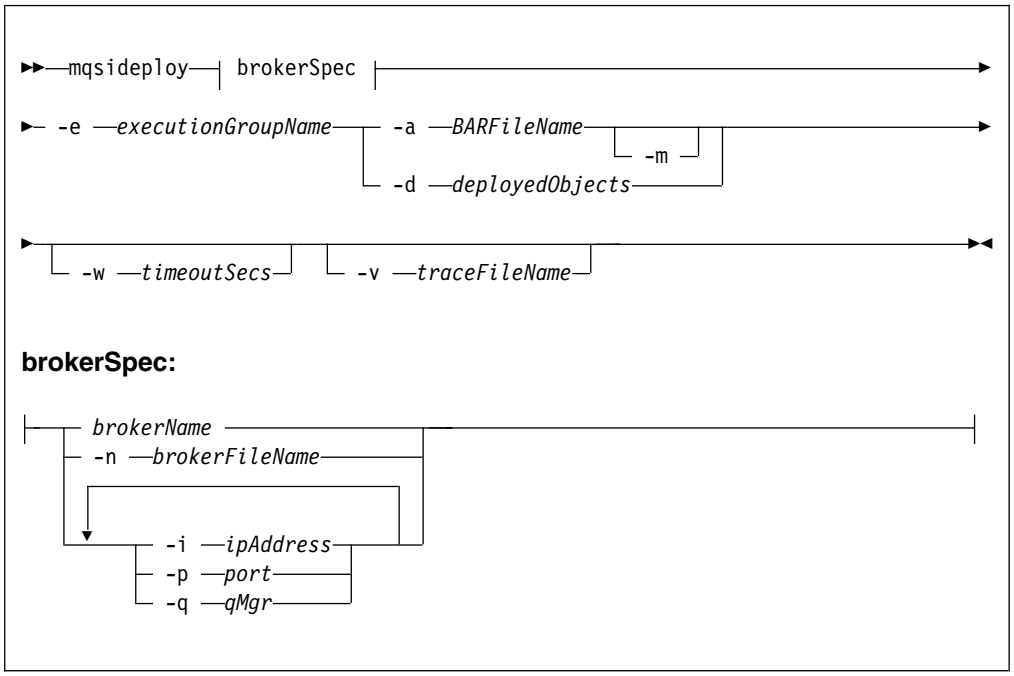
“**mqsideploy** command” on page 3872
Use the **mqsideploy** command to make a deployment request to the broker.

mqsideploy *command - z/OS:*

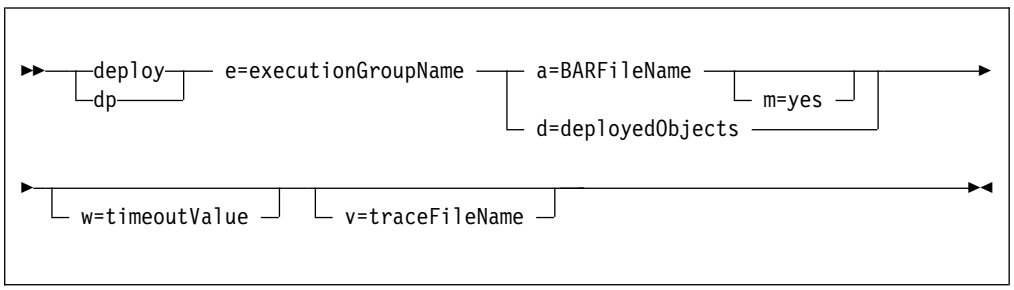
Use the **mqsideploy** command on z/OS to make a deployment request to a local broker.

Syntax:

z/OS command - BIPDPLY:



z/OS console command:
Synonym: dp



Parameters:

brokerSpec

You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker. If you specify a queue manager, it must be defined on the local computer.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is irrelevant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3878.

-a *BARFileName*
(Optional) This parameter specifies the name of the broker archive (BAR) file that is to be used for deployment of the message flow and other resources. You must also specify the **-e** parameter with this option.

The BAR file can be in a local or remote file system, if the user ID or the broker that is running the command can access the file and read it.

-d *deployedObjects*
(Optional) This parameter describes the set of objects that you want to remove from the execution group. You can specify multiple files to delete by separating the filenames with a colon (:).

You can specify objects of all types, but if you specify an ambiguous object name (for example, "top", when both "top.dictionary" and "top.cmf" are deployed to the same execution group), the entire command fails with the

message BIP1089. In these circumstances, you must specify the fully qualified name of the objects to remove; for example, "top.dictionary:top.cmf".

-e *executionGroupName*
(Optional) This parameter specifies the name of the execution group to which to deploy. You must also specify the **-a** parameter with this option.

-m (Optional) This parameter specifies deployment of complete information:

The default operation is a delta or incremental deployment. Use the **-m** parameter to override the default operation and run a complete deployment.

- For a *BAR file deployment*, **-m** removes all currently-deployed message flows and message sets from the execution group as part of the deployment. If you do not set **-m**, the contents of the BAR file are deployed in addition to what is already deployed to the execution group. Any deployed objects with the same name as an item inside the BAR file are replaced by the version inside the BAR file.
- For a *remove message flow or message set operation*, the **-m** parameter is ignored.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the maximum time in seconds that the command waits for the broker to complete the request before returning.

You can set this parameter to a value in the range 1 - 2 145 336 164. If you do not provide a *timeoutValue* value, or you set a value less than 1 or greater than 2 145 336 164 is specified, an error is returned.

Set this parameter to a value greater than the sum of the configuration timeout parameters **ConfigurationChangeTimeout** and **InternalConfigurationTimeout** that you specified for the broker, if you want to ensure that a response is received within the *timeoutValue* period. If you set a smaller value, the response returned might indicate that the state of the deploy request is unknown.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Examples:
The following examples show the use of the **-n** parameter to define the connection parameters for the broker. If the broker is on the local computer, you can specify it by name.

Deploy a BAR file to the broker identified by the connection parameters in the file `b1.broker`, and remove all deployed message flows and message sets from the execution group as part of the deployment. Allow 10 minutes for the broker to reply.

```
mqsideploy -n broker1.broker -e default -a mybar.bar -m -w 600
```

Remove the message flow `top` and the dictionary `bar` from the execution group `default` on the broker identified by the connection parameters in the file `b1.broker`.

```
mqsideploy –n b1.broker –e default –d top.cmf:bar.dictionary
```

Deploy a BAR file by using the console command:

```
F MQ01BRK,dp e=default,a=flows.bar
```

Related concepts:

"Packaging and deployment overview" on page 3210
Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

Related tasks:

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Related reference:

"Syntax diagrams" on page 3677

"**mqsideploy** command" on page 3872
Use the **mqsideploy** command to make a deployment request to the broker.

mqsiexplain command:

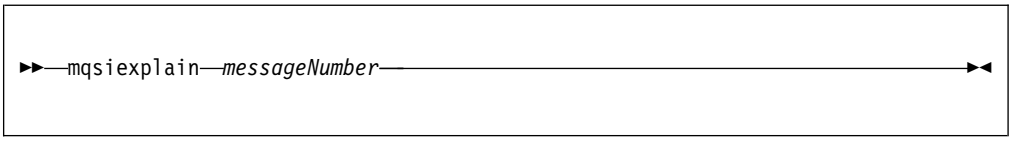
Use the **mqsiexplain** command to display the contents of a WebSphere Message Broker BIP message.

Supported platforms:

- Windows
- Linux and UNIX systems

Purpose:
The **mqsiexplain** command returns the full details of a BIP message that you specify, including the user response and explanation sections.

Syntax:



Parameters:

messageNumber
(Required) The BIP message for which you want to display details. You can identify the message by using a number only (for example, 2393), or you can precede the number with "BIP" (for example, BIP2393). You can also include the severity marker (I, E, or W) at the end of the number (for example, BIP2393E).

Authorization:
The user ID that is used to run this command must have Administrator authority on the local system.

Responses:
This command shows the full contents of the specified message, including the user response and explanation sections. Where inserts are expected in the message, this command substitutes them with "insert#".

Examples:
The following example is used to display the full content of error message BIP2393:

```
mqsiexplain 2393
```

The command returns the following information:

```
BIP2393E: Database error: ODBC return code 'insert1' from data source 'insert2' using ODBC driver mar
The broker received an error when processing a database operation. The ODBC return code was 'insert1
Use the following messages to determine the cause of the error. Typical problems are an incorrect dat

BIP8071I: Successful command completion.
```

The following example is used to display the full content of error message BIP3595:

```
mqsiexplain BIP3595E
```

The command returns the following information:

```
BIP3595E: The connection with the ID: 'insert1' on Hostname: 'insert2' and Port: 'insert3' exists but
There was a connection available with the specified details but no data arrived within the permitted
Ensure that the end application is running correctly and sending data on this connection.

BIP8071I: Successful command completion.
```

You can find details of error messages and return codes in several places.

Related reference:

Diagnostic messages
Diagnostic messages are listed in this section in numeric order, grouped according to the component to which they relate.

"Troubleshooting" on page 6864
Use the reference information in this section to help you diagnose errors in WebSphere Message Broker.

"Syntax diagrams" on page 3677

mqsiformatlog command:

Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

Supported platforms:

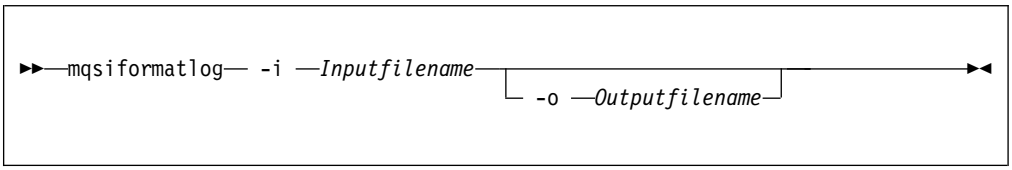
- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPFMLG; see "Contents of the broker PDSE" on page 3991

Purpose:
The **mqsiformatlog** command interprets an input log file that has been created on any system in a platform-independent code page, `utf-8`. Use this command to produce formatted output from input log files transferred from other systems to

the system on which you issue the command. If you use this facility, ensure that you use a file transfer program that does not convert the data (for example, by specifying a binary transfer option).

You can direct the output to a file, or to the command shell.

Syntax:



Parameters:

-i *Inputfilename*
(Required) The filename of the XML log file that is to be formatted. This file is created by the **mqsireadlog** command; it is encoded in utf-8.

-o *Outputfilename*
(Optional) The filename of the file into which the formatted log output is to be written. If this is not specified, the formatted log data is written to stdout.

Output written by this command (to file or stdout) is written in a code page suitable for the current user locale.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Examples:

```
mqsiformatlog -i trace.xml -o formattrace.log
```

The following extract shows the output that is generated by this command:

```
Timestamps are formatted in local time, local time is GMT.

Use the **mqsireadlog** command to retrieve trace records for the specified component.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

mqsilist command:

Use the **mqsilist** command to list installed brokers and their associated resources.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting BIPLIST; see "Contents of the broker PDSE" on page 3991

Purpose:
The **mqsilist** command reports on the configuration of one or more brokers. Your choice of parameters on the command determines which resources are included in the response, and the level of detail that the response provides.

The command returns information about the following resources:

- Local and remote brokers
- Execution groups defined on the brokers
- All resources that you have deployed to each execution group, including message flows and message sets
- Runtime versioning information for those resources, if applicable

You can also specify that you want the command to recursively examine resources and return information, so that you need only specify a single resource to get details about its children.

You can choose the level of detail that you want returned for each resource requested:

- A list of resource names. This level of output is compatible with previous versions of WebSphere Message Broker.

- A one line summary for each resource, including name and active or inactive status.
- A detailed view of each resource, including build level and platform for brokers, and resources that have been deployed to each execution group.

On Windows platforms, Linux, and UNIX systems, the command also reports whether a broker is configured as a WebSphere MQ service.

Only a subset of this information is returned if the broker is not running.

On Windows, Linux, and UNIX systems, the output is directed to STDOUT.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsilist** command - Windows, Linux, and UNIX systems"
- "**mqsilist** command - z/OS" on page 3888

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related tasks:

Use the **mqsilist** command to display the brokers that you have created on your computer.

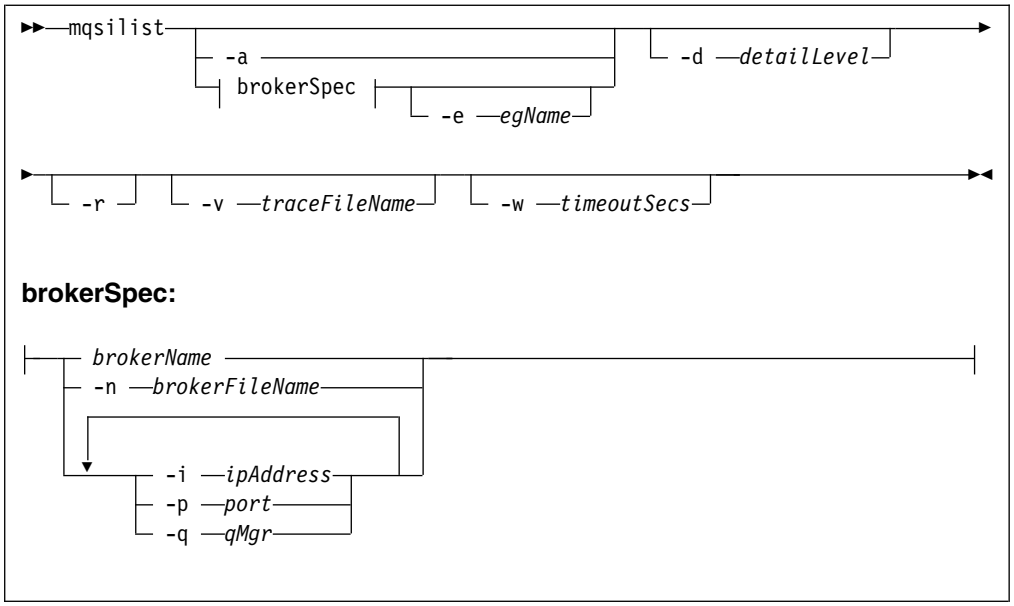
Related reference:

"Syntax diagrams" on page 3677

mqsilist *command - Windows, Linux, and UNIX systems:*

Use the **mqsilist** command to list information about one or more brokers and their deployed resources.

Syntax:



If you specify this command with no parameters, a summary is returned for broker that you have created in the current installation on this computer.

The current installation is associated with the command console that you have opened (on Windows), or the **mqsiprofile** that is active (on Linux and UNIX systems).

Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*

These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

-a (Optional) List all the brokers installed on the local computer, in all installations.

If you specify this option on a computer on which you have installed versions earlier than Version 7.0, only brokers are listed for those versions, if they exist; the level of detail corresponds to **-d 0** for these earlier brokers, even if you have specified (or allowed to default) a different level of detail on this command. If you want to view information about other components that you have created in earlier versions, you must use the corresponding version of the **mqsilist** command.

You cannot use this option to list information about remote brokers and their resources.

-d *detailLevel*

(Optional) Specify the level of detail to be returned; the default value is **1**.

- **0** returns only broker name and the names of their associated queue managers (this information is the same as the detail provided in previous versions). This list of local brokers is returned without connecting to a queue manager, and remote broker options are not supported.

  Note that while they are starting, execution groups might report a PID of `0`.
- **1** returns a one line summary of each resource.
- **2** returns detailed information about each resource.

-e *egName*

(Optional) Selects an execution group within a broker. Specify the label of the execution group for which you want to list message flows. The command returns a list of message flows assigned to the specified execution group within the broker.

The specified broker must be active for message flow information to be returned.

-r (Optional) Run the command recursively; display information about subcomponents.

-v *traceFileName*

(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Examples:
The following example lists all brokers created in the current installation:

```
mqsilist -d0
```

The following responses are generated:

```
BIP8099I: Broker: MB7BROKER  -  MB7QMGR
BIP8099I: Broker: test  -  testqm

BIP8071I: Successful command completion.
```

The following example requests a summary of the execution groups that are defined on a specific broker. (The **-d** parameter is not specified and therefore has the default value of 1.)

```
mqsilist MB7BROKER
```

The following responses are generated:

```
BIP1286I: Execution group 'ello' on broker 'MB7BROKER' is running.

BIP8071I: Successful command completion.
```

Display detailed information about all resources for brokers on the local computer:

```
mqsilist -a -r -d2
```

The following responses are generated:

```

"**mqsilist** command" on page 3882
Use the **mqsilist** command to list installed brokers and their associated resources.

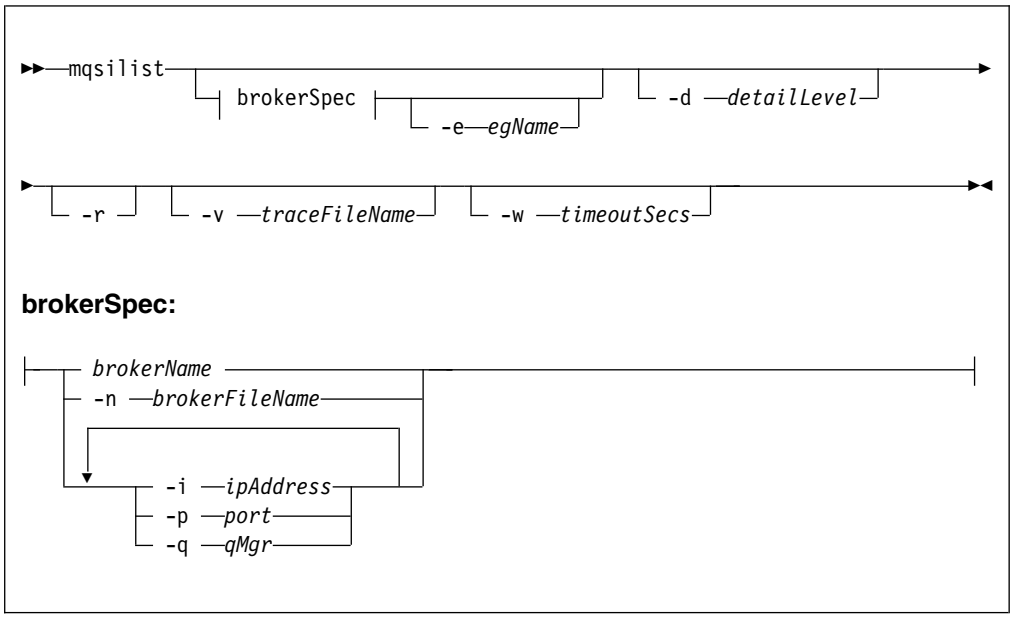
"Syntax diagrams" on page 3677

mqsilist *command - z/OS:*

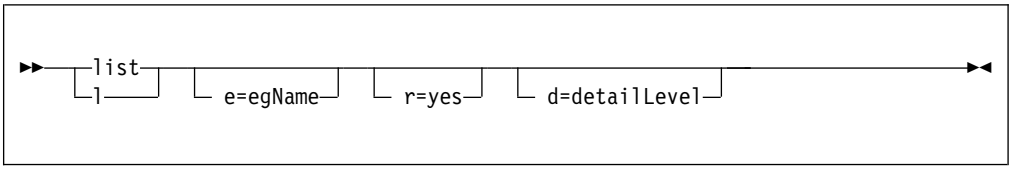
Use the **mqsilist** command to list information about one or more brokers and their deployed resources.

Syntax:

z/OS command - BIPLIST:



z/OS console command:
Synonym: l



If you specify this command with no parameters, a list of the execution groups is displayed.

Parameters:

brokerSpec
You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker. If you specify a queue manager, it must be defined on the local computer.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is irrelevant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3890.

-d *detailLevel*
(Optional) Specify the level of detail to be returned; the default value is **1**.

- **0** returns only broker name and the names of their associated queue managers (this information is the same as the detail provided in previous versions).

  Note that while they are starting, execution groups might report a PID of `0`.
- **1** returns a one line summary of each resource.
- **2** returns detailed information about each resource.

-e *egName*
(Optional) Selects an execution group within a broker. Specify the label of the execution group for which you want to list message flows. The command returns a list of message flows assigned to the specified execution group within the broker.

The specified broker must be active for message flow information to be returned.

-r (Optional) Run the command recursively; display information about subcomponents.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Examples:
Use the console command to request a summary of the execution groups for the broker. (The **d=** parameter is not specified and therefore has the default value of 1.)

```
F MQP1BRK,list
```

The following responses are generated:

```
BIP1286I: Execution group 'ello' on broker 'MQP1BRK' is running.

BIP8071I: Successful command completion.
```

Use the console command to list the message flows in the specified execution group:

```
F MQP1BRK,list e='exgrp1'
```

The responses generated are in the following form:

```
BIP1288I: Message flow 'simpleflow' on execution group 'ello' is running.

BIP8071I: Successful command completion
```

For examples of running the command by using BIPLIST, and the responses that are generated, see "**mqsilist** command - Windows, Linux, and UNIX systems" on page 3883.

mqsimanagexalinks command:

Use the **mqsimanagexalinks** command to set up links for a supported database on and UNIX systems for XA coordination under the control of WebSphere MQ.

Supported platforms:

- Linux and UNIX systems

Purpose:
The command sets up or removes the links required by WebSphere MQ to include databases in XA transactions.

You can also use the **mqsimanagexalinks** command to return a list of supported ODBC drivers.

Run the **mqsimanagexalinks** command before you create the database that you want the broker to connect to. You can run the command before or after you install your database; specify either the intended or the actual database installation directory where indicated.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsimanagexalinks** command - Linux and UNIX systems"

Related tasks:

"Working with databases" on page 2109
Create and configure databases to use with your message flow applications.

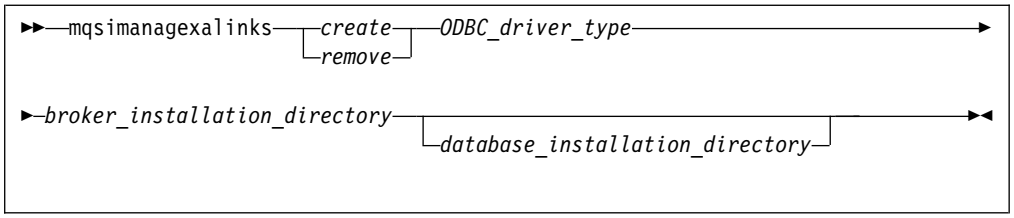
"Configuring databases for global coordination of transactions" on page 665
If your message flow interacts with a user database, and you want to globally coordinate the updates made to the database with other actions within the message flow, configure your databases for global coordination.

"Configuring ODBC connections for globally coordinated transactions" on page 699
Configure the definition of your ODBC databases to the transaction manager (the queue manager).

mqsimanagexalinks *command - Linux and UNIX systems:*

Set up links for a supported database on Linux and UNIX systems for XA coordination under the control of WebSphere MQ.

Syntax:



Parameters:

create
(Required) Specify that the required links are created.

remove
(Required) Specify that the defined links are removed.

ODBC_driver_type
(Required) The ODBC driver type. See the list command for the list of ODBC drivers that are supported.

This parameter is required if you specify **create**, and is optional if you specify **remove**. If you specify **remove** and omit this parameter, all links are removed.

broker_installation_directory
(Required) The full path to your broker installation.

This parameter is required only if you specify **create**.

database_installation_directory
(Optional). The full path to your database installation.

This parameter is required only if you specify **create**, and have created a DB2 database.

list
(Required) Display the list of supported ODBC driver versions. Use the output to check what values you can specify for **ODBC_driver_type**.

For example, the following output is generated on AIX:

Supported information for the **create** option.

Supported version of the ODBC drivers	Version number for **mqsimanagexalinks**
DB2	DB2
DataDirect Connect for ODBC V6.0	DD60

Supported information for the **remove** option.

Supported version of the ODBC drivers	Version number for **mqsimanagexalinks**
DB2	DB2
DataDirect Connect for ODBC V5.2	DD52
DataDirect Connect for ODBC V5.3	DD53
DataDirect Connect for ODBC V6.0	DD60

Links created in /var/mqm/exits:

Links are only created in `/var/mqm/exits` on Linux on x86. The links created for each supported database are shown here.

broker_install_dir/ODBC/V6.0/lib/libUKicu24.*x*
broker_install_dir/ODBC/V6.0/lib/UKase24.*so*
broker_install_dir/ODBC/V6.0/lib/UKasedtc24.*so*
broker_install_dir/ODBC/V6.0/lib/libodbcinst.*x*

Where *.x* is the library extension on your platform: `.a` on AIX or `.so` on all other platforms.

Authorization:
The user ID with which you run this command must be **root**.

Examples:
To create the links required for DB2:

```
mqsimanagexalinks create DB2 /opt/IBM/mqsi/V7.0 /opt/IBM/db2/V9.1
```

To create the links required for Oracle and Sybase databases (these databases use the DataDirect V5.3 drivers):

```
mqsimanagexalinks create DD60 /opt/IBM/mqsi/V7.0
```

To remove the links required for Oracle and Sybase databases (these databases previously used the DataDirect V5.3 drivers):

```
mqsimanagexalinks remove DD53
```

To list the supported database drivers:

```
mqsimanagexalinks list
```

`mqsimigratecomponents` command:

Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

Supported platforms:

- Windows.
- Linux and UNIX systems.
- z/OS. Run this command by customizing and submitting BIPMGCMP.

Purpose:
Migrate components to WebSphere Message Broker Version 7.0 from Version 6.1 or from Version 6.0:

- If you are migrating from Version 6.1 you must have installed Version 6.1.0.3 (Fix Pack 3) or later.

  If you are using WebSphere Application Server with WebSphere Message Broker, or you have publish/subscribe applications that use the SubIdentity option, you must upgrade WebSphere Message Broker to Fix Pack 4 before you can migrate to WebSphere Message Broker Version 7.0.
- If you are migrating from Version 6.0, you must have installed Version 6.0.0.9 (Fix Pack 9) or later.

  If you are using WebSphere Application Server with WebSphere Message Broker, or you have publish/subscribe applications that use the SubIdentity option, you

must upgrade WebSphere Message Broker Version 6.0 or WebSphere Event Broker Version 6.0 to Fix Pack 10 before you can migrate to WebSphere Message Broker Version 7.0.

When you migrate a broker to Version 7.0, its configuration is read from the broker database, and migrated to an internal repository that is maintained by the migrated broker. The broker database used by the Version 6.1 or Version 6.0 broker is no longer required by the Version 7.0 broker. When you have successfully completed migration, you can delete the database, or uninstall the database product, if you have no further use of it.

You can also use the **mqsimigratecomponents** command to return a broker from Version 7.0 to an earlier version to reverse the effects of forward migration; however, the broker is restored with the configuration that was active at the time of the forward migration, and updates that you have made after migration are not reflected in the database that is associated with the broker at the earlier version. You must retain the relevant broker database to be able to use the broker at the earlier version.

You must run this command from whichever version of the installed product is the later, regardless of whether it is the source version or the target version.

You must have an installation of the product at both target and source versions, with the required component code installed, to issue this command successfully.

Before you start migration, stop the broker and all active debug sessions in the WebSphere Message Broker Toolkit. You cannot migrate message flows that are being debugged.

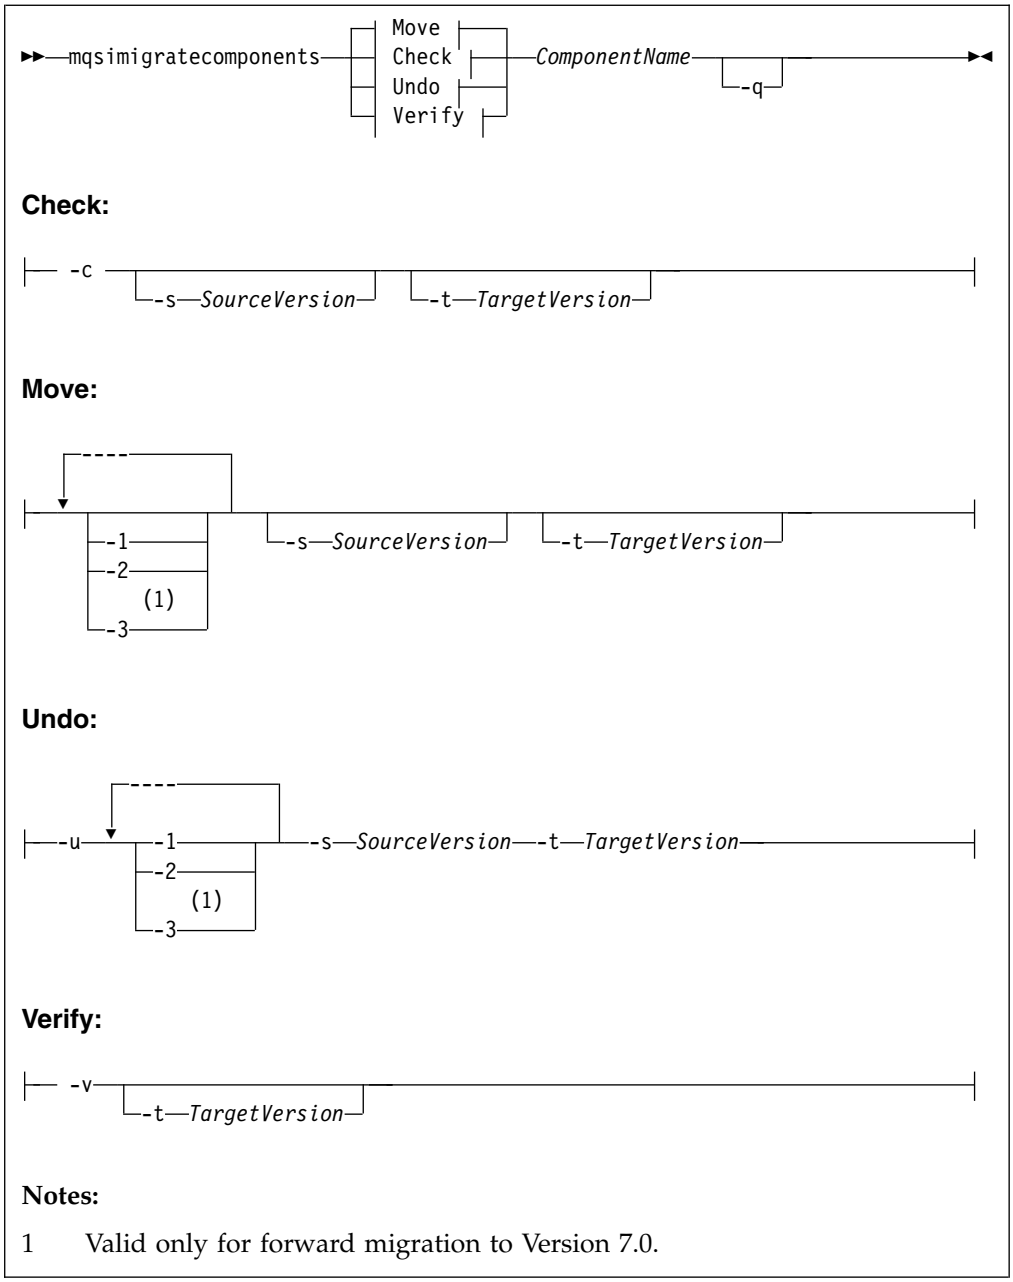
Specify appropriate options on this command to perform one of the following actions:

- Check that the component is suitable for the required migration, without changing that component (**-c**).
- Move a component to a different version, in full or part (**-s** and **-t**).
- Undo a failed migration step (**-u**).
- Verify that a move has been successful (**-v**).

Usage notes:
If you have specified a data source user ID and password on the **mqsicreatebroker** command for the broker that you are migrating, the values of these parameters are also migrated and saved in the format that is used by the **mqsisetdbparms** command. The values are used by the broker to access user databases for which you have not set alternative values by using the **mqsisetdbparms** command. After migration, if you want to change the user IDs or passwords that the broker uses to access user databases, you can use only the **mqsisetdbparms** command.

If you update the user ID and password values, and you migrate the broker back to the previous version, the new values are also migrated back to the original broker.

Syntax:



Parameters:

-c

(Optional) Check a specified component before migration, to ensure that:

- The auto-detected version of the broker matches any version specified on the command line.
- Any database tables accessed in a previous release do not contain any rows that are incorrectly indexed.

You can check a running component. The check does not affect the component, apart from a slight degradation of performance.

The check command either succeeds or fails, and prints a message about whether the migration will succeed, but no modifications are made during the process.

The **-c** and **-v** parameters are mutually exclusive. Additionally, if you specify either of these parameters, you cannot specify any other parameter when you run this command.

-v

(Optional) Check a specified component after migration, to ensure that:

- The registry is in the correct format for the new version.
- The correct queues exist for the new version.

The **-c** and **-v** parameters are mutually exclusive. Additionally, if you specify either of these parameters, you cannot specify any other parameter when you run this command.

-q

(Optional) Print fewer status messages during the operation.

-1

(Optional) Do only registry and file system work.

- When you migrate to Version 7.0, use the **-1** parameter before the **-2** or **-3** parameters.
- When you migrate backwards from Version 7.0 to a previous version, use the **-2** parameter before the **-1** parameter.

-2

(Optional) Do only WebSphere MQ work.

-3 (Optional) Do only database work.

This option is valid only for forward migration to Version 7.0. If you specify this parameter for backwards migration, it is ignored; changes that you have made to the broker state cannot be migrated back and applied to the database belonging to the broker at the earlier version.

-u (Optional) Undo a failed migration step; you must also specify at least one of **-1**, **-2**, or **-3**. Use this option only when migration has failed, and also failed to auto-recover (for example, if a failure occurs during split migration).

-3 is valid only for forward migration to Version 7.0.

-s *SourceVersion*

(Optional) The previous version of the component.

- If not specified, this value is detected automatically.
- When you perform split migration to Version 7.0, the **-s** parameter is mandatory after you run the **mqsimigratecomponents** command with the **-1** parameter, as shown in the split migration example.
- See “Purpose” on page 3894 for the restrictions to the version numbers of the product that are supported.

-t *TargetVersion*

(Optional) The destination version of the component.

- If not specified, this value is assumed to be the current version.
- When you perform split migration from Version 7.0 to a previous version, the **-t** parameter is mandatory.
- See “Purpose” on page 3894 for the restrictions to the version numbers of the product that are supported.

ComponentName

(Required) The name of the component to migrate.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

The **mqsimigratecomponents** command updates your registry, file system, and WebSphere MQ definitions.

If the user ID used to run this command does not have the authority to perform all these steps, you can run the command one part at a time. Different users can run the part for which they are authorized in order to achieve the overall result. This approach is referred to as *split migration*, and is performed by using the **-1**, **-2**, and **-3** parameters.

If you run single-step migration, your user ID must be able to:

- Write to the registry and the file system for the product
- Modify queue definitions
- Read from the database that is associated with the broker

If you run split migration, your user ID must always be able to read from the registry for the product.

If you are doing a backward split migration of the registry, an integrity check to verify the levels of both WebSphere MQ and the database are done that requires your user ID to have

- SELECT authority on the broker database tables
- WebSphere MQ authority to open the `SYSTEM.BROKER.*` queues.

The following specific authorization for each step is required in order to succeed:

- **-1** requires the ability to write to the registry and the file system for the product, SELECT from the broker database tables, and open the `SYSTEM.BROKER.*` queues
- **-2** requires the ability to modify queue definitions
- **-3** requires the ability to read from databases associated with the broker

Responses:
This command can produce many possible responses, depending on the results of the various operations. This command differs from other commands in the way it produces messages: they are displayed when they are generated, rather than being reported in a batch at the end of the program.

When you migrate database tables, z/OS produces more output than distributed systems. Use the **-q** parameter to reduce the number of messages displayed.

Examples:
The following example shows a split migration from Version 6.1 to Version 7.0:

```
mqsimigratecomponents BROKER1 -1
mqsimigratecomponents BROKER1 -2
mqsimigratecomponents BROKER1 -3
```

The following example shows a migration from Version 7.0 back to Version 6.1:

```
mqsimigratecomponents MYBROKER -t 6.1.0.3
```

Consider the factors involved in the migration of components and resources from Version 6.0 or Version 6.1 to Version 7.0.

mqsimode command:

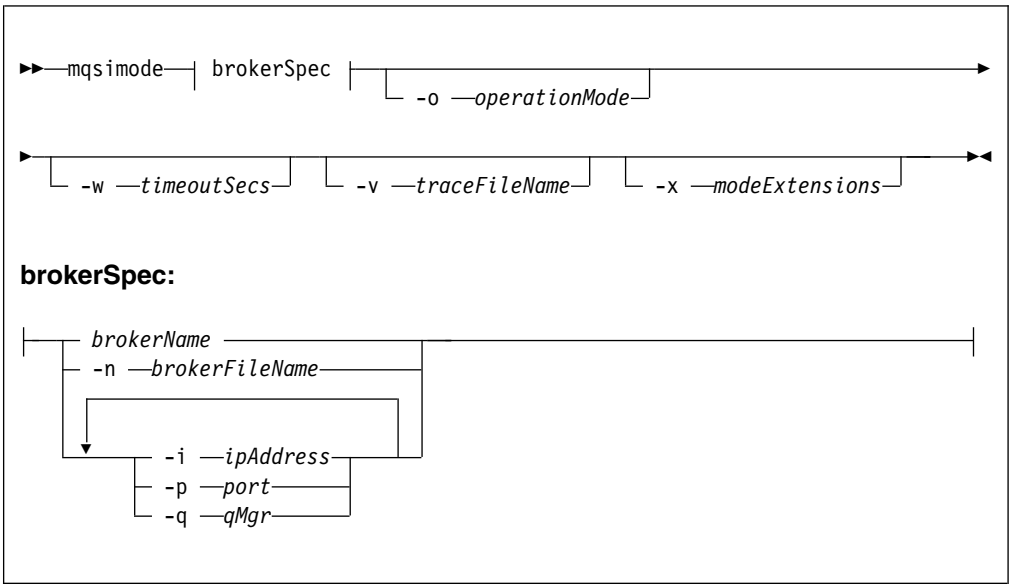
Use the **mqsimode** command to configure and retrieve operation mode information.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPMODE; see "Contents of the broker PDSE" on page 3991

Purpose:
Use the **mqsimode** command to change the operation mode of a broker, or to retrieve information about the mode in which the broker is currently working.

Syntax:



Parameters:

brokerSpec

(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName

This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*

This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*

These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3901.

-o *operationMode*

(Optional) This parameter sets the mode of the target broker. Valid values are `enterprise` (the full edition), `starter` (Starter Edition), `entry` (Entry Edition), and `adapter` (Remote Adapter Deployment mode). If you do not specify the **-o** parameter, the command displays the mode in which the broker is running.

-x *modeExtensions*

(Optional) This parameter uses a comma separated list of to specify the mode

extensions to which the broker is entitled. You can also use the **-x** parameter to switch off all mode extensions (See "Examples").

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Running the `mqsimode` command specifying the `-o` parameter

When you run the **mqsimode** command for broker `BROKER1`, and specify the **-o** parameter, the mode is updated, and you receive a report about all errors. For example, if you run the following **mqsimode** command to change your broker to the Remote Adapter Deployment mode, and your broker is in the following state:

- *Broker_Name1* is the name of your broker.
- *Message_Flow* is the name of your message flow.

- *Execution_Group* is the name of your execution group.
- The command changes *Broker_Name1* to the Remote Adapter Deployment mode, but contains a node *Node_Type* that is not valid in this mode.

```
mqsimode BROKER1 –o adapter
```

You receive the following messages:

```
BIP1044: Connecting to the broker's queue manager...
BIP1045: Connecting to the broker...
BIP1805: The mode for broker 'Broker_Name1' has been changed to 'adapter'.
BIP1823: WARNING: Broker 'Broker_Name1' has a message flow called 'Message_Flow'
 in execution group 'Execution_Group', which contains one or more nodes that are not
 valid in this mode: Node_Type.
BIP8229: The command completed with the following number of warnings: 1.
```

Running the mqsimode command without the -o parameter

When you run the **mqsimode** command without the **-o** parameter, you receive a report about the mode being used by your broker, a report about all mode violations, and a report for any mode extensions that are required and not set. For example, if you run the following **mqsimode** command, and your broker is in the following state:

- *Broker_Name* is the name of your broker.
- Your broker is in Starter Edition mode.
- Your broker has no violations.

```
mqsimode Broker_Name
```

You receive the following messages:

```
BIP1044: Connecting to the broker's queue manager...
BIP1807: Discovering mode information from broker 'Broker_Name'...
BIP1802: Broker 'Broker_Name' is in 'starter' mode.
BIP8071: Successful command completion.
```

Switching off all mode extensions

To switch off all mode extensions, run the **mqsimode** command with the **-x** parameter:

```
mqsimode Broker_Name –x
```

where *Broker_Name* is the name of your broker.

Running the mqsimode command specifying the -o parameter against a broker that is running a version before V6.1

When you run the **-o** parameter against a broker that is running a version before V6.1 you receive a report with an appropriate message. For example, where *Broker_Name* is the name of your broker:

```
BIP1044: Connecting to the broker's queue manager...
BIP1045: Connecting to the broker...
BIP1808: Broker 'Broker_Name' is not at the required software level to
 change the operation mode.
 BIP8229: The command completed with the following number of warnings: 1.
```

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Example: Changing the Trial Edition to the full edition:

You want to convert all of your brokers from the Trial Edition mode to the full edition (`enterprise` mode).

About this task

Contact your IBM representative to upgrade your license, and change the brokers that you have created to conform to your new license.

Before, or after, the Trial Edition expires complete the following steps:

Procedure

1. Open a command prompt.
   - Linux On Linux and UNIX, run the **mqsiprofile** command to initialize the command environment.
   - Windows On Windows, click **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console** to open a command console.
2. Run the following **mqsimode** command for every broker:

   ```
   mqsimode –i localhost –p 2414 –q MB7QMGR –o enterprise
   ```

   When this command completes successfully, the broker is fully functional, but all new brokers are still created in `trial` mode by default.
3. To ensure that all new brokers start in `enterprise` mode, uninstall the trial package and reinstall the full package; see "Moving from Trial Edition" on page 656.

Use the **mqsimode** command to configure and retrieve operation mode information.

mqsireadlog command:

Use the **mqsireadlog** command to retrieve trace records for the specified component.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPRELG; see "Contents of the broker PDSE" on page 3991

Purpose:
The **mqsireadlog** command is valid for:

User trace
Specify the **-u** option.

Service trace
Specify the **-t** option. You are recommended to use this option only if directed to do so by the action described in a BIPxxxx message, or by your IBM Support Center.

You can specify the output to be directed to file, or to STDOUT. The trace records returned by this command are in XML format and can be browsed with an XML browser. If you direct output to file, the data is written in code page `utf-8`. The file is therefore platform-independent, and can be transferred to other systems for browsing or formatting using the **mqsiformatlog** command.

On HP-UX, set the `size` parameter of the **mqsichangetrace** command to be less than 500 MB because the size of the XML generated files is often half as much again as the original trace file, and setting the value of the `size` parameter to be greater than 500 MB can cause problems.

If you transfer this file to another system, ensure that you use a file transfer program that does not convert the data (for example, by specifying a binary transfer option).

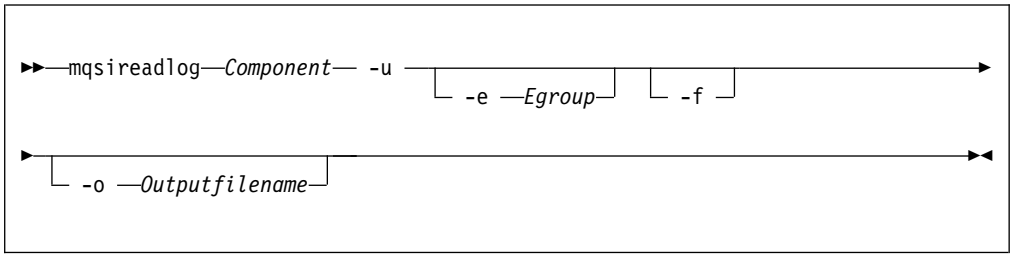
If you specify a broker, or any of its resources (execution group or message flow) you must have deployed them before you can start trace and read the log files.

To enable service trace of your CMP applications, take one of the following steps:

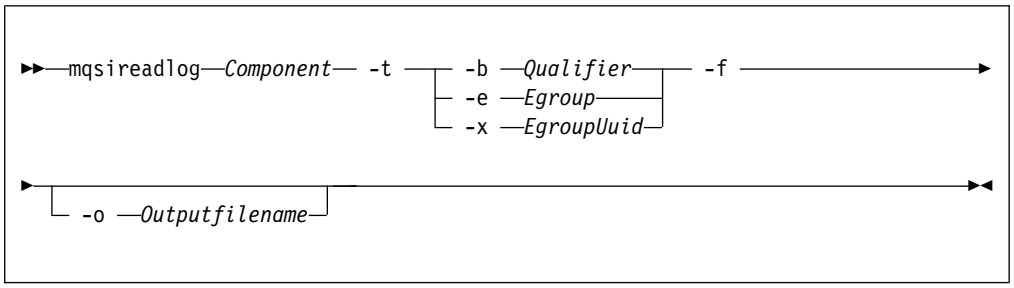
- Call the method BrokerProxy.enableAdministrationAPITracing(String filename).
- Before running your CMP application, set the environment variable MQSI_CMP_TRACE to the name of the file to which trace is sent.

Syntax:

User trace:



Service trace:



Parameters common to user trace and service trace:

Component
(Required) The name of the component for which the log is to be read. The component can be either a broker name, or the fixed values, `WebSphere Message Broker Toolkit`, or `utility` (all are case sensitive on Linux and UNIX systems, and on z/OS).

-e *Egroup*
(Optional) The label of the execution group for which log information is to be read.

-o *Outputfilename*
(Optional) The name of the file into which to write the log data. If you specify a full path name, the file is created in the directory specified. If you specify just the filename, the file is created in the current working directory. The contents of the file are written in code page `utf-8`, which is platform-independent and preserves data such as DBCS characters.

You must specify a file name if you want to format the log by using the **mqsiformatlog** command. If you do not specify a filename, the contents of the log are written to stdout. Use a file extension of `.xml`, which represents the format of the data.

-f (Optional for User trace; required for Service trace). Read the log file directly from the file system. If you do not specify this option, the command sends an XML message to the component to request the log contents. If you have specified **-t** (service trace), you must specify this flag as well.

If you specify this option, stop tracing (by using **mqsichangetrace**) before you run the **mqsireadlog** command. If the log file is in use when you issue this command with this flag specified, partial XML records might be returned. Specify **-m safe** on the **mqsichangetrace** command to reduce the risk of partial

records. If the component being traced has itself stopped, you do not then need to issue a **mqsichangetrace** command.

If you do not stop tracing before you issue this command, check the contents of the log file created, and remove any partial records from the end by using a text editor before running the **mqsiformatlog** command, as partial records cannot be read by the format command.

Additional parameter exclusive to user trace:

-u (Required) Read the log contents from the user trace log. This option is valid **only** if you select the `broker` component.

Additional parameters exclusive to service trace:
Use these options only when directed to do so by your IBM Support Center or by a BIPxxxx message.

-t (Required) Read the log contents from the service trace log.

-b *Qualifier*
(Required) Read the contents of the log for the broker `agent`, or for the specified command utility program. This option is valid only if you have specified **-t** (service trace).

The following table shows the valid combinations of `qualifier` and `component` for service trace.

This option is generally used to trace the commands themselves. If you want to trace a particular command, run that command with environment variable MQSI_UTILITY_TRACE set to `debug` or `normal` before you issue this command to read the trace output generated.

Enter these values exactly as shown.

The `agent` trace is initiated when you specify the **-b** flag on the **mqsichangetrace** command. Do this only when directed to do so by a WebSphere Message Broker error message, or when instructed to do so by your IBM Support Center.

The `service` trace is initiated when you specify the **-b** flag on the **mqsichangetrace** command. The format of the command is:

```
mqsireadlog brokername -t -b service -f -o service.xml
```

Run this command only when directed to do so by a WebSphere Message Broker error message, or when instructed to do so by your IBM Support Center.

-x*EgroupUuid*
(Optional) Read the contents of the log for the execution group UUID (Universally Unique Identifier).

This option is valid only if you have specified **-t** (service trace).

Use this option when the execution group label is not available. The execution group UUID can be obtained from the BIP2201I or BIP2208I message that is written to the system log when the execution group starts up.

The format of the command is:

```
mqsireadlog brokername -t
    -x ce40b73e-2701-0000-0080-85557ff4a8ad -f -o service.xml
```

httplistener	x		

Notes:

1. Because this command does not have a component parameter, trace information is recorded in, and retrieved from, the *utility* component trace files. For further details see the **mqsichangetrace** command.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651

- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Examples:
Retrieve the user trace for broker MB7BROKER:

```
mqsireadlog MB7BROKER -u -e default -o trace.xml
```

Retrieve service trace for utility **mqsiformatlog**:

```
mqsireadlog utility -t -b agent -f -o trace.xml
```

You can format the log file (`trace.xml` in the above examples) by using the command **mqsiformatlog**, or view it using an XML editor or viewer.

Related tasks:

"Using logs" on page 3526
There are a variety of logs that you can use to help with problem determination and troubleshooting.

Related reference:

"Syntax diagrams" on page 3677

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

mqsireload command:

Use the **mqsireload** command to request the broker to stop and restart execution groups.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS - as a console command

Purpose:
When you issue this command, a message is sent to the broker, which stops and restarts all its execution groups. You can specify a single execution group to be reloaded, but if you use the default form of this command to reload all execution groups you ensure state and data integrity is preserved.

Because an execution group does not stop until all message flows within it terminates, the ability of the broker to reload quickly depends on the processing time for the longest running message flow. This affects the performance of this command, therefore review any long-running message flows before running this command.

If you have included a user-defined node or parser within a message flow on the broker, these are deleted by this command, and the relevant termination functions called. When message flows are restarted, the resources used by user-defined nodes and parsers are re-accessed and reacquired. However, it is better programming practice to ensure that user-defined nodes and parsers provide their own mechanism to reload persistent state and data dynamically, and do not rely on the use of this command.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "mqsireload command - Windows, Linux, and UNIX systems"
- "mqsireload command - z/OS" on page 3911

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
No additional responses are returned.

Related tasks:

"Deleting a broker" on page 930
Delete a broker using the command line on the system where the broker component is installed.

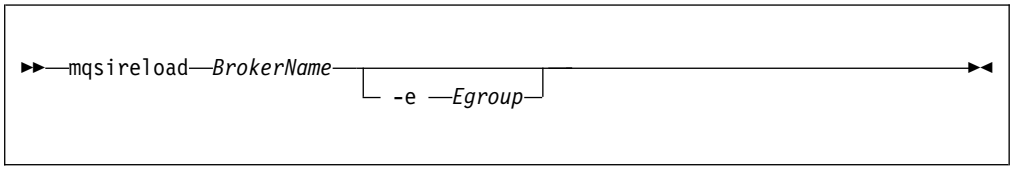
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

mqsireload command - Windows, Linux, and UNIX systems:

Use the **mqsireload** command on Windows, Linux, and UNIX systems to request the broker to stop and restart execution groups.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker to which the reload request is sent.

-e *Egroup*
(Optional) The name of the execution group that is to be reloaded. If this parameter is not specified, all execution groups on the specified broker are stopped and restarted.

Examples:

```
mqsireload broker1
```

Related reference:

"Syntax diagrams" on page 3677

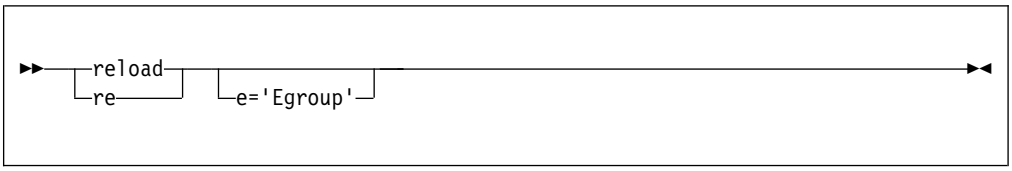
"**mqsireload** command" on page 3909
Use the **mqsireload** command to request the broker to stop and restart execution groups.

mqsireload command - z/OS:

Use the **mqsireload** command on z/OS to request the broker to stop and restart execution groups.

Syntax:

z/OS console command:
Synonym: re



Parameters:

e= *Egroup*
(Optional) The name of the execution group that is to be reloaded. If this parameter is not specified, all execution groups on the specified broker are stopped and restarted.

Examples:

```
F MQP1BRK,re e='EgName'
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsireload** command" on page 3909
Use the **mqsireload** command to request the broker to stop and restart execution groups.

mqsireloadsecurity command:

Use the **mqsireloadsecurity** command to force the immediate expiry of some or all the entries in the security cache.

Supported platforms:

- Windows
- Linux and UNIX systems

- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting BIPRLSEC; see "Contents of the broker PDSE" on page 3991

Purpose:
Entries in the security cache are valid for a specified length of time, after which the entries are marked as 'expired'. When an entry is marked as expired, it must be reauthenticated with the security provider before it can be reused, and its expiry time must be reset. If reauthentication fails, the entry remains marked as expired. All entries in the security cache marked as expired are removed when the next sweep of the cache is performed.

Use the **mqsichangeproperties** command to set the time for which entries in the cache are valid, and also the value for the sweep of the security cache. When the entries in the security cache have expired, you must reauthenticate them.

Select the appropriate link for details of this command on the operating system that is used by your enterprise:

- "**mqsireloadsecurity** command - Windows, Linux, and UNIX systems" on page 3913
- "**mqsireloadsecurity** command - z/OS" on page 3915

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

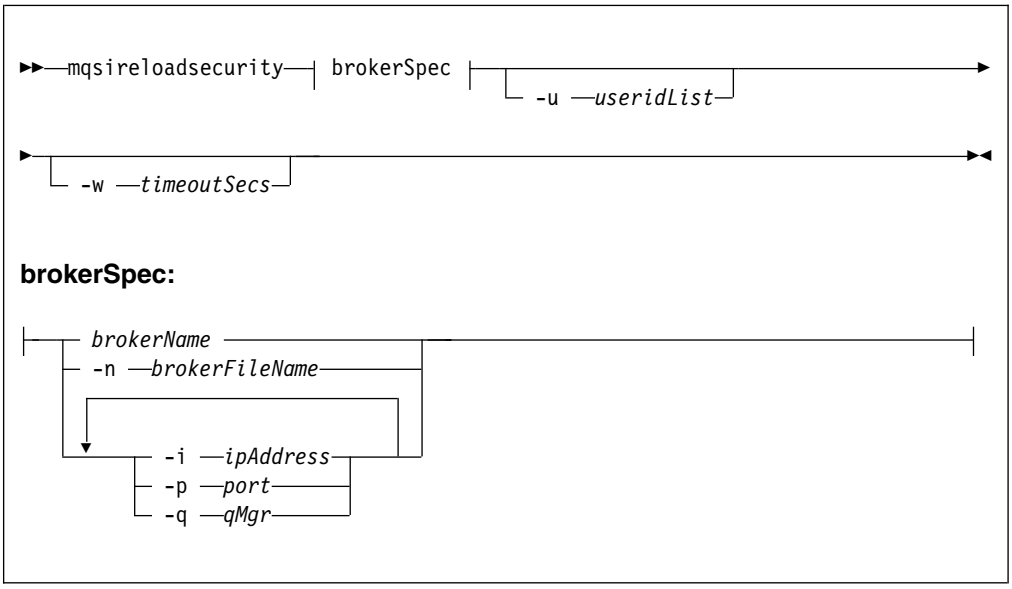
Use the **mqsireloadsecurity** command on z/OS to force the immediate expiry of some or all the entries in the security cache.

"Syntax diagrams" on page 3677

mqsireloadsecurity *command - Windows, Linux, and UNIX systems:*

Use the **mqsireloadsecurity** command on Windows, Linux, and UNIX to force the immediate expiry of some or all of the entries in the security cache.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

-u *useridList*
(Optional) This parameter reloads all entries in the security cache for the specified list of users (separated by colons). If you do not specify this parameter, all entries in the security cache are reloaded. For cached certificates, this value is the common name element value.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Examples:
Reload the cache for all users on the specified broker. :

```
mqsireloadsecurity BROKER1
```

Reload the cache for a single user on the specified broker. The connection parameters for the broker are defined in the file BROKER1.broker.

```
mqsireloadsecurity -n BROKER1.broker -u user1
```

Reload the cache for a list of users on the specified broker, and wait for five seconds before returning:

```
mqsireloadsecurity My_Broker -u user1:user2:user3 -w 5
```

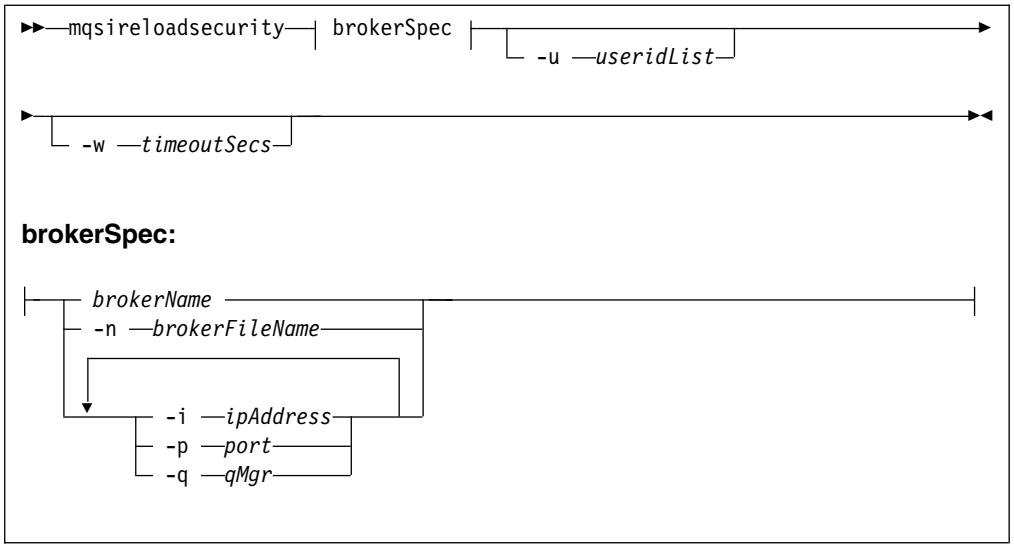
Select the objects and properties associated with the securitycache component that you want to change.

mqsireloadsecurity *command - z/OS:*

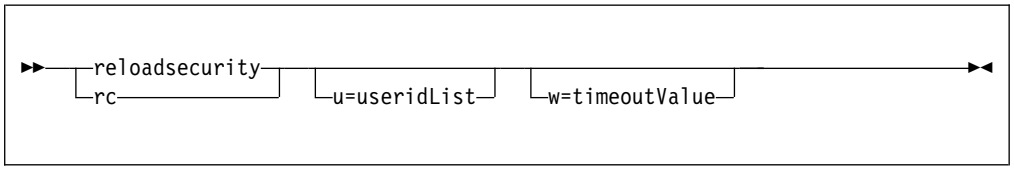
Use the **mqsireloadsecurity** command on z/OS to force the immediate expiry of some or all the entries in the security cache.

Syntax:

z/OS command - BIPRLSEC:



z/OS console command:



Parameters:

brokerSpec
You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker. If you specify a queue manager, it must be defined on the local computer.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is irrelevant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note."

-u *useridList*
(Optional) This parameter reloads all entries in the security cache for the specified list of users (separated by colons). If you do not specify this parameter, all entries in the security cache are reloaded. For cached certificates, this value is the common name element value.

-w *timeoutValue*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Examples:
Reload the cache for a single user on the specified broker. The connection parameters for the broker are defined in the file `BROKER1.broker`.

```
mqsireloadsecurity -n BROKER1.broker -u user1
```

Reload the cache for all users by using the console command:

```
F MQP1BRK,rc
```

Reload the cache for a single user:

```
F MQP1BRK,rc u=user1
```

Reload the cache for a list of users, and wait for 5 seconds before returning:

```
F MQP1BRK,rc u=user1:user2:user3,w=5
```

Select the objects and properties associated with the securitycache component that you want to change.

mqsiremovebrokerinstance command:

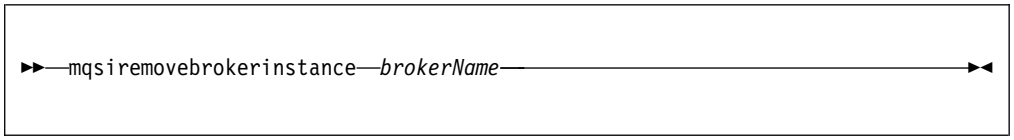
Use the **mqsiremovebrokerinstance** command to remove a multi-instance broker from a server where WebSphere Message Broker has been installed.

Supported platforms:

- Windows
- Linux and UNIX systems

Purpose:
Use the **mqsiremovebrokerinstance** command to remove a broker instance from any additional server on which you no longer require multi-instance support. You must first create a multi-instance enabled broker on one server using the **mqsicreatebroker** command.

Syntax:



Parameters:

brokerName
(Required) The name of the broker instance that you are deleting; the name is case-sensitive. The broker instance name must match that of a multi-instance enabled broker previously created by using the **mqsicreatebroker** command.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Examples:
The following example removes a broker instance from broker `Mybroker`:

```
mqsiremovebrokerinstance MyBroker
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

"**mqsiaddbrokerinstance** command" on page 3715
Use the **mqsiaddbrokerinstance** command to create a multi-instance broker on a server where WebSphere Message Broker has been installed.

mqsireportbroker command:

Use the **mqsireportbroker** command to display broker registry entries.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPRPBK; see "Contents of the broker PDSE" on page 3991

Purpose:
You can use the **mqsireportbroker** command to view the property values set when you create or change the broker.

On Windows platforms, Linux, and UNIX systems, the **mqsireportbroker** command also reports whether a broker is configured as a WebSphere MQ service.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsireportbroker** command - Windows, Linux, and UNIX systems" on page 3921
- "**mqsireportbroker** command - z/OS" on page 3923

Usage notes:
The following rules apply on the report:

- You can run this command if the broker is stopped or running.
- If values for a password are set, eight asterisks are displayed.
- Units are shown in the output for all numeric values.

Responses:
The following table shows the output returned when you run the **mqsireportbroker** command.

Property (Units)	Notes
brokerName	1
Service userId	2, 3, 4

Property (Units)	Notes
Service password	2, 3, 4
Queue manager	1
Work path	1
Trusted (fastpath) queue manager application - true	2, 3
Trusted (fastpath) queue manager application - false	3, 5
User LIL path	2
Configuration change timeout (seconds)	2
Internal configuration timeout (seconds)	2
Administration security enabled (true or false)	2
Statistics major interval (minutes)	2
LDAP principal	2
LDAP credentials	2
ICU converter path	2
User exit path	2
Operation mode	2, 3
Fix pack capability level	5
Active user exits	5
Broker UUID	7
Install path	8
Process ID	7

Notes:

1. This value is set by the **mqsicreatebroker** command.
2. This value is set by the **mqsicreatebroker** command or later modified by the **mqsichangebroker** command.
3. This option is applicable only on distributed systems.
4. This option is not relevant on Windows, because this value is stored in the service.
5. This option can be set only by the **mqsichangebroker** command.
6. (Not used.)
7. This value is generated automatically when the broker is started.
8. You cannot set this value by using a command.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Business-level monitoring" on page 3319
You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

"Configuring monitoring event sources using a monitoring profile" on page 762
You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

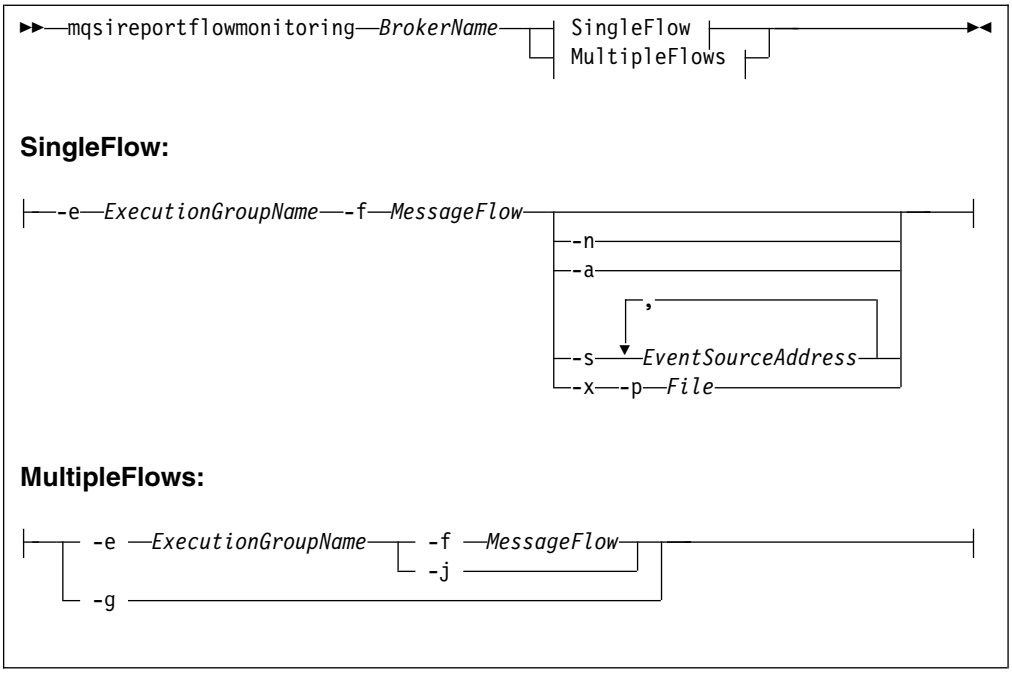
Related reference:

"**mqsichangeflowmonitoring** command" on page 3738
Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

mqsireportflowmonitoring command - Windows, Linux and UNIX systems:

Use the **mqsireportflowmonitoring** command on Windows, Linux and UNIX systems to display the current options for monitoring that have been set by the **mqsichangeflowmonitoring** command.

Syntax:



Parameters:

BrokerName
(Required) Specify the label of the broker, for which monitoring options are to be reported.

-a
(Optional) Report the flow-level monitoring properties and the properties of all event sources within the flow, whether configured or not.

-e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which monitoring options are to be reported.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

-f *MessageFlow*
(Required) Specify the label for the message flow, for which monitoring options are to be reported.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

-g
(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

-j
(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-n
(Optional) Report the flow-level monitoring properties and the properties of any configured event sources within the flow.

-p (Optional unless **-x** is specified.) The file name to which the monitoring profile will be written, in XML format.

-s *EventSourceAddress*
(Optional) Report the flow-level monitoring properties and the properties of the specified event sources within the flow, whether configured or not.

You must provide a comma-separated list of the event source addresses for which monitoring options are to be reported. An event source address takes the form <*node name*>.<*event source*>, where <*event source*> is one of the following values:

'terminal.<*terminal name*>'

'transaction.Start'

'transaction.End'

'transaction.Rollback'

If a message flow contains two or more nodes with identical names, the event sources on those nodes cannot be accurately addressed. If this is attempted, behavior is undefined.

Note: <*node name*> is the label of the node as known by the broker runtime components. If the node is in a subflow the label reflects this. For example, flow A contains an instance of flow B as a subflow labeled 'myB'; flow B contains an instance of a Compute node labeled 'myCompute'. The <*node name*> for the Compute node is 'myB.myCompute'.

-x
(Optional; if you specify -x you must also specify the -p parameter.) Outputs the current monitoring properties for the specified message flow as a monitoring profile XML file.

Note:

- If all flags are omitted, only the flow-level properties are reported.
- Flags -n, -a, -s and -x can be used only when -f is present.
- Flags -n, -a, -s and -x are alternatives and cannot be used together.

Examples:
Request a report of the monitoring options for message flow "MyFlow1" in the execution group "default" for broker "BrokerA":

```
mqsireportflowmonitoring BrokerA -e default -f MyFlow1
```

Request a report of the current monitoring options for all message flows in all execution groups for broker "BrokerA" :

```
mqsireportflowmonitoring BrokerA -g -j
```

Related tasks:

“Reporting monitoring settings” on page 3343
Use the **mqsireportflowmonitoring** command to report monitoring settings for a flow.

Related reference:

"Syntax diagrams" on page 3677

Use the **mqsireportflowmonitoring** command to display the current options for monitoring that have been set using the **mqsichangeflowmonitoring** command.

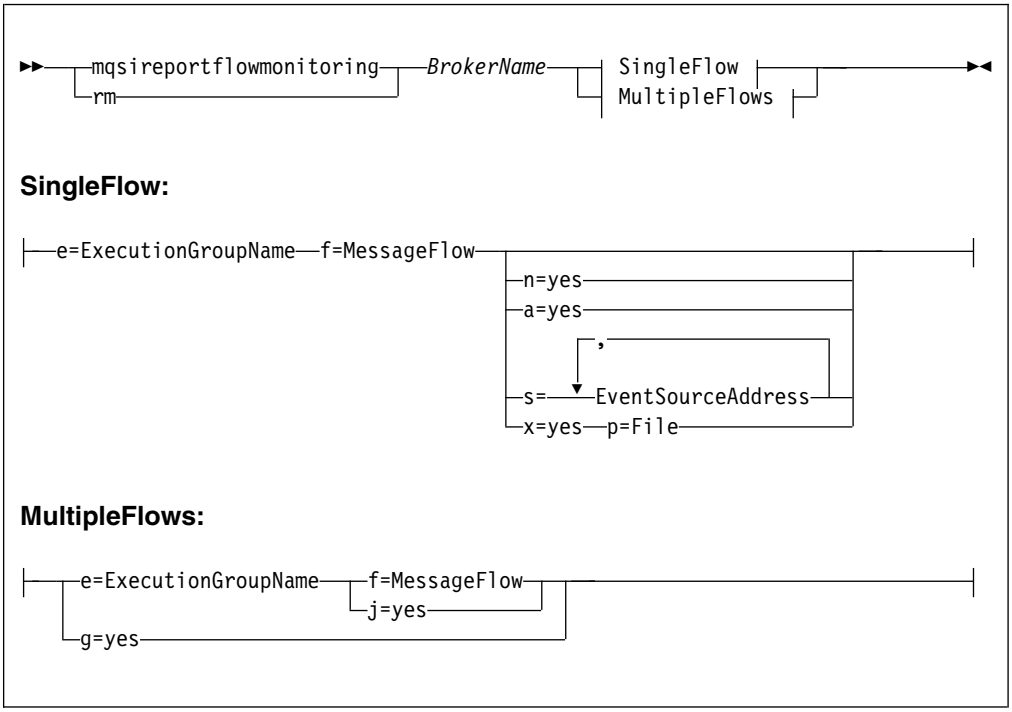
"**mqsichangeflowmonitoring** command" on page 3738
Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

mqsireportflowmonitoring command - z/OS:

Use the **mqsireportflowmonitoring** command on z/OS to display the current options for monitoring that have been set by the **mqsichangeflowmonitoring** command.

Syntax:

z/OS console command:
Synonym: rm



Parameters:

BrokerName
(Required) Specify the label of the broker, for which monitoring options are to be reported.

a (Optional) Report the flow-level monitoring properties and the properties of all event sources within the flow, whether configured or not.

e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which monitoring options are to be reported.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

f *MessageFlow*
(Required) Specify the label for the message flow, for which monitoring options are to be reported.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

g (Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive an error message.

j (Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive an error message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

n (Optional) Report the flow-level monitoring properties and the properties of any configured event sources within the flow.

p (Optional unless `-x` is specified.) The file name to which the monitoring profile will be written, in XML format.

s ***EventSourceAddress***
(Optional) Report the flow-level monitoring properties and the properties of the specified event sources within the flow, whether configured or not.

You must provide a comma-separated list of the event source addresses for which monitoring options are to be reported. An event source address takes the form <*node name*>.<*event source*>, where <*event source*> is one of the following values:

`'terminal.`<*terminal name*>'

`'transaction.Start'`

`'transaction.End'`

`'transaction.Rollback'`

If a message flow contains two or more nodes with identical names, the event sources on those nodes cannot be accurately addressed. If this is attempted, behavior is undefined.

Note: <*node name*> is the label of the node as known by the broker runtime components. If the node is in a subflow the label reflects this. For example, flow A contains an instance of flow B as a subflow labeled 'myB'; flow B contains an instance of a Compute node labeled 'myCompute'. The <*node name*> for the Compute node is 'myB.myCompute'.

x (Optional; if you specify -x you must also specify the -p parameter.) Outputs the current monitoring properties for the specified message flow as a monitoring profile XML file.

Note:

- If all flags are omitted, only the flow-level properties are reported.

- Flags -n, -a, -s and -x can be used only when -f is present.
- Flags -n, -a, -s and -x are alternatives and cannot be used together.

Examples:
Request a report of monitoring options for message flow "MFlow1" in the execution group "default":

```
F MI10BRK,rm e='default',f='MFlow1'
```

Request a report of the current monitoring options for all message flows in all execution groups:

```
F MI10BRK,rm g=yes,j=yes
```

Related tasks:

"Reporting monitoring settings" on page 3343
Use the **mqsireportflowmonitoring** command to report monitoring settings for a flow.

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

Related tasks:

"Optimizing message flow throughput" on page 587
Each message flow that you design must provide a complete set of processing for messages received from a certain source. This design might result in very complex message flows that include large numbers of nodes that can cause a performance overhead, and might create potential bottlenecks. You can increase the number of message flows that process your messages to provide the opportunity for parallel processing and therefore improved throughput.

"Optimizing message flow response times" on page 3264
You can use different solutions to improve message flow response times.

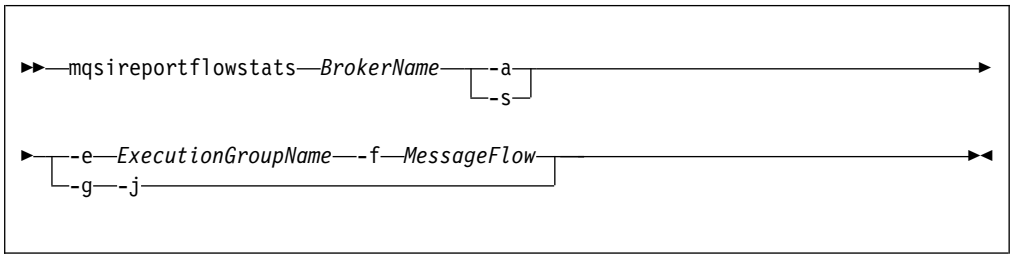
Related reference:

"**mqsichangeflowstats** command" on page 3744
Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

mqsireportflowstats command - Windows, Linux and UNIX systems:

Use the **mqsireportflowstats** command on Windows, Linux and UNIX systems to display the current options for accounting and statistics that have been set by the **mqsichangeflowstats** command.

Syntax:



Parameters:

BrokerName
(Required) Specify the label of the broker for which the previously stored accounting and statistics options are to be reported.

-a (Required) Specify that the command reports the stored settings for the archive accounting and statistics collection.

You must specify **-a** or **-s**, or both arguments. If you do not specify at least one of these arguments you receive a warning message.

-e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which accounting and statistics options are to be reported.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-f *MessageFlow*
(Required) Specify the label for the message flow, for which accounting and statistics options are to be reported.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

-g
(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-j
(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-s (Required) Specify that the command reports the stored settings for the snapshot accounting and statistics collection.

You must specify **-a** or **-s**, or both arguments. If you do not specify at least one of these arguments you receive a warning message.

Examples:
Request a report for message flow "MyFlow1" in the execution group "default" for broker "BrokerA" for both archive and snapshot statistics collection:

```
mqsireportflowstats BrokerA -s -a -e default -f MyFlow1
```

Request a report of the snapshot options that are currently stored for all message flows in all execution groups for broker "BrokerA" :

```
mqsireportflowstats BrokerA -s -g -j
```

Related reference:

"Syntax diagrams" on page 3677

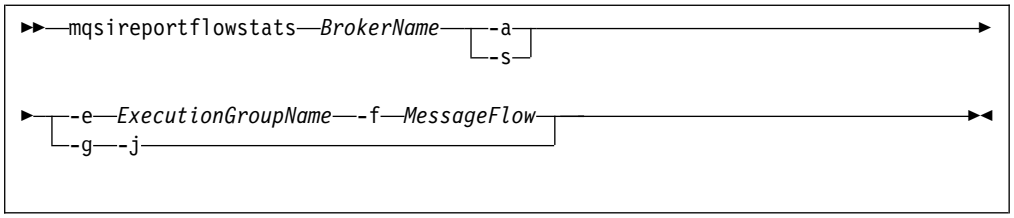
"**mqsireportflowstats** command" on page 3929
Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

mqsireportflowstats command - z/OS:

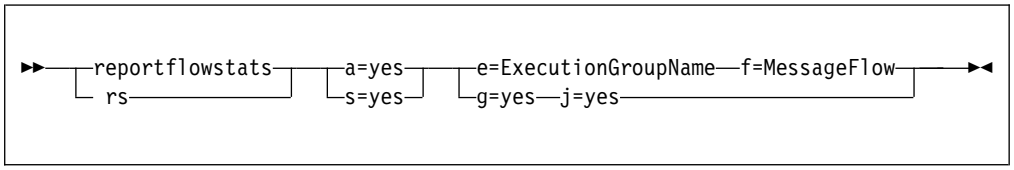
Use the **mqsireportflowstats** command on z/OS to display the current options for accounting and statistics that have been set by the **mqsichangeflowstats** command.

Syntax:

z/OS command - BIPRPMS:



z/OS console command:
Synonym: rs



Parameters:

BrokerName
(Required) Specify the label of the broker for which the previously stored accounting and statistics options are to be reported.

-a (Required) Specify that the command reports the stored settings for the archive accounting and statistics collection.

You must specify **-a** or **-s**, or both arguments. If you do not specify at least one of these arguments you receive a warning message.

-e *ExecutionGroupName*
(Required) Specify the name for the execution group, for which accounting and statistics options are to be reported.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-f *MessageFlow*
(Required) Specify the label for the message flow, for which accounting and statistics options are to be reported.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

-g
(Required) Specifies that the command applies to **all** execution groups that belong to the broker.

You must specify either **-e** or **-g**. If you do not specify one of these arguments you receive a warning message.

-j
(Required) Specifies that the command applies to **all** message flows that belong to the execution group.

You must specify either **-f** or **-j**. If you do not specify one of these arguments you receive a warning message.

Note: If you set the **-g** option for all execution groups, you must use **-j** instead of **-f**.

-s (Required) Specify that the command reports the stored settings for the snapshot accounting and statistics collection.

You must specify **-a** or **-s**, or both arguments. If you do not specify at least one of these arguments you receive a warning message.

Examples:
Using the command BIPRPMS:

- Request a report for message flow "MyFlow1" in the execution group "default" for both archive and snapshot statistics collection:

```
mqsireportflowstats  BrokerA -s -a -e default -f MyFlow1
```

- Request a report of the snapshot options that are currently stored for all message flows in all execution groups:

```
mqsireportflowstats BrokerA -s -g -j
```

Using the console form of the command, request a report for message flow "MyFlow1" in the execution group "default" for both archive and snapshot statistics collection:

```
mqsireportflowstats  s= a= e=default f=MyFlow1
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsireportflowstats** command" on page 3929
Use the **mqsireportflowstats** command to display the current options for accounting and statistics that have been set using the **mqsichangeflowstats** command.

mqsireportflowuserexits command:

Use the **mqsireportflowuserexits** command to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command in one of two ways - as a console command, or by customizing and submitting BIPRPUE; see "Contents of the broker PDSE" on page 3991

Purpose:
Use the **mqsireportflowuserexits** command to generate a report about the status of user exits:

- If you specify only the broker name, the command returns a list of all user exits that you have set to be active at the broker level by using the **mqsichangebroker** command.
- If you specify the broker and execution group names, the command returns the list returned for the broker name only, plus:
  - A list of all user exits that you have set to be active at the execution group level by using the **mqsichangeflowuserexits** command.
  - A list of all user exits that you have set to be inactive at the execution group level by using the **mqsichangeflowuserexits** command.
- If you specify the broker, execution group, and message flow names, the command returned the list returned for the broker and execution group names, plus:

– A list of all user exits that you have set to be active at the message flow level by using the **mqsichangeflowuserexits** command.
– A list of all user exits that you have set to be inactive at the message flow level by using the **mqsichangeflowuserexits** command.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "mqsireportflowuserexits command - Windows, Linux, and UNIX systems"
- "mqsireportflowuserexits command - z/OS" on page 3935

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related concepts:

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

Related tasks:

"Developing a user exit" on page 3114
Develop a user exit by declaring it, implementing its behavior, then compiling it.

"Deploying a user exit" on page 3116
Deploy your user exit to the broker.

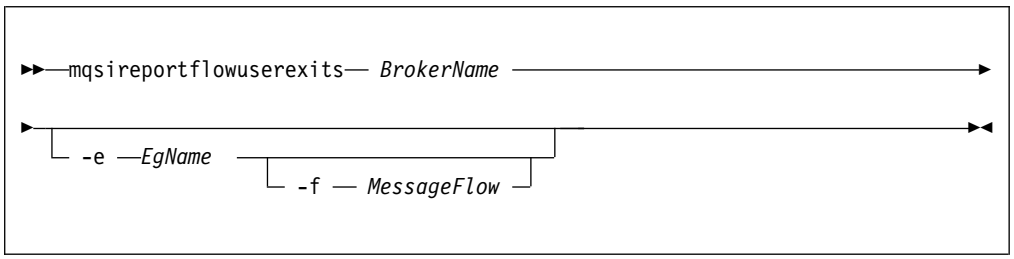
Related reference:

"**mqsichangeflowuserexits** command" on page 3751
Use the **mqsichangeflowuserexits** command to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

mqsireportflowuserexits command - Windows, Linux, and UNIX systems:

Use the **mqsireportflowuserexits** command on distributed systems to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

Syntax:



Parameters:

BrokerName
(Required). The name of the broker.

-e *EgName*
(Optional). The name of the execution group.

-f *MessageFlow*
(Optional). The name of the message flow.

The user exits that are reported by this command depend on the parameters that you specify.

- If you specify only the broker name, the command lists user exits that have been set to active at the broker level by using the **mqsichangebroker** command.
- If you specify the broker name and execution group name, the command lists the following user exits:
  - User exits that have been set to active at the broker level by using the **mqsichangebroker** command
  - User exits that have been set to active at the execution group level by using the **mqsichangeflowuserexits** command
  - User exits that have been set to inactive at the execution group level by using the **mqsichangeflowuserexits** command
- If you specify the broker name, execution group name, and a message flow name, the command lists the following user exits:
  - User exits that have been set to active at the broker level by using the **mqsichangebroker** command
  - User exits that have been set to active at the execution group level by using the **mqsichangeflowuserexits** command
  - User exits that have been set to inactive at the execution group level by using the **mqsichangeflowuserexits** command
  - User exits that have been set to active at the message flow level by using the **mqsichangeflowuserexits** command
  - User exits that have been set to inactive at the message flow level by using the **mqsichangeflowuserexits** command

Examples:

```
mqsireportflowuserexits MB7BROKER -e default -f MYFLOW
BIP8859 User Exits active for broker MYBROKER: exit1, exit2
BIP8854 User Exits active for Execution Group default: exit1,exit3
BIP8855 User Exits inactive for Execution Group default: exit2
BIP8856 User Exits active for Message Flow MYFLOW: exit2
BIP8857 User Exits inactive for Message Flow MYFLOW: exit1
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsireportflowuserexits** command" on page 3933

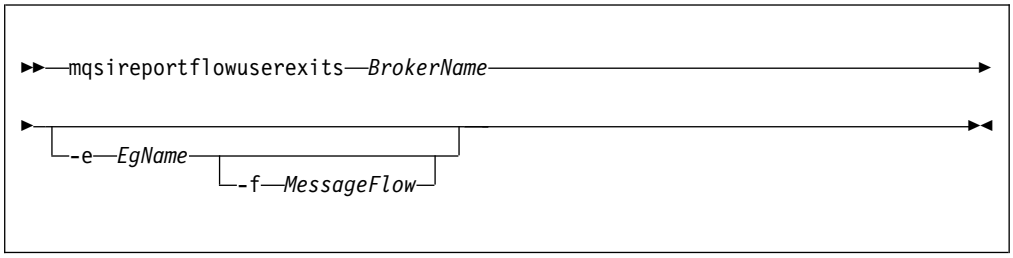
Use the **mqsireportflowuserexits** command to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

mqsireportflowuserexits command - z/OS:

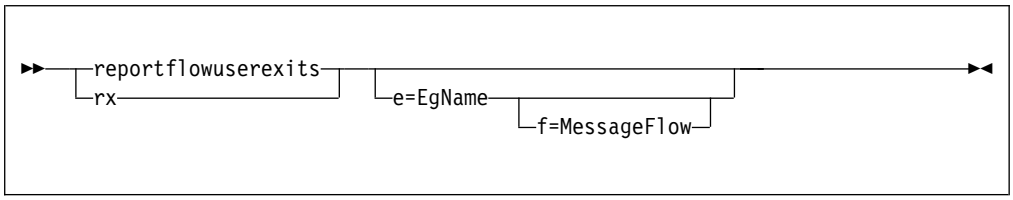
Use the **mqsireportflowuserexits** command on z/OS to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

Syntax:

z/OS command - BIPRPUE:



z/OS console command:
Synonym: rx



Parameters:

BrokerName
(Required). The name of the broker.

-e *EgName*
(Optional). The name of the execution group.

-f *MessageFlow*
(Optional). The name of the message flow.

The user exits that are reported by this command depend on the parameters that you specify.

- If you specify only the broker name, the command lists user exits that have been set to active at the broker level by using the **mqsichangebroker** command.
- If you specify the broker name and execution group name, the command lists the following user exits:
  - User exits that have been set to active at the broker level by using the **mqsichangebroker** command
  - User exits that have been set to active at the execution group level by using the **mqsichangeflowuserexits** command
  - User exits that have been set to inactive at the execution group level by using the **mqsichangeflowuserexits** command
- If you specify the broker name, execution group name, and a message flow name, the command lists the following user exits:
  - User exits that have been set to active at the broker level by using the **mqsichangebroker** command
  - User exits that have been set to active at the execution group level by using the **mqsichangeflowuserexits** command

- User exits that have been set to inactive at the execution group level by using the **mqsichangeflowuserexits** command
- User exits that have been set to active at the message flow level by using the **mqsichangeflowuserexits** command
- User exits that have been set to inactive at the message flow level by using the **mqsichangeflowuserexits** command

Examples:

```
mqsireportflowuserexits MB7BROKER -e default -f MYFLOW
BIP8859 User Exits active for broker MYBROKER: exit1, exit2
BIP8854 User Exits active for Execution Group default: exit1,exit3
BIP8855 User Exits inactive for Execution Group default: exit2
BIP8856 User Exits active for Message Flow MYFLOW: exit2
BIP8857 User Exits inactive for Message Flow MYFLOW: exit1
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsireportflowuserexits** command" on page 3933

Use the **mqsireportflowuserexits** command to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

mqsireportproperties command:

Use the **mqsireportproperties** command to display properties that relate to a broker, an execution group, or a configurable service.

You can also use the WebSphere Message Broker Explorer to create and view configurable services. See "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPRPPR; see "Contents of the broker PDSE" on page 3991.

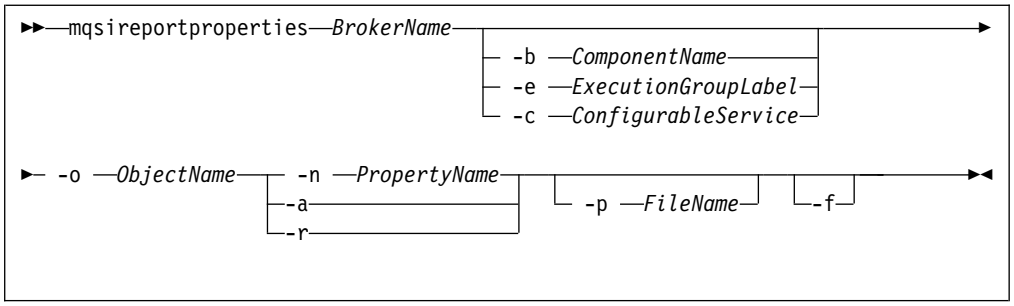
Purpose:

Use the **mqsireportproperties** command to examine the values of properties or broker resources that are set by using the **mqsichangeproperties** command, or created by using the **mqsicreateconfigurableservice** command.

Usage notes:

- Before you run the **mqsireportproperties** command, ensure that the broker is running.
- If you use the **mqsichangeproperties** command to change any value, the change is applied only after you stop and restart the broker or execution group.
- If you run the **mqsireportproperties** command after changing properties, but before you restart the broker or execution group, the command shows the changed value, even though that value is not yet in effect.

Syntax:



Parameters:

BrokerName
(Required) The name of the broker.

-b *ComponentName*
(Optional) The name of the component selected. Valid values are *httplistener*, *securitycache*, and *servicefederation*.

-c *ConfigurableService*
(Optional) The type of the configurable service. Specify a value of `AllTypes` to report on all configurable service types.

For a list of supplied configurable services, and their properties and values, see "Configurable services properties" on page 3766.

-e *ExecutionGroupLabel*
(Optional) The label of the execution group for which a report is required.

-o *ObjectName*
(Required) The name of the object whose properties you want to read.

You must also specify **-b**, **-e**, or **-c** after **-o**, except if you specify the object name `BrokerRegistry`.

Set *ObjectName* to match other parameters:

- Specify `BrokerRegistry` for broker registry parameters.
- Specify the name of a configurable service (predefined or user-defined) of a type that you have specified with **-c**.

  For example:

  – **-c EISProviders** with `SAP`, `Siebel`, or `PeopleSoft` for a predefined WebSphere Adapters configurable service.

  – **-c JMSProviders** with the name of a predefined or user-defined service, for example, `WebSphere_MQ`.
- Specify a communications object for the `httplistener` component that you have specified with **-b**; one of `HTTPListener`, `HTTPConnector`, or `HTTPSConnector`. Values are defined for all HTTP nodes that you have deployed to the broker.

  You can set a parameter to disable or enable the broker-wide listener for HTTP nodes; by default, this listener is active.
- Specify a communications object for the execution group that you have specified with **-e**; one of `HTTPListener`, `HTTPConnector`, or `HTTPSConnector`. Values are defined for all SOAP nodes that you have deployed to the specified execution group.

  You can configure the execution group such that all HTTP nodes use the embedded listener instead of the broker-wide listener. For more information, see "HTTP listeners" on page 1589.

- Specify `DynamicSubscriptionEngine` for inter-broker communications properties for the execution group that you have specified with **-e**. These properties apply to brokers that you have configured in collectives, or cloned.
- Specify `SecurityCache` for properties for the `securitycache` component that you have specified with **-b**.
- Specify an object for the `servicefederation` component that you have specified with **-b**; one of `scmp`, `HTTPConnector`, or `HTTPSConnector`. The properties apply to the broker HTTP(S) port that processes Service Federation Management (SFM) SCMP Atom requests.
- Specify `ServiceFederationManager` for properties involved in the creation of an SFM proxy for the execution group that you have specified with **-e**.

Specify a value of `AllReportableEntityNames` to return a list of all valid object names. If you run the **mqsireportproperties** command on the command line without any properties, `AllReportableEntityNames` is used.

-n *PropertyName*
(Optional) Display only the named property.

You must select only one option from **-n**, **-a**, and **-r**.

-a
(Optional) Indicates that all property values of the object are displayed, and does not act in a recursive manner on properties that have child values.

-r
(Optional) Indicates that all property values of the object are displayed and, additionally, displays the child values for all properties that have child values.

Note, that this option does not show all the possible values for `AllReportableEntityNames`. Furthermore, not all entities support this parameter.

-p *FileName*
(Optional) The location and name of the file to which the command writes all selected properties. If you do not specify **-n**, the property values, but not the property names, are written.

-f
(Optional) This parameter is valid only if you specify an execution group level object.

You can use this parameter only when the execution group is in the stopped state, and you must also specify **-e** and **-o**.

If you specify this parameter for other configurable services or components, an error is generated.

For more information about objects, properties, and values, and valid combinations of these parameters, see "**mqsichangeproperties** command" on page 3756.

For the *httplistener* component, the **mqsireportproperties** command does not report those properties that have not been explicitly set with the **mqsichangeproperties** command, even if those properties have a default setting.

For example, the default HTTPSConnector port that is used (unless it has been changed) is 7083. However, this value is not reported by the **mqsireportproperties** command unless you have changed it from this default by using the

mqsichangeproperties command. To see the default values for all properties that the **mqsireportproperties** command can report, see the **mqsichangeproperties** command description.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
Responses are of the form:

- `HTTPConnector`
  - PortNumber = 7800
- `HTTPSConnector`
  - PortNumber = 7843

Examples:
Always enter the command on a single line; in some examples, a line break has been added to enhance readability.

Displaying properties associated with broker components

The following examples include the **-b** parameter to specify the component to view.

- Check if the broker-wide listener is active for deployed HTTP nodes in one or more execution groups:

```
mqsireportproperties MB7BROKER -b httplistener -o HTTPListener -n startListener
```

- Display all the current HTTPListener settings associated with HTTP nodes (defined in the httplistener component):

  ```
  mqsireportproperties MB7BROKER -b httplistener -o HTTPListener -a
  ```

- Display the HTTPSConnector port setting for the HTTP nodes (defined in the httplistener component):

  ```
  mqsireportproperties MB7BROKER -b httplistener -o HTTPSConnector -n port
  ```

- Display all Service Federation object properties and their values:

```
mqsichangeproperties MB7BROKER -b servicefederation -o AllReportableEntityNames -r
```

Displaying properties associated with execution groups

The following example includes the **-e** parameter to specify the execution group to view.

- Display the FTE agent name for execution group FTESAMPLE in broker MB7BROKER:

  ```
  mqsireportproperties MB7BROKER -e FTESAMPLE -o FTEAgent -n agentName
  ```

  If the agent has been created, the command returns the agent name. If the agent has not been created, the command returns an empty string.

- Check if the deployed HTTP nodes are using the execution group embedded listener:

```
mqsireportproperties MB7BROKER -e exgroup1 -o ExecutionGroup -n httpNodesUseEmbeddedListener
```

- Display the properties that control the creation of an SFM proxy for an execution group that is to be used as an SFM Connectivity Provider:

  ```
  mqsireportproperties MB7BROKER -e exgroup1 -o ServiceFederationManager -a
  ```

  The result of this command has the following format:

```
ServiceFederationManager
  uuid='ServiceFederationManager'
  userTraceLevel='none'
  traceLevel='none'
  userTraceFilter='none'
  traceFilter='none'
  port='8811'
  securePort='8844'
  maxWaitTime='180'
  proxyURLHostName=' mbhost.ibm.com '
  proxyPathPrefix='proxy'
  proxyPathPrefixesEnabled='TRUE'
  creationTime='2009-09-11 15:37:52.639219'
  nextProxyPathPrefixCount='8'
  ownedProxyGroupCount='2'
```

Displaying properties associated with configurable services

The following examples include the **-c** parameter to specify the configurable service to view.

- Display all Aggregation configurable services:

  ```
  mqsireportproperties MB7BROKER -c Aggregation -o AllReportableEntityNames -r
  ```

- Display all CICSConnection configurable services:

  ```
  mqsireportproperties MB7BROKER -c CICSConnection -o AllReportableEntityNames -r
  ```

- Display all configurable services for Connect:Direct server (that you have defined to this broker with the **mqsicreateconfigurableservice** command)

  ```
  mqsireportproperties MB7BROKER -c CDServer -o AllReportableEntityNames -r
  ```

  The result of this command has the following format:

```
CDServer
  Default
    hostname='localhost'
    port='1363'
    brokerPathToStagingDir=''
    cdPathToStagingDir=''
    brokerPathToInputDir=''
    cdPathToInputDir=''
    queuePrefix= ''
    securityIdentity="Default"
```

- Display all Collector configurable services:

  ```
  mqsireportproperties MB7BROKER -c Collector -o AllReportableEntityNames -r
  ```

- Display all CORBA configurable services:

  ```
  mqsireportproperties MB7BROKER -c CORBA -o AllReportableEntityNames -r
  ```

- Display all EmailServer configurable services that EmailInput nodes or message flows are referring to at runtime:

  ```
  mqsireportproperties MB7BROKER -c EmailServer -o AllReportableEntityNames -r
  ```

- Display all properties of the FtpServer configurable service called TEST1:

  ```
  mqsireportproperties MB7BROKER -c FtpServer -o TEST1 -r
  ```

- Display the **protocol** property setting of the FtpServer configurable service called TEST1:

```
mqsireportproperties MB7BROKER -c FtpServer -o TEST1 -n protocol
```

- Display all IMSConnect configurable services:

```
mqsireportproperties MB7BROKER -c IMSConnect -o AllReportableEntityNames -r
```

- Report the properties of the Oracle JDBCProvider configurable service:

```
mqsireportproperties MB7BROKER -c JDBCProviders -o Oracle -r
```

- Display the properties for all the broker's JMS provider resources (default JMS provider resources and those configurable services that you have defined by using the **mqsicreateconfigurableservice** command):

```
mqsireportproperties MB7BROKER -c JMSProviders
     -o AllReportableEntityNames -r
```

- Display the properties for all the JMS provider resources of WebSphere MQ.

```
mqsireportproperties MB7BROKER -c JMSProviders
     -o WebSphere_MQ -r
```

- Display the properties for all the JMS provider resources (default JMS provider resources and those configurable services that you have defined to this broker with the **mqsicreateconfigurableservice** command):

```
mqsireportproperties MB7BROKER -c JMSProviders
     -o BEA_WebLogic –r
```

  The result of this command has the following format:

```
ReportableEntityName=''
JMSProviders
  BEA_Weblogic=''
    jarsURL='default_Path'
    nativeLibs='default_Path'
    proprietaryAPIAttr1='weblogic.jndi.WLInitialContextFactory'
    proprietaryAPIAttr2='t3://9.20.94.16:7001'
    proprietaryAPIAttr3='BEAServerName'
    proprietaryAPIAttr4='default_none'
    proprietaryAPIAttr5='default_none'proprietaryAPIHandler='BEAWebLogicAPIHandler.jar'
```

- Display all PeopleSoftConnection configurable services:

```
mqsireportproperties MB7BROKER -c PeopleSoftConnection -o AllReportableEntityNames -r
```

- Display all policy sets for broker MB7BROKER:

```
mqsireportproperties MB7BROKER -c PolicySets
     -o AllReportableEntityNames -a
```

- Display all policy set bindings for broker MB7BROKER:

```
mqsireportproperties MB7BROKER -c PolicySetBindings
     -o AllReportableEntityNames -a
```

- Export policy set Policy_2 in broker MB7BROKER to file `policyset.xml`:

```
mqsireportproperties MB7BROKER -c PolicySets
     -o Policy_2 -n ws-security -p policyset.xml
```

  You can use the output file to move policy sets between brokers, and for backup.

- Export a policy set bindings from a broker to a file:

```
mqsireportproperties MB7BROKER -c PolicySetBindings
     -o Bindings_2 -n ws-security -p bindings.xml
```

  This command writes the Policy Set Bindings file Bindings_2 in broker MB7BROKER to file `bindings.xml`. You can use this file to move policy set bindings between brokers, and for backup.

- Display all Resequence configurable services:

```
mqsireportproperties MB7BROKER -c Resequence -o AllReportableEntityNames -r
```

- Report the dependencies for the WebSphere Adapter for SAP:

```
mqsireportproperties MB7BROKER -c EISProviders -o SAP -r
```

- Display all SAPConnection configurable services:

  ```
  mqsireportproperties MB7BROKER -c SAPConnection -o AllReportableEntityNames -r
  ```

- Display the properties for all the security profiles (default security profiles and any that you have defined on this broker by using the **mqsicreateconfigurableservice** command):

  ```
  mqsireportproperties MB7BROKER -c SecurityProfiles
       -o AllReportableEntityNames -r
  ```

  The result of this command has the following format:

  ```
  ReportableEntityName=''
  SecurityProfiles

   Default_Propagation=''
    Authentication = 'NONE'
    AuthenticationConfig = ''
    Mapping = 'NONE'
    MappingConfig = ''
    Authorization = 'NONE'
    AuthorizationConfig = ''
    Propagation = 'TRUE'
    passwordValue = 'PLAIN'
  ```

- Display the properties for the security profile called MyFirstSecurityProfile:

  ```
  mqsireportproperties MB7BROKER -c SecurityProfiles
       -o MyFirstSecurityProfile -r
  ```

  The result of this command has the following format:

  ```
  ReportableEntityName=''
  SecurityProfiles
   MyFirstSecurityProfile=''
    Authentication = 'LDAP'
    AuthenticationConfig = 'ldap://localhost:389/ou=users,o=ibm'
    Mapping = 'TFIM'
    MappingConfig = 'http://tfimhost1:80'
    Authorization = 'NONE'
    AuthorizationConfig = ''
    Propagation = 'TRUE'
    passwordValue = 'PLAIN'
  ```

- Display all SiebelConnection configurable services:

  ```
  mqsireportproperties MB7BROKER -c SiebelConnection -o AllReportableEntityNames -r
  ```

- Display all TCPIPclient configurable services:

  ```
  mqsireportproperties MB7BROKER -c TCPIPClient
        -o AllReportableEntityNames -r
  ```

- Display all TCPIPServer configurable services:

  ```
  mqsireportproperties MB7BROKER -c TCPIPServer
        -o AllReportableEntityNames -r
  ```

- Display all Timer configurable services:

  ```
  mqsireportproperties MB7BROKER -c Timer -o AllReportableEntityNames -r
  ```

- Display all JavaClassLoader services:

  ```
  mqsireportproperties MB7BROKER -c JavaClassLoader
        -o AllReportableEntityNames -r
  ```

Select the properties associated with the ServiceFederationManager component that you want to change.

mqsireportresourcestats command:

Use the **mqsireportresourcestats** command to display current statistics gathering options for resources in the broker.

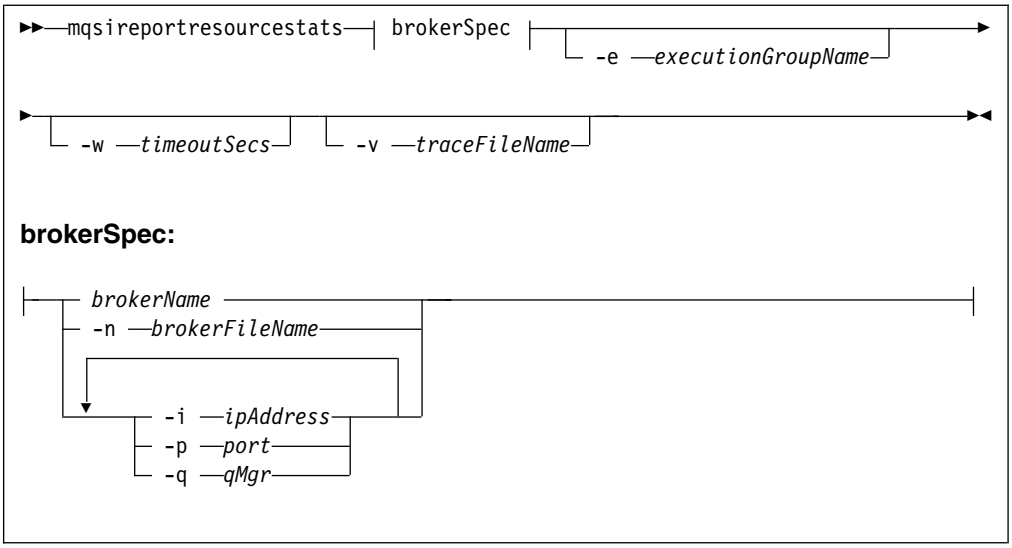
Supported platforms:

- Windows systems
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPRPRS; see "Contents of the broker PDSE" on page 3991

Purpose:
Use this command to view the status of statistics collection for the resource types listed in "Resource statistics data" on page 6745.

You can run this command only if the broker is running.

Syntax:



Parameters:

brokerSpec

(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName

This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*

This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*

These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note."

-e *executionGroupName*
(Optional) The name of the execution group for which resource statistics collection status is reported.

If you do not specify **-e**, resource statistics status is reported for all execution groups on the broker.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

If the command completes successfully, one report message per resource type is returned for each execution group specified by the command. Each message has the general format:

```
BIP8940I Statistics settings for resource type type in execution group execution_group_name is sta
```

where:

- *type* is the resource type. For more information about the resource types for which statistics can be requested, see "Resource statistics" on page 3306.
- *state* can be `active` or `inactive`
- *measurement* is a repeating field that depends on the resource type; for example, `TotalSocketsOpened` is returned for resource type `Sockets`. Details of all the measurements reported are provided in "Resource statistics data" on page 6745.

Examples:
Request a report for the execution group `default` on broker `BrokerA` for statistics collection for all resources:

```
mqsireportresourcestats BrokerA -e default
```

Request a report for all execution groups on broker `BrokerA` for statistics collection for all resources:

```
mqsireportresourcestats BrokerA
```

This example message shows an XML publication that contains resource statistics data.

mqsireporttrace command:

Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS as a console command

Purpose:
The **mqsireporttrace** command can be used to report on the current trace options that are currently set for an active broker. The broker name is a mandatory parameter, but if no other parameters are specified, the **mqsireporttrace** lists all **active** user and service trace settings for that broker. Alternatively, you can use the following options for more specific reports on the current trace settings:

- User trace. Specify the **-u** option.
- Service trace. Specify the **-t** option. Use this option only if directed to do so by the action described in a BIPxxxx message, or by your IBM Support Center.
- Trace nodes. Specify the **-n** option.

If you specify a broker, or any of its resources (execution group or message flow), you must have deployed those resources, and the broker must be running, before you can query trace settings.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsireporttrace** command - Windows, Linux, and UNIX systems" on page 3949
- "**mqsireporttrace** command - z/OS" on page 3951

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Related tasks:

"Using trace" on page 3533
You can use different types of trace to help you with problem determination and troubleshooting.

Related reference:

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"Service trace" on page 6875
Service trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Event Log or to user trace. Service trace is inactive by default; you must activate it explicitly by using a command.

"Trace node" on page 4942

"**mqsiformatlog** command" on page 3880
Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

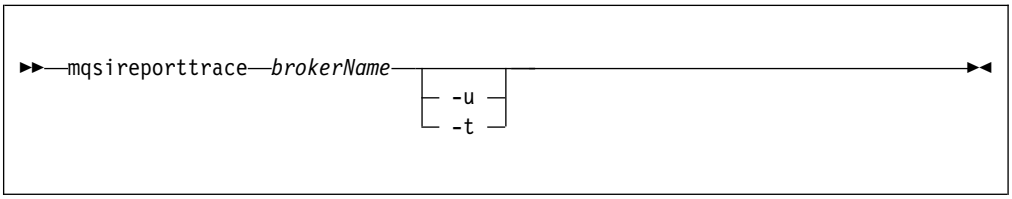
"**mqsireadlog** command" on page 3905
Use the **mqsireadlog** command to retrieve trace records for the specified component.

mqsireporttrace *command - Windows, Linux, and UNIX systems:*

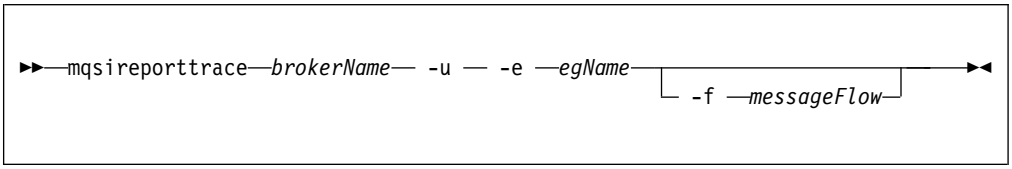
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

Syntax:

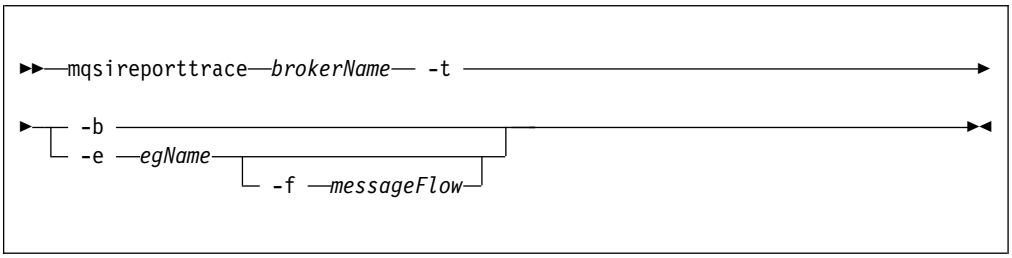
Report broker-wide active user and service trace settings:



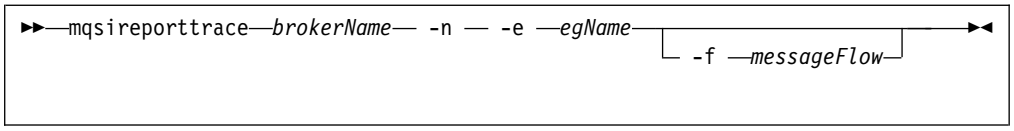
Report individual component user trace settings:



Report individual component service trace settings:



Report Trace nodes:



Parameters:

brokerName
(Required) The name of a broker; this name is case sensitive on Linux and UNIX systems.

-e *egName*
(Required for component user trace, otherwise optional) The label of the execution group for which a report is required.

-f *messageFlow*
(Optional) The label of the message flow for which a report is required. This option is valid only if you have specified an execution group.

-u (Required for component user trace, otherwise optional) Derive report information from the user trace.

Additional parameters exclusive to service trace:
Use these options only when directed to do so by your IBM Support Center, or by a `BIPxxxx` message.

-b (Alternative to **-e** on all platforms) Request a report for `agent` function.

-t (Required for component service trace, otherwise optional) Derive report information from the service trace.

Additional parameters exclusive to Trace nodes:

-n Report the setting of the Trace node switch. One BIP message is reported for each message flow.

Examples:
To derive report information from service trace for execution group exgrp1 in broker MB7BROKER, enter the command:

```
mqsireporttrace MB7BROKER -t -e "exgrp1"
```

To report the setting of the Trace node switch for execution group exgrp1 in broker MB7BROKER, enter the command:

```
mqsireporttrace MB7BROKER -n -e "exgrp1"
```

To report all active trace settings in broker MB7BROKER, enter the command:

```
mqsireporttrace MB7BROKER
```

Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

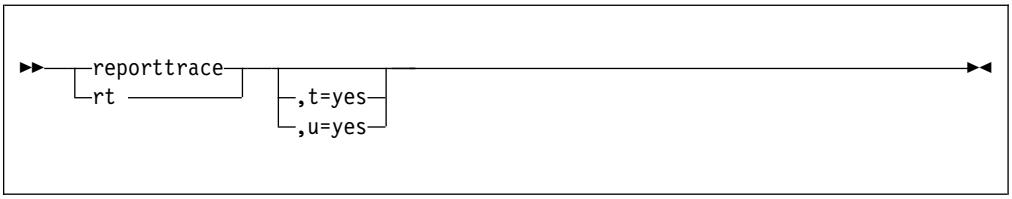
mqsireporttrace *command - z/OS:*

Use the **mqsireporttrace** command to display the trace options currently in effect.

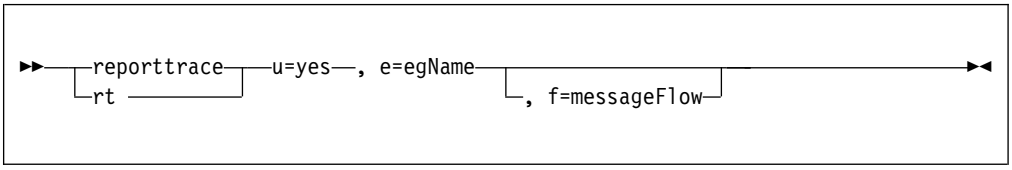
Syntax:

z/OS console command:

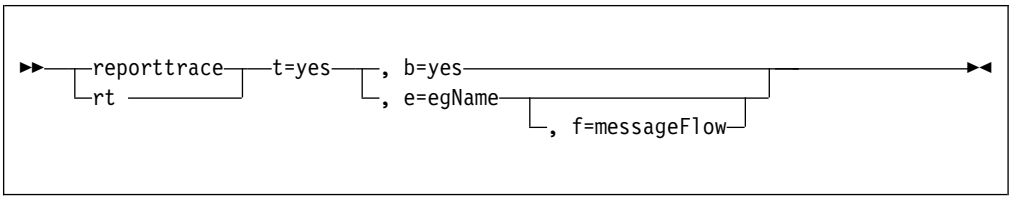
Report broker-wide active user and service trace settings:



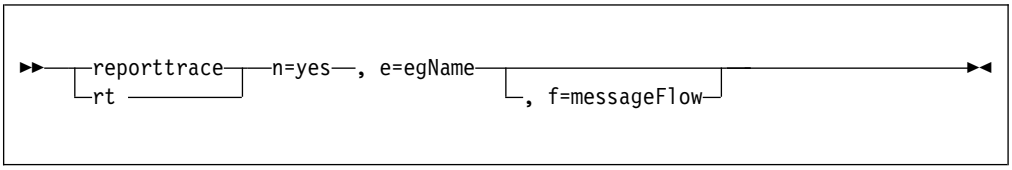
Report individual component user trace settings:



Report individual component service trace settings:



Report Trace nodes:



Parameters:

-e *egName*
(Required for component user trace, otherwise optional) The label of the execution group for which a report is required.

This name is case sensitive; include the name in single quotes if it contains mixed-case characters.

-f *messageFlow*
(Optional) The label of the message flow for which a report is required. This option is valid only if you have specified an execution group.

This name is case sensitive; include the name in single quotes if it contains mixed-case characters.

-u (Required for component user trace, otherwise optional) Derive report information from the user trace.

Additional parameters exclusive to service trace:
Use these options only when directed to do so by your IBM Support Center or by a BIPxxxx message.

-b (Alternative to **-e** on all platforms) Request a report for `agent` function.

-t (Required for component service trace, otherwise optional) Derive report information from the service trace.

Additional parameters exclusive to Trace nodes:

n=yes
Report the setting of the Trace node switch. One BIP message is reported for each message flow.

Examples:
To report information from service trace for execution group exgrp1, enter the command:

```
F MQP1BRK,rt t=yes, e='exgrp1'
```

To report the setting of the Trace node switch for execution group exgrp1, enter the command:

```
F MQP1BRK,rt n=yes, e='exgrp1'
```

To report all active trace settings in broker MQP1BRK, enter the command:

```
F MQP1BRK,rt
```

Related reference:

"Trace node" on page 4942
Use the Trace node to generate trace records that you can use to monitor the behavior of a message flow.

"Syntax diagrams" on page 3677

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

mqsirestorebroker command:

Use the **mqsirestorebroker** command to restore the broker configuration from a backup file.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting `BIPRSBK`; see "Contents of the broker PDSE" on page 3991.

Purpose:

The **mqsirestorebroker** command restores the broker configuration from a backup file that you have created by using the **mqsibackupbroker** command. You can restore a broker only on a computer that has an identical configuration; the operating system must be at the same level, and the broker and queue manager names must be identical.

Usage notes:
The command restores the following persistent configuration data associated with the broker that is contained in the backup file:

- Deployed resources; message flows, dictionaries, JAR files, and other runtime resources that you have previously deployed in a BAR file.
- Execution groups.
- Broker configuration; for example, configurable services.

Always stop the broker before you run this command. If you specify **-c** to restore common configuration data that is shared with other brokers, you must also stop all brokers with which this broker shares that data. If you run this command when a relevant broker is active, the results are unpredictable.

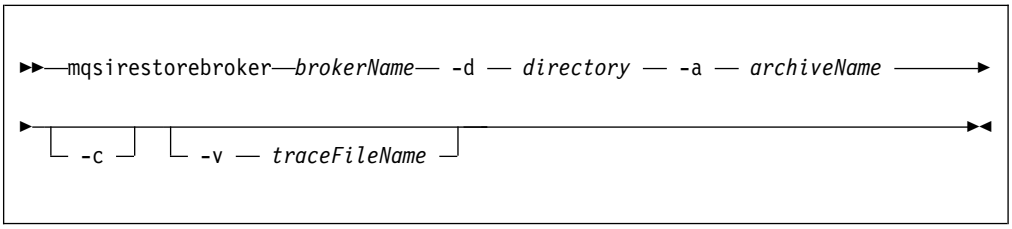
If the **mqsibackupbroker** command that created the backup file includes information about files that were locked when the backup was taken, and therefore cannot be backed up, the **mqsirestorebroker** command returns the names of the files affected.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Syntax:



Parameters:

brokerName
(Required) The name of the broker that you want to restore. You must specify the name as the first parameter. If the name that you specify does not match the name of the broker associated with the backup file, the command fails.

-d *directory*
(Required) The directory in which the backup file is stored. The file must be stored in a file system that can be accessed by the computer on which you run this command.

-a *archiveName*
(Required) The name of the backup (archive) file.

-c
(Optional) Specify this parameter to restore all configuration data that is shared with other brokers on the same computer; for example, profiles.

-v *traceFileName*
(Optional) The location of a trace file that records details of the actions taken by the command.

Examples:
The following example restores broker MB7BROKER on Windows:

```
mqsirestorebroker MB7BROKER -d C:\MQSI\BACKUP -a 20090101.zip
```

Related tasks:

"Restoring the broker" on page 1015
Restore a broker configuration that you backed up previously.

The sample BIPRSBK file that is shipped with WebSphere Message Broker is included here for your reference.

mqsisetdbparms command:

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPSDBP.

Purpose:
Use the **mqsisetdbparms** command to set security credentials for a specific user ID and password (or SSH identity file) for the following resources:

- A CICSConnection configurable service
- A data source name (DSN) that is accessed from a message flow
- An EmailServer configurable service
- An FtpServer configurable service
- An IMSConnect configurable service
- A JDBCProvider configurable service
- A JMS or JNDI resource, for example a JMSProviders configurable service
- Kerberos Key Distribution Center (KDC) client credentials for SOAPRequest nodes with a WS-Security policy set and bindings that specify Kerberos
- Lightweight Directory Access Protocol (LDAP) bind credentials for the broker security manager
- The Service Federation Manager (SFM) user ID and password credentials to authorize Service Control Management Protocol (SCMP) Atom requests
- An SMTP configurable service
- The broker keystore password
- An account name, with a user name and password, for the WebSphere Adapters
- A WebSphere Service Registry and Repository (WSRR) configurable service

The user ID and password pair is created in the DSN folder under the broker registry folder.

You can run the **mqsisetdbparms** command while the broker is running. However, you must stop and start each execution group that uses a particular DSN, before that information is read and used by that execution group.

This behavior is different from the default behavior in WebSphere Message Broker where the broker must be stopped to issue this command.

If you are using the **mqsisetdbparms** command on Linux or a UNIX console, add an escape character if you use one or more of the reserved characters. For example, you must specify these values:

```
mqsisetdbparms DUMMYBROKER -n ftp::DUMMYFTP -u dummy\\user -p abcdef
```

Do not use the following format:

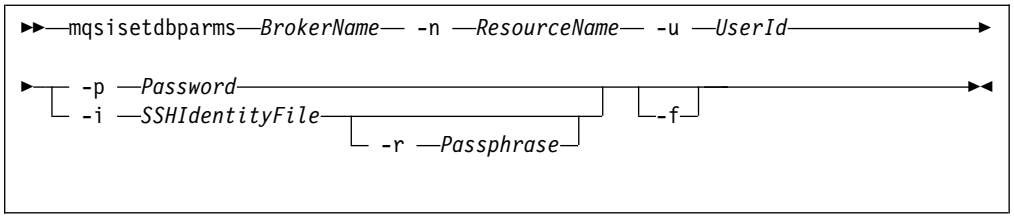
```
mqsisetdbparms DUMMYBROKER -n ftp::DUMMYFTP -u dummy\user -p abcdef
```

If you use the latter format, the backslash character (\) in the user ID or password is ignored. The example causes the FTP connection through the FileInput node to fail with incorrect user credentials.

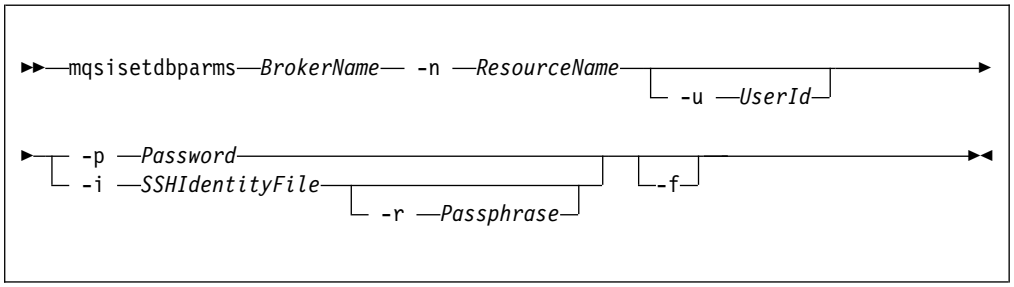
For a full list of reserved characters, and the rules that are associated with those characters when you use quotation marks and escape characters, see the documentation that is supplied with the shell.

Syntax:

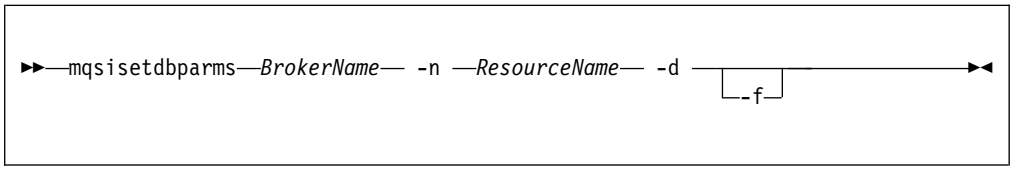
Create:



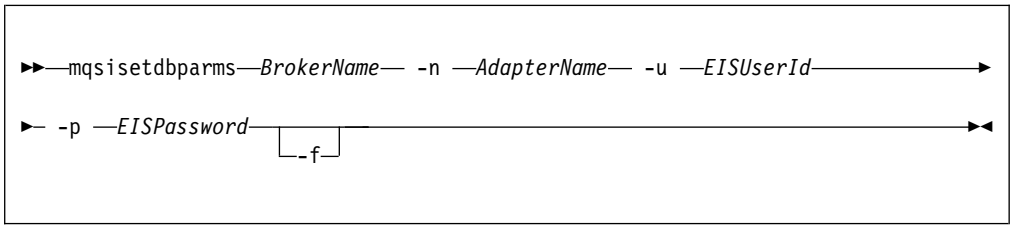
Alter:



Delete:



Adapter connection:



Parameters:

BrokerName
(Required) The name of the broker for which settings are to be created, altered, or deleted.

-n *ResourceName* **or** *AdapterName*
(Required) This parameter identifies one of the following resources:

- The ODBC data source for which the user ID and password pair are to be created or modified. The *ResourceName* takes the form `dsn::`*datasource_name*, where *datasource_name* identifies the data source name for the database to which you want to connect.

  Data source names are used by the following nodes:

  – Compute
  – Database
  – DatabaseRetrieve

- DatabaseRoute
- DataDelete
- DataInsert
- DataUpdate
- Filter
- Mapping
- Warehouse

If you use the same DSN to refer to the same database instance from multiple nodes, the same user ID and password pairing is used.

To define default values for user ID and password for the broker to use for all data source names for which you have not set specific values, specify `dsn::DSN`.

If you migrated the broker from a previous version, the values that you define on this command replace the values that you set on the **mqsicreatebroker** or **mqsichangebroker** commands before migration; the relevant parameters on those commands are deprecated in WebSphere Message Broker Version 7.0.

- The name of the security identity that is used to connect an IBM Sterling Connect:Direct CDOutput or node to itsConnect:Direct server. The *ResourceName* takes the form `cd::secId`, where `secId` is specified as the value of the security identity property on a `CDServer` configurable service. Change security identity `cd::default` to alter the default user ID and password.
- The name of the security identity that is used to authenticate a CICS Transaction Server for z/OS connection. The *ResourceName* takes the form `cics::secId`, where `secId` is specified as the value of the `Security identity` property on the CICSRequest node or in the **-n securityIdentity** property of the associated CICSConnection configurable service.
- The name of the security identity that the EmailInput node or EmailServer configurable service use to authenticate with an email server to retrieve email messages. The *ResourceName* takes the form `email::secId`, where `secId` is specified as the value of the `Security identity` property on the EmailInput node or in the **-n securityIdentity** property of the associated EmailServer configurable service.
- The name of the security identity that is used to authenticate a JDBC type 4 connection. The *ResourceName* takes the form `jdbc::secId`, where `secId` is specified as the value of the **-n securityIdentity** property of the associated JDBCProvider configurable service on the **mqsicreateconfigurableservice** or **mqsichangeproperties** command.

  Specify `jdbc::JDBC` to define default values for user ID and password for the broker to use for all JDBC connections for which you have not set specific values.
- The name of the security identity that is used to authenticate a connection to a JMS or JNDI resource. The *ResourceName* takes the form `jms::secId` or `jndi::secId`, where `secId` is specified as the value.
- The name of the security identity that is used for retrieving client credentials from the Kerberos Key Distribution Center (KDC) by a SOAPRequest node with a policy set and binding specifying Kerberos.
- The name of the security identity that is used to authenticate an LDAP directory.

Specify `ldap::<servername>` to define credentials for an individual server. If you want the broker to bind anonymously to this server, specify `anonymous` as the user ID.

Specify `ldap::LDAP` to define a default setting. The broker uses the specified user ID and password values for all servers that do not have an explicit `ldap::<servername>` entry. Therefore, all servers that previously used anonymous bind by default start to use the details defined in an `ldap::LDAP` entry.

- The name of the adapter connection to the external EIS. The *AdapterName* takes the form `eis::adapterName`, where `adapterName` is specified as the value.
- The name of the IMS connection. The *ResourceName* takes the form `ims::secId`, where `secId` is the same as the value of the `Security identity` property on the IMSRequest node or in the **-n securityIdentity** property of the associated IMSConnect configurable service.
- The name of the security identity that is used to authenticate an SMTP server.
- The name of the security identity that is used to authenticate a connection to an FTP server. The *ResourceName* takes the form `ftp::secId`, where `secId` is specified as the value of the `Security identity` property of the FileInput or FileOutput node, or in the **-n securityIdentity** property of the associated FtpServer configurable service on the **mqsicreateconfigurableservice** or **mqsichangeproperties** command.
- The name of the security identity that is used to authenticate a connection to an SFTP server. The security identity is used to locate the user name and password or the Secure Shell (SSH) identity file. The *ResourceName* takes the form `sftp::secId`, where `secId` is specified as the value of the `Security identity` property of the FileInput or FileOutput node, or in the **-n securityIdentity** property of the associated FtpServer configurable service on the **mqsicreateconfigurableservice** or **mqsichangeproperties** command.
- The name of the security identity that is used to authenticate a broker keystore.
- The name of the security identity that is used to authenticate a WSRR configurable service.
- The name of the security identity for SFM. Specify `sfm::scmp` to define the basic access authentication credentials that must be present in every SCMP Atom request that is received on the SFM HTTP(S) port.

  The user ID and password that are configured in this way must match the user ID and password that the SFM console can provide. It is good practice to configure SFM to use SSL when you set basic access authentication.

-u *UserId* **or** *EISUserId*
(Required for Create and adapter connection; Optional for Alter) The user ID to be associated with this resource or EIS.

-p *Password*
(Required for Create, Alter, and adapter connection) The password to be associated with this resource or EIS.

For compatibility with existing systems, you can still specify `<password>`. However, if you do not specify a password with this parameter when you run the command, you are prompted to enter a password during its invocation, and to enter the password a second time to verify that you have entered it correctly.

On z/OS only, this parameter is optional with the `dsn::DSN` resource type. If you omit this parameter, the broker uses the started task user ID to connect to DB2. The broker uses the user ID that you specified with the **-u** parameter when it constructs fully qualified SQL statements; for example, for stored procedures. If you create fully qualified SQL statements, the broker uses these statements as created.

This parameter is required with the `ftp::` resource type, but is optional with the `sftp::` resource type. However, if you do not specify a password with an `sftp::` resource, you must specify the *SSHIdentityFile* parameter.

-i *SSHIdentityFile*
(Optional) The name of an identity file, in the OpenSSH format, to be used for authentication with SFTP, in place of a password. You must specify either a password or an identity file, but not both. If you specify an identity file, you can also specify a pass phrase with the *Passphrase* parameter.

On z/OS systems, known hosts files and SSH identity files are stored in EBCDIC format, and on other operating systems they are stored in ASCII format.

-r *Passphrase*
(Optional) The pass phrase that is used for authentication with SFTP. This parameter is valid only when the *SSHIdentityFile* parameter is also specified. The pass phrase is used during decryption of the identity file.

-d (Required for Delete) This parameter deletes completely the resource from the broker registry.

-f (Optional) Specify this parameter to process the **mqsisetdbparms** command only when the broker itself is stopped.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Ensure that the registry is appropriately secured to prevent unauthorized access.

Examples:
CICS connections

Use the **mqsisetdbparms** command in the following format to associate a user ID and password pair with CICS.

```
mqsisetdbparms broker name -n ResourceName -u userID -p password
```

For example:

```
mqsisetdbparms MB7BROKER -n cics::mySecurityIdentity -u myUserID -p myPassword
```

Data source names

The following example show use of the command for a specific data source name (no Universal Record Identifier (URI) prefix is required for this purpose):

```
mqsisetdbparms MB7BROKER -n Database1 -u MQUserId -p password
```

The following example deletes all the values that are defined for a specific data source name from the broker registry:

```
mqsisetdbparms MB7BROKER -n ClientDB -d
```

The following example shows how to set up a default user ID and password for the broker to use for all data source names where no explicit values have been set:

```
mqsisetdbparms MB7BROKER -n dsn::DSN -u UserId1 -p password1
```

The following examples show the use of the additional prefix `odbc::`. Use this option to set the user ID and password at the execution group level, and at the broker level:

```
mqsisetdbparms MB7BROKER -n odbc::DSN -u myuserid
  -p mypassword
mqsisetdbparms MB7BROKER -n odbc::DSN::default -u myuserid -p mypassword
```

Email server connections

Use the **mqsisetdbparms** command in the following format to associate a user ID and password pair with an email server for the EmailInput node or the EmailServer configurable service to use to retrieve email messages.

```
mqsisetdbparms broker name -n ResourceName -u userID -p password
```

For example:

```
mqsisetdbparms MB7BROKER -n email::mySecurityIdentityObjectName
-u myUserID -p myPassword
```

IBM Sterling Connect:Direct

Use the **mqsisetdbparms** command in the following format to associate a user ID and password pair with a Connect:Direct server.

```
mqsisetdbparms broker name -n ResourceName -u userID -p password
```

For example:

```
mqsisetdbparms MB7BROKER -n cd::default -u mqbroker -p xxxxxxx
```

JDBC type 4 connections

Use the **mqsisetdbparms** command to associate a user ID and password pair with a JDBC type 4 connection. The value that you specify for the **-n ResourceName** must have a prefix of `jdbc::`, followed by the value that matches the **-n securityIdentity** property of the associated JDBCProvider configurable service.

```
mqsisetdbparms broker name -n resource_name -u userID -p password
```

For example:

```
mqsisetdbparms MB7BROKER -n jdbc::mySecurityIdentity -u myuserid -p secretpw
```

The following example shows how to set up a default user ID and password for the broker to use for all JDBC connections for which you have not set specific values:

```
mqsisetdbparms MB7BROKER -n jdbc::JDBC -u UserId2 -p password2
```

JMS and JNDI resource names

The following examples show the use of the command when the URI for a JMS or JNDI resource name is substituted for the **-n ResourceName** parameter.

For a JMS resource, the URL prefix is "jms::"; for JNDI, the prefix is "jndi::".

On Linux and UNIX systems, if the parameter string includes a backslash (\) character, you must escape from this character by using a second backslash character (\\) when you enter the **mqsisetdbparms** command.

For example, to specify a user ID of myuserid and password secret for JMS topic connection factory tcf1, use the following syntax:

```
mqsisetdbparms MB7BROKER -n jms::tcf1 -u myuserid -p secret
```

Similarly, to specify the same security for a JNDI initial context com.sun.jndi.fscontext.RefFSContextFactory, enter the following command:

```
mqsisetdbparms MB7BROKER -n jndi::com.sun.jndi.fscontext.RefFSContextFactory
     -u myuserid -p secret
```

JMS node account names

The preceding examples describe how to configure security for JMS and JNDI resources for *all* JMS nodes that use those resources in a broker.

To increase the degree of control that you have in the security of JMS nodes, you can associate a resource with an *account name*. The account name comprises the message flow name that is concatenated with the node label by using the underscore character (_):

Message Flow Name_Node label

For example, where the message flow name is MyJMSFlow1, and you require a specific user ID and password for JMSInput node MyJMSInput1, the resulting account name is:

MyJMSFlow1_MyJMSInput1

You can then specify the account name string in the **-n ResourceName** parameter on the **mqsisetdbparms** command by prefixing the account name with the *resource type*, and concatenating the account name with an at sign (@) character followed by the resource name:

resource typeaccount name@resource name

Therefore, assuming a JMS resource name of tcf1, used by JMSInput node MyJMSInput1 in message flow MyJMSFlow1, the following resource name is used:

jms::MyJMSFlow1_MyJMSInput1@tcf1

To specify a user ID of myuserid, a password of secret, and the resource name that is created from the account name, use the following syntax:

```
mqsisetdbparms MB7BROKER -n jms::MyJMSFlow1_MyJMSInput1@tcf1
                 -u myuserid -p secret
```

LDAP servers

Use the **mqsisetdbparms** command to set up authorization credentials for the LDAP server ldap.mydomain.com:

```
mqsisetdbparms MB7BROKER -n ldap::ldap.mydomain.com -u ldapuid -p ********
```

To set up authorization for other servers, use the command to set up default credentials:

```
mqsisetdbparms MB7BROKER -n ldap::LDAP -u ldapother -p ********
```

If you want the broker to bind anonymously to an LDAP server, specify the server name and the user ID `anonymous`:

```
mqsisetdbparms MB7BROKER -n ldap::ldap.mydomain2.com -u anonymous -p ********
```

For the user ID `anonymous`, the password is always ignored.

WebSphere Adapters account names

Use the **mqsisetdbparms** command in the following format to configure an account name with a user name and password for the WebSphere Adapters.

```
mqsisetdbparms broker name -n adapter name -u user name -p password
```

For example:

```
mqsisetdbparms MB7BROKER  -n eis::SAPCustomerInbound.inadapter -u sapuid -p ********
mqsisetdbparms MB7BROKER  -n eis::TwineballInbound.inadapter -u mqbroker -p ********
```

IMS connections

Use the **mqsisetdbparms** command in the following format to associate a user ID and password pair with an IMS Connect connection.

```
mqsisetdbparms broker name -n resource_name -u userID -p password
```

For example:

```
mqsisetdbparms MB7BROKER -n ims::mySecurityIdentity -u myuserid -p mypassword
```

FTP and SFTP server connections

Use the **mqsisetdbparms** command to associate a user ID and password with an FTP server connection:

```
mqsisetdbparms MB7BROKER -n ftp::identityA -u user1 -p MyPassword
```

Use the **mqsisetdbparms** command to associate a user ID and password with an SFTP server connection:

```
mqsisetdbparms MB7BROKER -n sftp::identityB -u user2 -p MyPassword
```

Use the **mqsisetdbparms** command to associate a user ID and SSH identity file with an SFTP server connection:

```
mqsisetdbparms MB7BROKER -n sftp::identityC -u user3 -i C:\key_rsa_no_pp
```

Use the **mqsisetdbparms** command to associate a user ID, SSH identity file, and pass phrase with an SFTP server connection:

```
mqsisetdbparms MB7BROKER -n sftp::identityD -u user4 -i C:\key_rsa_pp -r MyPassPhrase
```

Service Federation Management

Use the **mqsisetdbparms** command to set the SCMP enablement to be secured with basic access authentication by using a user ID and password:

```
mqsisetdbparms MB7BROKER  -n sfm::scmp -u user1 -p MyPassword
```

Use the **mqsisetdbparms** command to clear any previous settings and specify that the SCMP enablement does not require basic access authentication:

```
mqsisetdbparms MB7BROKER -n sfm::scmp -d
```

Kerberos

Use the **mqsisetdbparms** command to provide the broker with the Kerberos client credentials for accessing the Kerberos Key Distribution Center (KDC). These credentials (which are required for SOAPRequest nodes) can also be provided in the broker properties tree.

To set KDC credentials for a specific realm that is used by SOAPRequest nodes in a specific execution group:

```
mqsisetdbparms MB7BROKER -n kerberos::realm1::ExecutionGroup1 -u clientId -p ClientPassword
```

To set KDC credentials for a specific realm that is used by SOAPRequest nodes in any execution group:

```
mqsisetdbparms MB7BROKER -n kerberos::realm1 -u clientId -p ClientPassword
```

To set KDC credentials for any realm that is used by SOAPRequest nodes in any execution group:

```
mqsisetdbparms MB7BROKER -n kerberos::kerberos -u clientId -p ClientPassword
```

mqsisetsecurity command:

Use the **mqsisetsecurity** command to create the Windows groups that WebSphere Message Broker requires for secure access to its runtime libraries and data.

Supported platforms:

- Windows

Purpose:
The **mqsisetsecurity** command runs automatically as part of the installation process of the Broker component.

The installation wizard calls the **mqsisetsecurity** command which creates a new security group called mqbrkrs, adds your current (logged on) user ID to the group mqbrkrs, and adds your current user ID to the group mqm, if that group exists. If WebSphere MQ is installed after WebSphere Message Broker, you can issue this command to add your account to the group mqm.

Syntax:

Parameters:
None

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

In addition, this command is supported on Linux and UNIX systems where it only creates the group mqbrkrs.

Related concepts:

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

Related reference:

"Security requirements for Windows systems" on page 3651
Security requirements depend on the administrative task that you want to perform.

`mqsistart` command:

Use the **`mqsistart`** command to start the specified broker if all initial verification tests complete successfully.

Supported platforms:

- Windows
- Linux and UNIX systems
- z/OS as a console command.

Purpose:
The **`mqsistart`** command:

- On distributed systems, starts the associated queue manager if it is not running.
- Checks that the broker environment is set up correctly; for example, that the installed level of Java is supported.
- Verifies that the WebSphere MQ queues are defined and accessible.

  The command completes these checks, and reports all errors in the system log, or to the command line, or both. If one or more checks fail, the command does not start the component.
- On Linux and UNIX systems, where the **`mqsisetdbparms`** command has been used to associate the datasource with the broker, the **`mqsistart`** command:
  - Checks broker connectivity to, and
  - Performs tests against

  any user data sources where the WebSphere Message Broker Database Extender (IE02) SupportPac is being used for extended database support.

  If any issues are identified, a warning is reported to the system log and command line. However, this step does not prevent the broker from starting cleanly.
- Checks the publish/subscribe mode (attribute PSMODE) of the queue manager associated with the broker. If the PSMODE is set to DISABLED, it is changed to

COMPAT and this is reported to the system log. If the PSMODE is already set to COMPAT or ENABLED, the setting is not changed.

Select the appropriate link for details of this command on the platform, or platforms, that your enterprise uses:

- "**mqsistart** command - Windows, Linux, and UNIX platforms"
- "**mqsistart** command - z/OS" on page 3968

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

The broker starts only if the user ID under which it will run is authorized to access both the following locations. On Windows, the user ID is defined by the *ServiceUserID* specified on **mqsicreatebroker**; on Linux and UNIX systems, it is the user ID with which you run this command:

- Home directory, where WebSphere Message Broker has been installed.
- Working directory, if specified by the **-w** flag on the **mqsicreatebroker** command.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsistart *command - Windows, Linux, and UNIX platforms:*

Use the **mqsistart** command to start a broker.

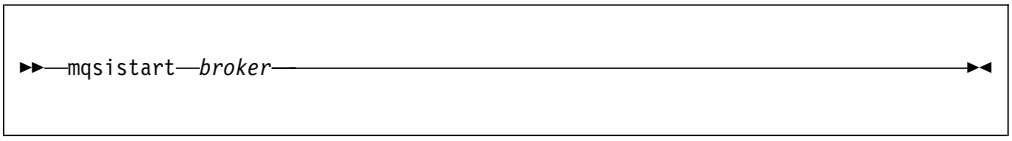
Purpose:
If the queue manager associated with this broker (defined by the **mqsicreatebroker** command) is not already running, it is also started by this command. However, no listeners, channels, or channel initiators associated with the started broker are started. Use WebSphere MQ Explorer to start any required listeners, channels, or channel initiators.

Successful completion of this command indicates that the Windows service, or Linux or UNIX daemon, has started successfully, and that the broker startup has been initiated. Check the Windows system event log or the Linux or UNIX syslog to determine if the broker and all related software have started successfully, are initially active, and remain in an active state.

All errors that have prevented successful startup, that are detected by the broker, are recorded in the log. Continue to monitor the Windows system event log or Linux or UNIX syslog.

On Windows platforms, the queue manager is not started as a service, and stops if you log off. To avoid this happening, either remain logged on, or change the startup status of the queue manager service as described in "Starting a WebSphere MQ queue manager as a Windows service" on page 929. (If you lock your workstation, the queue manager does not stop).

Syntax:



Parameters:

broker
(Required) Specify the name of the broker that you want to stop.

On Linux and UNIX systems, all names are case sensitive.

Responses:

- BIP8012 Unable to connect to system components
- BIP8013 Broker does not exist
- BIP8015 Broker cannot be started
- BIP8018 Broker running
- BIP8024 Unable to locate executable
- BIP8025 Broker disabled
- BIP8026 Unable to start broker
- BIP8027 Unable to start WebSphere MQ
- BIP8028 WebSphere MQ unavailable
- BIP8030 Unable to modify user privileges
- BIP8048 Unable to start queue manager
- BIP8056 Unknown queue manager
- BIP8093 Queue manager being created
- BIP8094 Queue manager stopping
- BIP8116 Starts a broker

Examples:
To start the broker MB7BROKER:

```
mqsistart MB7BROKER
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsistart *command - z/OS:*

Use the **startcomponent** command to start a broker when its controller (control process) is already running, or the **start (/S)** command to bring a broker into a state in which you can run the appropriate **change** command.

Purpose:
The following table distinguishes between the **start (/S)** and **startcomponent** commands, and lists the available options.

Command	Description
/S *Broker started task name*	Starts the broker.
/F *Broker started task name*,SC	Starts the broker from a 'stop component' state.

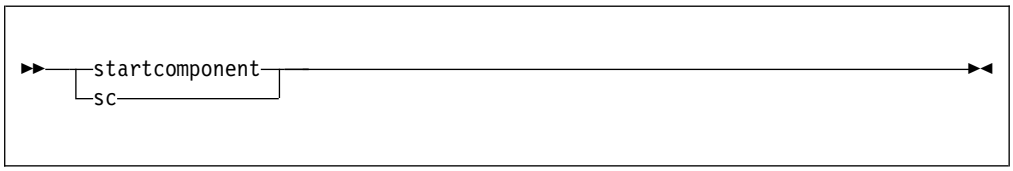
When the controller address space is started, the broker starts automatically. You can change this behavior by using an optional start parameter in the started task. If you set the parameter to MAN, the broker does not start automatically; the default is AUTO.

Issuing commands against the controller means issuing start, stop, or modify commands from the console to the controller address space. Two scenarios apply when you use this command:

1. The controller is started with the parameter MAN instead of AUTO.
2. After a **stopcomponent** command, you must restart the broker.

Syntax:

z/OS console command - startcomponent:
Synonym: sc



Examples:

```
/F MQ00BRK,sc
```

Related tasks:

"Starting and stopping a broker" on page 921
Run the appropriate command to start or stop a broker.

Related reference:

"Syntax diagrams" on page 3677

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification

tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsistartmsgflow command:

Use the **mqsistartmsgflow** command to start execution groups and message flows.

Supported operating systems:

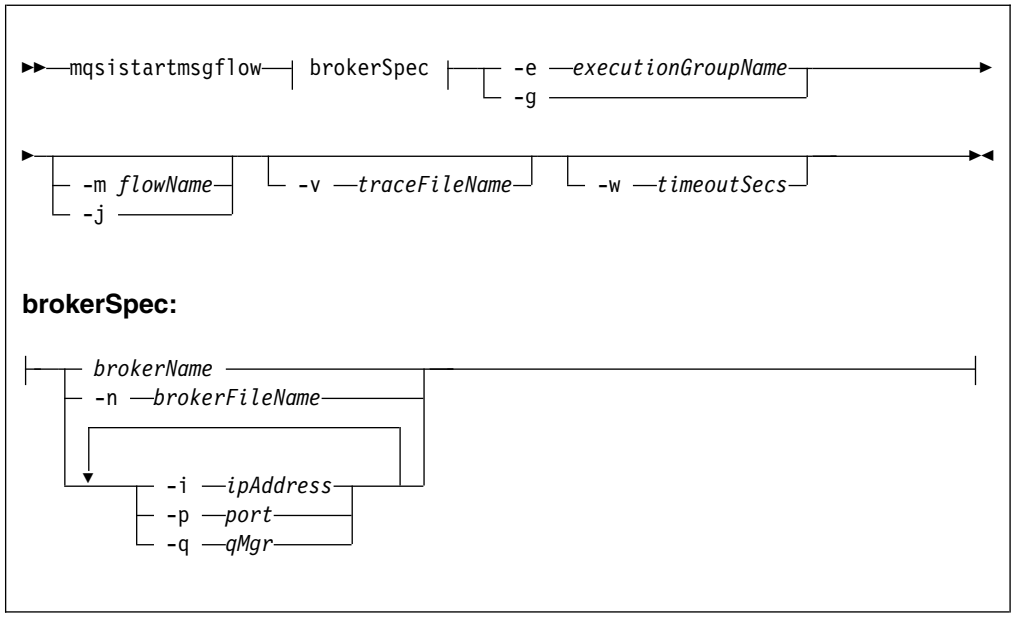
- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPSTMF; see "Contents of the broker PDSE" on page 3991

Purpose:
You can use the **mqsistartmsgflow** command for the following purposes:

- To start a specific message flow in an execution group
- To start all message flows in the execution group
- To start a specific execution group
- To start all execution groups

To use this command, you must have already deployed message flows, if specified, to the broker in a broker archive (BAR) file. You can start message flows only if the execution group to which the message flow is deployed is running.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3971.

-e *executionGroupName*
(Optional) The name of the execution group for which to start message flows. You must specify either **-e** or **-g**.

If you specify **-e** without **-m** or **-j**, the execution group is started. Message flows are started only if they were running when the execution group was stopped.

If you specify **-e** with **-m** or **-j**, the execution group must be running. If the execution group is stopped, the request is rejected.

-g (Optional) The specified message flow or flows are started on all execution groups on the specified broker. You must specify either **-e** or **-g**.

If you specify **-g** without **-m** or **-j**, all execution groups are started, but message flows are started only if they were running when the execution group was stopped.

If you specify **-g** with **-m** or **-j**, the specified message flow or flows are started only if the execution group is running. The request checks all execution groups, and starts message flows on execution groups that are currently running. Error BIP2851 is reported for each execution group that is not running.

-j

(Optional) All message flows in the specified execution group are started.

If you do not specify **-j** or **-m**, the execution group identified by **-e** (if specified), or all execution groups on this broker, are started. Message flows that were running when the execution group was last stopped are also restarted.

-m *flowName*
(Optional) The name of the message flow being started.

If you do not specify **-m** or **-j**, the execution group identified by **-e** (if specified), or all execution groups on this broker, are started. Message flows that were running when the execution group was last stopped are also restarted.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to

process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Start a named message flow that you have deployed to execution group `eg1` on the broker MB7BROKER:

```
mqsistartmsgflow MB7BROKER -e eg1 -m simpleflow
```

Ensure that all message flows are running on the local broker MB7BROKER:

```
mqsistartmsgflow MB7BROKER -g -j
```

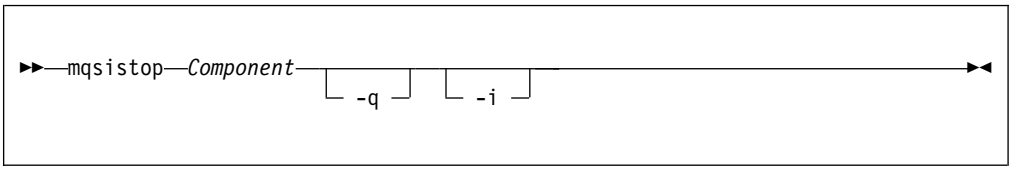
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

mqsistop *command - Windows, Linux, and UNIX systems:*

How to use the **mqsistop** command on Windows, Linux, and UNIX systems.

Purpose:
Use the **mqsistop** command to stop a WebSphere Message Broker component.

Syntax:



Parameters:

Component
(Required) Specify the name of the broker that you want to stop.

On Linux and UNIX systems, all names are case sensitive.

-q (Optional) Stops the WebSphere MQ queue manager associated with this component.

Specify this flag only if the WebSphere Message Broker component is the last (or only) WebSphere Message Broker component active on this queue manager. The **mqsistop** command initiates a controlled shutdown of the queue manager, and informs other users of the queue manager that it is closing.

Stop other WebSphere Message Broker components that use this queue manager before you issue the **mqsistop** command with this option; alternatively stop them afterward or restart the queue manager.

If you use this option, be aware that any listeners associated with this queue manager are not stopped with the queue manager. Stop these listeners manually after issuing the **mqsistop** command.

-i (Optional) Immediately stops the broker.

Specify this flag only if you have already tried, and failed, to stop the broker in a controlled fashion by using the **mqsistop** command without the **-i** flag.

Responses:

- BIP8012 Unable to connect to system components
- BIP8013 Component does not exist
- BIP8016 Component cannot be stopped

- BIP8019 Component stopped
- BIP8030 Unable to modify user privileges
- BIP8049 Unable to stop queue manager
- BIP8093 Queue manager being created
- BIP8094 Queue manager stopping

Examples:
To stop the broker, *mybroker*, and the WebSphere MQ queue manager associated with it:

```
mqsistop mybroker -q
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsistop *command - z/OS:*

Use the **mqsistop** command to stop a WebSphere Message Broker broker; the controller must be running.

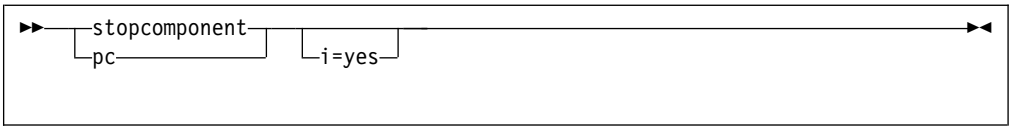
Purpose:
The following table distinguishes between the **stop (/P)** and **stopcomponent** commands, and lists the available options:

- Use the **stop (/P)** command to bring a component into a state in which you can run the appropriate **change** command.
- Use the **stopcomponent** command to stop a broker when its controller (control process) is already running.

Component	Command	Description
Broker	/P <Broker started task name> /F <Broker started task name>,P /F <Broker started task name>,PC	Stop broker. Stop broker; this is the same as /P. You can also use /F <broker started task name>,STOP Stop broker component. This stops the broker process (including any execution group address spaces), but leaves the message broker console command server running inside the controller address space. This allows you to run the "**mqsichangebroker** command" on page 3723 console command. Restart the broker afterward by running the "**mqsistart** command" on page 3965 (SC) console command.

Syntax:

z/OS console command - stopcomponent:
Synonym: pc



Parameters:

-i (Optional) Immediately stop the broker.

Specify this flag only if you have already tried, and failed, to stop the broker in a controlled fashion by using the **mqsistop** command without the **-i** flag.

This command is rejected by the WebSphere Message Broker console command server if a previous stop command has failed to complete. This can occur, for example, if one or more execution group address spaces cannot shutdown.

Examples:

```
F MQ00BRK,pc
```

Related reference:

"Syntax diagrams" on page 3677

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

mqsistopmsgflow command:

Use the **mqsistopmsgflow** command to stop execution groups and message flows.

Supported operating systems:

- Windows
- Linux and UNIX systems
- z/OS. Run this command by customizing and submitting BIPSPMF; see "Contents of the broker PDSE" on page 3991

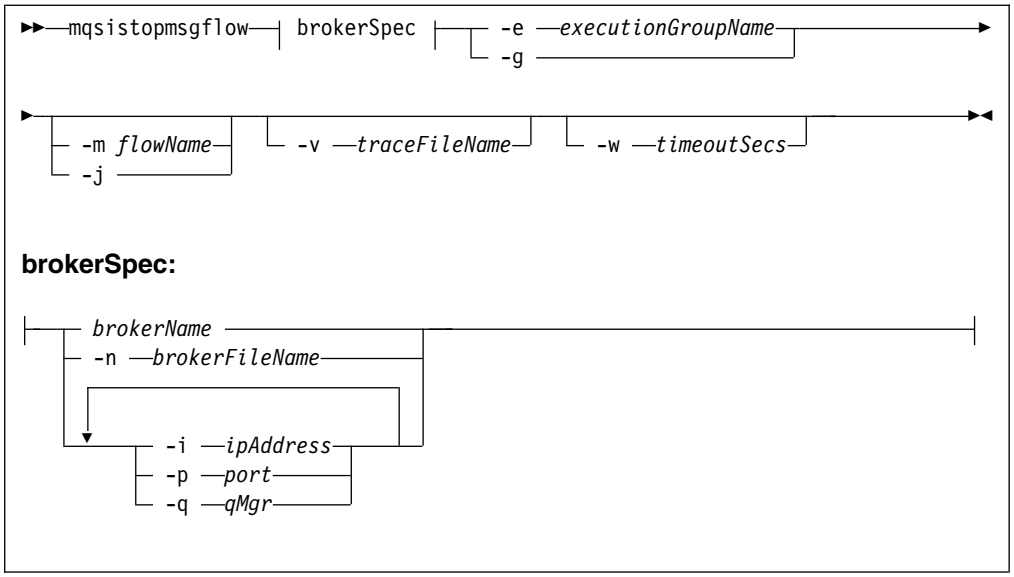
Purpose:
You can use the **mqsistopmsgflow** command for the following purposes:

- To stop a specific message flow in an execution group
- To stop all message flows in the execution group
- To stop a specific execution group
- To stop all execution groups

To use this command, you must have already deployed message flows, if specified, to the broker in a broker archive (BAR) file.

The broker processes all inflight messages and associated transactions for each message flow before stopping it. For information about how outstanding units of work are handled in this situation, see "Message flow transactions" on page 1281.

Syntax:



Parameters:

brokerSpec
(Required) You must specify at least one parameter to identify the target broker for this command, in one of the following forms:

brokerName
This parameter identifies the name of a locally defined broker. You cannot use this option if the broker is on a remote computer.

-n *brokerFileName*
This parameter identifies the name of a file that contains the connection details for a local or remote broker.

Use this option if multiple users want to connect to the same broker, or if you are using advanced connection parameters such as SSL.

To create this file, right-click the broker in the WebSphere Message Broker Explorer and select **Export *.broker file**. When prompted, navigate to the location in which you want to save the file and enter the file name; the extension `.broker` is appended automatically when you click **Save**. Include the location (path) and file name when you specify this parameter. You must ensure that the location is accessible when you run this command.

If you want to run a command that uses SSL to administer a remote broker over a secured channel, you must specify the keystore and truststore password for the connection using the IBM_JAVA_OPTIONS environment variable. See "Resolving problems when running commands" on page 3364 for further information.

-i *ipAddress*, **-p** *port*, **-q** *qMgr*
These parameters identify the connection details for the broker.

Use this option for connections to remote brokers that do not require advanced connection parameters.

If you choose this option, you must specify at least one of these three parameters; the order in which you specify them is insignificant. You cannot specify each parameter more than once.

Parameters that you omit assume default values:

- **-i** *ipAddress*: The host name or the IP address of the computer on which the broker is running. If you do not specify this parameter, a value that represents the local computer is used.
- **-p** *port*: The TCP port on which the broker's queue manager is listening. If you do not specify this parameter, the value 1414 is used.
- **-q** *qMgr*: The name of the broker's queue manager. If you do not specify this parameter, a value that represents the default queue manager on the local computer is used.

You cannot connect to a remote queue manager on z/OS; see "Usage note" on page 3978.

-e *executionGroupName*
(Optional) The name of the execution group for which to stop message flows. You must specify either **-e** or **-g**.

If you specify **-e** without **-m** or **-j**, the execution group is stopped. The state of every message flow (stopped or started) is retained, and started message flows are started when the execution group is started again.

If you specify **-e** with **-m** or **-j**, the execution group must be running. If the execution group is stopped, the request is rejected.

-g (Optional) The specified message flow or flows are stopped on all execution groups on the specified broker. You must specify either **-e** or **-g**.

If you specify **-g** without **-m** or **-j**, all execution groups are stopped. The state of every message flow (stopped or started) is retained for each execution group, and started message flows are started when the execution group is started again.

If you specify **-g** with **-m** or **-j**, the specified message flow or flows are stopped only if the execution group is running. The request checks all execution groups, and stops message flows on execution groups that are currently running. Error BIP2851 is reported for each execution group that is not running.

-j

(Optional) All message flows in the specified execution group are stopped; the execution group is not stopped.

If you do not specify **-j** or **-m**, the execution group identified by **-e** (if specified), or all execution groups on this broker, are stopped.

-m *flowName*
(Optional) The name of the message flow being stopped.

You can specify only one message flow in a single command. If you want to stop all message flows deployed to the broker, or to the execution group identified by **-e**, specify **-j**.

If you do not specify **-m** or **-j**, the execution group identified by **-e** (if specified), or all execution groups on this broker, are stopped.

-v *traceFileName*
(Optional) This parameter sends internal debug trace information to the specified file.

-w *timeoutSecs*
(Optional) This parameter specifies the time in seconds that the utility waits to ensure that the command completed; the default value is 60.

Usage note:
If you try to connect to a remote broker by specifying the **i**, **p**, and **q** parameters, or by using a connection parameter file (`.broker`), the command attempts to use WebSphere MQ Java client code. This option is not supported on z/OS, and returns the following error:

```
BIP1046E: Unable to connect with the broker (name)
```

The reported reason code is `MQRC_ENVIRONMENT_ERROR`. You must specify a local queue manager.

Authorization:
For information about platform-specific authorizations, see the following topics:

- "Security requirements for Linux and UNIX platforms" on page 3648
- "Security requirements for Windows systems" on page 3651
- "Security requirements for z/OS" on page 3655

If you have enabled broker administration security, you must also set up the authority detailed in "Tasks and authorizations for broker administration security" on page 3645.

Responses:
This command returns the following responses:

0 The command completed successfully.

2 (Failure) The broker received the deployment request but was unable to process it successfully. See the messages issued from the utility (or the Administration log) for more information.

9 (Failure) The request has been submitted to the broker, but no response was received before the timeout expired.

10 (Failure) Another user or application canceled the request operation before the broker was able to process it.

98 The broker is not running.

99 One or more of the parameters that you specified is invalid.

Examples:
Stop a named execution group on broker MB7BROKER:

```
mqsistopmsgflow MB7BROKER -e eg2
```

Stop all execution group processes on the local broker MB7BROKER:

```
mqsistopmsgflow MB7BROKER -g
```

z/OS configuration and administration specific information

The following links provide more information:
- "Administration in z/OS"
- "z/OS customization" on page 3983
- "z/OS JCL variables" on page 3994

Related concepts:

"z/OS customization overview" on page 592
After you have used SMP/E to install WebSphere Message Broker for z/OS, the installed executable code is located inside the file system. JCL samples are located in the PDS `<hlq>.SBIPSAMP`, the JCL procedures are located in the PDS `<hlq>.SBIPPROC`, and load module for synchronizing statistics with SMF are located in the PDS `<hlq>.SBIPAUTH`.

Related tasks:

Chapter 7, "Configuring brokers for test and production environments," on page 579
Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Administration in z/OS

In the z/OS environment, commands are issued through the console and others in batch jobs.

- *hlq*.`SBIPSAMP` has all the JCL samples to customize.
- *hlq*.`SBIPPROC` has all the JCL procedures to customize.

STEPNAME

The processes `BIPSERVICE` and `BIPBROKER` are in the same address space (control address space). After an Execution Group address space is started on z/OS, the STEPNAME of the address space has the following value:

- The last eight characters are taken from the Execution Group label.
- Any lowercase characters are folded to uppercase.
- Any non alphanumeric characters are changed to the character @.
- If the first character is not an alpha character, it is changed to `A`.

The STEPNAME is not guaranteed to be a unique value. However, you are strongly recommended to ensure that the last eight characters of any Execution Group labels that are deployed to a z/OS broker are unique, and contain only alphanumeric characters; note that an Execution Group label has a maximum size of 3000 bytes.

See the following topics for more information:

- "Issuing commands to the z/OS console"
- "Guidance for issuing console commands in z/OS" on page 3981
- "START and STOP commands on z/OS" on page 3981

Related tasks:

"Creating an execution group specific environment file" on page 627
You can create an execution group specific environment file, which is used instead of the default broker environment file when you restart the execution group.

Related reference:

"Issuing commands to the z/OS console"
You operate the broker using the z/OS START, STOP, and MODIFY commands.

"Guidance for issuing console commands in z/OS" on page 3981

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

Issuing commands to the z/OS console

You operate the broker using the z/OS START, STOP, and MODIFY commands.

You can issue commands, and get responses back from:

- The z/OS operator console
- The TSO CONSOLE facility
- The CONSOLE interface from REXX
- Products such as SDSF
- z/OS automation products, such as NetView

However, you are likely to need to issue commands with mixed case, because execution group names are often in mixed case. You can issue commands with mixed case on the z/OS console, using the REXX CONSOLE interface, with products like SDSF V2.10 and higher, and NetView. Releases of SDSF before V2.10, and the TSO CONSOLE facility, do not support passing mixed case data.

If you do not have support for mixed case, you can submit the commands through a batch job. For example:

```
//MI01CMD JOB MSGCLASS=H
//  COMMAND 'f MQP1BRK,ct t=yes,e='default',l=debug,f='lowmfl''
//STEP1 EXEC PGM=IEFBR14
```

If your product for issuing console commands supports mixed case input, you might need to take special actions to use mixed case. For example in SDSF on OS/390 V2.10 and above, you can enter mixed case keyword values by typing `/`, pressing `ENTER`, and entering the command in the popup window. If you enter `/` followed by the command, the command is translated to uppercase. In NetView, prefix the command with `NETVASIS` to get lowercase support.

Related reference:

"Administration in z/OS" on page 3979
In the z/OS environment, commands are issued through the console and others in batch jobs.

"Guidance for issuing console commands in z/OS" on page 3981

Guidance for issuing console commands in z/OS

These examples use a broker called MQP1BRK. Start and stop the broker using the MVS START (S) and STOP (P) commands. If you want to pass information to the broker while it is running, use the MVS MODIFY command (F) to issue commands. For example:

```
F MQP1BKR,rt
```

This list summarizes the rules you must follow when issuing console commands:

- Each command starts with a verb followed by zero or more keyword=value pairs.
- There must be one or more blanks between the verb and the first keyword.
- All characters are converted to lowercase, unless they are within quotation marks.
- Multiple keywords are separated by , with no blanks.
- The keyword is never case sensitive.
- The value is case sensitive, unless specified otherwise (for example Yes/No, trace-modes).
- Each keyword must be followed by the equals sign = and parameter value. Enter parameters in any order in the form:

  ```
  flag=value
  ```

  and separate them with commas. Repeated parameters are not allowed.
- Strings that contain blanks or special characters must be enclosed in single quotation marks ('). If the string itself contains a quotation mark, the quotation mark is represented by two single quotation marks.
- The verb and keywords are not case sensitive.
- On mixed case consoles the case of values in single quotation marks (') is not changed.
- For YES/NO flags, all case combinations are allowed.
- The maximum length of the MODIFY command is 126 characters, including

  ```
  F taskname,
  ```

An example console command:

```
F MQP1BRK,changetrace u=Yes,l=normal,e='myExecutionGroup'
```

Related reference:

"Administration in z/OS" on page 3979
In the z/OS environment, commands are issued through the console and others in batch jobs.

"Issuing commands to the z/OS console" on page 3980
You operate the broker using the z/OS START, STOP, and MODIFY commands.

START and STOP commands on z/OS

These examples use a broker called MQP1BRK. Start and stop the broker using the MVS START (S) and STOP (P) commands. If you want to pass information to the broker while it is running, use the MVS MODIFY command (F) to issue commands. For example:

```
F MQP1BRK,rt
```

The MVS command START (S) starts a broker on MVS. This initiates the control address space, plus other address spaces as needed, to run that component.

If you have problems starting the broker, use the command:

```
S <broker name>,STRTP=MAN
```

This command starts the administration task but not the execution groups.

The MVS command STOP (P) stops a server component completely, including its control address space.

For administration purposes you can bring the server component into another state, where the control address space is still running, but all other components are stopped.

For example, this is needed in order to change broker startup parameters, see "**mqsichangebroker** command" on page 3723. You can do this by using the MODIFY (/F) command on the started component, and using the startcomponent (SC) or stopcomponent (PC) options. See "**mqsistart** command" on page 3965 and "**mqsistop** command" on page 3972 for more information.

You operate the broker using the z/OS START, STOP, and MODIFY commands.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Usage data on z/OS

This topic introduces SMF 89 subtype 1 records as a method of recording accumulated usage data on z/OS.

Whenever an execution group (DataFlowEngine) address space starts on z/OS, the system registers the address space for usage data collection; the system writes this usage data information to SMF 89 subtype 1 records.

When the execution group address space stops, the system deregisters the address space. The data that is collected in the SMF 89 subtype 1 records does not correspond to the data that is collected by the Accounting and Statistics SMF 117 records.

The system writes the accumulated usage data at a scheduled interval, the maximum period of which is one hour. The timing of the interval is set by the INTERVAL value that is specified for the SMF address space.

The system writes any usage data that is produced by other products to the same SMF 89 subtype 1 record.

On registering for usage data collection, the system writes the following message to the system log:

```
BIP9272I MQ05BRK default 0 THE DATAFLOWENGINE PROCESS HAS REGISTERED SMF 89
         SUBTYPE 1 RECORD COLLECTION. RETURN CODE '0', : ImbMain(316)
```

On deregistering from usage data collection, the system writes the following message to the system log:

```
BIP9273I MQ05BRK default 0 THE DATAFLOWENGINE PROCESS HAS DEREGISTERED SMF 89
         SUBTYPE 1 RECORD COLLECTION. RETURN CODE '0', : ImbMain(1079)
```

The values set in the SMF 89 subtype 1 records are defined in the following table..

Name	Description	WebSphere Message Broker value
SMF89UPO	Product owner	"IBM CORP"
SMF89UPN	Product name	"WMB" WebSphere Message Broker "WRF" WebSphere Message Broker Rules and Formatter
SMF89UPV	Product version	"NOTUSAGE"
SMF89UPQ	Product qualifier	""
SMF89UPI	Product ID	"5655-74" for WMB "5697-J09" for WRF

In all cases, the values are left-aligned and padded with blanks.

All execution groups that are started and stopped on a single system provide the same values when registering and deregistering. Therefore, the usage data that is written at the end of an interval in the SMF 89 subtype 1 record is an accumulation of all execution group address spaces.

For further information about SMF 89 subtype 1 records, see the *MVS System Management Facilities (SMF)* manual.

"Naming conventions for WebSphere Message Broker for z/OS" on page 3984
Decide upon a naming convention for your WebSphere Message Broker for z/OS broker to make customizing, operating, and administering easier.

"Customization tasks and roles on z/OS" on page 3984
System programmers do most of the customization of WebSphere Message Broker.

"Customization planning checklist for z/OS" on page 3991
Use the information contained in the following tables to make a note of the values to use when you customize your system variables on z/OS.

"Disk space requirements on z/OS" on page 3586
The installation of WebSphere Message Broker for z/OS uses approximately 400 MB of disk space; plan on using 500 MB to allow for the component directories, and for new service fixes to be applied.

"Contents of the broker PDSE" on page 3991
After you have successfully customized the broker, the broker PDSE members have been set up.

Naming conventions for WebSphere Message Broker for z/OS

Decide upon a naming convention for your WebSphere Message Broker for z/OS broker to make customizing, operating, and administering easier.

Each broker requires its own queue manager. Base your broker name on the queue manager name. For example, append `BRK` to the queue manager name of `MQP1`, to give `MQP1BRK`. This naming convention has the following advantages:

- It is easy to associate the broker with the queue manager, because they both begin with the same characters.
- The started task name has the same name as the broker.

Using this convention, you might have the following broker name `MQP1BRK` for a queue manager `MQP1`:

- A started task name of `MQP1BRK`.
- A started task user ID of `MQP1BRK`.
- A PDSE containing definitions called `hlq.MQP1BRK.xxx`.
- A UNIX System Services directory structure like `/xxx/yyy/MQP1BRK`.

Plan for expansion by selecting names that allow growth.

If your broker name is in uppercase, ensure that the broker name is also in uppercase in the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

"Creating a broker on z/OS" on page 620
Create the broker component and the other resources on which it depends.

Customization tasks and roles on z/OS

System programmers do most of the customization of WebSphere Message Broker.

Tasks that need to be completed by other people in your organization are identified in the following table.

Role	Task
z/OS system programmer	"Customizing the z/OS environment" on page 591
	"Setting up z/OS security" on page 556
	"Summary of required access (z/OS)" on page 3985

Role	Task
	"Customizing UNIX System Services on z/OS" on page 598
	"Creating the broker component" on page 629
	"Starting and stopping a broker on z/OS" on page 924
	"Checking APF attributes of `bipimain` on z/OS" on page 607
WebSphere MQ administrator	"Setting up WebSphere MQ" on page 558
	"Summary of required access (z/OS)"
	"WebSphere MQ planning for z/OS" on page 601
	"Creating the broker component" on page 629
	"Defining the started tasks to z/OS Workload Manager (WLM)" on page 602
WebSphere Message Broker administrator	"Setting up WebSphere Message Broker Toolkit access on z/OS" on page 559
	"Summary of required access (z/OS)"
	"Creating a broker on z/OS" on page 620
	"Creating the broker component" on page 629
	"Checking APF attributes of `bipimain` on z/OS" on page 607
Performance specialist	"Defining the started tasks to z/OS Workload Manager (WLM)" on page 602
Security administrator	"Setting up z/OS security" on page 556
	"Summary of required access (z/OS)"
Data administrator	"Setting up z/OS security" on page 556
	"Summary of required access (z/OS)"
	"Disk space requirements on z/OS" on page 3586
	"Starting and stopping a broker on z/OS" on page 924
	"Using the file system on z/OS" on page 596

Some tasks, for example defining queue security, overlap two different roles.

Related reference:

"Summary of required access (z/OS)"
The professionals in your organization require access to components and resources on z/OS.

Summary of required access (z/OS):

The professionals in your organization require access to components and resources on z/OS.

Authorizations required for the WebSphere Message Broker started-task user ID:
The following directory authorizations are required for all brokers:

- *READ* and *EXECUTE* access to `<INSTPATH>`, where `<INSTPATH>` is the directory where WebSphere Message Broker for z/OS is installed by SMP/E.

- *READ*, *WRITE*, and *EXECUTE* access to the component directory ++COMPONENTDIRECTORY++.
- *READ* and *WRITE* access to the home directory.
- *READ* and *WRITE* access to the directory identified by ++HOME++.
- In UNIX System Services, the started task user ID and the WebSphere Message Broker administrator user ID must both be members of the groups that have access to the installation and component directories, because they both need privileges over these resources. The owner of these directories must give the appropriate permissions to this group.

All brokers need the following RACF authorizations:

- *READ* and *WRITE* access to RACF class BPX.SMF, when you need to create SMF 117 records for accounting and statistics.
- *READ* access to the CSFRNG resource in the CSFSERV class.

READ access to the component PDSE is required.

WebSphere MQ authorizations

Enable WebSphere MQ security to protect your WebSphere MQ resources. If all WebSphere MQ security switches are enabled, define the following profiles, and give the started task user ID the listed access to each profile. For each profile access listed, <MQ_QMNAME> represents the WebSphere MQ queue manager that the WebSphere Message Broker component is connected to, and TASKID represents the started task user ID.

- Connection security: *READ* access to profile <MQ_QMNAME>.BATCH of class MQCONN. For example, for queue manager MQP1 and started task ID TASKID, use the RACF commands:

  ```
  RDEFINE MQCONN MQP1.BATCH UACC(NONE)
  PERMIT MQP1.BATCH CLASS(MQCONN) ID(TASKID) ACCESS(READ)
  ```

- Connection security when content-based filtering with publish/subscribe is used: *UPDATE* access to profile <MQ_QMNAME>.BATCH of class MQCONN. For example, for queue manager MQP1 and started task ID TASKID, use the RACF commands:

  ```
  RDEFINE MQCONN MQP1.BATCH UACC(NONE)
  PERMIT MQP1.BATCH CLASS(MQCONN) ID(TASKID) ACCESS(UPDATE)
  ```

- Queue security: *UPDATE* access to profile <MQ_QMNAME>.queue of class MQQUEUE for all queues. Consider creating profiles for the following queues:
  - All component queues, by using the generic profile SYSTEM.BROKER.**
  - All transmissions queues that you have defined between component queue managers.
  - All queues that you have specified in message flows.
  - Dead-letter queues.
  - Model queues.

  For example, for queue manager MQP1 and started task ID TASKID, use the following RACF commands to restrict access to the component queues:

  ```
  RDEFINE MQQUEUE MQP1.SYSTEM.BROKER.** UACC(NONE)
  PERMIT MQP1.SYSTEM.BROKER.** CLASS(MQQUEUE) ID(TASKID) ACCESS(UPDATE)
  ```

- Context security: *CONTROL* access to profile <MQ_QMNAME>.CONTEXT of class MQADMIN. For example, for queue manager MQP1 and started task ID TASKID, use the following RACF commands:

  ```
  RDEFINE MQADMIN MQP1.CONTEXT UACC(NONE)
  PERMIT MQP1.CONTEXT.** CLASS(MQADMIN) ID(TASKID) ACCESS(CONTROL)
  ```

- Alternate user security: Define the alternate user authority as: *UPDATE* access to profile <MQ_QMNAME>.ALTERNATE.USER.id of class MQADMIN, where id represents the start task ID of the broker component. For example, for queue manager MQP1, started task ID TASKID, and configuration service ID CFGID, use the following RACF commands:

  ```
  RDEFINE MQADMIN MQP1.ALTERNATE.USER.CFGID UACC(NONE)
  PERMIT MQP1.ALTERNATE.USER.CFGID  CLASS(MQADMIN) ID(TASKID) ACCESS(UPDATE)
  ```

  UPDATE access to profile <MQ_QMNAME>.ALTERNATE.USER.id of class MQADMIN, where id represents the user ID of, for example, a publish/subscribe request.
- Process and namelist security: If you have WebSphere MQ security switches enabled in your system for process and namelist security, you do not have to define access profiles in a WebSphere Message Broker default configuration.

For users connecting remotely from the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit or from a CMP API application to the broker on z/OS, the following authorizations are required. CMP applications include the commands that use that interface; **mqsichangeresourcestats**, **mqsicreateexecutiongroup**, **mqsideleteexecutiongroup**, **mqsideploy**, **mqsilist**, **mqsimode**, **mqsireloadsecurity**, **mqsireportresourcestats**, **mqsistartmsgflow**, and **mqsistopmsgflow**.

- Connection security: *READ* access to profile <MQ_QMNAME>.CHIN of class MQCONN. For example, for queue manager MQP1 and started task ID TASKID, use the following RACF commands:

  ```
  RDEFINE MQCONN MQP1.CHIN UACC(NONE)
  PERMIT MQP1.CHIN CLASS(MQCONN) ID(TASKID) ACCESS(READ)
  ```
- Alternate user security: Define the alternate user authority as: *UPDATE* access to profile <MQ_QMNAME>.ALTERNATE.USER.id of class MQADMIN, where id represents the user ID of the WebSphere Message Broker Toolkit or CMP API application. For example, for queue manager MQP1, started task ID TASKID, and user ID USERID, use the following RACF commands:

  ```
  RDEFINE MQADMIN MQP1.ALTERNATE.USER.USERID UACC(NONE)
  PERMIT MQP1.ALTERNATE.USER.USERID  CLASS(MQADMIN) ID(TASKID) ACCESS(UPDATE)
  ```

Authorizations required for the WebSphere Message Broker administrator:
The broker administrator requires the following authorizations:

- *ALTER* access to the component PDSE.
- *READ*, *WRITE*, and *EXECUTE* access to the component directory ++COMPONENTDIRECTORY++.
- *READ* and *EXECUTE* access to <INSTPATH>, where <INSTPATH> is the directory where WebSphere Message Broker for z/OS is installed by SMP/E.
- *READ* and *WRITE* access to the directory identified by ++HOME++.
- In UNIX System Services, the started task user ID and the WebSphere Message Broker administrator user ID must both be members of the groups that have access to the installation and component directories, because they both need privileges over these resources. The owner of these directories needs to give the appropriate permissions to this group. In addition, the WebSphere Message Broker administrator must be a member of the group that is the primary group of the started task user ID.

Authorizations required for the WebSphere MQ administrator:
If the WebSphere MQ administrator runs the WebSphere MQ pass when creating a broker, the administrator user ID requires the following authorizations.

Alternatively, you can grant authorization to the WebSphere Message Broker administrator to run the WebSphere MQ pass.

- *ALTER* access to the component PDSE.
- Directory authorizations:
  - *READ* and *EXECUTE* access to <INSTPATH>, where <INSTPATH> is the directory where WebSphere Message Broker for z/OS is installed by SMP/E.
  - *READ*, *WRITE*, and *EXECUTE* access to the component directory ++COMPONENTDIRECTORY++.
  - *READ* and *WRITE* access to the directory identified by ++HOME++.

Enable WebSphere MQ security to protect your WebSphere MQ resources. If all WebSphere MQ security switches are enabled, define the following profiles and give the WebSphere MQ administrator the listed access to each profile in order to run the WebSphere MQ configurations jobs. For each profile access listed, MQ_QMNAME represents the WebSphere MQ queue manager that the WebSphere Message Broker component is connected to, and MQADMIN represents the WebSphere MQ administrator ID:

- Connection security: *READ* access to profile <MQ_QMNAME>.BATCH of class MQCONN. For example, for queue manager MQP1 and WebSphere MQ administrator ID MQADMIN, use the following RACF commands:

  ```
  RDEFINE MQCONN MQP1.BATCH UACC(NONE)
  PERMIT MQP1.BATCH CLASS(MQCONN) ID(MQADMIN) ACCESS(READ)
  ```

- Queue security: *UPDATE* access to profile <MQ_QMNAME>.queue of class MQQUEUE for component queues created or deleted. You can create a generic profile SYSTEM.BROKER.** For example, for queue manager MQP1 and WebSphere MQ administrator ID MQADMIN, use the following RACF commands to restrict access to the component queues:

  ```
  RDEFINE MQQUEUE MQP1.SYSTEM.BROKER.** UACC(NONE)
  PERMIT MQP1.SYSTEM.BROKER.** CLASS(MQQUEUE) ID(MQADMIN) ACCESS(UPDATE)
  ```

- System command server: *UPDATE* access to profile <MQ_QMNAME>.queue of class MQQUEUE for SYSTEM.COMMAND.**. For example, for queue manager MQP1 and WebSphere MQ administrator ID MQADMIN, use the following RACF commands to restrict access to the system command server:

  ```
  RDEFINE MQQUEUE MQP1.SYSTEM.COMMAND.** UACC(NONE)
  PERMIT MQP1.SYSTEM.COMMAND.** CLASS(MQQUEUE) ID(MQADMIN) ACCESS(UPDATE)
  ```

  UPDATE access to profile <MQ_QMNAME>.queue of class MQQUEUE for some system queues used during the create/delete job. You can create a generic profile <MQ_QMNAME>.**

- Command security:
  - To run the WebSphere MQ pass when creating a component you need:
    - *ALTER* access to <MQ_QMNAME>.DEFINE.QLOCAL of class MQCMDS.
    - *ALTER* access to <MQ_QMNAME>.DEFINE.QMODEL of class MQCMDS.
    - *ALTER* access to <MQ_QMNAME>.DEFINE.CHANNEL of class MQCMDS.
  - To run the WebSphere MQ pass when deleting a component you need:
    - *ALTER* access to <MQ_QMNAME>.DELETE.QLOCAL of class MQCMDS.
    - *ALTER* access to <MQ_QMNAME>.DELETE.QMODEL of class MQCMDS.
    - *ALTER* access to <MQ_QMNAME>.DELETE.CHANNEL of class MQCMDS.

  For queue manager MQP1 and WebSphere MQ administrator ID MQADMIN, use the following RACF commands:

```
RDEFINE MQCMDS MQP1.DELETE.QLOCAL UACC(NONE)
PERMIT MQP1.DELETE.QLOCAL CLASS(MQCMDS) ID(MQADMIN) ACCESS(ALTER)
```

- Resource command security: *ALTER* access to `MQP1.QUEUE.queue` of class `MQADMIN` for each queue created or deleted. You can create a generic profile SYSTEM.BROKER.**. For example, for queue manager `MQP1` and WebSphere MQ administrator ID `MQADMIN`, use the RACF commands:

  ```
  RDEFINE MQADMIN MQP1.QUEUE.SYSTEM.BROKER.** UACC(NONE)
  PERMIT MQP1.QUEUE.SYSTEM.BROKER.** CLASS(MQADMIN) ID(MQADMIN) ACCESS(ALTER)
  ```

- Process and namelist security: If you have WebSphere MQ security switches enabled in your system for process and namelist security, you do not need to define any access profiles in a WebSphere Message Broker default configuration.

For a description of how to implement WebSphere MQ security using RACF, see "Setting up WebSphere MQ" on page 558.

Disk space requirements on z/OS

The installation of WebSphere Message Broker for z/OS uses approximately 400 MB of disk space; plan on using 500 MB to allow for the component directories, and for new service fixes to be applied.

When you apply service, if you do not replace your existing installation (for example, you apply the new fix pack level alongside your existing installation), you must plan the same amount of disk space for the higher service level libraries.

If you are transferring the files by using *tar* to package them, you need approximately 200 MB of space for the `.tar` file.

You can check how much space is used and how much is free in a file system by using the OMVS command:

```
df -P /pathname
```

100 MB is 3 276 800 512 byte sectors.

The following table gives guidance on the space required for a minimum installation (base installation and verification test) of WebSphere Message Broker for each component implemented on z/OS.

Component	Space required	Purpose
Component directory	20 MB	Holds the runtime-deployed configuration information and output directories for the component. This information includes all deployment information, such as ESQL, JAR files, message sets, XSLT files, and so on. This information also includes WebSphere Message Broker trace files and other user problem determination data, which might become large. Consideration must be given to the potential size of deployments to the WebSphere Message Broker runtime environment and, therefore, the size of this directory (including sub directories).

Component	Space required	Purpose
Component PDSE	1 MB	Holds the customization and administration jobs, procedures, and data for the component. The data set must be allocated with a fixed record length of 80 (LRECL=80) and a format of FB 80. Reserve directory space for 50 members, or use a PDSE if possible.
Started task user ID home directory	8 GB	Collects diagnostic materials: for example, dumps. Dumps are usually more than 500 MB in size. 8 GB of space must be available in the file system, but many user IDs can have their home directory in the file system.

The Component directory and the Started task user ID home directory must be separate to ensure that, when dumps are taken in the Started task user ID home directory, they do not cause problems with the runtime broker that still has to write to the Component directory.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

"Using the file system on z/OS" on page 596
If you have more than one MVS image, consider how you will use the file system. You can share files in a file system with different members of a sysplex. The file system is mounted on one MVS image and requests to the file are routed to the owning system using XCF from systems which do not have it mounted.

Binding a DB2 plan to use data-sharing groups on z/OS

During customization, you can specify which plan name to use, or use the default DSNACLI. If you are using XPLINK, the default plan is called DSNACLX. If you want your broker to access DB2 data-sharing groups other than its own, the DSNACLI plan must be bound in a special way. If the broker uses one data sharing group, but might want to access tables on DSNONE and DSNTWO, which are in different data-sharing groups, amend the DB2 supplied job DSNTIJCL to do the following:

```

This is part of the larger task of creating a broker on z/OS.

Contents of the broker PDSE

After you have successfully customized the broker, the broker PDSE members have been set up.

Broker PDSE members originating in <hlq>.SBIPSAMP

The PDSE members are described in the following table.

Description	Name
Broker profile	BIPBPROF

Description	Name
Broker DB2 dsnaoini file (for user databases) "Sample BIPDSNAO file" on page 4008 lists the shipped BIPDSNAO file.	BIPDSNAO
Execution group specific profile	BIPEPROF

Broker PDSE members originating in <hlq>.SBIPPROC

The PDSE members are described in the following table.

Description	Name
Commented sample job to identify WebSphere MQ resources, including queues for performance tuning purposes	BIPALMQ
Job to run the "**mqsibackupbroker** command" on page 3720. "Sample BIPBUBK file" on page 4004 lists the shipped BIPBUBK file.	BIPBUBK
Job to run the **mqsibrowse** command. Use this command only at the request of IBM service.	BIPBRWS
Job to run the "**mqsichangebroker** command" on page 3723	BIPCHBK
Job to run the "**mqsichangeflowmonitoring** command" on page 3738	BIPCHME
Job to run the "**mqsichangeflowstats** command" on page 3744	BIPCHMS
Job to run the "**mqsichangeflowuserexits** command" on page 3751	BIPCHUE
Job to run the "**mqsichangeproperties** command" on page 3756	BIPCHPR
Job to run the "**mqsichangeresourcestats** command" on page 3819	BIPCHRS
Job to run the "**mqsicreatebroker** command" on page 3831 to: • Create the WebSphere MQ resources • Create the broker registry "Sample BIPCRBK file" on page 4006 lists the shipped BIPCRBK file.	BIPCRBK
Job to run the "**mqsicreateconfigurableservice** command" on page 3849	BIPCRCS
Job to run the "**mqsicreateexecutiongroup** command" on page 3854	BIPCREG
Job to run the "**mqsideletebroker** command" on page 3863	BIPDLBK
Job to run the "**mqsideleteconfigurableservice** command" on page 3866	BIPDLCS
Job to run the "**mqsideleteexecutiongroup** command" on page 3869	BIPDLEG
Job to run the "**mqsideploy** command" on page 3872	BIPDPLY
Edit macro for customization. Rename BIPEDIT to a unique name that identifies it to the current component; for example, MQ01EDBK "Sample BIPEDIT file" on page 4009 lists the shipped BIPEDIT file.	BIPEDIT (MQP1BRK)
PROC that is called by BIPGEN to convert BIPBPROF, and an execution group specific profile (renamed BIPEPROF), to a valid execution group specific ENVFILE.	BIPEGEN
Job to run the "**mqsiexplain** command" on page 3879	BIPEXPL

Description	Name
Job to run the "**mqsiformatlog** command" on page 3880	BIPFMLG
Job to convert BIPBPROF profile to a valid ENVFILE. "Sample BIPGEN file" on page 4010 lists the shipped BIPGEN file.	BIPGEN
Job to run the "**mqsilist** command" on page 3882	BIPLIST
Job to run the "**mqsimigratecomponents** command" on page 3894	BIPMGCMP
Job to run the "**mqsimode** command" on page 3899	BIPMODE
Job to run the "**mqsiapplybaroverride** command" on page 3684	BIPOBAR
Job to run the "**mqsireadbar** command" on page 3697	BIPRBAR
Job to run the "**mqsireadlog** command" on page 3905	BIPRELG
Job to run the "**mqsireloadsecurity** command" on page 3911	BIPRLSEC
Job to run the "**mqsireportbroker** command" on page 3919	BIPRPBK
Job to run the "**mqsireportflowmonitoring** command" on page 3924	BIPRPME
Job to run the "**mqsireportflowstats** command" on page 3929	BIPRPMS
Job to run the "**mqsireportflowuserexits** command" on page 3933	BIPRPUE
Job to run the "**mqsireportproperties** command" on page 3937	BIPRPPR
Job to run the "**mqsireportresourcestats** command" on page 3944	BIPRPRS
Job to run the "**mqsirestorebroker** command" on page 3952. "Sample BIPRSBK file" on page 4012 lists the shipped BIPRSBK file.	BIPRSBK
Job to run the "**mqsisetdbparms** command" on page 3954 to define a data source, user ID, and password for user data sources.	BIPSDBP
(started task). Rename BIPBRKP to **the same name as the ++STARTEDTASKNAME++**. "Sample BIPBRKP file" on page 4000 lists the shipped BIPBRKP file.	BIPBRKP
Job to run the "**mqsistartmsgflow** command" on page 3969	BIPSTMF
Job to run the "**mqsistopmsgflow** command" on page 3975	BIPSPMF

Use the standard z/OS IPCS facilities to take a dump. You require access to the following resources:

- COMPONENT_PDSE
- ComponentDirectory
- SYS1.MIGLIB
- SYS1.SBLSCLI0
- SYS1.PARMLIB
- IPCS

Related concepts:

"Component PDSE on z/OS" on page 595
On z/OS, the *component PDSE* contains jobs customized for a single component. These jobs are used to create and administer the component.

Related tasks:

"Customizing the broker component data set" on page 624
This is part of the larger task of creating a broker on z/OS.

z/OS JCL variables

Customize JCL variables in BIPEDIT to modify the configuration of your brokers.

The following table lists the JCL variables in alphabetic order, together with a description and an example value. For JCL variables that apply to specific commands, see the information that relates to that command.

JCL variable	Description	Example value	Corresponding value in BIPEDIT
++COMPONENTDATASET++	The data set where all JCL relevant to a particular component is saved.	TESTDEV.MQP1BRK.BROKER	componentdataset_value
++COMPONENTDIRECTORY++	The file system directory where the component exists. This directory includes subdirectories, for example, `/log` and `/registry`	`mqsi/brokers/MQP1BRK`	compdir_value
++COMPONENTNAME++	The name you give the component when you create it.	MQP1BRK	MQ01BRK
++HOME++	The file system home directory for the user ID of this component. This value is required to dynamically generate the `ENVFILE`. You must have the appropriate external security manager authorities to write to this file system directory when submitting JCL to run a command. For example, use RACF to define authorities.	`/u/mqp1usr/mqp1brk`	`/u/mq01brk`
++INSTALL++	The directory where you install the product.	`/usr/lpp/mqsi`	install_value
++JAVA++	Location of your Java installation.	`/usr/lpp/java/IBM/J1.5`	`/usr/lpp/java/IBM/J1.5`
++LANGLETTER++	The letter for the language in which you want messages shown.	E (English)	E
++LOCALE++	Locale of environment where commands are run by submitting JCL.	C	C
++MQPATH++	WebSphere MQ location.	`/usr/lpp/mqm`	`/usr/lpp/mqm`
++OPTIONS++	Many commands submitted by JCL require additional options. See the reference material for additional information about options specific to each command.	N/A	options_value
++QUEUEMANAGER++	The name of the queue manager associated with the component for which you submit the JCL.	MQP1	MQ01
++STARTEDTASKNAME++	Name of the Started Task JCL. This name can be a maximum of eight characters.	MQP1BRK	MQ01BRK
++TIMEZONE++	Time zone of environment where commands are run by submitting JCL.	GMT0BST	GMT0BST

JCL variable	Description	Example value	Corresponding value in BIPEDIT
++WMQHLQ++	WebSphere MQ high-level-qualifier	MQM.V700	MQM.V700

Related tasks:

"Collecting the information required to create a broker" on page 620
This is part of the larger task of creating a broker on z/OS.

The sample BIPEDIT file that is shipped with WebSphere Message Broker is included here for your reference.

z/OS sample files supplied

Several samples files are provided for you to customize on z/OS.

About this task

- "Sample BIPBPROF file"
- "Sample BIPBRKP file" on page 4000
- "Sample BIPBUBK file" on page 4004
- "Sample BIPCRBK file" on page 4006
- "Sample BIPDSNAO file" on page 4008
- "Sample BIPEDIT file" on page 4009
- "Sample BIPGEN file" on page 4010
- "Sample BIPRSBK file" on page 4012

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

#*
#**********************************************************************
# 1. Component Settings
#**********************************************************************
#
# 1.1 MQSI_REGISTRY references the component path. Also needed by
#     commands.
#     e.g. MQSI_REGISTRY=/mqsi/brokers/MQ01BRK
#
# 1.2 MQSI_COMPONENT_NAME is set to the broker name.
#     e.g. MQSI_COMPONENT_NAME=MQ01BRK
#
# 1.3 MQSI_FILEPATH needed by commands to reference the component
#     version install path.
#     e.g. MQSI_FILEPATH=usr/lpp/mqsi/V7R0M0
#
# 1.4 MQSI_LILPATH needed by components to find LILs
#     e.g. MQSI_LILPATH=usr/lpp/mqsi/V7R0M0/lil
#
```

```
# 1.5 MQSI_SECURITY_PROVIDER_PATH needed by components to find LSLs
#     e.g. MQSI_SECURITY_PROVIDER_PATH=usr/lpp/mqsi/V7R0M0/SecurityProviders
#
export MQSI_REGISTRY=++COMPONENTDIRECTORY++
export MQSI_COMPONENT_NAME=++COMPONENTNAME++
export MQSI_FILEPATH=++INSTALL++
export MQSI_LILPATH=$MQSI_FILEPATH/lil
export MQSI_SECURITY_PROVIDER_PATH=$MQSI_FILEPATH/SecurityProviders

#*****************************************************************
# 2. NLS Settings
#*****************************************************************
#
# 2.1 LANG and LC_ALL determine in which locale the component
#     will run.
#     e.g. LANG=Ja_JP.IBM-939 and LC_ALL=Ja_JP.IBM-939 for
#          japanese locale.
#          LANG=C, LC_ALL=C for US English locale.
#
# 2.2 TZ has the timezone setting in which you are located.
#     e.g. TZ=EST5                    for USA Eastern Standard Time
#          TZ=MEZ-1MES,M3.5.0,M10.5.0 for Central Europe
#          TZ=GMT0BST                 for the UK
#          Please refer to the IBM Manual
#          "Unix System Services Command Reference SC28-1892.
#
# 2.3 NLSPATH contains the location of the message catalog(s).
#     (NO NEED TO CHANGE FROM DEFAULT!)
#
# 2.4 MQSI_CONSOLE_NLSPATH is used to locate the messages for
#     the console.
#     For Japanese or S-Chinese messages, change En_US to
#     Ja_JP or Zh_CN below. For English messages these can be
#     displayed in mixed or upper case only. (see MC_MESSAGES)
#     Note that MQSI_CONSOLE_NLSPATH does not use %L or %N
#
export LANG=++LOCALE++
export LC_ALL=++LOCALE++
export TZ=++TIMEZONE++
export NLSPATH=$MQSI_FILEPATH/messages/%L/%N
export NLSPATH=$NLSPATH:$MQSI_FILEPATH/nnsy/MIF/messages/%N
export MQSI_CONSOLE_NLSPATH=$MQSI_FILEPATH/messages/En_US

#*****************************************************************
# 3. Automatic Restart Management (ARM) Settings
#*****************************************************************
#
# 3.1 MQSI_USE_ARM specifies whether to use ARM.
#     e.g. MQSI_USE_ARM=YES for ARM enabled.
#          MQSI_USE_ARM=NO  for ARM not enabled.
#
# 3.2 MQSI_ARM_ELEMENTNAME required if ARM enabled.
#
# 3.3 MQSI_ARM_ELEMENTTYPE required if ARM enabled.
#
export MQSI_USE_ARM=NO
export MQSI_ARM_ELEMENTNAME=++COMPONENTNAME++
export MQSI_ARM_ELEMENTTYPE=

#*****************************************************************
# 4. DB2 Settings
#*****************************************************************
#
# 4.1 MQSI_DB2_ALWAYS_PREPARE
```

```
#     (NO NEED TO CHANGE FROM DEFAULT!)
#
# 4.2 MQSI_DB2_CONVERSION specifies the DB2 Converter.
#     (ONLY REQUIRED FOR USER DATABASES)
#     e.g. MQSI_DB2_CONVERSION=SINGLE
#                     WBIMB uses a SQL_EBCDIC_SCCSID to determine
#                     the DB2 converter.
#                     Note that this setting reflects the current
#                     WBIMB behavior.
#          MQSI_DB2_CONVERSION=MIXED
#                     WBIMB uses SQL_EBCDIC_MCCSID to determine
#                     the DB2 converter.
#                     Note that this setting requires that DB2 is
#                     configured to accept mixed byte data. This
#                     setting should be used when the customer
#                     wants data to be stored in the configured
#                     DB2 EBCDIC mixed byte code page.
#          MQSI_DB2_CONVERSION=LOCAL
#                     WBIMB uses localConverter identified by
#                     LC_ALL/LANG settings. This complies to what
#                     is done on distributed. This setting
#                     requires that WBIMB and DB2 are using the same
#                     codepage, otherwise only WBIMB can read DB2
#                     data correctly, it gets unreadable for other
#                     ( non-WBIMB ) applications that want to read
#                     the data.
#
# 4.3 DSNAOINI references the component dsnaoini file.
#     (NO NEED TO CHANGE FROM DEFAULT!)
#
export MQSI_DB2_ALWAYS_PREPARE=NO
#export MQSI_DB2_CONVERSION=++DB2CONVERSION++
export DSNAOINI=//\'++COMPONENTDATASET++\(BIPDSNAO\)\'

#*********************************************************************
# 5. Java Settings
#*********************************************************************
#
# 5.1 JAVAHOME contains the root directory of the JAVA install.
#     e.g. JAVAHOME=/usr/lpp/java/IBM/J1.6
#     Note that the Java version must be at least 1.6.0
#
export JAVAHOME=++JAVA++

#*********************************************************************
# 6. WebSphere Message Broker Settings
#*********************************************************************
#
# 6.1 _BPX_BATCH_SPAWN
#     (MUST NOT CHANGE FROM DEFAULT!)
#
# 6.2 MQSI_MC_MESSAGES determines if messages should appear in
#     mixed case or upper case.
#     e.g. MQSI_MC_MESSAGES=YES for mixed case
#          MQSI_MC_MESSAGES=NO for upper case
#
# 6.3 MQSI_COMMAND_DATABASE_ECHO if defined, mqsi commands
#     display information when creating DB2 tables/indexes.
#
# 6.4 MQSI_COMMAND_ZOS_MQ_ECHO if defined, mqsi commands display
#     information returned from the MQ command server when
#     creating/deleting queues.
#
# 6.5 MQSI_COMMAND_ZOS_MQ_ECHO_RC if defined, mqsi commands display
#     reason and return codes from the MQ command server when
#     creating/deleting queues.
```

```
#
# 6.6 MQSI_DEPLOY_PROGRESS if defined, shows deployment progress
#     by the execution group
#
# 6.7 STEPLIB
#     (MUST NOT CHANGE FROM DEFAULT!)
#
# 6.8 MQSI_COMMAND_ZOS_ERROR_RC if defined, mqsi commands return
#     this value as the return code if an error occurs.
#
# 6.9 MQSI_FAD current FAD level.
#

Related reference:

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsideletebroker** command" on page 3863
Use the **mqsideletebroker** command to delete a named broker. The command also deletes the queues on the associated queue manager (created when the broker was created). You can also specify that the queue manager is to be deleted.

Data sources on z/OS

The `Data Source` name in the Compute and Database nodes identifies the location of the table referred to in the respective node's ESQL. Data sources on z/OS correspond to DB2 subsystems rather than DB2 databases. The DB2 owning region for a particular database table is identified using a combination of the DSNAOINI file and DB2 subsystem configuration.

The MVSDEFAULTSSID parameter in the DSNAOINI file identifies the local DB2 subsystem to which the broker is connected. This subsystem is used to locate the data source which is either a local or remote DB2. The mapping between a particular data source and DB2 subsystem is shown in the DSNTIPR installation panel of the default DB2 subsystem and SYSIBM.LOCATIONS table.

When you access remote DB2 subsystems, ensure that the DBRMs for ODBC are bound at the remote subsystem. For more information, refer to the 'Programming for ODBC' topics in the DB2 Information Management Software Information Center for z/OS Solutions .

If you need to access databases that are not on DB2 on z/OS, you can use the DB2 Distributed Data Facility (DDF) and Distributed Relational Architecture (DRDA) to incorporate a remote unit of work within a message flow.

Message flow preferences

You can change preferences that determine properties of message flows when you create them.

To edit message flow preferences, open the Preferences dialog box by clicking **Window** > **Preferences**. Select **Message Flow** from the list of categories.

For a new message flow, you can set the default version tag, which is described in the following table.

Property	Type	Meaning
Default version tag	String	Provide the default version information that you want to be set in the message flow `Version` property when you create a message flow.

Related concepts:

"Message flow version and keywords" on page 1445

Description properties for a message flow

The description properties for a message flow include the `Version`, `Short Description` and `Long Description`. To view and edit the properties of a message flow click **Flow** > **Properties**.

Property	Type	Meaning
Version	String	You can enter a version for the message flow in this field. This allows the version of the message flow to be displayed using the Eclipse properties view. A default for this field can be set in the messages flow preferences.
Short Description	String	You can enter a short description of the message flow in this field.
Long Description	String	You can add information to enhance the understanding of the message flow's function in this field. It is a string field and any standard alphanumeric characters can be used. You can also use this field to define a keyword and its value that will display for the deployed message flow in the properties view of Eclipse. An example is: `$MQSI Author=Fred MQSI$` When the properties of the deployed message flow are displayed, this will add a row to the display showing "Author" as the property name and "Fred" as its value. For information on keywords see "Guidance for defining keywords."

Related concepts:

"Version and keyword information for deployable objects" on page 1443
Use the Broker Archive editor to view the version and keyword information of deployable objects.

Related reference:

"Guidance for defining keywords"
You can add extra information to an object in the form of one or more keywords.

Guidance for defining keywords:

You can add extra information to an object in the form of one or more keywords.

This information can display information about an object after the object has been deployed. The default information that is displayed is the time the object was deployed and the last time the object was modified.

You can define custom keywords, and their values that the WebSphere Message Broker Toolkit interprets as additional information to be displayed, in the properties view. For example, you can define keywords for "Author" and "Subflow 1 Version":

```
$MQSI Author=John Smith MQSI$
$MQSI Subflow 1 Version=v1.3.2 MQSI$
```

The following table contains the information that is displayed by the WebSphere Message Broker Toolkit:

Object name	Example
Deployment Time	28-Aug-2009 15:04
Modification Time	28-Aug-2009 14:27
Version	v1.0
Author	John Smith

Object name	Example
Subflow 1 Version	v1.3.2

In this display, the version information has been defined by using the **Version** property of the object. If the version information had not been defined, it would be omitted from this display.

Use the following syntax to define a keyword and its associated value:

```
$MQSI KeywordName = KeywordValue MQSI$
```

Where:

$MQSI
$MQSI opens the definition. It can be followed by an optional underscore or white-space character that is ignored.

KeywordName
The name of the keyword for which you are setting the value. It is made up of a sequence of alphanumeric characters apart from the equals (=) sign. It can contain white-space characters, but leading or trailing white-space characters are omitted.

= The equals (=) sign is the delimiter between the keyword and the value that you are setting it to.

KeywordValue
The value to which the keyword is set. It is made up of a sequence of alphanumeric characters. It can contain white-space characters, but leading or trailing white-space characters are omitted.

MQSI$
MQSI$ closes the keyword definition.

Examples

Example definitions	Interpreted keyword and value	Comments
$MQSIAuthor=JohnMQSI$ or $MQSI Author=John MQSI$ or $MQSI Author = John MQSI$	Keyword = "Author" Value = "John"	Each of these examples shows what can be set and that the leading and trailing white-space characters for the name and value parameters are ignored.
$MQSI_Author = John MQSI$	Keyword = "Author" Value = "John"	The first character after $MQSI can be an underscore character. The underscore character is omitted in the interpreted keyword. If a second underscore character appears, this forms part of the keyword name.
$MQSI Flow designer = John Smith MQSI$	Keyword = "Flow designer" Value = "John Smith"	White-space characters are accepted for each parameter value.
$MQSI bar = MQSI$	Keyword = "bar" Value = ""	The keyword value can be set to an empty ("") string.

Example definitions	Interpreted keyword and value	Comments
$MQSI_mqsitag=$MQSI$MQSI$	Keyword = "mqsitag" Value = "$"	This example is a poorly formatted definition. After defining the keyword name, the parser is looking to find the delimiters that form the boundary of the value to be set. In this case, the only character before the MQSI$ that closes the definition is a '$', and that is set as the keyword value.
$MQSI=barMQSI$		This pattern is ignored because the keyword name cannot be an empty string.
$MQSItagbarMQSI$		This pattern is ignored because there is not a separator (=) between the keyword name and the keyword value.

Do not use the following keywords:

VERSION
When you use the WebSphere Message Broker Toolkit to edit message flows and dictionaries, it is possible to set the **Version** property in the Properties pane, which you can then view in the Broker Archive file editor. If you set this property, a keyword called VERSION is added to the resulting `.cmf` or dictionary file. For this reason, do not add `$MQSI_VERSION=...MQSI$` to these files.

BAR The BAR keyword is associated with each object automatically when it is deployed and it contains the full path name of the broker archive file that deployed the object.

The values of both keywords are defined programmatically in the class `com.ibm.broker.config.proxy.DeployedObject`.

Restrictions within keywords

Do not use the following characters within keywords because they cause unpredictable behavior:

```
^ $ . | \ < > ? + * = & [ ] ( )
```

You can use these characters in the values that are associated with keywords; for example:

- `$MQSI RCSVER=$id$ MQSI$` is acceptable
- `$MQSI $name=Fred MQSI$` is not acceptable

"Description properties for a message flow" on page 4016
The description properties for a message flow include the `Version`, `Short Description` and `Long Description`. To view and edit the properties of a message flow click **Flow** > **Properties**.

Configurable message flow properties

When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

Additional Instances

This property specifies the number of additional threads that the broker can use to service the message flow. These additional threads are created only if there are sufficient input messages. You can use up to 256 threads. The default value is 0. Additional threads can increase the throughput of a message flow but you must consider the potential effect on message order.

If the message flow processes WebSphere MQ messages, you can configure the message flow to control the message order. Set the `Order Mode` property on the MQInput node accordingly. You might also need to set the `Commit by Message Group` and `Logical Order` properties.

An MQInput node opens the input queue with MQOO_INPUT_AS_Q_DEF, which uses the DEFSOPT property of the input queue. Therefore, you must ensure that the input queue has been defined with DEFSOPT(SHARED) and with the SHARE property set to enable multiple broker threads to read from the input queue. If these properties are not set in this way, the message flow threads report that the queue is in use (MQRC=2042), and the message flow might stop processing messages on the input queue.

If you have multiple input nodes in your message flow, the available additional threads might not be allocated evenly between the different input nodes. In an extreme case, all the threads might be allocated to a single input node, and only one aspect of message flow throughput is improved. To avoid this problem, you can use the `Additional Instances`

Pool property, together with the Additional Instances property, to allocate a pool of additional instance threads for each input node.

Commit Count
For WebSphere MQ messages, this property specifies how many input messages are processed by a message flow before a sync point is taken (by issuing an MQCMIT).

The default value of 1 is also the minimum permitted value. Change this property to avoid frequent MQCMIT calls when messages are being processed quickly and the lack of an immediate commit can be tolerated by the receiving application.

Use the Commit Interval to ensure that a commit is performed periodically when not enough messages are received to fulfill the Commit Count.

This property has no effect if the message flow does not process WebSphere MQ messages.

Commit Interval
This property specifies the maximum time interval between the last WebSphere MQ message being received, and a sync point being taken. If no message is received in the specified time interval, a sync point is taken (by issuing an MQCMIT command), even if the number of messages processed does not fulfill the value of the Commit Count property.

The time interval is specified in seconds, as a decimal number with a maximum of three decimal places (millisecond granularity). The value must be in the range 0.000 through 60.000. The default value is 0.

This property has no effect if the message flow does not process WebSphere MQ messages, or if the value of the Commit Count is 1

Consumer policy set
This property specifies the consumer policy to use to authenticate, encrypt, and sign messages for the SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes.

Consumer policy set bindings
This property associates a policy set binding with a consumer policy set and contains information that is specific to the environment and operating system, such as information about keys.

Coordinated Transaction
This property controls whether the message flow is processed as a global transaction, coordinated by WebSphere MQ. Such a message flow is said to be fully globally coordinated. The default value is No.

Use coordinated transactions only where you need to process the message and any database updates that are performed by the message flow in a single unit-of-work, using a two-phase commit protocol. In this case, both the message is read and the database updates are performed, or neither is done.

If you change this value, ensure that the queue manager for the broker is configured correctly. If you do not set up the queue manager correctly, the broker generates a message when the message flow receives a message to indicate that, although the message flow is to be globally coordinated, the queue manager configuration does not support coordination.

See “Supported databases” on page 3591 for information about which databases are supported as participants in a global transaction, and the

System Administration section of the WebSphere MQ Version 7 Information Center online for how to configure WebSphere MQ and the database managers.

This property has no effect if the message flow does not process WebSphere MQ messages.

Monitoring profile name
This property specifies the name of the monitoring profile configurable service to apply to one or more message flows in a BAR file. The monitoring profile is used to configure your message flows to emit monitoring events.

For more information, see "Configuring monitoring event sources using a monitoring profile" on page 762.

Provider policy set
This property specifies the provider policy to use to authenticate, encrypt, and sign messages for the SOAPInput and SOAPReply nodes.

Provider policy set bindings
This property associates a policy set binding with a provider policy set and contains information that is specific to the environment and operating system, such as information about keys.

Security profile name
This property specifies a security profile that has authorization enabled so that a message flow can complete authorization with Tivoli Federated Identity Manager (TFIM). You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

For more information, see "Configuring authorization with TFIM V6.1" on page 483.

User-defined properties
The initial value of a user-defined property (UDP) can be modified at design time by the "Message Flow editor" on page 6810, or overridden at deployment time by the "Broker Archive editor" on page 6794. The advantage of UDPs is that their values can be changed by operational staff at deployment time. If, for example, you use UDPs to hold configuration data, you can configure a message flow for a particular computer, task, or environment at deployment time, without having to change the code at the node level. You can also query and set the values of user-defined properties at run time by using the Administration API for WebSphere Message Broker (also known as the CMP API). For example, a systems monitoring tool might use the CMP API to modify the value of a user-defined property at run time to change the behavior of the message flow.

For introductory information about UDPs and dynamic UDPs, see "User-defined properties in ESQL" on page 2376 and "User-defined properties" on page 1147.

For information about configuring UDPs at deployment time, see "Configuring a message flow at deployment time with user-defined properties" on page 2626.

For information about configuring UDPs at run time, see "Setting message flow user-defined properties at run time in a CMP application" on page 985.

You can view and update other configurable properties for the message flow. The properties that are displayed depend on the nodes within the message flow; some have no configurable properties to display. The node properties that are configurable are predominantly system-related properties that are likely to change for each broker to which the message flow is deployed. These properties include data source names and the names of WebSphere MQ queues and queue managers. For full details of configurable properties for a node, see the appropriate node description.

Business object information (SAP):

A business object contains application-specific information (metadata) about how the adapter processes the business object, and about the operation to be performed on the business object.

The name of the business object is generated by the Adapter Connection wizard in accordance with the naming convention for the adapter.

For more information, see the following topics:

- "Supported data operations (SAP)" on page 4026
- "Naming conventions" on page 4034

Supported data operations (SAP):

For outbound processing, an operation is the name of the action that is implemented by the adapter so that the message flow can perform the operation on the SAP server.

The adapter uses the application-specific information (ASI) inside the business object definition to implement the operation. The name of the operation typically indicates the type of action to be implemented, such as create or update. For inbound processing, adapters implement an operation by delivering events to their endpoints. For inbound processing, the action that is associated with the event varies depending on the interface (ALE or Advanced event processing). When the interface is ALE, the action is pushed to the adapter and the adapter delivers the event to an endpoint. When the interface is Advanced event processing, the event status is polled by the adapter and processed accordingly.

For more information, see the following topics:

- "Supported data operations on BAPI business objects" on page 4028

Supported data operations on BAPI business objects:

The operations that are supported by BAPI business objects are the same as those supported by BAPI work units. BAPI result sets support only the RetrieveAll operation.

For BAPI outbound processing, the operation of a BAPI business object is the name of the BAPI call that an adapter issues on the SAP server. The BAPI method determines the operation that is associated with it. The adapter uses the application-specific information (ASI) inside the business object definition to implement the operation. Operations of a business object are called by the component that makes calls to SAP through the adapter. The SAP JCo APIs are used to make the call to the SAP system.

BAPIs and BAPI unit of work

The following table defines operations that the adapter supports for BAPIs and BAPI work units. The definitions in the table are the expected uses for the operations. The action that is taken in the SAP application is based on the meaning of the BAPI itself.

Table 53. Supported operations: BAPI business objects

Operation	Definition
Create	The top-level business object and all contained children are created.
Update	The top-level business object is modified. This operation can include adding and deleting child objects.
Delete	The top-level business object and any contained children are deleted.
Retrieve	The top-level business object and any contained children are retrieved.

For an operation that is not supported, the adapter logs the appropriate error and produces a ResourceException.

Result sets

The following table defines the operation that the adapter supports for BAPI result sets.

Table 54. Supported operation: BAPI result sets

Operation	Definition
RetrieveAll	All the matching records for the BAPI result set are retrieved.

Supported data operations on ALE business objects:

The operations that are supported by ALE business objects vary, depending on whether the business object is an outbound or inbound object. The adapter uses the application-specific information (ASI) inside the business object definition to implement the operation.

Business objects that are generated with the ALE pass-through IDoc interface are not associated with an operation.

Outbound business objects

The operation of an ALE outbound business object is called by the application component that makes calls to SAP through the adapter. The adapter supports the following outbound operation:

Table 55. Supported operation: ALE outbound business objects

Operation	Definition
Execute	This operation posts the IDoc business object to the SAP application. This operation is one-way and asynchronous. For the `CWYAP_SAPAdapter_TX.rar` version of the adapter, the transaction ID is returned.

Inbound business objects

For ALE inbound business objects, the application-specific information of an operation contains the message type, message code, and message function for an IDoc type. The adapter supports the following inbound operations:

Table 56. Supported operations: ALE inbound business objects

Operation	Definition
Create	The top-level business object and all contained children are created.
Update	The top-level business object is modified. This operation can include adding and deleting child objects.
Delete	The top-level business object and any contained children are deleted.

The adapter uses the IDoc control record field data to determine the operation that is set on the business object before sending it to the endpoint. The following fields in the control record are used to determine the operation:

- Logical_message_type (MESTYP)
- Logical_message_code (MESCOD)
- Logical_message_function(MESFCT)

Supported data operations of Query interface for SAP Software business objects:

The SAP Query interface supports the RetrieveAll operation, with which you can have the results of an SAP table returned to you, and the Exists operation, which you use to determine whether data can be found in the SAP table. The adapter uses the application-specific information (ASI) inside the business object definition to implement the operation.

The supported operations for the Query interface for SAP Software are listed in the following table.

Table 57. Supported operations: Query interface for SAP Software business objects

Operation	Description
RetrieveAll	This operation returns a result set in the form of a container of SAP query business objects, which represent the data for each row that is retrieved from the table. If a table business object is sent to the SAP server (instead of a container business object), the rows are returned one at a time.
Exists	This operation provides a means to check for the existence of any records in SAP for defined search criteria. The Exists operation does not return any data; it indicates whether the data exists in SAP. If no data is found, the adapter generates an exception.

Supported data operations on Advanced event processing business objects:

The operations that are supported by Advanced event processing business objects vary, depending on whether the business object is an outbound or inbound object. The adapter uses the application-specific information (ASI) inside the business object definition to implement the operation.

Outbound business objects

The operation of an Advanced event processing outbound business object is called by the message flow that makes calls to SAP through the adapter. The adapter supports the following outbound operation.

Table 58. Supported operation: Advanced event processing outbound business objects

Operation	Definition
Create	The top-level business object and all contained children are created.
Update	The top-level business object is modified. This operation can include adding and deleting child objects.
Delete	The top-level business object and any contained children are deleted.
Retrieve	The top-level business object and any contained children are retrieved.

Inbound business objects

For Advanced event processing inbound business objects, the application-specific information of an operation contains the message type, message code, and message function for an IDoc type. The adapter supports the following inbound operations.

Table 59. Supported operations: Advanced event processing inbound business objects

Operation	Definition
Create	The top-level business object and all contained children are created.
Update	The top-level business object is modified. This operation can include adding and deleting child objects.
Delete	The top-level business object and any contained children are deleted.

Naming conventions:

When the Adapter Connection wizard generates a business object, it provides a name for the business object that is based on the name of the corresponding business function in the SAP server.

The convention that is applied by the SAP server when naming a business object varies depending on whether the name is for a BAPI business object, an ALE business object, an Advanced event processing business object, or a Query interface for SAP Software business object.

For more information, see the following topics:

- "Naming conventions for BAPI business objects" on page 4035

Naming conventions for BAPI business objects:

The Adapter Connection wizard provides names for the business objects for BAPIs, BAPI work units, and BAPI result sets. The business object name reflects the structure of the business function on the SAP server.

BAPIs

When it names business objects for BAPIs, the Adapter Connection wizard adds the prefix `Sap`. The wizard also converts the name of the business function to mixed case, removing any separators such as spaces or underscores, capitalizes the first letter of each word, and it can add an element-specific suffix (for example, `Wrapper` for a top-level business object).

The following table describes the convention that is applied by the Adapter Connection wizard when it names BAPI business objects.

Table 60. Naming conventions for BAPI business objects

Element	Naming convention
Name of the top-level business object	Sap + *Name of the wrapper object that you specify in the Adapter Connection wizard* + Wrapper For example: SapSalesOrderWrapper
Name of the BAPI business object	Sap + *Name of the BAPI interface* For example: SapBapiSalesOrderCreateFromDat1 The top-level object can contain more than one BAPI object.
Name of the child object	Sap + *Name of the Structure/Table* For example: SapReturn

If structures with the same name exist in different BAPIs, or exist in a BAPI (for example, one at the export level and one at the table level), the Adapter Connection wizard adds a unique suffix to differentiate the structures. The first structure is assigned a name (for example, SapReturn) and the second structure is assigned a name such as SapReturn619647890, where 619647890 is the unique identifier that is appended to the name by the wizard.

BAPI work units

The following table describes the convention that is applied by the Adapter Connection wizard when it names a BAPI work unit business object.

Table 61. Naming conventions for BAPI unit of work business objects

Element	Naming convention
Name of the top-level business object	Sap + *Name of the wrapper object that you specify in the Adapter Connection wizard* + Txn For example: SapCustomerTxn
Name of the BAPI business object	Sap + *Name of the BAPI interface* For example: SapCustomer
Name of the child object	Sap + *Name of the Structure/Table* For example: SapReturn

If structures with the same name exist in different BAPIs, or exist in a BAPI (for example, one at the export level and one at the table level), the Adapter Connection wizard adds a unique suffix to differentiate the structures. The first structure is assigned a name (for example, SapReturn) and the second structure is assigned a name such as SapReturn619647890, where 619647890 is the unique identifier that is appended to the name by the wizard.

BAPI result sets

The following table describes the convention that is applied by the Adapter Connection wizard when it names a BAPI result-sets business object.

Table 62. Naming conventions for BAPI result sets

Element	Naming convention
Name of the result set BAPI business object	`Sap + Name of the BAPI interface` For example: `SapBapiCustomerGetDetail`
Name of the child object	`Sap + Name of the Structure/Table` For example: `SapReturn`
Name of the query business object	`Sap + Formatted name of the query BAPI interface` For example: `SapBapiCustomerGetList`

If structures with the same name exist in different BAPIs, or exist in a BAPI (for example, one at the export level and one at the table level), the Adapter Connection wizard adds a unique suffix to differentiate the structures. The first structure is assigned a name (for example, `SapReturn`) and the second structure is assigned a name such as `SapReturn619647890`, where 619647890 is the unique identifier that is appended to the name by the wizard.

Naming conventions for ALE business objects:

The Adapter Connection wizard provides names for the ALE business object. The business object name reflects the structure of the business function on the SAP server.

If you are using the ALE pass-through IDoc interface, the following naming conventions apply:

- When you select **Generic IDoc** from the Object Discovery and Selection window, the Adapter Connection wizard creates a business object named `SapGenericIDocObject`. The naming convention described in the following sections does not apply to generic IDocs.
- When you discover an IDoc from the system or from a file, the object is named according to the naming convention for top-level wrapper objects, as described in Table 63. No other objects are generated.

When it names business objects for ALE, the Adapter Connection wizard adds a prefix of `Sap`. The wizard also converts the name of the IDoc and extension to mixed case, removing any separators such as spaces or underscores, capitalizes the first letter of each word, and it can add an element-specific suffix.

The following table describes the conventions that are applied by the Adapter Connection wizard when it names ALE business objects. The *[Name of Extension type IDoc]* in the Naming convention column represents an optional entry. It is included in the name only if the selected IDoc is an Extension Type IDoc.

Table 63. Naming conventions for ALE business objects

Element	Naming convention
Name of the top-level wrapper object	`Sap` + *`Name of IDoc`* + *`[Name of Extension type IDoc]`* For example: `SapAlereq01`
Name of the IDoc business object for basic IDocs	`Sap` + *`Name of IDoc`* + *`BO`* For example, the business object for the IDoc MATMAS03 is: `SapMatmas03BO`
Name of the IDoc business object for extension type IDocs	`Sap` + *`Name of IDoc`* + *`Name of Extension type IDoc`* For example, the business object for the IDoc DELVRY03 and extension SD_DESADV_PDC is: `SapDelvry03SdDesadvPdc`

For an IDoc duplicate name, the Adapter Connection wizard adds a unique suffix to differentiate the business object. If an IDoc packet has two segments with the

same name (for example, segOrder), the first business object is assigned the name `SapSegOrder` and the second business object is assigned a name such as `SapSegOrder619647890`, where 619647890 is the unique identifier that the Adapter Connection wizard appends to the name.

Naming conventions for Query interface for SAP Software business objects:

The Adapter Connection wizard provides names for the Query interface for SAP Software container, business graph, top-level business object, table object, and query object. The business object name reflects the structure of the business function on the SAP server.

When it names business objects for the Query interface for SAP Software, the Adapter Connection wizard adds the prefix `Sap`. The wizard also converts the name of the business function or SAP table to mixed case, removing any separators such as spaces or underscores, capitalizes the first letter of each word, and it can add an element-specific suffix (for example, `Container` for a container).

The following table describes the convention that is applied by the Adapter Connection wizard when it names a Query interface for SAP Software business object.

Table 64. Naming convention for a Query interface for SAP Software business object

Element	Naming convention
Name of the container	`Sap` + *Name of the object that you specify in the wizard* + `Container` For example: `SapCustomerContainer`
Name of the table object	`Sap` + *Name of the SAP table* For example: `SapKna1`
Name of the query object	`Sap` + *Name of the SAP table* + `Querybo` For example: `SapKna1Querybo`

Naming conventions for Advanced event processing business objects:

The Adapter Connection wizard provides names for the Advanced event processing top-level business object, and the business object. The name of the business object reflects the structure of the business function on the SAP server.

When it names business objects for the Advanced event processing interface, the Adapter Connection wizard adds a prefix of `Sap`. The wizard also converts the name of the IDoc and extension to mixed case, removing any separators such as spaces or underscores, capitalizes the first letter of each word, and it might add an element-specific suffix.

The following table describes the convention that is applied by the Adapter Connection wizard when it names Advanced event processing business objects. The *[Name of Extension type IDoc]* in the Naming convention column represents an optional entry; it is included in the name only if the selected IDoc is an Extension Type IDoc.

Table 65. Naming convention for advanced event processing business objects

Element	Naming convention
Name of the top-level wrapper object	`Sap` + *`Name of IDoc`* + *`[Name of Extension type IDoc]`* For example: `SapAepreq01`
Name of the IDoc business object for basic IDocs	`Sap` + *`Name of IDoc`* + *`BO`* For example, the business object for the IDoc MATMAS03 is: `SapMatmas03BO`
Name of the IDoc business object for extension type IDocs	`Sap` + *`Name of IDoc`* + *`Name of Extension type IDoc`* For example, the business object for the IDoc DELVRY03 and extension SD_DESADV_PDC is: `SapDelvry03SdDesadvPdc`

For an IDoc duplicate name, the Adapter Connection wizard adds a unique suffix to differentiate the business object. If an IDoc packet has two segments with the same name (for example, segOrder), the first business object is assigned the name `SapSegOrder` and the second business object is assigned a name such as `SapSegOrder619647890`, where 619647890 is the unique identifier that is appended to the name by the Adapter Connection wizard.

SAP connection properties for the Adapter Connection wizard:

Connection properties establish a connection between the Adapter Connection wizard, a tool that is used to create business objects, and the SAP server. The properties that you configure in the Adapter Connection wizard specify such things as connection configuration, and tracing and logging options.

After you have established a connection between the Adapter Connection wizard and the SAP server, the wizard can access the metadata that it needs from the SAP server to create business objects.

Some of the properties that you set in the Adapter Connection wizard are used as the initial values for resource adapter, managed connection factory, and activation specification properties that you can specify at a later time in the wizard.

The connection properties and their purpose are described in the following table. A complete description of each property is provided in the sections that follow the table. If you set any of these connection properties using bidirectional script, you must set values that identify the format of the bidirectional script that is entered for that property.

Table 66. Connection properties for the Adapter for SAP Software

Property name	Description
"Bidi direction " on page 4045	The orientation component of the bidi format specification.
"Bidi ordering schema" on page 4046	The ordering schema of the bidi format specification.
"Bidi numeric shaping" on page 4046	The numeric shaping component of the bidi format specification.
"Bidi shaping" on page 4046	The shaping component of the bidi format specification.
"Bidi symmetric swapping" on page 4047	The symmetric swapping component of the bidi format specification.
"Client" on page 4047	The client number of the SAP system to which the adapter connects
"Codepage number (Codepage)" on page 4047	Indicates the numeric identifier of the code page
"Folder for RFC trace files (RfcTracePath)" on page 4048	Sets the fully qualified local path to the folder into which the RFC trace files are written
"Host name (ApplicationServerHost)" on page 4048	Specifies the IP address or the name of the application server host that the adapter logs on to
"Language code" on page 4049	Specifies the language in which the adapter logs on.
"Log file output location property" on page 4049	The location of the log file for enterprise metadata discovery.
"Logging level property" on page 4049	The type error for which logging occurs during enterprise metadata discovery.
"Password" on page 4050	The password of the user account of the adapter on the SAP application server
"RFC trace level (RcfTraceLevel)" on page 4051	Specifies the global trace level

Table 66. Connection properties for the Adapter for SAP Software (continued)

Property name	Description
"RFC trace on (RcfTraceOn)" on page 4051	Specifies whether to generate a text file detailing the RFC activity for each event listener
"SAP interface name" on page 4052	The SAP interface to be used.
"System number (SystemNumber)" on page 4052	The system number of the SAP application server
"User name (userName)" on page 4053	The user account for the adapter on the SAP server

The Adapter Connection wizard uses the bidirectional connection properties to apply the correct bidirectional transformation on the data that is passed to the SAP server.

The bidi properties specify the bidirectional format for data coming from an external application into the adapter in the form of any business object that is supported by this adapter.

Accept the default values for the bidirectional formatting properties on the Adapter Connection wizard that provides SAP server bidirectional format specification. When combined, these bidirectional properties define one single bidirectional format.

The default values for bidirectional formatting properties listed in this section are based on Windows bidirectional formatting. If the Enterprise Information System supports a bidirectional format other than the Windows standard bidirectional format, you must make appropriate changes to the bidi properties that are listed in the following sections.

Bidi direction

This property specifies the orientation component of the bidi format specification.

Table 67. Bidi direction details

Required	No
Possible values	Possible values include: • `LTR` The orientation is left-to-right. • `RTL` The orientation is right-to-left. • `contextualLTR` The orientation is left-to-right because of the context. A character that is not categorized as LTR, and hat is located between two strong characters with a different writing direction, inherits the main context's writing direction (in a LTR document the character becomes LTR). • `contextualRTL` The orientation is right-to-left because of the context. A character that is not categorized as RTL, and is located between two strong characters with a different writing direction, inherits the main context's writing direction (in a RTL document the character becomes RTL).
Default	`LTR`
Property type	String
Usage	Specifies the orientation component of the bidi format specification.
Globalized	Yes

Table 67. Bidi direction details (continued)

Bidi supported	No

Bidi ordering schema

This property specifies the ordering schema of the bidi format specification.

Table 68. Bidi ordering schema details

Required	No
Possible values	`Implicit` `Visual`
Default	`Implicit`
Property type	String
Usage	Specifies the ordering schema of the bidi format specification.
Globalized	Yes
Bidi supported	No

Bidi numeric shaping

This property specifies the numeric shaping component of the bidi format specification.

Table 69. Bidi numeric details

Required	No

Possible values	`Nominal`
	`National`
	`Contextual`

Default	`Nominal`
Property type	String
Usage	Specifies the numeric shaping component of the bidi format specification.
Globalized	Yes
Bidi supported	No

Bidi shaping

This property specifies the shaping component of the bidi format specification.

Table 70. Bidi shaping details

Required	No

Possible values	`Nominal`
	`Shaped`
	`Initial`
	`Middle`
	`Final`
	`Isolated`

Default	`Nominal`
Property type	String
Usage	Specifies the shaping component of the bidi format specification.

Table 70. Bidi shaping details (continued)

Globalized	Yes
Bidi supported	No

Bidi symmetric swapping

This property specifies the symmetric swapping component of the bidi format specification.

Table 71. Bidi symmetric swapping details

Required	No
Possible values	`True` `False`
Default	`True`
Property type	Boolean
Usage	This property specifies the symmetric swapping component of the bidi format specification.
Globalized	Yes
Bidi supported	No

Client

This property is the client number of the SAP system to which the adapter connects.

Table 72. Client details

Required	Yes
Possible values	You can enter a range of values from `000` to `999`.
Default	`100`
Property type	Integer
Usage	When an application attempts to log on to the SAP server, the application must have a Client number associated with it. The Client property value identifies the client (the adapter) that is attempting to log onto the SAP server.
Globalized	No
Bidi supported	No

Codepage number (Codepage)

The numeric identifier of the code page.

Table 73. Codepage number details

Required	No
Possible values	You can enter a range of values from `0000` to `9999`. For a full listing of languages and associated code page numbers that are supported by SAP, see SAP Note 7360.
Default	The default value for this property is conditionally determined by the value set for the **Language code** property.
Property type	Integer

Table 73. Codepage number details (continued)

Usage	The value that is assigned to the **Codepage number** defines the code page to be used and has a one-to-one relationship with the value set for the **Language code** property. The **Codepage number** establishes a connection to the appropriate language. Each language code value has a code page number value associated with it. For example, the language code for English is EN. If you select EN (English) as your language code, the code page number is automatically set to the numeric value that is associated with EN (English). The SAP code page number for EN (English) is `1100`.
Example	If **Language code** is set to `JA` (Japanese), **Codepage number** is set to `8000`.
Globalized	No
Bidi supported	No

Folder for RFC trace files (RfcTracePath)

This property sets the fully qualified local path to the folder in which to write RFC trace files.

Table 74. Folder for RFC trace files details

Required	No
Default	No default value
Property type	String
Usage	Identifies the fully qualified local path into which RFC trace files are written. If **RFC trace on** is set to False (not selected), you are not permitted to set a value in the **Folder for RFC trace files** property.
Example	`c:\temp\rfcTraceDir`
Globalized	Yes
Bidi supported	No

Host name (ApplicationServerHost)

Specifies the IP address or the name of the application server host that the adapter logs on to.

Table 75. Host name details

Required	Yes (when load balancing is not used).
Default	No default value
Property type	String
Usage	When the adapter is configured to run without load balancing, this property specifies the IP address or the name of the application server that the adapter logs on to.
Example	`sapServer`
Globalized	No
Bidi supported	No

Language code

SAP logon language code.

Table 76. Language code details

Required	Yes
Possible values	Each of the supported languages is preceded by a 2 character language code. The language itself is displayed in parentheses. The language codes in the list represent the SAP default set of 41 languages for non Unicode systems plus Arabic. For a full listing of supported language codes and languages, see the SAP documentation.
Default	The default language code will be your current locale. If your current locale is not listed as one of the supported language codes, then a default language code of `EN (English)` is used.
Property type	String
Usage	If you manually enter a language code, you do not need to enter the language in parentheses.
Example	If the system locale is English, the value for this property is `EN (English)`
Globalized	No
Bidi supported	No

Log file output location property

This property specifies the location of the log file for external metadata discovery.

Table 77. Log file output location details

Required	Yes
Default	The `.metadata` directory of the workspace
Property type	String
Usage	Use this directory to hold the log file that lists the errors that occur during the discovery process. The type of discovery errors for which logging occurs is controlled by the **Logging level** property
Example	`C:\IBM\WMBT700\workspace\.metadata\SAPMetadataDiscovery.log`
Globalized	Yes
Bidi supported	No

Logging level property

This property specifies the type error for which logging occurs during enterprise metadata discovery.

Table 78. Logging level details

Required	No

Table 78. Logging level details (continued)

Possible values	FATAL SEVERE WARNING AUDIT INFO CONFIG DETAIL
Default	SEVERE
Property type	String
Usage	Use this property to tailor tracing capabilities. When you specify an error type, you indicate that trace operations occur only for errors of the specified type.
Example	If you accept the default value of SEVERE, trace information is provided on errors that fall into the SEVERE category. Severe errors mean that an operation cannot continue, although the adapter can still function. Severe errors also include error conditions that indicate an impending fatal error, that is, reporting on situations that strongly suggest that resources are on the verge of being depleted. Other error descriptions are listed here: • Fatal Adapter cannot continue. Adapter cannot function • Warning Potential error or impending error, including conditions that indicate a progressive failure (for example, the potential leaking of resources). • Audit Significant event affecting adapter state or resources • Info General information outlining overall operation progress. • Config Configuration change or status. • Detail General information detailing operation progress
Globalized	Yes
Bidi supported	No

Password

This property is the password of the user account of the adapter on the SAP application server.

Table 79. Password details

Required	Yes
Default	No default value
Property type	String

Table 79. Password details (continued)

Usage	The restrictions on the password depend on the version of SAP Web Application Server. • For SAP Web Application Server version 6.40 or earlier, the password: – Must be uppercase – Must be 8 characters in length • For versions of SAP Web Application Server later than 6.40, the password: – Is not case-sensitive – Can be up to 40 characters in length
Globalized	No
Bidi supported	Yes

RFC trace level (RcfTraceLevel)

This property specifies the global trace level.

Table 80. RFC trace level details

Required	No
Possible values	`1` - This is the default RFC trace level. When specified, SAP JCo Java API logging occurs. `3` - When specified, SAP JCo JNI API logging occurs. `5` - When specified, error diagnostic logging occurs.
Default	`1`
Property type	Integer
Usage	If **RFC trace on** is set to `False` (not selected), you cannot set a value in the **RFC trace level** property.
Globalized	No
Bidi supported	No

RFC trace on (RcfTraceOn)

This property specifies whether to generate a text file detailing the RFC activity for each event listener.

Table 81. RFC trace on details

Required	No
Possible values	`True` `False`
Default	`False`
Property type	Boolean
Usage	A value of `True` activates tracing, which generates a text file. This file is created in the directory in which the adapter process was started. The file has a prefix of `rfx` and a file type of trc (for example, rfc03912_02220.trc). Use these text files in a development environment only, because the files can grow rapidly. If **RFC trace on** is set to `False` (not selected), you cannot set values in the **Folder for RFC trace files** or **RFC trace level** properties.

Table 81. RFC trace on details (continued)

Example	Examples of the information in the file are RfcCall FUNCTION BAPI_CUSTOMER_GETLIST, followed by the information for the parameters in the interface, or RFC Info rfctable, followed by the data from one of the interface tables. The trace file is created in the directory where the adapter process has been started. The trace file has a .trc file extension and the file name will start with the letters `rfc` followed by a unique identifier. For example, `rfc03912_02220.trc`.
Globalized	No
Bidi supported	No

SAP interface name

This property indicates whether you are creating business objects for the ALE, BAPI, Advanced event processing, or Query interface for SAP Software.

Table 82. SAP interface name details

Required	Yes

Possible values	For outbound:
	`Advanced event processing (AEP)`
	`ALE`
	`ALE pass-through IDoc`
	`BAPI`
	`BAPI work unit`
	`BAPI result set`
	`Query interface for SAP Software (QSS)`
	
	For inbound:
	`Advanced event processing (AEP)`
	`ALE`
	`ALE pass-through IDoc`
	`BAPI`

Default	For outbound: `BAPI` For inbound:`ALE`
Property type	String
Usage	Specifies the interface used by the adapter. The adapter interacts with the interface to support outbound or inbound processing by enabling the exchange of data in the form of business objects.
Globalized	No
Bidi supported	No

System number (SystemNumber)

This property is the system number of the SAP application server.

Table 83. System number details

Required	Yes
Possible values	You can enter a range of values from `00` to `99`.

Table 83. System number details (continued)

Default	`00`
Property type	Integer
Usage	The system number further identifies the Gateway service.
Globalized	No
Bidi supported	No

User name (userName)

This property is the user account for the adapter on the SAP server.

Table 84. User name details

Required	Yes
Default	No default value
Property type	String
Usage	Maximum length of 12 characters. The user name is not case sensitive. It is recommended that you set up a CPIC user account in the SAP application and that you give this account the necessary privileges to manipulate the data required by the business objects supported by the adapter. For example, if the adapter must perform certain SAP business transactions, the adapter's account in the SAP application must have the permissions set to allow it to perform these transactions.
Example	`SapUser`
Globalized	Yes
Bidi supported	Yes

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and PeopleSoft.

Use the SAPRequest node to send requests to an SAP application.

Inbound adapter properties for SAP:

Inbound adapter properties hold the inbound event processing configuration information for a message endpoint. These properties also control the general operation of the adapter. Use the Adapter Connection wizard to set these properties.

These properties are used during endpoint activation to notify the adapter of eligible event listeners. During inbound processing, the adapter uses these event listeners to receive events before it forwards them to the endpoint.

The following table lists the properties for inbound processing that you set by using the Adapter Connection wizard. A more detailed description of each property is provided in the sections that follow the table.

Table 85. Activation specification properties for ALE inbound processing

Property name	Description
Adapter ID to use for logging and tracing (AdapterID)	A specific deployment, or instance, of the adapter
ALE packet audit (alePacketUpdate)	Specifies if the adapter should send ALEAUD per IDoc or per packet (TID)
ALE update status (aleUpdateStatus)	Specifies whether an audit trail is required for all message types
Assured once-only delivery (AssuredOnceDelivery)	Specifies whether to provide assured once-only delivery for inbound events
Auto create event table (EP_CreateTable)	Specifies whether the adapter should create the event recovery table automatically if it does not already exist

Table 85. Activation specification properties for ALE inbound processing (continued)

Property name	Description
Client (Client)	The client number of the SAP system to which the adapter connects
Codepage number (Codepage)	Indicates the numeric identifier of the code page
Database schema name (EP_SchemaName)	The schema that is used for automatically creating the event recovery table
Delivery type (DeliveryType)	Determines the order in which events are delivered by the adapter to the export component.
Enable secure network connection (SncMode)	Indicates whether secure network connection mode is used
Event recovery data source (JNDI) name (EP_SchemaName)	The JNDI name of the data source that is configured for event recovery
Event recovery table name (EP_TableName)	The name of the event recovery table
Event types to process (EventTypeFilter)	A delimited list of event types that the WebSphere Adapter for SAP Software should deliver.
Failure code (aleFailureCode)	The status code for dispatch failure
Failure text (aleFailureText)	The descriptive text for dispatch failure
Folder for RFC trace files (RfcTracePath)	Sets the fully qualified local path to the folder into which the RFC trace files are written
Gateway host (GatewayHost)	The host name of the SAP gateway
Gateway service (GatewayService)	The identifier of the gateway on the gateway host that carries out the RFC services
Host name (ApplicationServerHost)	Specifies the IP address or the name of the application server host that the adapter logs on to
Ignore IDoc packet errors (IgnoreIDocPacketErrors)	Specifies what the adapter does when it encounters an error while processing the IDoc packet
Language code (Language code)	Specifies the Language code in which the adapter logs on to SAP
Logon group name (Group)	An identifier of the name of the group of application server instances that have been defined in transaction SMLG and linked together for logon load balancing
Maximum number of events collected during each poll (PollQuantity)	The number of events that the adapter delivers to the export during each poll period.
Message server host (MessageServerHost)	Specifies the name of the host on which the message server is running
Number of listeners (NumberOfListeners)	Specifies the number of event listeners that are to be started
Partner character set (PartnerCharset)	Specifies PartnerCharset encoding
Password (Password)	The password of the user account of the adapter on the SAP application server
Password used to connect to event data source (EP_Password)	The user password for connecting to the database
RFC program ID (RfcProgramID)	The remote function call identifier under which the adapter registers in the SAP gateway
RFC trace level (RcfTraceLevel)	Specifies the global trace level
RFC trace on (RcfTraceOn)	Specifies whether to generate a text file detailing the RFC activity for each event listener

Table 85. Activation specification properties for ALE inbound processing (continued)

Property name	Description
SAP system ID (SAPSystemID)	Specifies the system ID of the SAP system for which logon load balancing is allowed
Secure network connection library path (SncLib)	Specifies the path to the library that provides the secure network connection service
Secure network connection name (SncMyname)	Specifies the name of the secure network connection
Secure network connection partner (SncPartnername)	Specifies the name of the secure network connection partner
Secure network connection security level (SncQop)	Specifies the level of security for the secure network connection
Selective update (aleSelectiveUpdate)	The IDoc Type and MessageType combinations that are to be updated when the adapter is configured to update a standard SAP status code
Status message code (aleStatusMsgCode)	If required, the message code to use when the adapter posts the ALEAUD Message IDoc (ALEAUD01)
Stop polling on error (StopPollingOnError)	Specifies whether the adapter stops polling for events when it encounters an error during polling.
Success code (aleSuccessCode)	The success status code for Application Document Posted
Success text (aleSuccessText)	The descriptive text for successful Application Document Posted
System number (SystemNumber)	The system number of the SAP application server
Interval between polling periods (PollPeriod)	The length of time that the adapter waits between polling periods.
Retry interval if connection fails (RetryInterval)	The length of time that the adapter waits between attempts to establish a new connection after an error during inbound operations.
User name (userName)	The user account for the adapter on the SAP server
User name used to connect to event data source (EP_UserName)	The user name for connecting to the database
X509 certificate (X509cert)	Specifies the X509 certificate to be used as the logon ticket

Adapter ID to use for logging and tracing (AdapterID)

This property identifies a specific deployment, or instance, of the adapter.

Table 86. Adapter ID to use for logging and tracing details

Required	Yes
Default	`001`
Property type	String

Table 86. Adapter ID to use for logging and tracing details (continued)

Usage	This property identifies the adapter instance in the log and trace files, and also helps identify the adapter instance while monitoring adapters. The adapter ID is used with an adapter-specific identifier, SAPRA, to form the component name used by the Log and Trace Analyzer tool. For example, if the adapter ID property is set to 001, the component ID is SAPRA001. If you run multiple instances of the same adapter, ensure that the first eight characters of the adapter ID property are unique for each instance so that you can correlate the log and trace information to a particular adapter instance. By making the first seven characters of an adapter ID property unique, the component ID for multiple instances of that adapter is also unique, allowing you to correlate the log and trace information to a particular instance of an adapter. For example, when you set the adapter ID property of two instances of WebSphere Adapter for SAP Software to 001 and 002. The component IDs for those instances, SAPRA001 and SAPRA002, are short enough to remain unique, enabling you to distinguish them as separate adapter instances. However, instances with longer adapter ID properties cannot be distinguished from each other. If you set the adapter ID properties of two instances to Instance01 and Instance02, you will not be able to examine the log and trace information for each adapter instance because the component ID for both instances is truncated to SAPRAInstance. For inbound processing, this property is retrieved from the resource adapter properties. For outbound processing, it is retrieved from the managed connection factory properties.
Globalized	Yes
Bidi supported	No

ALE packet audit

ALE update per packet indicates whether the adapter should send ALEAUD audit IDocs per packet or per IDoc.

Table 87. ALE packet audit details

Required	No
Default	`False` (send ALEAUD per IDoc).
Property type	Boolean
