Creating ESQL for a node:

Create ESQL code to customize the behavior of a Compute, Database, DatabaseInput, or Filter node in an ESQL file.

Before you begin

Before you start:

This topic assumes that you have created an ESQL file. For more information, see "Creating an ESQL file" on page 2391.

About this task

In the ESQL file, create a module that is associated with a node in your message flow. A module can be associated with only one node of a particular type (Compute, Database, DatabaseInput, or Filter). Within the module, you can create and use functions and procedures in addition to the supplied statements and functions. You can also create local constants and variables.

If you have created constants, functions, or procedures at the broker schema level, you can also refer to these in the module. You can define routines at a level at which many different modules can use them, which can save you development time and maintenance effort.

To create ESQL for a node, complete the following steps.

Procedure

1. In the Broker Development view, double-click the message flow that includes the node for which you want to create ESQL. The message flow opens in the editor view.
2. Right-click a Compute, Database, DatabaseInput, or Filter node, then click **Open ESQL**. The default ESQL file for this message flow, *message_flow_name*.esql, opens in the editor view. If the file does not already exist, it is created, containing a skeleton module for this node at the end. The exact content depends on the type of node.

   If you have already created the file, it is opened in the editor view and a new module is created and highlighted.

   The following module is created for a Compute node:

```
CREATE COMPUTE MODULE module_name
       CREATE FUNCTION Main() RETURNS BOOLEAN
       BEGIN
              -- CALL CopyMessageHeaders();
              -- CALL CopyEntireMessage();
              RETURN TRUE;
       END;

       CREATE PROCEDURE CopyMessageHeaders() BEGIN
              DECLARE I INTEGER 1;
              DECLARE J INTEGER CARDINALITY(InputRoot.*[]);
              WHILE I < J DO
                     SET OutputRoot.*[I] = InputRoot.*[I];
                     SET I = I + 1;
              END WHILE;
       END;

       CREATE PROCEDURE CopyEntireMessage() BEGIN
              SET OutputRoot = InputRoot;
       END;
END MODULE;
```

   The module name is determined by the value that you have set for the corresponding node property. The default name is *message_flow_name_node_type*. The main function contains calls to two procedures (described in the following list) that are declared in the Compute node module following the function Main. These calls are commented out. To include the function that they provide, uncomment the lines and place them at the appropriate point in the ESQL that you create for Main.

   CopyMessageHeaders
   : This procedure loops through the headers contained in the input message and copies each one to the output message.

   CopyEntireMessage
   : This procedure copies the entire contents of the input message, including the headers, to the output message.

   If you create an ESQL module for a Database node, the following module is created:

```
CREATE DATABASE MODULE module_name
       CREATE FUNCTION Main() RETURNS BOOLEAN
       BEGIN
              RETURN TRUE;
       END;
END MODULE;
```

For a DatabaseInput node, the module that is created contains three procedures, ReadEvents, BuildMessage, and EndEvent. Each of these procedures contains boilerplate text, which describes how the procedure works. For more information about configuring DatabaseInput nodes, see "Configuring a DatabaseInput node" on page 2120. For a DatabaseInput node, the following first line of the module is created:

```
CREATE DATABASEEVENT MODULE module_name
```

For a Filter node, the module is identical to the module created for the Database node, except for the first line, which reads:

```
CREATE FILTER MODULE module_name
```

3. Add ESQL to this file to customize the behavior of the node.

   For Compute, Database, or Filter nodes, start by adding ESQL statements in the Main function, (after the BEGIN statement, and before RETURN TRUE). For DatabaseInput nodes, add ESQL statements in the ReadEvents, BuildMessage, and EndEvent procedures. You can add DECLARE statements in the module that are not within the Main function. To add a new line into the file, press Enter.

   To help you to code valid ESQL, the editor shows a list of valid statements and functions at the point of the cursor. To start this assistance, click **Edit** > **Content Assist**. On some systems, you can use the key combination Ctrl+Space. Scroll through the list to find and highlight the statement or function that you want, and press Enter. The appropriate code is inserted into your module.

   Content assistance is provided in the following areas:

   - Applicable keywords, based on language syntax.
   - Blocks of code that go together, such as `BEGIN END;`.
   - Constants that you have defined, identifiers, labels, functions, and procedures that can be used, where the routines can be in any projects, even if the current project does not reference them.
   - Database schema and table names after the database correlation name, table column names in INSERT, UPDATE, DELETE, and SELECT statements, and, in most cases, the WHERE clauses of those statements.
   - Elements of message field reference: runtime domain (parser) names, format of type expression, namespace identifiers, namespace-qualified element and attribute names, and format of index expression.
   - Content in the Properties folder under the output message.
   - For the DECLARE NAMESPACE statement, target namespaces of message sets and schema names.

   Content assistance works only if the ESQL can be parsed correctly. Errors such as END missing after BEGIN, and other unterminated block statements, cause parser failures and no content assistance is provided. Try content assistance in other areas around the statement where it does not work to narrow down the point of error. Alternatively, save the ESQL file; saving the file causes validation, and all syntax errors are written to the Problems view. Refer to the errors reported to understand and correct the ESQL syntax. If you use content assistance to generate most statements (such as block statements), these statements are correctly entered and there is less opportunity for error.
4. When you have finished working with this module, save and close the ESQL file.

Results

You can also open the ESQL file directly and create the module in that file by using the editor:

1. Open the ESQL file in which you want to create the module.
2. In the editor view, position your cursor on a new line and use content assistance to select the appropriate module skeleton for this type of node, for example `CREATE COMPUTE MODULE END MODULE;`. You can also type in this text, but you must ensure that what you type is consistent with the required skeleton, shown earlier. Use content assistance to give you additional help by inserting only valid ESQL, and by inserting matching end statements (for example, `END MODULE;`) where they are required.
3. Complete the coding of the module as appropriate.

Whichever method you use to open the ESQL file, be aware that the editor provides functions to help you to code ESQL. This section refers to content assistance; other functions are available. For information about these functions, see "ESQL editor" on page 6798.

"ESQL editor" on page 6798
The ESQL editor is the default editor provided by the Broker Application Development perspective for editing ESQL (`.esql`) files.

Modifying ESQL for a node:

To change the customization of a node that requires ESQL (Compute, Database, DatabaseInput, or Filter node), modify the ESQL statements in the module that you created for that node.

Before you begin

Before you start:

This topic assumes that you have created ESQL code for a file. For more information, see "Creating ESQL for a node" on page 2394.

About this task

To modify ESQL code, complete the following steps.

Procedure

1. In the Broker Development view, select the message flow that you want to work with and double-click it. The message flow is opened in the editor view.
2. Right-click the node that corresponds to the ESQL module that you want to modify and click **Open ESQL**. The ESQL file is opened in the editor view. The module for this node is highlighted.
3. Make the required changes in the module by entering new statements, changing existing statements by over-typing, or deleting statements by using the Delete or backspace keys. You can use Content Assist, available from the **Edit** menu or, on some systems, by pressing Ctrl+Space). To get Content Assist to work with message references, you must set up a project reference from the project containing the ESQL to the project containing the message set. For information about setting up a project reference, see "Project references" on page 44.
4. You can change the name of the module with which you are working by over-typing the current name with the new one. In this case, you must also change the node property `ESQL Module` to reflect the new name, to ensure that the correct ESQL code is deployed with the node.
5. When you have finished working with this module, save and close the ESQL file.

Results

You can also open the ESQL file directly by double-clicking it in the Broker Development view. You can select the module with which you want to work from the Outline view.

The editor provides functions that you can use to help you modify your ESQL code. These functions are described in "ESQL editor" on page 6798.

You can also modify the ESQL source by clicking **Source** > **Format**. This option formats all selected lines of code (unless only partially selected, when they are ignored), or, if no lines are selected, formats the entire file (correcting alignments and indentation).

Adding comments to ESQL:

About this task

You can add and remove comments in your ESQL code.

Procedure

- To change an existing line of code into a comment line, click **Source** > **Comment**.
- To change a comment line to a code line, click **Source** > **Uncomment**.
- To create a new comment line, press Enter to create a new line, then either type the comment identifier `--` or click **Source** > **Comment**. You can enter any text after the identifier; everything that you type is ignored by the ESQL editor.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

"ESQL editor" on page 6798
The ESQL editor is the default editor provided by the Broker Application Development perspective for editing ESQL (`.esql`) files.

Saving an ESQL file:

When you edit an ESQL file, you can save it to preserve the additions and modifications that you have made, and to force the editor to validate the content of the file.

Before you begin

Before you start:

This task assumes that you have created or opened an ESQL file. For more information, see “Creating an ESQL file” on page 2391 or “Opening an existing ESQL file” on page 2393.

About this task

To save an ESQL file, complete the following steps.

Procedure

1. Change the contents of the ESQL file.
2. Save the file by clicking **File** > **Save** or **File** > **Save All**.

   When you save the file, the validator is called by the editor to check that the ESQL obeys all grammar and syntax rules (specified by the syntax diagrams and explanations in “ESQL reference” on page 5019).

   You can request additional validation when you set ESQL preferences:

   a. Click **Window** > **Preferences**. The Preferences dialog box is displayed.
   b. Expand **Broker Development** and **ESQL**, then click **Validation**.
   c. Select the level of validation that you require for each category of error:
      1) Unresolved identifiers
      2) Message references do not match message definitions
      3) Database references do not match database schema
      4) Use of deprecated keywords

      The default level is *warning*; you can change this value to *error* or *ignore*.

      Validating message definitions can affect response times in the editor, particularly if you have complicated ESQL that makes many references to a complex message definition. You might choose to delay this validation. Call validation when you have finished developing the message flow and are about to deploy it, to avoid runtime errors. For each error found, the editor writes the code line number and the reason for the error; errors are created as entries in the Problems view.
3. If you double-click the error, the editor positions your cursor on the line in which it found that error. The line is also highlighted by the error icon  . The editor might also find potential error situations, which it highlights as warnings (with the warning icon ); the editor also writes these warnings to the Problems view. For example, you might have included a `BROKER SCHEMA` statement that references an invalid schema (namespace).

   Check your code, and make the corrections required by that statement or function.

Save As:
About this task

You can save a copy of this ESQL file by using **File** > **Save As**.

Procedure

1. Click **File** > **Save As**.

2. Specify the message flow project in which you want to save a copy of the ESQL file. The project name defaults to the current project. You can accept this name, or choose another name from the valid options that are displayed in the File Save dialog box.
3. Specify the name for the new copy of the ESQL file. To save this ESQL file in the same project, either rename it, or confirm that you want to overwrite the current copy (that is, copy the file to itself).

   To save this ESQL file in another project, the project must exist. You can save the file with the same or another name in another project.
4. Click **OK**. The message flow is saved and the message flow editor validates its contents. The editor provides a report of all errors that it finds in the Problems view.

Copying an ESQL file:

You can copy an ESQL file as a starting point for a new ESQL file that has similar function.

Before you begin

Before you start:

This topic assumes that you have created an ESQL file. For more information, see "Creating an ESQL file" on page 2391.

About this task

To copy an ESQL file, complete the following steps.

Procedure

1. In the Broker Development view, right-click the ESQL file that you want to copy, and click **Copy**.

   Alternatively, you can select the ESQL file and click **Edit** > **Copy**.
2. Right-click the broker schema in the message flow project to which you want to copy the ESQL file and click **Paste**. You can copy the ESQL file to the same broker schema within the same message flow project, or to a different broker schema within the same message flow project, or to a broker schema in a different message flow project.

   When you copy an ESQL file, the associated files (message flow, and mapping if present) are not automatically copied to the same target message flow project. If you want these files copied as well, you must do this explicitly following this procedure.

   If you want to use this ESQL file with another message flow, ensure that the modules within the ESQL file match the nodes that you have in the message flow, and that the node properties are set correctly.

Results

You can also copy an ESQL file by using **File** > **Save As**; for more information, see "Saving an ESQL file" on page 2399.

Related concepts:

Analyzing planned changes to ESQL objects:

Use impact analysis to analyze the effect of renaming or moving ESQL objects, or moving or changing the broker schema of an ESQL file.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message flow project" on page 1425
- "Creating an ESQL file" on page 2391
- "Enabling and disabling indexing" on page 1454

About this task

This information covers the following tasks:

- "Renaming ESQL objects"
- "Moving ESQL objects" on page 2404
- "Moving an ESQL file" on page 2404

If a node in the message flow contains either an ESQL path expression, or an XPath expression, it might not be possible to unambiguously determine which structure in the message set the expression refers to. Ambiguity occurs when multiple constructs have the same name, and the parent of the construct cannot be determined. For example, consider a message definition that has the following constructs:

Global element declaration with name G1

Global element declaration with name G2

Global element declaration with name G3

G2 contains an element reference to global element G1

G3 contains a local element declaration with name G1

An ESQL path is in the MRM domain as follows:

```
InputRoot.MRM.ns1:G1
```

The construct G1 cannot be unambiguously determined. It can refer to G2/G1 or G3/G1. In this case, impact analysis reports both G2/G1 and G3/G1 as potential impacts. The list of secondary impacts might contain references to elements that are not in fact affected by the primary change.

Renaming ESQL objects:
About this task

You can rename the following objects:

- ESQL modules

- Schema-scope ESQL routines
- Schema-scope ESQL constants

Procedure

1. In the Broker Development view, right-click the object that you want to rename, then click **Impact Analysis** > **Rename**.
2. In the Impact Analysis - Rename Artifact window, type the new name of the object, then click **Analyze Impact**.

   The Rename Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Moving ESQL objects:
About this task

You can move the following objects to a different file:

- ESQL modules
- Schema-scope ESQL constants
- Schema-scope ESQL routines

Procedure

1. Right-click the object that you want to move, then click **Impact Analysis** > **Move**. The Impact Analysis - Move Artifact window is displayed.
2. In the bottom panel, under 'Choose the new container for the selected items', select the new ESQL file for the object, then click **Analyze Impact**.

   The Impact Analysis - Move Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Moving an ESQL file:
Procedure

1. In the Broker Development view, right-click the file, then click **Impact Analysis** > **Move**.
2. In the bottom panel, select the new broker schema for the object, then click **Analyze Impact**.

   The Impact Analysis - Move Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

Renaming an ESQL file:

You might want to rename an ESQL file if you have renamed the message flow with which it is associated.

Before you begin

Before you start:

This task assumes that you have created an ESQL file, as described in "Creating an ESQL file" on page 2391.

To find out which other objects are likely to be affected by the change, see "Analyzing planned changes to ESQL objects" on page 2403.

About this task

To rename an ESQL file, complete the following steps.

Procedure

1. In the Broker Development view, right-click the ESQL file that you want to rename and click **Rename**. Alternatively, you can select the ESQL file, then click **File** > **Rename**.

   The Rename Resource dialog box opens.
2. Enter the new name for the ESQL file, then click **OK**.

   The ESQL file is renamed.

SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Moving an ESQL file:

If you move a message flow from one broker schema to another, or from one project to another, you might want to move all ESQL files that are associated with that message flow.

Before you begin

Before you start

To complete this task, you must have completed the following task:
- "Creating an ESQL file" on page 2391

About this task

To move an ESQL file:

Procedure

1. Move the ESQL file in one of the following ways:
   - Drag the ESQL file that you want to move from its current location to a broker schema within the same or another message flow project.

     If the target location that you have chosen is not valid (for example, if an ESQL file of this name exists in the broker schema), the invalid icon is displayed and the move is not completed. If you have created an empty broker schema for this purpose, it might not be visible in the Broker

Development view if category mode is selected. To see an empty schema in the Broker Development view, click Hide Categories  .

- Right-click the ESQL file and click **Move**, or click **File** > **Move**. The Move dialog is displayed.

  Select the project and the broker schema from the list of valid targets that is shown in the dialog.

  Click **OK** to complete the move, or **Cancel** to cancel the request.

  If you click **OK**, the ESQL file is moved to its new location.

2. Check the Problems view for errors (indicated by the error icon ) or warnings (indicated by the warning icon ) generated by the move.

   The errors in the Problems view include those errors caused by broken references. When the move is completed, all references to this ESQL file are checked. If you have moved the file within the same named broker schema within the same message flow project, all references are still valid. If you have moved the file to another broker schema in the same or another message flow project, the references are broken. If you have moved the file to the same named broker schema in another message flow project, the references might be broken if the project references are not set correctly to recognize external references in this file. These errors occur because resources are linked by a fully qualified name.

3. Double-click each error or warning to open the message flow that has the error in the editor view, and highlight the node in error. You can now correct the error.

Results

When you move an ESQL file, its associated files (for example, the message flow file) are not automatically moved to the same target broker schema. You must move these files yourself.

Changing ESQL editor settings:

When you open an ESQL file in the editor view, you can tailor the editor appearance by changing editor settings.

Procedure

1. **To change ESQL editor settings:**
   a. Click **Window** > **Preferences**. The Preferences dialog box opens.
   b. Expand the item for ESQL on the left and click **ESQL Editor**.
   c. Update the settings available for tab width and colors:
      - Click the **General** tab to change the displayed tab width within the ESQL editor.
      - Click the **Colors** tab to change the color of the editor view background, and of the entities displayed in the editor view. These include comments and keywords in your ESQL code.
   d. When you have completed your changes, click either **Apply** (to apply your changes and leave the Preferences dialog box open), or **OK** (to apply your changes and close the dialog box). Alternatively, to close the dialog box and discard your changes, click **Cancel**.
   e. To return the ESQL editor settings to the initial values, click **Restore Defaults**. All values are reset to the original settings.

      If you change the editor settings when you have an editor session active, the changes are implemented immediately. If you do not have an editor session open, you see the changes when you next edit an ESQL file.
2. **To change font settings for the ESQL editor:**
   a. Click **Window** > **Preferences**. The Preferences dialog box opens.
   b. Expand the item for Workbench on the left of the Preferences dialog box, and click **Colors and Fonts**.
   c. On the **Colors and Fonts** tab, expand Basic.
   d. Select a font or text color option and click **Change**. The Font dialog box opens.
   e. When you have completed your changes, click either **Apply** (to apply your changes and leave the Preferences dialog box open) or **OK** (to apply your changes and close the dialog box). Alternatively, to close the dialog box and discard your changes, click **Cancel**.
   f. To return the ESQL editor settings to the initial values, click **Restore Defaults**.

Changing ESQL validation settings:

You can specify the level of validation that the ESQL editor performs when you save a `.esql` file. If the validation you have requested results in warnings, you can deploy a BAR file containing this message flow. However, if errors are reported, you cannot deploy the BAR file.

About this task

To change ESQL validation settings:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click **Window** > **Preferences**. The Preferences dialog is displayed.
3. Expand the item for ESQL on the left and click Validation.
4. Update the settings for what is validated, and for what warnings or errors are reported. See "ESQL editor" on page 6798 for details of the settings and their values.
5. When you have completed your changes, click **Apply** to close the Preferences dialog, apply your changes and leave the Preferences dialog open. Click **OK** to apply your changes and close the dialog. Click **Cancel** to close the dialog and discard your changes.
6. If you want to return your ESQL editor preferences to the initial values, click **Restore Defaults**. All values are reset to the original settings.

Results

If you make changes to the validation settings, the changes are implemented immediately for currently open edit sessions and for subsequent edit sessions.

Deleting ESQL for a node:

If you delete a node from a message flow, you can delete the ESQL module that you created to customize its function.

Before you begin

Before you start

This topic assumes that you have created ESQL code for a node. For more information, see "Creating ESQL for a node" on page 2394.

About this task

To delete ESQL code, complete the following steps.

Procedure

1. Open the message flow with which you want to work by double-clicking it in the Broker Development view. The message flow is opened in the editor view.
2. Right-click the node for which you want to delete the ESQL module, then click **Open ESQL**. The ESQL file is opened in the editor view, with the module for this node highlighted.
3. Press the Delete or backspace key to delete the whole module.
4. When you have finished working with this module, save and close the ESQL file. Saving the file also validates the ESQL; for more details, see "Saving an ESQL file" on page 2399.

Related concepts:

Deleting an ESQL file:

If you delete a message flow, or if you have deleted all the ESQL code in an ESQL file, you can delete the ESQL file.

Before you begin

Before you start:

This task assumes that you have created an ESQL file. For more information, see "Creating an ESQL file" on page 2391.

About this task

To delete an ESQL file, complete the following steps.

Procedure

1. In the Broker Development view, right-click the ESQL file that you want to delete, and click **Delete**.

   You can also select the file in the Broker Development view, and click **Edit** > **Delete**. A dialog box is displayed that asks you to confirm the deletion.
2. Click **Yes** to delete the file, or **No** to cancel the delete request.

   If you maintain resources in a shared repository, a copy is retained in that repository. You can follow the instructions provided by the repository supplier to retrieve the file if required.

If you are using the local file system or a shared file system to store your resources, no copy of the file is retained. Be careful to select the correct file when you complete this task.

Writing ESQL

How you can use ESQL to customize nodes.

About this task

When you create a message flow, you include input nodes that receive the messages and, optionally, output nodes that send out new or updated messages. If required by the processing that must be performed on the message, you can include other nodes after the input node that complete the actions that your applications need.

Some of the built-in nodes enable you to customize the processing that they provide. The Compute, Database, DatabaseInput, and Filter nodes require you to provide a minimum level of ESQL, and you can provide much more than the minimum to control precisely the behavior of each node. This set of topics discusses ESQL and the ways in which you can use it to customize these nodes.

The DataDelete, DataInsert, DataUpdate, Extract, Mapping, and Warehouse nodes provide a mapping interface with which you can customize their function. The

ways in which you can use the mapping functions associated with these nodes are described in developing message mappings, see “Using message mappings” on page 2228.

ESQL provides a rich and flexible syntax for statements and functions that enable you to check and manipulate message and database content. You can:

- Read the contents of the input message
- Modify message content with data from databases
- Modify database content with data from messages
- Construct new output messages created from all, part, or none of the input message (in the Compute node only)

The following topics provide more information about these and other tasks that you can perform with ESQL. Unless otherwise stated, these guidelines apply to messages in all message domains except the BLOB domain, for which you can implement a limited set of actions.

- “Tailoring ESQL code for different node types” on page 2416
- “Manipulating message body content” on page 2418
- “Manipulating other parts of the message tree” on page 2452
- “Transforming from one data type to another” on page 2473

- “Manipulating messages in the IDOC domain” on page 2610
- “Manipulating messages in the MIME domain” on page 2612
- “Manipulating messages in the BLOB domain” on page 2615
- “Manipulating messages in the JSON domain” on page 2617

ESQL examples:
About this task

Most of the examples included in the topics listed previously show parser-independent ESQL. If examples include a reference to MRM, they assume that you have modeled the message in the MRM and that you have set the names of the MRM objects to be identical to the names of the corresponding tags or attributes in the XML source message. Some examples are also shown for the XML domain. Unless stated otherwise, the principals illustrated are the same for all message domains. For domain-specific information, use the appropriate link in the previous list.

Most of the topics that include example ESQL use the ESQL sample message, Invoice, as the input message to the logic. This message is provided in XML source format (with tags and attributes), see “Example message” on page 5311. The example message is shown in the following diagram.

The topics specific to the MRM domain use the message that is created in the following sample:

- Video Rental

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

A few other input messages are used to show ESQL that provides function on messages with a structure or content that is not included in the Invoice or Video samples. Where this occurs, the input message is included in the topic that refers to it.

Tailoring ESQL code for different node types:

When you code ESQL to configure Compute, Database, DatabaseInput, and Filter node behavior, be aware of the limitations of each type of node.

About this task

Compute node

You can configure the Compute node to do any of the following operations:

- Update data in a database.
- Insert data into a database.
- Delete data from a database.
- Update the environment tree.
- Update the local environment tree.
- Create one or more output messages, with none, some, or all the content of the input message, and propagate these new messages to the next node in the message flow.

  To propagate the input LocalEnvironment to the output LocalEnvironment, remember to set the Compute node property `Compute mode` to an appropriate value. The Environment is always propagated in the output message.

Database node

You can configure the Database node to do any of the following operations:

- Update data in a database.
- Insert data into a database.
- Delete data from a database.
- Update the environment tree.
- Update the local environment tree.
- Propagate the input message to the next node in the message flow.

DatabaseInput node

You can configure the DatabaseInput node to do any of the following operations:

- Respond to updates that are made to the data in a database.
- Create one or more output messages, with none, some, or of all the content retrieved from a database, and propagate these new messages to the next node in the message flow.

Filter node

You can configure the Filter node to do any of the following operations:

- Update data in a database.
- Insert data into a database.
- Delete data from a database.
- Update the environment tree.
- Update the local environment tree.
- Propagate the input message to the next node in the message flow (the terminal through which the message is propagated depends on the result of the filter expression).

View the remaining tasks in this section to find the details of how you can perform these operations.

SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Referencing field types:

Some message parsers have complex models in which it is not enough to identify a field by its name and an array subscript. In these cases, you associate an optional field type with an element of data in the tree format.

About this task

Each element within the parsed tree can be one of three types:

Name element
A name element has a string, which is the name of the element, associated with it. An example of a name element is `XMLElement`, described in "XML element" on page 4267.

Value element
A value element has a value associated with it. An example of a value element is `XMLContent`, described in "XML content" on page 4267.

Name-value element
A name-value element is an optimization of the case where a name element contains only a value element and nothing else. The element contains both a name and a value. An example of a name-value element is `XMLAttribute`, described in "XML attribute" on page 4264.

Accessing elements in the message body:

When you want to access the contents of a message, for reading or writing, use the structure and arrangement of the elements in the tree that is created by the parser from the input bit stream.

About this task

Follow the relevant parent and child relationships from the top of the tree downwards, until you reach the required element.

- If you are referring to the input message tree to interrogate its content in a Compute node, use correlation name `InputBody` followed by the path to the element to which you are referring. `InputBody` is equivalent to `InputRoot` followed by the parser name (for example, `InputRoot.MRM`), which you can use if you prefer.

- If you are referring to the output message tree to set or modify its content in the Compute node, use correlation name `OutputRoot` followed by the parser name (for example, `OutputRoot.MRM`).
- If you are referring to the input message to interrogate its contents in a Database or Filter node, use correlation name `Body` to refer to the start of the message. `Body` is equivalent to `Root` followed by the parser name (for example, `Root.XMLNS`), which you can use if you prefer. You cannot use the `Body` correlation name in a DatabaseInput node.

  You must use these different correlation names because there is only one message to which to refer in a Database or Filter node; you cannot create an output message in these nodes. Use a Compute node to create an output message.

When you construct field references, the names that you use must be valid ESQL identifiers that conform to ESQL rules. If you enclose an item in double quotation marks, ESQL interprets it as an identifier. If you enclose an item in single quotation marks, ESQL interprets it as a character literal. You must enclose all strings (character strings, byte strings, or binary (bit) strings) in quotation marks, as shown in the following examples. To include a single or double quotation mark within a string, include two consecutive single or double quotation marks.

Important: For a full description of field reference syntax, see "ESQL field reference overview" on page 5049.
For more information about ESQL data types, see "ESQL data types in message flows" on page 5020.

Assume that you have created a message flow that handles the message Invoice, shown in the figure in "Writing ESQL" on page 2413. If, for example, you want to interrogate the element `CardType` from within a Compute node, use the following statement:

```
IF InputBody.Invoice.Payment.CardType='Visa' THEN
   DO;
     -- more ESQL --
END IF;
```

If you want to make the same test in a Database or Filter node (where the reference is to the single input message), code:

```
IF Body.Invoice.Payment.CardType='Visa' THEN
   DO;
     -- more ESQL --
END IF;
```

If you want to copy an element from an input XML message to an output message in the Compute node without changing it, use the following ESQL:

```
SET OutputRoot.XMLNS.Invoice.Customer.FirstName =
               InputBody.Invoice.Customer.FirstName;
```

If you want to copy an element from an input XML message to an output message and update it, for example by folding to uppercase or by calculating a new value, code:

```
SET OutputRoot.XMLNS.Invoice.Customer.FirstName =
               UPPER(InputBody.Invoice.Customer.FirstName);
SET OutputRoot.XMLNS.Invoice.InvoiceNo = InputBody.Invoice.InvoiceNo + 1000;
```

If you want to set a STRING element to a constant value, code:

```
SET OutputRoot.XMLNS.Invoice.Customer.Title = 'Mr';
```

You can also use the equivalent statement:

```
SET OutputRoot.XMLNS.Invoice.Customer.Title VALUE = 'Mr';
```

If you want to update an INTEGER or DECIMAL, for example the element `TillNumber`, with the value `26`, use the following assignment (valid in the Compute node only):

```
SET OutputRoot.MRM.Invoice.TillNumber=26;
```

The integer data type stores numbers using the 64-bit twos complement form, allowing numbers in the range -9223372036854775808 to 9223372036854775807. You can specify hexadecimal notation for integers as well as normal integer literal format. The hexadecimal letters A to F can be written in uppercase or lowercase, as can the X after the initial zero, which is required. The following example produces the same result as the example shown earlier:

```
SET OutputRoot.MRM.Invoice.TillNumber= 0x1A;
```

The following examples show SET statements for element types that do not appear in the "Example message" on page 5311.

To set a FLOAT element to a non-integer value, code:

```
SET OutputRoot.MRM.FloatElement1 = 1.2345e2;
```

To set a BINARY element to a constant value, code:

```
SET OutputRoot.MRM.BinaryElement1 = X'F1F1';
```

For BINARY values, you must use an initial character X (uppercase or lowercase) and enclose the hexadecimal characters (also uppercase or lowercase) in single quotation marks, as shown.

To set a BOOLEAN element to a constant value (the value 1 equates to true, 0 equates to false), code:

```
SET OutputRoot.MRM.BooleanElement1 = true;
```

or

```
SET OutputRoot.MRM.BooleanElement1 = 1;
```

You can use the SELECT statement to filter records from an input message without reformatting the records, and without any knowledge of the complete format of each record. Consider the following example:

```
-- Declare local variable
DECLARE CurrentCustomer CHAR 'Smith';

-- Loop through the input message
SET OutputRoot.XMLNS.Invoice[] =
    (SELECT I FROM InputRoot.XMLNS.Invoice[] AS I
               WHERE I.Customer.LastName = CurrentCustomer
    );
```

This code writes all records from the input message to the output message if the WHERE condition (LastName = Smith) is met. All records that do not meet the

condition are not copied from input message to output message. I is used as an alias for the correlation name InputRoot.XMLNS.Invoice[].

The declared variable CurrentCustomer is initialized on the DECLARE statement: this option is the most efficient way of declaring a variable for which the initial value is known.

You can use this alias technique with other SELECT constructs. For example, if you want to select all the records of the input message, and create an additional record:

```
-- Loop through the input message
SET OutputRoot.XMLNS.Invoice[] =
    (SELECT I, 'Customer' || I.Customer.LastName AS ExtraField
              FROM InputRoot.XMLNS.Invoice[] AS I
    );
```

You could also include an AS clause to place records in a subfolder in the message tree:

```
-- Loop through the input message
SET OutputRoot.XMLNS.Invoice[] =
    (SELECT I AS Order
             FROM InputRoot.XMLNS.Invoice[] AS I
    );
```

If you are querying or setting elements that contain, or might contain, null values, be aware of the following considerations:

Querying null values

When you compare an element to the ESQL keyword NULL, this tests whether the element is present in the logical tree that has been created from the input message by the parser.

For example, you can check whether an invoice number is included in the current invoice message with the following statement:

```
IF InputRoot.XMLNS.Invoice.InvoiceNo IS NULL THEN
   DO;
     -- more ESQL --
END IF;
```

You can also use an ESQL reference, as shown in the following example:

```
DECLARE cursor REFERENCE TO InputRoot.MRM.InvoiceNo;

IF LASTMOVE(cursor) = FALSE THEN
   SET OutputRoot.MRM.Analysis = 'InvoiceNo does not exist in logical tree';
ELSEIF FIELDVALUE(cursor) IS NULL THEN
   SET OutputRoot.MRM.Analysis =
       'InvoiceNo does exist in logical tree but is defined as an MRM NULL value';
ELSE
   SET OutputRoot.MRM.Analysis = 'InvoiceNo does exist and has a value';
END IF;
```

For more information about declaring and using references, see “Creating dynamic field references” on page 2431. For a description of the LASTMOVE and FIELDVALUE functions, see “LASTMOVE function” on page 5237 and “FIELDTYPE function” on page 5231.

If the message is in the MRM domain, there are additional considerations for querying null elements that depend on the physical format. For further details, see "Querying null values in a message in the MRM domain" on page 2597.

Setting null values

You can use two statements to set null values:

1. If you set the element to NULL by using the following statement, the element is deleted from the message tree:

```
SET OutputRoot.XMLNS.Invoice.Customer.Title = NULL;
```

   If the message is in the MRM domain, there are additional considerations for null values that depend on the physical format. For further details, see "Setting null values in a message in the MRM domain" on page 2599.

   This technique is called implicit null processing.

2. If you set the value of this element to NULL as follows:

```
SET OutputRoot.XMLNS.Invoice.Customer.Title VALUE = NULL;
```

   the element is not deleted from the message tree. Instead, a special value of NULL is assigned to the element.

```
SET OutputRoot.XMLNS.Invoice.Customer.Title = NULL;
```

   If the message is in the MRM domain, the content of the output bit stream depends on the settings of the physical format null handling properties. For further details, see "Setting null values in a message in the MRM domain" on page 2599.

   This technique is called explicit null processing.

If you set an MRM complex element or an XML, XMLNS, or JMS parent element to NULL without using the VALUE keyword, that element and all its children are deleted from the logical tree.

Accessing known multiple occurrences of an element:

When you refer to or create the content of messages, it is very likely that the data contains repeating fields. If you know how many instances there are of a repeating field, and you want to access a specific instance of such a field, you can use an array index as part of a field reference.

About this task

For example, you might want to filter on the first line of an address, to expedite the delivery of an order. Three instances of the element Billling.Address are always present in the sample message. To test the first line, write an expression such as:

```
IF Body.Invoice.Customer.Billing.Address[1] = 'Patent Office' THEN
   DO;
     -- more ESQL --
END IF;
```

The array index [1] indicates that it is the first instance of the repeating field that you are interested in (array indices start at 1). An array index such as this can be

used at any point in a field reference, so you could, for example, filter on the following test:

```
IF Body.Invoice."Item"[1].Quantity> 2 THEN
   DO;
     -- more ESQL --
END IF;
```

You can refer to the last instance of a repeating field using the special [<] array index, and to instances relative to the last (for example, the second to last) as follows:

- `Field[<]` indicates the last element.
- `Field[<1]` indicates the last element.
- `Field[<2]` indicates the last but one element (the penultimate element).

You can also use the array index [>] to represent the first element, and elements relative to the first element in a similar way.

- `Field[>]` indicates the first element. This is equivalent to `Field[1]`.

The following examples refer to the "Example message" on page 5311 using these indexes:

```
IF Body.Invoice.Customer.Billing.Address[<] = 'Hampshire' THEN
      DO;
     -- more ESQL --
END IF;
IF Body.Invoice.Customer.Billing.Address[<2 ] = 'Southampton' THEN
   DO;
     -- more ESQL --
END IF;
```

You can also use these special indexes for elements that repeat an unknown number of times.

Deleting repeating fields:
About this task

If you pass a message with several repeats of an element through a message flow and you want to delete some of the repeats, be aware that the numbering of the repeats is reordered after each delete. For example, if you have a message with five repeats of a particular element, and in the message flow you have the following ESQL:

```
SET OutputRoot.MRM.e_PersonName[1] = NULL;
SET OutputRoot.MRM.e_PersonName[4] = NULL;
```

You might expect elements one and four to be deleted. However, because repeating elements are stored on a stack, when you delete one, the one above it takes its place. This means that, in the above example, elements one and five are deleted. To avoid this problem, delete in reverse order, that is, delete element four first, then delete element one.

"Example message" on page 5311

Accessing unknown multiple occurrences of an element:

To access repeating fields in a message, you must use a construct that can iterate over all instances of a repeating field.

About this task

You are likely to deal with messages that contain repeating fields with an unknown number of repeats (such as the `Item` field in "Example message" on page 5311).

To write a filter that takes into account all instances of the `Item` field, you need to use a construct that can iterate over all instances of a repeating field. The quantified predicate allows you to execute a predicate against all instances of a repeating field, and collate the results.

For example, you might want to verify that none of the items that are being ordered has a quantity greater than 50. To do this you could write:

```
FOR ALL Body.Invoice.Purchases."Item"[]
    AS I (I.Quantity <= 50)
```

With the quantified predicate, the first thing to note is the brackets [] on the end of the field reference after FOR ALL. These tell you that you are iterating over all instances of the `Item` field.

In some cases, this syntax appears unnecessary because you can get that information from the context, but it is done for consistency with other pieces of syntax.

The AS clause associates the name `I` with the current instance of the repeating field. This is similar to the concept of iterator classes used in some object oriented languages such as C++. The expression in parentheses is a predicate that is evaluated for each instance of the `Item` field.

A description of this example is:

Procedure

Iterate over all instances of the field Item inside `Body.Invoice`. For each iteration:

1. Bind the name `I` to the current instance of `Item`.
2. Evaluate the predicate `I.Quantity <= 50`. If the predicate:
   - Evaluates to TRUE for all instances of `Item`, return TRUE.
   - Is FALSE for any instance of `Item`, return FALSE.
   - For a mixture of TRUE and UNKNOWN, return UNKNOWN.

Results

The above is a description of how the predicate is evaluated if you use the ALL keyword. An alternative is to specify SOME, or ANY, which are equivalent. In this case the quantified predicate returns TRUE if the sub-predicate returns TRUE for any instance of the repeating field. Only if the sub-predicate returns FALSE for all instances of the repeating field does the quantified predicate return FALSE. If a mixture of FALSE and UNKNOWN values are returned from the sub-predicate, an overall value of UNKNOWN is returned.

In the following filter expression:

```
FOR ANY Body.Invoice.Purchases."Item"[]
    AS I (I.Title = 'The XML Companion')
```

the sub-predicate evaluates to TRUE. However this next expression returns FALSE:

```
FOR ANY Body.Invoice.Purchases."Item"[]
    AS I (I.Title = 'C Primer')
```

because the `C Primer` is not included on this invoice. If some of the items in the invoice do not include a book title field, the sub-predicate returns UNKNOWN, and the quantified predicate returns the value UNKNOWN.

To deal with the possibility of null values appearing, write this filter with an explicit check on the existence of the field, as follows:

```
FOR ANY Body.Invoice.Purchases."Item"[]
  AS I (I.Book IS NOT NULL AND I.Book.Title = 'C Primer')
```

The predicate IS NOT NULL ensures that, if an `Item` field does not contain a `Book`, a FALSE value is returned from the sub-predicate.

You can also manipulate arbitrary repeats of fields within a message by using a SELECT expression, as described in “Referencing columns in a database” on page 2489.

You can refer to the first and last instances of a repeating field using the [>] and [<] array indexes, and to instances relative to the first and last, even if you do not know how many instances there are. These indexes are described in “Accessing known multiple occurrences of an element” on page 2425.

Alternatively, you can use the CARDINALITY function to determine how many instances of a repeating field there are. For example:

```
DECLARE I INTEGER CARDINALITY(Body.Invoice.Purchases."Item"[])
```

Using anonymous field references:

You can refer to the array of all children of a particular element by using a path element of `*`.

About this task

For example:

```
InputRoot.*[]
```

is a path that identifies the array of all children of InputRoot. This is often used in conjunction with an array subscript to refer to a particular child of an entity by position, rather than by name. For example:

`InputRoot.*[<]`
: Refers to the last child of the root of the input message, that is, the body of the message.

`InputRoot.*[1]`
: Refers to the first child of the root of the input message, the message properties.

You might want to find out the name of an element that has been identified with a path of this kind. To do this, use the FIELDNAME function, which is described in "FIELDNAME function" on page 5229.

Creating dynamic field references:

You can use a variable of type REFERENCE as a dynamic reference to navigate a message tree. This acts in a similar way to a message cursor or a variable pointer.

About this task

It is generally simpler and more efficient to use reference variables in preference to array indexes when you access repeating structures. Reference variables are

accepted everywhere that field references are accepted, and come with a set of statements and functions to allow detailed manipulation of message trees.

You must declare a dynamic reference before you can use it. A dynamic reference is declared and initialized in a single statement.

All examples in this topic use the "Example message" on page 5311 as their input message. The following example shows how to create and use a reference.

```
-- Declare the dynamic reference
DECLARE myref REFERENCE TO OutputRoot.XMLNS.Invoice.Purchases.Item[1];

--  Continue processing for each item in the array
WHILE LASTMOVE(myref)=TRUE
DO
-- Add 1 to each item in the array
   SET myref = myref + 1;
-- Move the dynamic reference to the next item in the array
   MOVE myref NEXTSIBLING;
END WHILE;
```

The example works if the message tree was created with typed fields, based on a message model for the "Example message" on page 5311. If this is not the case, you can modify the ESQL to work without a model, for example:

```
SET myref = CAST (myref AS INTEGER) + 1;
```

This example declares a dynamic reference, `myref`, which points to the first item in the array within Purchases. The value in the first item is incremented by one, and the pointer (dynamic reference) is moved to the next item. Once again the item value is incremented by one. This process continues until the pointer moves outside the scope of the message array (all the items in this array have been processed) and the LASTMOVE function returns FALSE.

The following examples show further examples.

```
DECLARE ref1 REFERENCE TO InputBody.Invoice.Purchases.Item[1];

DECLARE ref2 REFERENCE TO
 InputBody.Invoice.Purchases.NonExistentField;

DECLARE scalar1 CHARACTER;
DECLARE ref3 REFERENCE TO scalar1;
```

In the second example, `ref2` is set to point to InputBody because the specified field does not exist.

With the exception of the MOVE statement, which changes the position of the dynamic reference, you can use a dynamic reference anywhere that you can use a static reference. The value of the dynamic reference in any expression or statement is the value of the field or variable to which it currently points. For example, using the message in "Example message" on page 5311, the value of `Invoice.Customer.FirstName` is Andrew. If the dynamic reference `myref` is set to point at the Customer field as follows:

```
DECLARE myref REFERENCE TO Invoice.Customer;
```

you can then extend this dynamic reference to address children of that field:

```
SET myref.Billing.Address[1] = 'Oaklands';
```

This changes the address in the example to Oaklands Hursley Village Hampshire SO213JR.

The position of a dynamic reference remains fixed even if a tree is modified. To illustrate this point the steps that follow use the message in "Example message" on page 5311 as their input message and create a modified version of this message as an output message:

Procedure

1. Copy the input message to the output message.
2. To modify the output message, first declare a dynamic reference `ref1` that points at the first item, The XML Companion.

```
DECLARE ref1 REFERENCE TO
 OutputRoot.XMLNS.Invoice.Purchases.Item[1];
```

   The dynamic reference is now equivalent to the static reference `OutputRoot.XMLNS.Invoice.Purchases.Item[1].`
3. Use a create statement to insert a new first item for this purchase.

```
CREATE PREVIOUSSIBLING OF ref1 VALUES 'Item';
```

   The dynamic reference is now equivalent to the static reference `OutputRoot.XMLNS.Invoice.Purchases.Item[2].`

Creating new fields:

You can use a Compute node to create a new output message by adding new fields to an existing input message.

About this task

This topic provides example ESQL code for a Compute node that creates a new output message based on the input message, to which are added a number of additional fields.

The input message received by the Compute node within the message flow is an XML message, and has the following content:

```
<TestCase description="This is my TestCase">
    <Identifier>ES03B305_T1</Identifier>
    <Sport>Football</Sport>
    <Date>01/02/2000</Date>
    <Type>LEAGUE</Type>
</TestCase>
```

The Compute node is configured and an ESQL module is created that includes the following ESQL. The following code copies the headers from the input message to the new output message, then creates the entire content of the output message body.

```
-- copy headers
DECLARE i INTEGER 1;

Generating multiple output messages:

You can use the PROPAGATE statement to generate multiple output messages in the Compute node. The output messages that you generate can have the same or different content. You can also direct output messages to any of the four alternate output terminals of the Compute node, or to a Label node.

About this task

For example, to create three copies of the input message received by the Compute node, and send one to the standard Out terminal of the Compute node, one to the first alternate Out1 terminal of the Compute node, and one to the Label node ThirdCopy, code the following ESQL:

```
SET OutputRoot = InputRoot;
PROPAGATE;
SET OutputRoot = InputRoot;
PROPAGATE TO TERMINAL 'out1';
SET OutputRoot = InputRoot;
PROPAGATE TO LABEL 'ThirdCopy';
```

In the above example, the content of OutputRoot is reset before each PROPAGATE, because by default the node clears the output message buffer and reclaims the memory when the PROPAGATE statement completes. An alternative method is to instruct the node not to clear the output message on the first two PROPAGATE statements, so that the message is available for routing to the next destination. The code to achieve this result is:

```
SET OutputRoot = InputRoot;
PROPAGATE DELETE NONE;
PROPAGATE TO TERMINAL 'out1' DELETE NONE;
PROPAGATE TO LABEL 'ThirdCopy';
```

If you do not initialize the output buffer, an empty message is generated, and the message flow detects an error and throws an exception.

Also ensure that you copy all required message headers to the output message buffer for each output message that you propagate.

If you want to modify the output message content before propagating each message, code the appropriate ESQL to make the changes that you want before you code the PROPAGATE statement.

If you set up the contents of the last output message that you want to generate, and propagate it as the final action of the Compute node, you do not have to include the final PROPAGATE statement. The default action of the Compute node is to propagate the contents of the output buffer when it terminates. This is implemented by the RETURN TRUE statement, included as the final statement in the module skeleton.

For example, to generate three copies of the input message, and not perform any further action, include this code immediately before the RETURN TRUE statement:

```
SET OutputRoot = InputRoot;
PROPAGATE DELETE NONE;
PROPAGATE DELETE NONE;
```

Alternatively, you can modify the default behavior of the node by changing RETURN TRUE to RETURN FALSE:

```
SET OutputRoot = InputRoot;
PROPAGATE DELETE NONE;
PROPAGATE DELETE NONE;
PROPAGATE;
RETURN FALSE;
```

Three output messages are generated by the three PROPAGATE statements. The final RETURN FALSE statement causes the node to terminate but not propagate a final output message. Note that the final PROPAGATE statement does not include the DELETE NONE clause, because the node must release the memory at this stage.

Using numeric operators with datetime values:

The following examples show the ESQL that you can code to manipulate datetime values with numeric operators.

About this task

Adding an interval to a datetime value

The simplest operation that you can perform is to add an interval to, or subtract an interval from, a datetime value. For example, you could write the following expressions:

```
DATE '2000-03-29' + INTERVAL '1' MONTH
TIMESTAMP '1999-12-31 23:59:59' + INTERVAL '1' SECOND
```

The following example shows how to calculate a retirement date by adding the retirement age to the birth date.

```
DECLARE retAge CHARACTER '65';
DECLARE birthDate DATE DATE '1953-06-01';

SET OutputRoot.XML.Test.retirementDate = birthDate + CAST(retAge AS INTERVAL YEAR);
```

The repetition of the word DATE in the above example is intentional. The first occurrence of DATE specifies the data type of the declared variable, birthDate. The second occurrence initializes the same variable with the constant character string that is enclosed in single quotation marks as a DATE.

Adding or subtracting two intervals

You can combine two interval values by using addition or subtraction. The two interval values must be of compatible types. It is not valid to add a year-month interval to a day-second interval as shown in the following example:

```
INTERVAL '1-06' YEAR TO MONTH + INTERVAL '20' DAY
```

The interval qualifier of the resultant interval is sufficient to encompass all the fields that are present in the two operand intervals. For example:

```
INTERVAL '2 01' DAY TO HOUR + INTERVAL '123:59' MINUTE TO SECOND
```

results in an interval with qualifier DAY TO SECOND, because both day and second fields are present in at least one of the operand values.

Subtracting two datetime values

You can subtract two datetime values to return an interval. You must include an interval qualifier in the expression to indicate what precision the result should be returned in. For example:

```
(CURRENT_DATE - DATE '1776-07-04') DAY
```

returns the number of days since the 4th July 1776, whereas:

```
(CURRENT_TIME - TIME '00:00:00') MINUTE TO SECOND
```

returns the age of the day in minutes and seconds.

Scaling intervals

You can multiply or divide an interval value by an integer factor:

```
INTERVAL '2:30' MINUTE TO SECOND / 4
```

Calculating a time interval:

You can use ESQL to calculate the time interval between two events, and to set a timer to be triggered after a specified interval.

About this task

This ESQL example calculates the time interval between an input WebSphere MQ message being put on the input queue, and the time that it is processed in the current Compute node.

(When you make a call to a CURRENT_ datetime function, the value that is returned is identical to the value returned to another call in the same node. This ensures that you can use the function consistently within a single node.)

```
CALL CopyMessageHeaders();
Declare PutTime INTERVAL;

SET PutTime = (CURRENT_GMTTIME - InputRoot.MQMD.PutTime) MINUTE TO SECOND;

SET OutputRoot.XMLNS.Test.PutTime = PutTime;
```

The output message has the format (although actual values vary):

```
<Test>
 <PutTime>INTERVAL &apos;1:21.862&apos; MINUTE TO SECOND</PutTime>
</Test>
```

Example

The following code snippet sets a timer, to be triggered after a specified interval from the start of processing, in order to check that processing has completed. If processing has not completed within the elapsed time, the firing of the timer might, for example, trigger some recovery processing.

The StartTime field of the timeout request message is set to the current time plus the allowed delay period, which is defined by a user-defined property on the flow. (The user-defined property has been set to a string of the form "HH:MM:SS" by the administrator.)

```
DECLARE StartDelyIntervalStr EXTERNAL CHARACTER '01:15:05';

CREATE PROCEDURE ValidateTimeoutRequest() BEGIN

  -- Set the timeout period
  DECLARE timeoutStartTimeRef REFERENCE TO
          OutputRoot.XMLNSC.Envelope.Header.TimeoutRequest.StartTime;
  IF LASTMOVE(timeoutStartTimeRef)
```

```
  THEN
  -- Already set
 ELSE
  -- Set it from the UDP StartDelyIntervalStr
  DECLARE startAtTime TIME CURRENT_TIME
         + CAST(StartDelyIntervalStr AS INTERVAL HOUR TO SECOND);

  -- Convert "TIME 'hh.mm.ss.fff'" to hh.mm.ss format
      -- needed in StartTime field
  DECLARE startAtTimeStr CHAR;
  SET startAtTimeStr = startAtTime;
  SET startAtTimeStr = SUBSTRING(startAtTimeStr FROM 7 FOR  8);
  SET OutputRoot.XMLNSC.Envelope.Header.TimeoutRequest.StartTime
                           = startAtTimeStr;
 END IF;
END;
```

Selecting a subfield from a larger field:

You might have a message flow that processes a message containing delimited subfields. You can code ESQL to extract a subfield from the surrounding content if you know the delimiters of the subfield.

About this task

If you create a function that performs this task, or a similar one, you can invoke it both from ESQL modules (for Compute, Database, DatabaseInput, and Filter nodes) and from mapping files (used by DataDelete, DataInsert, DataUpdate, Extract, Mapping, and Warehouse nodes).

The following function example extracts a particular subfield of a message that is delimited by a specific character.

```
CREATE FUNCTION SelectSubField
       (SourceString CHAR, Delimiter CHAR, TargetStringPosition INT)
d       RETURNS CHAR
-- This function returns a substring at parameter position TargetStringPosition within the
-- passed parameter SourceString.  An example of use might be:
-- SelectSubField(MySourceField,' ',2) which will select the second subfield from the
-- field MySourceField delimited by a blank.  If MySourceField has the value
-- "First Second Third" the function will return the value "Second"
  BEGIN
    DECLARE DelimiterPosition INT;
    DECLARE CurrentFieldPosition INT 1;
    DECLARE StartNewString INT 1;
    DECLARE WorkingSource CHAR SourceString;
    SET DelimiterPosition = POSITION(Delimiter IN SourceString);
    WHILE CurrentFieldPosition < TargetStringPosition
      DO
       IF DelimiterPosition = 0  THEN
      -- DelimiterPosition will be 0 if the delimiter is not found
         -- exit the loop
        SET CurrentFieldPosition = TargetStringPosition;
       ELSE
        SET StartNewString = DelimiterPosition + 1;
        SET WorkingSource = SUBSTRING(WorkingSource FROM StartNewString);
        SET DelimiterPosition = POSITION(Delimiter IN WorkingSource);
        SET CurrentFieldPosition = CurrentFieldPosition + 1;
       END IF;
    END WHILE;
    IF DelimiterPosition> 0 THEN
       -- Remove anything following the delimiter from the string
       SET WorkingSource = SUBSTRING(WorkingSource FROM 1 FOR DelimiterPosition);
       SET WorkingSource = TRIM(TRAILING Delimiter FROM WorkingSource);
    END  IF;
    RETURN WorkingSource;
END;
```

Copying repeating fields:

You can configure a node with ESQL to copy repeating fields in several ways.

About this task

Consider an input XML message that contains a repeating structure:

```
...
 <Field_top>
   <field1></field1>
   <field1></field1>
   <field1></field1>
   <field1></field1>
   <field1></field1>
 </Field_top>
.....
```

You cannot copy this whole structure field with the following statement:

```
SET OutputRoot.XMLNS.Output_top.Outfield1 = InputRoot.XMLNS.Field_top.field1;
```

That statement copies only the first repeat, and therefore produces the same result as this statement:

```
SET OutputRoot.XMLNS.Output_top.Outfield1[1] = InputRoot.XMLNS.Field_top.field1[1];
```

You can copy the fields within a loop, controlling the iterations with the CARDINALITY of the input field:

```
SET I = 1;
SET J = CARDINALITY(InputRoot.XMLNS.Field_top.field1[]);
WHILE  I <= J DO
 SET OutputRoot.XMLNS.Output_top.Outfield1[I] = InputRoot.XMLNS.Field_top.field1[I];
 SET I = I + 1;
END WHILE;
```

This might be appropriate if you want to modify each field in the output message as you copy it from the input field (for example, add a number to it, or fold its contents to uppercase), or after it has been copied. If the output message already contained more Field1 fields than existed in the input message, the surplus fields would not be modified by the loop and would remain in the output message.

The following single statement copies the iterations of the input fields to the output fields, and deletes any surplus fields in the output message.

```
SET OutputRoot.XMLNS.Output_top.Outfield1.[] = InputRoot.XMLNS.Field_top.field1[];
```

The following example shows how you can rename the elements when you copy them into the output tree. This statement does not copy across the source element name, therefore each `field1` element becomes a `Target` element.

```
SET OutputRoot.XMLNS.Output_top.Outfield1.Target[] =
    (SELECT I FROM InputRoot.XMLNS.Field_top.field1[] AS I );
```

The next example shows a different way to do the same operation; it produces the same end result.

```
SET OutputRoot.XMLNS.Output_top.Outfield2.Target[]
              = InputRoot.XMLNS.Field_top.field1[];
```

The following example copies across the source element name. Each `field1` element is retained as a `field1` element under the `Target` element.

```
SET OutputRoot.XMLNS.Output_top.Outfield3.Target.[]
              = InputRoot.XMLNS.Field_top.field1[];
```

This example is an alternative way to achieve the same result, with `field1` elements created under the `Target` element.

```
SET OutputRoot.XMLNS.Output_top.Outfield4.Target.*[]
              = InputRoot.XMLNS.Field_top.field1[];
```

These examples show that there are several ways in which you can code ESQL to copy repeating fields from source to target. Select the most appropriate method to achieve the results that you require.

The principals shown here apply equally to all areas of the message tree to which you can write data, not just the output message tree.

A note about copying fields:

When you copy an input message element to an output element, the *value* and *type* of the output element is set to that of the input element. Therefore, if, for example, you have an input XML document with an attribute, and you want to set a Field element (rather than an attribute) in your output message to the value of the input attribute, you must include a TYPE clause cast to change the element-type from attribute to Field.

About this task

For example, given the following input:

```
<Field01 Attrib01='Attrib01_Value'>Field01_Value</Field01>
```

To create an output, such as in the following example:

```
<MyField_A MyAttrib_A='Attrib01_Value' MyAttrib_B='Field01_Value' >
  <MyField_B>Field01_Value</MyField_BC>
  <MyField_C>Attrib01_Value</MyField_C>
 </MyField_A'>
```

You would use the following ESQL:

```
-- Create output attribute from input attribute
SET OutputRoot.XMLNSC.MyField_A.MyAttrib_A = InputRoot.XMLNSC.Field01.Attrib01;
-- Create output field from input field
```

```
SET OutputRoot.XMLNSC.MyField_A.MyField_B = InputRoot.XMLNSC.Field01;

-- Create output attribute from input field value, noting we have to
-- "cast" back to an attribute  element
SET OutputRoot.XMLNSC.MyField_A.(XMLNSC.Attribute)MyAttrib_B =
               InputRoot.XMLNSC.Field01;

-- Create output field from input attribute value, noting we have to
-- "cast" back to a field element
SET OutputRoot.XMLNSC.MyField_A.(XMLNSC.Field)MyField_C =
               InputRoot.XMLNSC.Field01.Attrib01;
```

Working with elements of type list:

The XML Schema specification allows an element, or attribute, to contain a list of values that are based on a simple type, with the individual values separated by white space.

About this task

In the message tree, an `xsd:list` element is represented as a name node, with an anonymous child node for each list item. Repeating lists can be handled without any loss of information.

Consider the following XML input message:

```
<message1>
  <listE1>one two three</listE1>
</message1>
```

This XML element produces the following message tree:

```
MRM
listEl  (Name)
 "one"   (Value)
 "two"   (Value)
 "three" (Value)
```

Individual list items can be accessed as `ElementName.*[n]`.

For example, use the following ESQL to access the third item of listE1:

```
SET X = FIELDVALUE (InputBody.message1.listE1.*[3]);
```

An attribute can also be of type `xsd:list`.

Consider the following XML input message:

```
<message1>
<Element listAttr="one two three"/>
</message1>
```

This XML element produces the following message tree:

```
MRM
Element (Name)
 listAttr (Name)
  "one" (Value)
  "two" (Value)
  "three" (Value)
```

As before, individual list items can be accessed as `AttrName.*[n]`.

For example, use the following ESQL to access the third item of listAttr:

```
SET X = FIELDVALUE (InputBody.message1.Element.listAttr.*[3]);
```

A list element can occur more than once.

Consider the following XML message:

```
<message1>
<listE1>one two three/listE1>
<listE1>four five six/listE1>
</message1>
```

The message tree for this XML message is:

```
MRM
listE1 (Name)
 "one" (Value)
 "two" (Value)
 "three" (Value)
listE1 (Name)
 "four" (Value)
 "five" (Value)
 "six" (Value)
```

Code the following ESQL to access the first item in the second occurrence of the list:

```
SET X = FIELDVALUE (InputBody.message1.listE1[2].*[1]);
```

Mapping between a list and a repeating element:

This task shows how to map between a list and a repeating element.

About this task

Consider the form of the following XML input message:

```
<MRM>
  <inner>abcde fghij 12345</inner>
</MRM>
```

where the element inner is of type `xsd:list`, and therefore has three associated string values, rather than a single value.

To copy the three values into an output message, where each value is associated with an instance of repeating elements as shown here:

```
<MRM>
  <str1>abcde</str1>
  <str1>fghij</str1>
  <str1>12345</str1>
</MRM>
```

you might expect that the following ESQL syntax works:

```
DECLARE D INTEGER;
SET D = CARDINALITY(InputBody.str1.*[]);
DECLARE M INTEGER 1;
```

```
WHILE M <= D DO
   SET OutputRoot.MRM.str1[M] = InputBody.inner.*[M];
   SET M = M + 1;
END WHILE;
```

However, the statement:

```
SET OutputRoot.MRM.str1[M] = InputBody.inner.*[M];
```

requests a tree copy from input to output. Because the output element does not yet exist, the statement creates it, and its value and type are set from the input.

Therefore, to create the output message with the required format, given an input element which is of type `xsd:list`, use the "FIELDVALUE function" on page 5234 to explicitly retrieve only the value of the input element:

```
SET OutputRoot.MRM.str1[M] = FIELDVALUE(InputBody.inner.*[M]);
```

Manipulating repeating fields in a message tree:

This topic describes the use of the SELECT function, and other column functions, to manipulate repeating fields in a message tree.

About this task

Suppose that you want to perform a special action on invoices that have a total order value greater than a certain amount. To calculate the total order value of an `Invoice` field, you must multiply the `Price` fields by the `Quantity` fields in all the `Items` in the message, and total the result. You can do this using a SELECT expression as follows:

```
(
 SELECT SUM( CAST(I.Price AS DECIMAL) * CAST(I.Quantity AS INTEGER) )
  FROM Body.Invoice.Purchases."Item"[] AS I
)
```

The example assumes that you need to use CAST expressions to cast the string values of the fields `Price` and `Quantity` into the correct data types. The cast of the `Price` field into a decimal produces a decimal value with the *natural* scale and precision, that is, whatever scale and precision is necessary to represent the number. These CASTs would not be necessary if the data were already in an appropriate data type.

The SELECT expression works in a similar way to the quantified predicate, and in much the same way that a SELECT works in standard database SQL. The FROM

clause specifies what is being iterated, in this case, all Item fields in Invoice, and establishes that the current instance of Item can be referred to using I. This form of SELECT involves a column function, in this case the SUM function, so the SELECT is evaluated by adding together the results of evaluating the expression inside the SUM function for each Item field in the Invoice. As with standard SQL, NULL values are ignored by column functions, with the exception of the COUNT column function explained later in this section, and a NULL value is returned by the column function only if there are no non-NULL values to combine.

The other column functions that are provided are MAX, MIN, and COUNT. The COUNT function has two forms that work in different ways with regard to NULLs. In the first form you use it much like the SUM function above, for example:

```
SELECT COUNT(I.Quantity)
  FROM Body.Invoice.Purchases."Item"[] AS I
```

This expression returns the number of Item fields for which the Quantity field is non-NULL. That is, the COUNT function counts non-NULL values, in the same way that the SUM function adds non-NULL values. The alternative way of using the COUNT function is as follows:

```
SELECT COUNT(*)
  FROM Body.Invoice.Purchases."Item"[] AS I
```

Using COUNT(*) counts the total number of Item fields, regardless of whether any of the fields is NULL. The above example is in fact equivalent to using the CARDINALITY function, as in the following:

```
CARDINALITY(Body.Invoice.Purchases."Item"[])
```

In all the examples of SELECT given here, just as in standard SQL, you could use a WHERE clause to provide filtering on the fields.

Accessing headers:

If the input message received by an input node includes message headers that are recognized by the input node, the node invokes the correct parser for each header. You can access these headers using ESQL.

About this task

Parsers are supplied for most WebSphere MQ headers. The following topics provide some guidance for accessing the information in the MQMD, MQRFH2, and MQPCF headers, which you can follow as general guidance for accessing other headers also present in your messages.

Every header has its own correlation name, for example, MQMD, and you must use this name in all ESQL statements that refer to or set the content of this tree:

- "Accessing the MQMD header" on page 2455
- "Accessing the MQRFH2 header" on page 2456
- "Accessing the MQCFH header" on page 2458

For further details of the contents of these and other WebSphere MQ headers for which WebSphere Message Broker provides a parser, see "Element definitions for message parsers" on page 4237.

Accessing transport headers:

About this task

You can manipulate WebSphere MQ, HTTP, and JMS transport headers and their properties without writing Compute nodes:

- Use the MQHeader node to add, modify, or delete MQ Message Descriptor (MQMD) and MQ Dead Letter Header (MQDLH) headers.
- Use the HTTPHeader node to add, modify, or delete HTTP headers such as HTTPRequest and HTTPReply.
- Use the JMSHeader node to modify contents of the JMS Header_Values and Application properties so that you can control the node's output without programming.

programming.

Accessing the MQMD header:

Code ESQL statements to access the fields of the MQMD header.

About this task

WebSphere MQ and WebSphere MQ Everyplace messages include an MQMD header.

You can refer to the fields within the MQMD, and you can update them in a Compute node.

For example, you might want to copy the message identifier MSGID in the MQMD to another field in your output message. To do that, code:

```
SET OutputRoot.MRM.Identifier = InputRoot.MQMD.MsgId;
```

If you send a message to an EBCDIC system from a distributed system, you might need to convert the message to a compatible CodedCharSetId and Encoding. To do this conversion, code the following ESQL in the Compute node:

```
SET OutputRoot.MQMD.CodedCharSetId = 500;
SET OutputRoot.MQMD.Encoding = 785;
```

The MQMD properties of CodedCharSetId and Encoding define the code page and encoding of the section of the message that follows (typically this is either the MQRFH2 header or the message body itself).

Differences exist in the way the Properties folder and the MQMD folder are treated with respect to which folder takes precedence for the same fields. For more information, see “Properties versus MQMD folder behavior for various transports” on page 1050.

Accessing the MQRFH2 header:

Code ESQL statements to access the fields of the MQRFH2 header.

About this task

When you construct an MQRFH2 header in a Compute node, it includes two types of fields:

- Fields in the MQRFH2 header structure; for example, Format and NameValueCCSID.
- Fields in the MQRFH2 NameValue buffer; for example, mcd and psc.

To differentiate between these two field types, insert a value in front of the referenced field in the MQRFH2 field to identify its type; a value for the NameValue buffer is not required because this is the default. The value that you specify for the header structure is `(MQRFH2.Field)`.

For example:

- To create or change an MQRFH2 Format field, specify the following ESQL:

```
SET OutputRoot.MQRFH2.(MQRFH2.Field)Format = 'MQSTR   ';
```

- To create or change the psc folder with a topic:

```
SET OutputRoot.MQRFH2.psc.Topic = 'department';
```

- To add an MQRFH2 header to an outgoing message that is to be used to make a subscription request:

```
DECLARE I INTEGER 1;
DECLARE J INTEGER CARDINALITY(InputRoot.*[]);

WHILE I < J DO
 SET OutputRoot.*[I] = InputRoot.*[I];
 SET I=I+1;
END WHILE;

SET OutputRoot.MQRFH2.(MQRFH2.Field)Version = 2;
SET OutputRoot.MQRFH2.(MQRFH2.Field)Format = 'MQSTR';
SET OutputRoot.MQRFH2.(MQRFH2.Field)NameValueCCSID = 1208;
SET OutputRoot.MQRFH2.psc.Command = 'RegSub';
SET OutputRoot.MQRFH2.psc.Topic = "InputRoot"."MRM"."topel";
SET OutputRoot.MQRFH2.psc.QMgrName = 'DebugQM';
SET OutputRoot.MQRFH2.psc.QName = 'PUBOUT';
SET OutputRoot.MQRFH2.psc.RegOpt = 'PersAsPub';
```

Variable J is initialized to the value of the cardinality of the existing headers in the message. Using a variable is more efficient than calculating the cardinality on each iteration of the loop, which happens if you code the following WHILE statement:

```
WHILE I < CARDINALITY(InputRoot.*[]) DO
```

The MQRFH2 header can be parsed using either the MQRFH2 parser or the MQRFH2C compact parser. To consume less memory, use the MQRFH2C compact parser by selecting the `Use MQRFH2C compact parser for MQRFH2 Header` check box on the input node of the message flow. This results in paths that contain MQRFH2C instead of MQRFH2; for example: `SET OutputRoot.MQRFH2C.psc.Topic = 'department';`

Target MQRFH2 fields are created only if the headers are copied, and the MQRFH2C parser option is not selected on the MQInput node. In all other circumstances, an MQRFH2C field is created on output.

The MQRFH2 header can be parsed using either the MQRFH2 parser or the MQRFH2C compact parser.

Accessing the MQCFH header:

Code ESQL statements to access the fields of the MQCFH header (root name MQPCF).

About this task

Messages that are of PCF format (MQPCF, MQADMIN, and MQEVENT) include the MQCFH header. You can process the contents of the MQCFH header, accessing parameters, parameter lists, strings, and groups.

The *ParameterCount* field is hidden from view to keep the value synchronized with the true number of parameters. As a result, you cannot directly view, access, or edit the *ParameterCount* field and this applies when you are using:

- ESQL
- The Mapping Node
- Trace, or debugging code.

You can implement your own *ParameterCount* field with a specific value, but this value will be overwritten by the actual number of parameters on the flow exit.

- To access or to construct parameters in the header, use the following syntax:

  ```
  SET OutputRoot.MQPCF.Parameter[nn] =
   Integer parameter ID
  ```

  If you access a 64-bit parameter, use the following syntax to differentiate from 32-bit parameters:

  ```
  SET OutputRoot.MQPCF.Parameter64[nn] =
   Integer parameter ID
  ```

  For example:

  ```
  SET OutputRoot.MQPCF.Parameter[1] =
   MQCACF_AUTH_PROFILE_NAME;
  ```

- For parameter lists, use the following syntax:

```
SET OutputRoot.MQPCF.ParameterList64[nn] =
 Integer parameter ID
SET OutputRoot.MQPCF.ParameterList64[nn].*[xx] =
 Integer parameter values
```

For example:

```
SET OutputRoot.MQPCF.ParameterList[1] =
 MQIACF_AUTH_ADD_AUTHS;
SET OutputRoot.MQPCF.ParameterList[1].*[1] =
 MQAUTH_SET;
SET OutputRoot.MQPCF.ParameterList[1].*[2] =
 MQAUTH_SET_ALL_CONTEXT;
```

- A byte string is a byte array data type, and is supported with this syntax:

```
SET OutputRoot.MQPCF.Parameter[nn] =
 Integer parameter ID
SET OutputRoot.MQPCF.Parameter[nn].* =
 Integer, String or ByteArray Parameter value
```

- A group is implemented as a folder containing more PCF, and requires the following syntax:

```
SET OutputRoot.MQPCF.Group[xx] =
 Group Parameter ID
```

For example:

```
SET OutputRoot.MQPCF.Group[1] =
 MQGACF_Q_ACCOUNTING_DATA;
SET OutputRoot.MQPCF.Group[1].Parameter[1] =
 MQCA_CREATION_DATE;
SET OutputRoot.MQPCF.Group[1].Parameter[1].* =
 '2007-02-05';
```

You can also use nested groups; for example;

```
SET OutputRoot.MQPCF.Group[1].Group[1] =
 MQGACF_Q_ACCOUNTING_DATA;
SET OutputRoot.MQPCF.Group[1].Group[1].Parameter[1] =
 MQCA_CREATION_DATE;
SET OutputRoot.MQPCF.Group[1].Group[1].Parameter[1].* =
 '2007-02-05';
```

- A filter is almost identical to a parameter, but it also includes an operator. Therefore the syntax is a tree with named values:

```
SET OutputRoot.MQPCF.Filter[xx] =
 Integer parameter ID
SET OutputRoot.MQPCF.Filter[xx].Operator =
 Integer Filter name
SET OutputRoot.MQPCF.Filter[xx].Value =
 Byte, Integer or String Filter Value
```

- The following is sample code that can be used as an example to create an MQPCF message in a Compute node:

```
CREATE NEXTSIBLING OF OutputRoot.Properties DOMAIN 'MQMD';
CREATE NEXTSIBLING OF OutputRoot.MQMD DOMAIN 'MQADMIN'
NAME 'MQPCF';
CREATE FIELD OutputRoot.MQPCF;
SET OutputRoot.MQMD.MsgType = MQMT_REQUEST;
SET OutputRoot.MQMD.ReplyToQ = 'REPLYQ';
DECLARE refRequest REFERENCE TO OutputRoot.MQPCF;
SET refRequest.Type = 16; --MQCFT_COMMAND_XR z/OS
SET refRequest.StrucLength = MQCFH_STRUC_LENGTH;
SET refRequest.Version = 3; -- required for z/OS
SET refRequest.Command = MQCMD_INQUIRE_Q;
SET refRequest.MsgSeqNumber = 1;
SET refRequest.Control = MQCFC_LAST;
/* First parameter: Queue Name. */
```

```
SET refRequest.Parameter[1] = MQCA_Q_NAME;
SET refRequest.Parameter[1].* = 'QUEUENAME.*';
SET refRequest.ParameterList[1] = MQIACF_Q_ATTRS;
SET refRequest.ParameterList[1].*  = MQIACF_ALL;
```

"The MQCFH parser" on page 4245
The elements of the MQCFH parser are listed in this topic.

Accessing the Properties tree:

The Properties tree has its own correlation name, Properties, and you must use this in all ESQL statements that refer to or set the content of this tree.

About this task

The fields in the Properties tree contain values that define the characteristics of the message. For example, the Properties tree contains message template information for model-driven parsers, fields for the encoding and CCSID in which message data is encoded, and fields that hold the security identity of the message. For a full list of fields in this tree, see "Data types for elements in the Properties subtree" on page 4239.

You can interrogate and update these fields using the appropriate ESQL statements. If you create a new output message in the Compute node, you must set values for the message properties.

Setting output message properties:
About this task

If you use the Compute node to generate a new output message, you must set its properties in the Properties tree. The output message properties do not have to be the same as the input message properties.

For example, to set the output message properties for an output MRM message, set the following properties:

Property	Value
MessageSet	Message set identifier
MessageType	Message name[1]
MessageFormat	Physical format name[2]

Notes:

1. For details of the syntax of Message type, see "Specifying namespaces in the Message Type property" on page 1208.
2. The name that you specify for the physical format must match the name that you have defined for it. The default physical format names are Binary1, XML1, and Text1.

This ESQL procedure sets message properties to values passed in by the calling statement. You might find that you have to perform this task frequently, and you can use a procedure such as this in many different nodes and message flows. If you prefer, you can code ESQL that sets specific values.

```
CREATE PROCEDURE setMessageProperties(IN OutputRoot REFERENCE, IN setName char,
                 IN typeName char, IN formatName char) BEGIN
 /*****************************************************************************
 * A procedure that sets the message properties
 *****************************************************************************/
 set OutputRoot.Properties.MessageSet    = setName;
 set OutputRoot.Properties.MessageType   = typeName;
 set OutputRoot.Properties.MessageFormat = formatName;
END;
```

To set the output message domain, you can code ESQL statements that refer to the required domain in the second qualifier of the SET statement, the parser field. For example, the ESQL statement sets the domain to MRM:

```
SET OutputRoot.MRM.Field1 = 'field1 data';
```

This ESQL statement sets the domain to XMLNS:

```
SET OutputRoot.XMLNS.Field1 = 'field1 data';
```

Do not specify more than one domain in the ESQL for any single message. However, if you use PROPAGATE statements to generate several output messages, you can set a different domain for each message.

For information about the full list of elements in the Properties tree, see "Data types for elements in the Properties subtree" on page 4239.

Differences exist in the way the Properties folder and the MQMD folder are treated with respect to which folder takes precedence for the same fields. For more information, see "Properties versus MQMD folder behavior for various transports" on page 1050.

Accessing the local environment tree:

The local environment tree has its own correlation name, LocalEnvironment, and you must use this name in all ESQL statements that refer to or set the content of this tree.

About this task

The local environment tree is used by the broker, and you can refer to and modify this information. You can also extend the tree to contain information that you create yourself. You can create subtrees of this tree that you can use as a scratchpad or working area.

The message flow sets up information in two subtrees, Destination and WrittenDestination, below the LocalEnvironment root. You can refer to the content of both of these subtrees, and you can write to the Destination tree to influence the way in which the message flow processes your message. However, if you write to the Destination tree, follow the defined structure to ensure that the tree remains valid.

The WrittenDestination subtree contains the addresses to which the message has been written. Its name is fixed and it is created by the message flow when a message is propagated through the Out terminal of a request, output, or reply node. The subtree includes transport-specific information (for example, if the output message has been put to a WebSphere MQ queue, it includes the queue manager and queue names). You can use one of the following methods to obtain information about the details of a message after it has been sent by the nodes:

- Connect a Compute node to the Out terminal.
- Configure a user exit to process an output message callback event, as described in "Exploiting user exits" on page 2985.

The topic for each node that supports WrittenDestination information contains details about the data that it contains.

If you want the local environment tree to be included in the output message that is propagated by the Compute node, you must set the Compute node property `Compute mode` to a value that includes the local environment (for example, `All`). If you do not, the local environment tree is not copied to the output message.

The information that you insert into DestinationData or Defaults depends on the characteristic of the corresponding node property:

- If a node property is represented by a check box (for example, `New Message ID`), set the Defaults or DestinationData element to `Yes` (equivalent to selecting the check box) or `No` (equivalent to clearing the check box).
- If a node property is represented by a drop-down list (for example, `Transaction Mode`), set the Defaults or DestinationData element to the appropriate character string (for example `Automatic`).
- If a node property is represented by a text entry field (for example, `Queue Manager Name`), set the Defaults or DestinationData element to the character string that you would enter in this field.

If necessary, configure the sending node to indicate where the destination information is. For example, for the output node MQOutput, set `Destination Mode`:

- If you set `Destination Mode` to `Queue Name`, the output message is sent to the queue identified in the output node properties `Queue Name` and `Queue Manager Name`. Destination is not referenced by the node.
- If you set `Destination Mode` to `Destination List`, the node extracts the destination information from the Destination subtree. If you use this value you can send a single message to multiple destinations, if you configure Destination and a single output node correctly. The node checks the node properties only if a value is not available in Destination (as described above).
- If you set `Destination Mode` to `Reply To Queue`, the message is sent to the reply-to queue identified in the MQMD in this message (field ReplyToQ). Destination is not referenced by the node.

To find more information about ESQL procedures that perform typical updates to the local environment, see "Populating Destination in the local environment tree" on page 2467. Review the ESQL statements in these procedures to see how to modify the local environment. You can use these procedures unchanged, or modify them for your own requirements.

To find more information about how to extend the contents of this tree for your own purposes, see "Using scratchpad areas in the local environment" on page 2465.

For another example of how you can use the local environment to modify the behavior of a message flow, refer to the XML_PassengerQuery message flow in the following sample program:

- Airline Reservations

The Compute node in this message flow writes a list of destinations in the RouterList subtree of Destination that are used as labels by a later RouteToLabel node that propagates the message to the corresponding Label node. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Use the RouteToLabel node in combination with one or more Label nodes to dynamically determine the route that a message takes through the message flow, based on its content.

"Data types for elements in the MQ DestinationData subtree" on page 4240
The DestinationData subtree is part of the Destination subtree in the local environment. Local environment trees are created by input nodes when they receive a message and, optionally, by Compute nodes. When created, the trees are empty but you can create data in them by using ESQL statements coded in any of the SQL nodes.

Using scratchpad areas in the local environment:

The local environment tree includes a subtree called variables. This subtree is always created, but is never populated by the message flow. Use this area for your own purposes; for example, to pass information from one node to another. You can create other subtrees of the local environment tree.

About this task

The advantage of creating your own data in a scratchpad in the local environment is that this data can be propagated as part of the logical tree to subsequent nodes in the message flow. If you create a new output message in a Compute node, you can also include all or part of the local environment tree from the input message in the new output message.

To ensure that the information in the local environment is propagated further down the flow, the `Compute mode` property of the Compute node must be set to include the local environment as part of the output tree (for example, specify `LocalEnvironment and Message`). For further details about the `Compute mode` property, see "Setting the mode" on page 4344.

However, any data updates or additions that you make in one node are not retained if the message moves backwards through the message flow (for example, if an exception is thrown). If you create your own data, and want that data to be preserved throughout the message flow, you must use the environment tree.

You can set values in the variables subtree in a Compute node and those values can be used later by another node (Compute, Database, or Filter) for some purpose that you determine when you configure the message flow.

The local environment is not in scope in a Compute node, therefore you must use `InputLocalEnvironment` and `OutputLocalEnvironment` instead. For example, you might use the scratchpad in the local environment to propagate the destination of an output message to subsequent nodes in a message flow. Your first Compute node determines that the output messages from this message flow must go to WebSphere MQ queues. Include the following ESQL to insert this information into the local environment by setting the value of *OutputLocation* in the OutputLocalEnvironment:

```
SET OutputLocalEnvironment.Variables.OutputLocation = 'MQ';
```

Your second Compute node can access this information from its input message. In the ESQL in this node, use the correlation name InputLocalEnvironment to identify the local environment tree in the input message that contains this data. The following ESQL sets *queueManagerName* and *queueName* based on the content of *OutputLocation* in the local environment, by using InputLocalEnvironment:

```
IF InputLocalEnvironment.Variables.OutputLocation = 'MQ' THEN
   SET OutputLocalEnvironment.Destination.MQ.DestinationData.queueManagerName = 'myQManagerName';
   SET OutputLocalEnvironment.Destination.MQ.DestinationData.queueName = 'myQueueName';
END IF;
```

In the example, *queueManagerName* and *queueName* are set for the Destination subtree in the output message. You must set the `Compute mode` of the second Compute node to include the local environment tree in the output message. Configure the MQOutput node to use the destination list that you have created in the local environment tree by setting the `Destination Mode` property to `Destination List`.

For information about the full list of elements in the DestinationData subtree, see "Data types for elements in the MQ DestinationData subtree" on page 4240.

Populating Destination in the local environment tree:

Use the Destination subtree to set up the target destinations that are used by output nodes, the HTTPRequest node, the SOAPRequest node, the SOAPAsyncRequest node, and the RouteToLabel node. The following examples show how you can create and use an ESQL procedure to perform the task of setting up values for each of these uses.

About this task

Copy and use these procedures as shown, or you can modify or extend them to perform similar tasks.

If you are creating this ESQL code for a Compute node, you must configure the node by setting the `Compute Mode` property so that it has access to the local environment tree in the output message. You must select one of the three values `LocalEnvironment`, `LocalEnvironment And Message`, or `All`.

Adding a queue name for the MQOutput node with the `Destination Mode` property set to `Destination List`

```
CREATE PROCEDURE addToMQDestinationList(IN LocalEnvironment REFERENCE, IN newQueue char) BEGIN
  /******************************************************************************
  * A procedure that adds a queue name to the MQ destination list in the local environment.
  * This list is used by an MQOutput node that has its mode set to Destination list.
  *
  * IN LocalEnvironment: the LocalEnvironment to be modified.
  * IN queue: the queue to be added to the list
  *
  ******************************************************************************/
DECLARE I INTEGER CARDINALITY(LocalEnvironment.Destination.MQ.DestinationData[]);
  IF I = 0 THEN
   SET OutputLocalEnvironment.Destination.MQ.DestinationData[1].queueName = newQueue;
  ELSE
   SET OutputLocalEnvironment.Destination.MQ.DestinationData[I+1].queueName = newQueue;
  END IF;
 END;
```

For full details of these elements, see "Data types for elements in the MQ DestinationData subtree" on page 4240.

Changing the default URL for a SOAPRequest node or a SOAPAsyncRequest node request

```
CREATE PROCEDURE overrideDefaultSOAPRequestURL(IN LocalEnvironment REFERENCE, IN newUrl char) BEGIN
  /******************************************************************************
  * A procedure that changes the URL to which the SOAPRequest node or
  * SOAPAsyncRequest node sends the request.
```

```
  *
  * IN LocalEnvironment: the LocalEnvironment to be modified.
  * IN queue:  the URL to which to send the request.
  *
  ********************************************************************************/
SET OutputLocalEnvironment.Destination.SOAP.Request.Transport.HTTP.WebServiceURL = newUrl;
END;
```

Changing the default URL for an HTTPRequest node request

```
CREATE PROCEDURE overrideDefaultHTTPRequestURL(IN LocalEnvironment REFERENCE, IN newUrl char) BEGIN
  /********************************************************************************
  * A procedure that changes the URL to which the HTTPRequest node sends the request.
  *
  * IN LocalEnvironment: the LocalEnvironment to be modified.
  * IN queue: the URL to which to send the request.
  *
  ********************************************************************************/
  SET OutputLocalEnvironment.Destination.HTTP.RequestURL = newUrl;
END;
```

Adding a label for the RouteToLabel node

```
CREATE PROCEDURE addToRouteToLabelList(IN LocalEnvironment REFERENCE, IN newLabel char) BEGIN
  /********************************************************************************
  * A procedure that adds a label name to the RouteToLabel list in the local environment.
  * This list is used by a RoteToLabel node.
  *
  * IN LocalEnvironment: the LocalEnvironment to be modified.
  * IN label:  the label to be added to the list
  *
  ********************************************************************************/
 IF LocalEnvironment.Destination.RouterList.DestinationData is null THEN
     SET OutputLocalEnvironment.Destination.RouterList.DestinationData."label" = newLabel;
  ELSE
     CREATE LASTCHILD OF LocalEnvironment.Destination.RouterList.DestinationData
     NAME 'label' VALUE newLabel;
  END IF;
END;
```

Setting up JMS destination lists

You can configure a JMSOutput node to send to multiple JMS Queues, or to publish to multiple JMS Topics by using a destination list that is created in the local environment tree by a transformation node. The following example shows how to set up JMS destination lists in the local environment tree:

```
CREATE PROCEDURE CreateJMSDestinationList() BEGIN
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[1]  = 'jndi://TestDestQueue1';
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[2]  = 'jndi://TestDestQueue2';
  SET OutputLocalEnvironment.Destination.JMSDestinationList.DestinationData[3]  = 'jndi://TestDestQueue3';
END;
```

The CREATE PROCEDURE statement defines a callable function or procedure.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

Accessing the environment tree:

The environment tree has its own correlation name, Environment, and you must use this name in all ESQL statements that refer to, or set, the content of this tree.

About this task

The environment tree is always created when the logical tree is created for an input message. However, the message flow neither populates it, nor uses its contents. You can use this tree for your own purposes, for example, to pass information from one node to another. You can use the whole tree as a scratchpad or working area.

The advantage of creating your own data in environment is that this data is propagated as part of the logical tree to subsequent nodes in the message flow. If you create a new output message in a Compute node, the environment tree is also copied from the input message to the new output message. (In contrast to the local environment tree, which is only included in the output message if you explicitly request that it is).

Only one environment tree is present for the duration of the message flow. Any data updates, or additions, that you make in one node are retained, and all of the nodes in the message flow have access to the latest copy of this tree. Even if the message flows back through the message flow (for example, if an exception is thrown, or if the message is processed through the second terminal of the FlowOrder node), the latest state is retained. (In contrast to the local environment tree, which reverts to its previous state if the message flows back through the message flow.)

You can use this tree for any purpose you choose. For example, you can use the following ESQL statements to create fields in the tree:

```
SET Environment.Variables =
      ROW('granary' AS bread, 'reisling' AS wine, 'stilton' AS cheese);
SET Environment.Variables.Colors[] =
      LIST{'yellow', 'green', 'blue', 'red', 'black'};
SET Environment.Variables.Country[] = LIST{ROW('UK' AS name, 'pound' AS currency),
     ROW('USA' AS name, 'dollar' AS currency)};
```

This information is now available to all nodes to which a message is propagated, regardless of their relative position in the message flow.

For another example of how you can use environment to store information used by other nodes in the message flow, look at the Reservation message flow in the following sample:

- Airline Reservations

The Compute node in this message flow writes information to the subtree Environment.Variables that it has extracted from a database according to the value of a field in the input message.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Accessing the ExceptionList tree using ESQL:

The ExceptionList tree has its own correlation name, ExceptionList, and you must use this in all ESQL statements that refer to or set the content of this tree.

About this task

This tree is created with the logical tree when an input message is parsed. It is initially empty, and is only populated if an exception occurs during message flow processing. It is possible that more than one exception can occur; if more than one exception occurs, the ExceptionList tree contains a subtree for each exception.

You can access the ExceptionList tree in Compute, Database, and Filter nodes, and you can update it in a Compute node. You must use the appropriate correlation name; ExceptionList for a Database or Filter node, and InputExceptionList for a Compute node.

You might want to access this tree in a node in an error handling procedure. For example, you might want to route the message to a different path based on the type of exception, for example one that you have explicitly generated using an ESQL THROW statement, or one that the broker has generated.

The following ESQL shows how you can access the ExceptionList and process each child that it contains:

```
-- Declare a reference for the ExceptionList
-- (in a Compute node use InputExceptionList)
DECLARE start REFERENCE TO ExceptionList.*[1];

-- Loop through the exception list children
WHILE start.Number IS NOT NULL DO
   -- more ESQL

   -- Move start to the last child of the field to which it currently points
   MOVE start LASTCHILD;
END WHILE;
```

The following example shows an extract of ESQL that has been coded for a Compute node to loop through the exception list to the last (nested) exception description and extract the error number. This error relates to the original cause of the problem and normally provides the most precise information. Subsequent action taken by the message flow can be decided by the error number retrieved in this way.

```
CREATE PROCEDURE getLastExceptionDetail(IN InputTree reference,OUT messageNumber integer,
OUT messageText char)
    /*********************************************************************
  * A procedure that will get the details of the last exception from a message
  * IN InputTree:  The incoming exception list
  * IN messageNumber:  The last message numberr.
  * IN messageText: The last message text.
  *********************************************************************/
   BEGIN
        -- Create a reference to the first child of the exception list
        declare ptrException reference to InputTree.*[1];
        -- keep looping while the moves to the child of exception list work
  WHILE lastmove(ptrException) DO
   -- store the current values for the error number and text
   IF ptrException.Number is not null THEN
          SET messageNumber = ptrException.Number;
          SET messageText = ptrException.Text;
     END IF;
     -- now move to the last child which should be the next exceptionlist
   move ptrException lastchild;
  END WHILE;
 END;
```

For more information about the use of ExceptionList, look at the subflow in the following sample which includes ESQL that interrogates the ExceptionList structure and takes specific action according to its content:

- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Casting data from message fields:

You can use the CAST function to transform the data type of one value to match the data type of the other. For example, you can use the CAST function when you process generic XML messages. All fields in an XML message have character values, so if you want to perform arithmetic calculations or datetime comparisons, for example, you must convert the string value of the field into a value of the appropriate type using CAST.

About this task

When you compare an element with another element, variable or constant, ensure that the value with which you are comparing the element is consistent (for example, character with character). If the values are not consistent, the broker generates a runtime error if it cannot provide an implicit casting to resolve the inconsistency. For details of what implicit casts are supported, see "Implicit casts" on page 5282.

In the "Example message" on page 5311, the field InvoiceDate contains the date of the invoice. If you want to refer to or manipulate this field, you must CAST it to

the correct format first. For example, to refer to this field in a test:

```
IF CAST(Body.Invoice.InvoiceDate AS DATE) = CURRENT_DATE THEN
```

This converts the string value of the InvoiceDate field into a date value, and compares it to the current date.

Another example is casting from integer to character:

```
DECLARE I INTEGER 1;
DECLARE C CHARACTER;

-- The following statement generates an error
SET C = I;

-- The following statement is valid
SET C = CAST(I AS CHARACTER);
```

Converting code page and message encoding:

You can use ESQL within a Compute node to convert data for code page and message encoding.

About this task

If your message flow is processing WebSphere MQ messages, you can use WebSphere MQ facilities (including get and put options and WebSphere MQ data conversion exits) to provide these conversions. If you are not processing WebSphere MQ messages, or you choose not to use WebSphere MQ facilities, you can use WebSphere Message Broker facilities by coding the appropriate ESQL in a Compute node in your message flow.

The contents of the MQMD, the MQRFH2, and the message body of a message in the MRM domain that has been modeled with a CWF physical format can be subject to code page and encoding conversion. The contents of a message body of a message in the XML, XMLNS, and JMS domains, and those messages in the MRM domain that have been modeled with an XML or TDS physical format, are treated as strings. Only code page conversion applies; no encoding conversion is required.

For messages in the MRM domain modeled with a CWF physical format, you can set the MQMD CCSID and Encoding fields of the output message, plus the CCSID and Encoding of any additional headers, to the required target value.

For messages in the MRM domain modeled with an XML or TDS physical format, you can set the MQMD CCSID field of the output message, plus the CCSID of any additional headers. XML and TDS data is handled as strings and is therefore subject to CCSID conversion only.

An example WebSphere MQ message has an MQMD header, an MQRFH2 header, and a message body. To convert this message to a mainframe CodedCharSetId and Encoding, code the following ESQL in the Compute node:

```
SET OutputRoot.MQMD.CodedCharSetId = 500;
SET OutputRoot.MQMD.Encoding = 785;
SET OutputRoot.MQRFH2.CodedCharSetId = 500;
SET OutputRoot.MQRFH2.Encoding = 785;
```

The following example illustrates what you must do to modify a CWF message so that it can be passed from WebSphere Message Broker to IMS on z/OS.

Procedure

1. You have defined the input message in XML and are using an MQRFH2 header. Remove the header before passing the message to IMS.
2. The message passed to IMS must have MQIIH header, and must be in the z/OS code page. This message is modeled in the MRM and has the name IMS1. Define the PIC X fields in this message as logical type string for conversions between EBCDIC and ASCII to take place. If the fields are binary logical type, no data conversion occurs; binary data is ignored when a CWF message is parsed by the MRM parser.
3. The message received from IMS is also defined in the MRM and has the name IMS2. Define the PIC X fields in this message as logical type string for conversions between EBCDIC and ASCII to take place. If the fields are binary logical type, no data conversion occurs; binary data is ignored when a CWF message is parsed by the MRM parser.
4. Convert the reply message to the Windows code page. The MQIIH header is retained on this message.
5. You have created a message flow that contains the following nodes: :
   a. The outbound flow, **MQInput1 --> Compute1 --> MQOutput1**.
   b. The inbound flow, **MQInput2 --> Compute2 --> MQOutput2**.
6. Code ESQL in Compute1 (outbound) node as follows, specifying the relevant MessageSet ID. This code shows the use of the default CWF physical layer name. You must use the name that matches your model definitions. If you specify an incorrect value, the broker fails with message BIP5431.

```
-- Loop to copy message headers
DECLARE I INTEGER 1;
DECLARE J INTEGER CARDINALITY(InputRoot.*[]);

WHILE I < J - 1 DO
  SET OutputRoot.*[I] = InputRoot.*[I];
  SET I=I+1;
END WHILE;

SET OutputRoot.MQMD.CodedCharSetId = 500;
SET OutputRoot.MQMD.Encoding = 785;
SET OutputRoot.MQMD.Format = 'MQIMS   ';
SET OutputRoot.MQIIH.Version = 1;
SET OutputRoot.MQIIH.StrucLength = 84;
SET OutputRoot.MQIIH.Encoding = 785;
SET OutputRoot.MQIIH.CodedCharSetId = 500;
SET OutputRoot.MQIIH.Format = 'MQIMSVS ';
SET OutputRoot.MQIIH.Flags = 0;
SET OutputRoot.MQIIH.LTermOverride = '        ';
SET OutputRoot.MQIIH.MFSMapName = '        ';
SET OutputRoot.MQIIH.ReplyToFormat = 'MQIMSVS ';
SET OutputRoot.MQIIH.Authenticator = '        ';
SET OutputRoot.MQIIH.TranInstanceId = X'00000000000000000000000000000000';
SET OutputRoot.MQIIH.TranState = ' ';
SET OutputRoot.MQIIH.CommitMode = '0';
SET OutputRoot.MQIIH.SecurityScope = 'C';
SET OutputRoot.MQIIH.Reserved = ' ';
SET OutputRoot.MRM.e_elen08 = 30;
SET OutputRoot.MRM.e_elen09 = 0;
SET OutputRoot.MRM.e_string08 = InputBody.e_string01;
SET OutputRoot.MRM.e_binary02 = X'31323334353637383940';
SET OutputRoot.Properties.MessageSet = 'DHCJOEG072001';
SET OutputRoot.Properties.MessageType = 'IMS1';
SET OutputRoot.Properties.MessageFormat = 'Binary1';
```

The use of a variable, J, that is initialized to the value of the cardinality of the existing headers in the message, is more efficient than calculating the cardinality on each iteration of the loop, which happens if you code the following WHILE statement:

```
WHILE I < CARDINALITY(InputRoot.*[]) DO
```

7. Create ESQL in Compute2 (inbound) node as follows, specifying the relevant MessageSet ID. This code shows the use of the default CWF physical layer name. You must use the name that matches your model definition. If you specify an incorrect value, the broker fails with message BIP5431.

```
-- Loop to copy message headers
DECLARE I INTEGER 1;
DECLARE J INTEGER CARDINALITY(InputRoot.*[]);

WHILE I < J DO
  SET OutputRoot.*[I] = InputRoot.*[I];
  SET I=I+1;
END WHILE;

SET OutputRoot.MQMD.CodedCharSetId = 437;
SET OutputRoot.MQMD.Encoding = 546;
SET OutputRoot.MQMD.Format = 'MQIMS   ';
SET OutputRoot.MQIIH.CodedCharSetId = 437;
SET OutputRoot.MQIIH.Encoding = 546;
SET OutputRoot.MQIIH.Format = '        ';
SET OutputRoot.MRM = InputBody;
SET OutputRoot.Properties.MessageSet = 'DHCJOEG072001';
SET OutputRoot.Properties.MessageType = 'IMS2';
SET OutputRoot.Properties.MessageFormat = 'Binary1';
```

Results

You do not have to set any specific values for the MQInput1 node properties, because the message and message set are identified in the MQRFH2 header, and no conversion is required.

You must set values for message domain, set, type, and format in the MQInput node for the inbound message flow (MQInput2). You do not need to set conversion parameters.

One specific situation in which you might need to convert data in one code page to another is when messages contain newline characters and are passed between EBCDIC and ASCII systems. The required conversion for this situation is described in “Converting EBCDIC NL to ASCII CR LF” on page 2480.

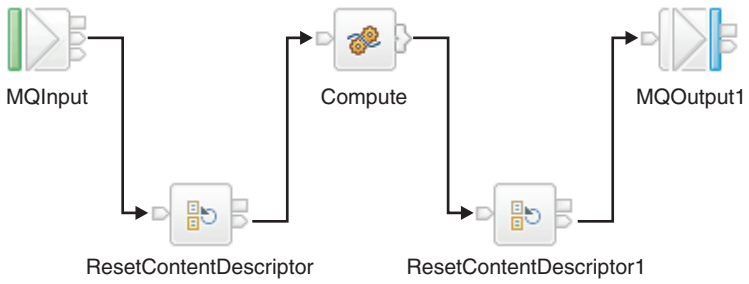
Converting EBCDIC NL to ASCII CR LF:

You might want to change newline (NL) characters in a text message to carriage return (CR) and line feed (LF) character pairs. This example shows one way in which you can convert these characters.

About this task

This conversion might be useful if messages from an EBCDIC platform (for example, using CCSID 1047) are sent to an ASCII platform (for example, using CCSID 437). Problems can arise because the EBCDIC NL character hex '15' is converted to the undefined ASCII character hex '7F'. The ASCII code page has no corresponding code point for the NL character.

In this example, a message flow is created that interprets the input message as a message in the BLOB domain. This message is passed into a ResetContentDescriptor node to reset the data to a message in the MRM domain. The message is called msg_nl (a set of repeating string elements delimited by EBCDIC NL characters). A Compute node is then used to create an output based on another message in the MRM domain called msg_crlf (a set of repeating string elements delimited by CR LF pairs). The message domain is then changed back to BLOB in another ResetContentDescriptor node. This message flow is shown in the following diagram.



The following instructions show how to create the messages and configure the message flow.

Procedure

1. Create the message models for the messages in the MRM domain:
   a. Create a message set project called myProj.
   b. Create a message set called myMessageSet with a TDS physical format (the default name is Text1).
   c. Create an element string1 of type xsd:string.
   d. Create a complex type called t_msg_nl and specify the following complex type properties:
      - `Composition` = Ordered Set
      - `Content Validation` = Closed
      - `Data Element Separation` = All Elements Delimited
      - `Delimiter` = <U+0085> (hex '0085' is the UTF-16 representation of an NL character)
      - `Repeat` = Yes
      - `Min Occurs` = 1
      - `Max Occurs` = 50 (the text of the message is assumed to consist of no more than 50 lines)
   e. Add Element string1, and set the following property:
      - `Repeating Element Delimiter` = <U+0085>
   f. Create a Message msg_nl, and set its associated complex type to t_msg_nl
   g. Create a complex type called t_msg_crlf, and specify the following complex type properties:
      - `Composition` = Ordered Set
      - `Content Validation` = Closed
      - `Data Element Separation` = All Elements Delimited
      - `Delimiter` = <CR><LF> (<CR> and <LF> are the mnemonics for the CR and LF characters)
      - `Repeat` = Yes
      - `Min Occurs` = 1
      - `Max Occurs` = 50
   h. Add Element string1, and set the following property:
      - `Repeating Element Delimiter` = <CR><LF>
   i. Create a Message msg_crlf, and set complex type to t_msg_crlf.
2. Configure the message flow shown in the previous figure:
   a. Start with the MQInput node:
      - Set `Message Domain` = BLOB
      - Set `Queue Name` = <Your input message queue name>

b. Add the ResetContentDescriptor node, connected to the Out terminal of the MQInput node:
   - Set Message Domain = MRM
   - Select Reset Message Domain
   - Set Message Set = <Your Message Set ID> (this field has a maximum of 13 characters)
   - Select Reset Message Set
   - Set Message Type = msg_nl
   - Select Reset Message Type
   - Set Message Format = Text1
   - Select Reset Message Format

c. Add the Compute node, connected to the Out terminal of the ResetContentDescriptor node:
   - Enter a name for the ESQL Module for this node, or accept the default (<message flow name>_Compute).
   - Right-click the Compute node, and select **Open ESQL**. Add the following ESQL code in the module:

```
-- Declare local working variables
DECLARE I INTEGER 1;
DECLARE J INTEGER CARDINALITY(InputRoot.*[]);

-- Loop to copy all message headers from input to output message
WHILE I < J DO
  SET OutputRoot.*[I] = InputRoot.*[I];
  SET I=I+1;
END WHILE;

-- Set new output message type which uses CRLF delimiter
SET OutputRoot.Properties.MessageType = 't_msg_crlf';

-- Loop to copy each instance of string1 child within message body
SET I = 1;
SET J = CARDINALITY("InputBody"."string1"[]);
WHILE I <= J DO
  SET "OutputRoot"."MRM"."string1"[I] = "InputBody"."string1"[I];
  SET I=I+1;
END WHILE;
```

The use of a variable, J, initialized to the value of the cardinality of the existing headers in the message, is more efficient than calculating the cardinality on each iteration of the loop, which happens if you code the following WHILE statement:

```
WHILE I < CARDINALITY(InputRoot.*[]) DO
```

d. Add the ResetContentDescriptor1 node, connected to the Out terminal of the Compute node:
   - Set Message Domain = BLOB
   - Select Reset Message Domain.

e. Finally, add the MQOutput node, connected to the Out terminal of the ResetContentDescriptor1 node. Configure its properties to direct the output message to the required queue or queues.

Changing message format:

Use the Compute node to copy part of an input message to an output message. The results of such a copy depend on the type of input and output parsers involved.

Like parsers:
About this task

Where both the source and target messages have the same folder structure at root level, a *like-parser-copy* is performed. For example:

```
SET OutputRoot.MQMD = InputRoot.MQMD;
```

This statement copies all the children in the MQMD folder of the input message to the MQMD folder of the output message.

Another example of a tree structure that supports a like-parser-copy is:

```
SET OutputRoot.XMLNS.Data.Account = InputRoot.XMLNS.Customer.Bank.Data;
```

To transform an input message in the MRM domain to an output message also in the MRM domain, you can use either the Compute or the Mapping node. The Mapping node can interpret the action that is required because it knows the format of both messages. Content Assist in the ESQL module for the Compute node can also use the message definitions for those messages. If the messages are not in the same namespace, you must use the Compute node.

To use Content Assist with message references, you must set up a project reference from the project containing the ESQL to the project containing the message set. For information about setting up a project reference, see “Project references” on page 44.

If both input and output messages are not in the MRM domain, you must use the Compute node and specify the structure of the messages yourself.

Unlike parsers:
About this task

Where the source and target messages have different folder structures at root level, you cannot make an exact copy of the message source. Instead, the *unlike-parser-copy* views the source message as a set of nested folders terminated by a leaf name-value pair. For example, copying the following message from XML to MRM:

```
<Name3><Name31>Value31</Name31>Value32</Name3>
```

produces a name element Name3, and a name-value element called Name31 with the value Value31. The second XML pcdata (Value32) cannot be represented and is discarded.

The unlike-parser-copy scans the source tree, and copies folders, also known as name elements, and leaf name-value pairs. Everything else, including elements flagged as *special* by the source parser, is not copied.

An example of a tree structure that results in an unlike-parser-copy is:

```
SET OutputRoot.MRM.Account = InputRoot.XMLNS.Data.Account;
```

If the algorithm used to make an unlike-parser-copy does not suit your tree structure, youmust further qualify the source field to restrict the amount of the tree that is copied.

Be careful when you copy information from input messages to output messages in different domains. You might code ESQL that creates a message structure or content that is not consistent with the rules of the parser that processes the output message. This action can result in an output message not being created, or being created with unexpected content. If you believe that the output message generated by a particular message flow does not contain the correct content, or have the expected form, check the ESQL that creates the output message, and look for potential mismatches of structure, field types, field names, and field values.

When copying trees between unlike parsers, you must set the message format of the target parser. For example, if a message set has been defined with XMLNS and CWF formats, the following commands are required to copy an input XMLNS stream to the MRM parser and set the latter to be generated in CWF format:

```
-- Copy message to the output, moving from XMLNS to MRM domains
SET OutputRoot.MRM = InputRoot.XMLNS.rootElement;

-- Set the CWF format for output by the MRM domain
SET OutputRoot.Properties.MessageType = '<MessageTypeName>';
SET OutputRoot.Properties.MessageSet = '<MessageSetName>';
SET OutputRoot.Properties.MessageFormat = 'CWF';
```

"SET statement" on page 5159
The SET statement assigns a value to a variable.

Adding keywords to ESQL files:

You can add keywords to ESQL files to contain information that you want to associate with a message flow.

Use one or more of the following methods:

Comment fields

Add the keyword as a comment in the ESQL file:

```
-- $MQSI compiled by = John MQSI$
```

Static strings

Include the keyword as part of a static string in the ESQL file:

```
SET target = '$MQSI_target = production only MQSI$'
```

Variable string

Include the keyword value as a variable string in the ESQL file:

```
$MQSI_VERSION=$id$MQSI$
```

In this example, when the message flow source is extracted from the file repository, the repository's plug-in has been configured to substitute the identifier *id* with the actual version number. The identifier value that is required depends on the capability and configuration of the repository, and is not part of WebSphere Message Broker.

Restrictions within keywords

Do not use the following characters within keywords, because they cause unpredictable behavior:

```
^ $ . | \ < > ? + * = & [ ] ( )
```

You can use these characters in the values that are associated with keywords; for example:

- `$MQSI RCSVER=$id$ MQSI$` is acceptable
- `$MQSI $name=Fred MQSI$` is not acceptable

Related concepts:

Interaction with databases using ESQL:

Use ESQL statements and functions to read from, write to, and modify databases from your message flows.

About this task

ESQL has a number of statements and functions for accessing databases:

- The "CALL statement" on page 5077 invokes a stored procedure.
- The "DELETE FROM statement" on page 5127 removes rows from a database table.
- The "INSERT statement" on page 5135 adds a row to a database table.
- The "PASSTHRU function" on page 5297 can be used to make complex selections.
- The "PASSTHRU statement" on page 5147 can be used to invoke administrative operations (for example, creating a table).
- The "SELECT function" on page 5260 retrieves data from a table.
- The "UPDATE statement" on page 5163 changes one or more values stored in zero or more rows.

You can access user databases from Compute, Database, DatabaseInput, and Filter nodes. The same ESQL functions and procedures are supported in all these nodes.

You can use the data in the databases to update or create messages, or use the data in the message to update or create data in the databases.

Select **Throw exception on database error** and **Treat warnings as errors**, and set **`Transaction`** to `Automatic` on each node that access a database, to provide maximum flexibility.

For information about configuring the broker and the database to support access from message flows, see "Accessing databases from ESQL" on page 2115.

"Data types of values from external databases" on page 5288
How database data types are implicitly cast to ESQL data types.

Referencing columns in a database:
About this task

While the standard SQL SELECT syntax is supported for queries to an external database, there are a number of points to be borne in mind. You must prefix the name of the table with the keyword Database to indicate that the SELECT is to be targeted at the external database, rather than at a repeating structure in the message.

The basic form of database SELECT is:

```
SELECT ...
  FROM Database.TABLE1
  WHERE ...
```

If necessary, you can specify a schema name:

```
SELECT ...
  FROM Database.SCHEMA.TABLE1
  WHERE ...
```

where SCHEMA is the name of the schema in which the table TABLE1 is defined. Include the schema if the user ID under which you are running does not match the schema. For example, if your userID is USER1, the expression Database.TABLE1 is equivalent to Database.USER1.TABLE1. However, if the schema associated with the table in the database is db2admin, you must specify Database.db2admin.TABLE1. If you do not include the schema, and this does not match your current user ID, the broker generates a runtime error when a message is processed by the message flow.

If, as in the two previous examples, a data source is not specified, TABLE1 must be a table in the default database specified by the node's `data source` property. To access data in a database other than the default specified on the node's `data source` property, you must specify the data source explicitly. For example:

```
SELECT ...
  FROM Database.DataSource.SCHEMA.TABLE1
  WHERE ...
```

Qualify references to column names with either the table name or the correlation name defined for the table by the FROM clause. So, where you could normally execute a query such as:

```
SELECT column1, column2 FROM table1
```

you must write one of the following two forms:

```
SELECT T.column1, T.column2 FROM Database.table1 AS T

SELECT table1.column1, table1.column2 FROM Database.table1
```

This is necessary in order to distinguish references to database columns from any references to fields in a message that might also appear in the SELECT:

```
SELECT T.column1, T.column2 FROM Database.table1
  AS T WHERE T.column3 = Body.Field2
```

You can use the AS clause to rename the columns returned. For example:

```
SELECT T.column1 AS price, T.column2 AS item
  FROM Database.table1 AS T WHERE...
```

The standard select all SQL option is supported in the SELECT clause. If you use this option, you must qualify the column names with either the table name or the correlation name defined for the table. For example:

```
SELECT T.* FROM Database.Table1 AS T
```

When you use ESQL procedure and function names within a database query, the positioning of these within the call affects how these names are processed. If it is determined that the procedure or function affects the results returned by the query, it is not processed as ESQL and is passed as part of the database call.

This applies when attempting to use a function or procedure name with the column identifiers within the SELECT statement.

For example, if you use a CAST statement on a column identifier specified in the Select clause, this is used during the database query to determine the data type of the data being returned for that column. An ESQL CAST is not performed to that ESQL data type, and the data returned is affected by the database interaction's interpretation of that data type.

If you use a function or procedure on a column identifier specified in the WHERE clause, this is passed directly to the database manager for processing.

The examples in the subsequent topics illustrate how the results sets of external database queries are represented in WebSphere Message Broker. The results of database queries are assigned to fields in a message using a Compute node.

A column function is a function that takes the values of a single column in all the selected rows of a table or message and returns a single scalar result.

Selecting data from database columns:

You can configure a Compute, Filter, or Database node to select data from database columns and include it in an output message.

About this task

The following example assumes that you have a database table called USERTABLE with two char(6) data type columns (or equivalent), called Column1 and Column2. The table contains two rows:

	Column1	**Column2**
Row 1	value1	value2
Row 2	value3	value4

Configure the Compute, Filter, or Database node to identify the database in which you have defined the table. For example, if you are using the default database (specified on the `data source` property of the node), right-click the node, select

Open ESQL, and code the following ESQL statements in the module for this node:

```
SET OutputRoot = InputRoot;
DELETE FIELD OutputRoot.*[<];
SET OutputRoot.XML.Test.Result[] =
  (SELECT T.Column1, T.Column2 FROM Database.USERTABLE AS T);
```

This ESQL produces the following output message:

```
<Test>
   <Result>
      <Column1>value1</Column1>
      <Column2>value2</Column2>
   </Result>
   <Result>
      <Column1>value3</Column1>
      <Column2>value4</Column2>
   </Result>
</Test>
```

Figure 4. Output message

To trigger the SELECT, send a trigger message with an XML body that is of the following form:

```
<Test>
   <Result>
      <Column1></Column1>
      <Column2></Column2>
   </Result>
   <Result>
      <Column1></Column1>
      <Column2></Column2>
   </Result>
</Test>
```

The exact structure of the XML is not important, but the enclosing tag must be `<Test>` to match the reference in the ESQL. If the enclosing tag is not `<Test>`, the ESQL statements result in top-level enclosing tags being formed, which is not valid XML.

If you want to create an output message that includes all the columns of all the rows that meet a particular condition, use the SELECT statement with a WHERE clause:

```
-- Declare and initialize a variable to hold the
--      test vaue (in this case the surname Smith)
DECLARE CurrentCustomer STRING 'Smith';

-- Loop through table records to extract matching information
SET OutputRoot.XML.Invoice[] =
    (SELECT R FROM Database.USERTABLE AS R
              WHERE R.Customer.LastName = CurrentCustomer
    );
```

The message fields are created in the same order as the columns occur in the table.

If you are familiar with SQL in a database environment, you might expect to code SELECT *. This syntax is not accepted by the broker, because you must start all references to columns with a correlation name to avoid ambiguities with declared

variables. Also, if you code SELECT I.*, this syntax is accepted by the broker, but the * is interpreted as the first child element, not all elements, as you might expect from other database SQL.

The assignment of the result set of a database into a parser-owned message tree requires the result set to exactly match the message definition. Because the generic XML parser is self-defining, the example creates a new subtree off the Invoice folder, and the parser can parse the new elements in the subtree. If the structure of the result set exactly matches the message definition, the result set can be assigned directly into the `OutputRoot` message body tree.

If the structure of the result set does not exactly match the MRM message definition, you must first assign the result set into a ROW data type, or an Environment tree that does not have a parser associated with it.

The required data can then be assigned to `OutputRoot` to build a message tree that conforms to the message definition.

Selecting data from a table in a case-sensitive database system:
About this task

If the database system is case sensitive, you must use an alternative approach. This approach is also necessary if you want to change the name of the generated field to something different:

```
SET OutputRoot = InputRoot;
SET OutputRoot.XML.Test.Result[] =
  (SELECT T.Column1 AS Column1, T.Column2 AS Column2
  FROM Database.USERTABLE AS T);
```

This example produces the output message as shown in Figure 4 on page 2492. Ensure that references to the database columns (in this example, T.Column1 and T.Column2) are specified in the correct case to match the database definitions exactly. If you do not match the database definitions exactly (for example if you specify T.COLUMN1), the broker generates a runtime error. `Column1` and `Column2` are used in the SELECT statement to match the columns that you have defined in the database, although you can use any values here; the values do not have to match.

Selecting bitstream data from a database:
About this task

These samples show how to retrieve XML bitstream data from a database, and include it in an output message. See “INSERT statement” on page 5135 for examples that show how you can insert bitstream data into a database.

Example

In the following example, bitstream data is held in a database column with a BLOB data type. The database table used in the example (TABLE1) is the one created in the “INSERT statement” on page 5135 examples, and the table contains the following columns:

- `MSGDATA`
- `MSGCCSID`
- `MSGENCODING`

If the bit stream from the database does not need to be interrogated or manipulated by the message flow, the output message can be constructed in the BLOB domain without any alteration.

In the following example, the message data, along with the MQMD header, is held in a database column with a BLOB data type. To re-create the message tree, including the MQMD header, from the bit stream, you can use a CREATE statement with a PARSE clause and DOMAIN('MQMD'). The output message can then be modified by the message flow:

```
SET Environment.Variables.DBResult = THE( SELECT T.* FROM Database.TABLE1 AS T);
DECLARE resultRef REFERENCE TO Environment.Variables.DBResult;

IF LASTMOVE(resultRef) THEN

  DECLARE outMsg BLOB resultRef.MSGDATA ;
  DECLARE outCCSID INT resultRef.MSGCCSID;
  DECLARE outEncoding INT resultRef.MSGENCODING;
  DECLARE outMsgPriority INT resultRef.MSGPRIORITY;
  DECLARE outMsgSeqNum INT resultRef.MSGSEQNUMBER;

  SET OutputRoot.Properties.CodedCharSetId = outCCSID;
  SET OutputRoot.Properties.Encoding = outEncoding ;

  CREATE LASTCHILD OF OutputRoot DOMAIN('MQMD') PARSE(outMsg, outEncoding, outCCSID);

    SET OutputRoot.MQMD.Version = MQMD_VERSION_2;

  SET OutputRoot.MQMD.Priority = outMsgPriority;
  SET OutputRoot.MQMD.MsgSeqNumber = outMsgSeqNum;

  DECLARE HDRL INT ;
  SET HDRL = LENGTH(BITSTREAM(OutputRoot.MQMD));
  CREATE FIELD OutputRoot."BLOB"."BLOB";
  DECLARE MSGB BLOB;
  SET MSGB = SUBSTRING(outMsg FROM HDRL +1);
  SET OutputRoot."BLOB"."BLOB" = MSGB;

END IF;
```

If you want to interrogate or manipulate a bit stream extracted from a database, you must re-create the original message tree. To re-create the XML message tree from the bit stream, you can use a CREATE statement with a PARSE clause. The output message can then be modified by the message flow.

For example, you might create a database table by using the following statement:

```
INSERT INTO Database.TABLE1(MSGDATA, MSGENCODING, MSGCCSID)
   VALUES (msgBitStream, inEncoding, inCCSID);
```

The following code snippet shows how to re-create the message tree in the XMLNS domain by using the data read from the table:

```
CALL CopyMessageHeaders();
  SET Environment.Variables.DBResult = THE( SELECT T.* FROM Database.TABLE1 AS T);
  DECLARE resultRef REFERENCE TO Environment.Variables.DBResult;
  IF LASTMOVE(resultRef) THEN
    DECLARE outCCSID INT resultRef.MSGCCSID;
    DECLARE outEncoding INT resultRef.MSGENCODING;
    DECLARE outMsg BLOB resultRef.MSGDATA;
    SET OutputRoot.Properties.CodedCharSetId = outCCSID;
    SET OutputRoot.Properties.Encoding = outEncoding;
    CREATE LASTCHILD OF OutputRoot DOMAIN('XMLNS') PARSE(outMsg, outEncoding, outCCSID);
```

```
    -- Now modify the message tree fields
    SET OutputRoot.XMLNS.A.B = 4;
    SET OutputRoot.XMLNS.A.E = 5;
  END IF;
```

In the following example, the data is held in a database column with a character data type, such as CHAR or VARCHAR. A cast is used to convert the data extracted from the database into BLOB format. If the bitstream data from the database does not need to be interrogated or manipulated by the message flow, the output message can be constructed in the BLOB domain, without any alteration.

```
CALL CopyMessageHeaders();
  SET Environment.Variables.DBResult = THE( SELECT T.* FROM Database.TABLE1 AS T);
  DECLARE resultRef REFERENCE TO Environment.Variables.DBResult;
  IF LASTMOVE(resultRef) THEN
    DECLARE outCCSID INT resultRef.MSGCCSID;
    DECLARE outMsg BLOB CAST(resultRef.MSGDATA AS BLOB CCSID outCCSID);
    SET OutputRoot.Properties.CodedCharSetId = outCCSID;
    SET OutputRoot.Properties.Encoding = resultRef.MSGENCODING;
    SET OutputRoot.BLOB.BLOB = outMsg;
  END IF;
```

In the following example, the data is held in a database column with a character data type, such as CHAR or VARCHAR. A cast is used to convert the data extracted from the database into BLOB format. To manipulate or interrogate this data within the message flow, you must re-create the original message tree. In this example, a `CREATE` statement with a `PARSE` clause is used to re-create the XML message tree in the `XMLNS` domain.

```
CALL CopyMessageHeaders();
  SET Environment.Variables.DBResult = THE( SELECT T.* FROM Database.TABLE1 AS T);
  DECLARE resultRef REFERENCE TO Environment.Variables.DBResult;
  IF LASTMOVE(resultRef) THEN
    DECLARE outCCSID INT resultRef.MSGCCSID;
    DECLARE outEncoding INT resultRef.MSGENCODING;
    DECLARE outMsg BLOB CAST(resultRef.MSGDATA AS BLOB CCSID outCCSID);
    SET OutputRoot.Properties.CodedCharSetId = outCCSID;
    SET OutputRoot.Properties.Encoding = outEncoding;
    CREATE LASTCHILD OF OutputRoot DOMAIN('XMLNS') PARSE(outMsg, outEncoding, outCCSID);
    -- Now modify the message tree fields
    SET OutputRoot.XMLNS.A.B = 4;
    SET OutputRoot.XMLNS.A.E = 5;
  END IF;
```

Accessing multiple database tables:

You can refer to multiple tables that you have created in the same database. Use the FROM clause on the SELECT statement to join the data from the two tables.

About this task

The following example assumes that you have two database tables called USERTABLE1 and USERTABLE2. Both tables have two char(6) data type columns (or equivalent).

USERTABLE1 contains two rows:

	Column1	**Column2**
Row 1	value1	value2
Row 2	value3	value4

USERTABLE2 contains two rows:

	Column3	Column4
Row 1	value5	value6
Row 2	value7	value8

All tables referenced by a single SELECT function must be in the same database. The database can be either the default (specified on the Data Source property of the node) or another database (specified on the FROM clause of the SELECT function).

Configure the Compute, Database, or Filter node that you are using to identify the database in which you have defined the tables. For example, if you are using the default database, right-click the node, select **Open ESQL**, and code the following ESQL statements in the module for this node:

```
SET OutputRoot.XML.Test.Result[] =
         (SELECT A.Column1 AS FirstColumn,
                 A.Column2 AS SecondColumn,
                 B.Column3 AS ThirdColumn,
                 B.Column4 AS FourthColumn
            FROM Database.USERTABLE1 AS A,
                 Database.USERTABLE2 AS B
           WHERE A.Column1 = 'value1' AND
                 B.Column4 = 'value8'
         );
```

This code results in the following output message content:

```
<Test>
  <Result>
    <FirstColumn>value1</FirstColumn>
    <SecondColumn>value2</SecondColumn>
    <ThirdColumn>value7</ThirdColumn>
    <FourthColumn>value8</FourthColumn>
  </Result>
</Test>
```

This example shows how to access data from two database tables. You can code more complex FROM clauses to access multiple database tables (although all the tables must be in the same database). You can also refer to one or more message trees, and can use SELECT to join tables with tables, messages with messages, or tables with messages. “Joining data from messages and database tables” on page 2531 provides an example of how to merge message data with data in a database table.

If you specify an ESQL function or procedure on the column identifier in the WHERE clause, it is processed as part of the database query and not as ESQL.

Consider the following example:

```
SET OutputRoot.XML.Test.Result =
   THE(SELECT ITEM T.Column1 FROM Database.USERTABLE1 AS T
   WHERE UPPER(T.Column2) = 'VALUE2');
```

This code attempts to return the rows where the value of `Column2` converted to uppercase is `VALUE2`. However, only the database manager can determine the value of `T.Column2` for any given row, therefore it cannot be processed by ESQL before the database query is issued, because the WHERE clause determines the rows that are returned to the message flow.

Therefore, the UPPER is passed to the database manager to be included as part of its processing. However, if the database manager cannot process the token within the SELECT statement, an error is returned.

Changing database content:

You can use Compute, Database, and Filter nodes to change the contents of a database by updating, inserting, or deleting data.

About this task

The following ESQL code includes statements that show all three operations. This code is appropriate for a Database and Filter node; if you create this code for a Compute node, use the correlation name InputRoot in place of Root.

```
IF Root.XMLNS.TestCase.Action = 'INSERT' THEN
   INSERT INTO Database.STOCK (STOCK_ID, STOCK_DESC, STOCK_QTY_HELD,
   BROKER_BUY_PRICE, BROKER_SELL_PRICE, STOCK_HIGH_PRICE, STOCK_HIGH_DATE,
   STOCK_HIGH_TIME) VALUES
   (CAST(Root.XMLNS.TestCase.stock_id AS INTEGER),
    Root.XMLNS.TestCase.stock_desc,
    CAST(Root.XMLNS.TestCase.stock_qty_held AS DECIMAL),
    CAST(Root.XMLNS.TestCase.broker_buy_price AS DECIMAL),
    CAST(Root.XMLNS.TestCase.broker_sell_price AS DECIMAL),
    Root.XMLNS.TestCase.stock_high_price,
    CURRENT_DATE,
    CURRENT_TIME);

ELSEIF Root.XMLNS.TestCase.Action = 'DELETE' THEN

        DELETE FROM Database.STOCK WHERE STOCK.STOCK_ID =
                    CAST(Root.XMLNS.TestCase.stock_id AS INTEGER);

   ELSEIF Root.XMLNS.TestCase.Action = 'UPDATE' THEN

           UPDATE Database.STOCK as A SET STOCK_DESC = Root.XMLNS.TestCase.stock_desc
                  WHERE  A.STOCK_ID = CAST(Root.XMLNS.TestCase.stock_id AS INTEGER);
END IF;
```

Checking returns to SELECT:

If a SELECT function returns no data, or no further data, this result is handled as a normal situation and no error code is set in SQLCODE, regardless of the setting of the `Throw Exception On Database Error` and `Treat Warnings As Errors` properties on the current node.

About this task

To recognize that a SELECT function has returned no data, include ESQL that checks what has been returned. You can use various methods:

1. EXISTS

   This ESQL returns a Boolean value that indicates if a SELECT function returned one or more values (TRUE), or none (FALSE).

   ```
   IF EXISTS(SELECT T.MYCOL FROM Database.MYTABLE) THEN
   ...
   ```

2. CARDINALITY

   If you expect an array in response to a SELECT, you can use CARDINALITY to calculate how many entries have been received.

   ```
   SET OutputRoot.XMLNS.Testcase.Results[] = (
       SELECT T.MYCOL FROM Database.MYTABLE)
   ......
   IF CARDINALITY (OutputRoot.XMLNS.Testcase.Results[])> 0 THEN
   ........
   ```

3. IS NULL

   If you have used either THE or ITEM keywords in your SELECT function, a scalar value is returned. If no rows have been returned, the value set is NULL. However, it is possible that the value NULL is contained within the column, and you might want to distinguish between these two cases.

   Distinguish between cases by including COALESCE in the SELECT function, for example:

   ```
   SET OutputRoot.XMLNS.Testcase.Results VALUE = THE (
      SELECT ITEM COALESCE(T.MYCOL, 'WAS NULL')
      FROM Database.MYTABLE);
   ```

   If this example returns the character string WAS NULL, it indicates that the column contained NULL, and not that no rows were returned.

In previous releases, an SQLCODE of 100 was set in most cases if no data, or no further data, was returned. An exception was raised by the broker if you chose to handle database errors in the message flow.

Committing database updates:

When you create a message flow that interacts with databases, you can choose whether the updates that you make are committed when the current node has completed processing, or when the current invocation of the message flow has terminated.

About this task

The information in this topic does not apply to the DatabaseInput node. For more information about the DatabaseInput node, see “Event-based database integration” on page 2118.

For each node, select the appropriate option for the `Transaction` property to specify when its database updates are to be committed:

- Choose `Automatic` (the default) if you want updates made in this node to be committed or rolled back as part of the whole message flow. The actions that you define in the ESQL module are performed on the message and it continues through the message flow. If the message flow completes successfully, the updates are committed. If the message flow fails, the message and the database updates are rolled back.
- Choose `Commit` if you want to commit the action of the node on the database, irrespective of the success or failure of the message flow as a whole. The database update is committed when the node processing is successfully completed, that is, after all ESQL has been processed, even if the message flow itself detects an error in a subsequent node that causes the message to be rolled back.

The value that you choose is implemented for the database tables that you have updated. You cannot select a different value for each table.

If you have set `Transaction` to `Commit`, the behavior of the message flow and the commitment of database updates can be affected by the use of the PROPAGATE statement in the node's ESQL.

If you choose to include a PROPAGATE statement that generates one or more output messages from the node, the processing of the PROPAGATE statement is not considered complete until the entire path that the output message takes has completed. This path might include several other nodes, including one or more output nodes. Only then does the node that issues the PROPAGATE statement receive control back and its ESQL terminate. At that point, a database commit is performed, if appropriate.

If one of the nodes on the propagated path detects an error and throws an exception, the processing of the node in which you have coded the PROPAGATE statement never completes. If the error processing results in a rollback, the message flow and the database update in this node are rolled back. This behavior is consistent with the stated operation of the `Commit` option, but might not be the behavior that you expect.

Invoking stored procedures:

To invoke a procedure that is stored in a database, use the ESQL CALL statement. The stored procedure must be defined by a CREATE PROCEDURE statement that has a Language clause of DATABASE and an EXTERNAL NAME clause that identifies the name of the procedure in the database and, optionally, the database schema to which it belongs.

About this task

When you invoke a stored procedure with the CALL statement, the broker ensures that the ESQL definition and the database definition match:

- The external name of the procedure must match a procedure in the database.
- The number of parameters must be the same.
- The type of each parameter must be the same.
- The direction of each parameter (IN, OUT, INOUT) must be the same.

The following restrictions apply to the use of stored procedures:

- Overloaded procedures are not supported. (An overloaded procedure is one that has the same name as another procedure in the same database schema with a different number of parameters, or parameters with different types.) If the broker detects that a procedure has been overloaded, it raises an exception.
- In an Oracle stored procedure declaration, you are not permitted to constrain CHAR and VARCHAR2 parameters with a length, and NUMBER parameters with a precision or scale, or both. Use %TYPE when you declare CHAR, VARCHAR and NUMBER parameters to provide constraints on a formal parameter.

You can also invoke a database stored procedure or a database user-defined function from a Mapping node. See "Mapping a target element from database stored procedures" on page 2290 or "Mapping a target element from database user-defined functions" on page 2292.

Creating a stored procedure in ESQL:
About this task

When you define an ESQL procedure that corresponds to a database stored procedure, you can specify either a qualified name (where the qualifier is a database schema) or an unqualified name.

To create a stored procedure:

Procedure

1. Code a statement similar to this example to create an unqualified procedure:
   ```
   CREATE PROCEDURE myProc1(IN p1 CHAR) LANGUAGE DATABASE EXTERNAL NAME "myProc";
   ```
   The EXTERNAL NAME that you specify must match the definition you have created in the database, but you can specify any name you choose for the corresponding ESQL procedure.
2. Code a statement similar to this example to create a qualified procedure:
   ```
   CREATE PROCEDURE myProc2(IN p1 CHAR) LANGUAGE DATABASE EXTERNAL NAME "Schema1.myProc";
   ```
3. Code a statement similar to this example to create a qualified procedure in an Oracle package:
   ```
   CREATE PROCEDURE myProc3(IN p1 CHAR) LANGUAGE DATABASE EXTERNAL
                   NAME "mySchema.myPackage.myProc";
   ```

Results

For examples of stored procedure definitions in the database, see the "CREATE PROCEDURE statement" on page 5103.

Calling a stored procedure:
Procedure

1. Code a statement similar to this example to invoke an unqualified procedure:
   ```
   CALL myProc1('HelloWorld');
   ```
   Because it is not defined explicitly as belonging to any schema, the `myProc1` procedure must exist in the default schema (the name of which is the user name used to connect to the data source) or the command fails.
2. The following example calls the `myProc` procedure in schema `Schema1`.
   ```
   CALL myProc2('HelloWorld');
   ```
3. Code a statement similar to this example to invoke an unqualified procedure with a dynamic schema:
   ```
   DECLARE Schema2 char 'mySchema2';
   CALL myProc1('HelloWorld') IN Database.{'Schema2'};
   ```
   This statement calls the `myProc1` procedure in database `Schema2`, overriding the default "`username`" schema.

Calling a stored procedure that returns two result sets:
About this task

To call a stored procedure that takes one input parameter and returns one output parameter and two result sets:

Procedure

1. Define the procedure with a CREATE PROCEDURE statement that specifies one input parameter, one output parameter, and two result sets:

```
CREATE PROCEDURE myProc1 (IN P1 INT, OUT P2 INT)
  LANGUAGE DATABASE
  DYNAMIC RESULT SETS 2
  EXTERNAL NAME "myschema.myproc1";
```

2. To invoke the myProc1 procedure using a field reference, code:

```
/* using a field reference */
CALL myProc1(InVar1, OutVar2, Environment.ResultSet1[],
            OutputRoot.XMLNS.Test.ResultSet2[]);
```

3. To invoke the myProc1 procedure using a reference variable, code:

```
/* using a reference variable*/
DECLARE cursor REFERENCE TO OutputRoot.XMLNS.Test;

CALL myProc1(InVar1, cursor.OutVar2, cursor.ResultSet1[],
                     cursor.ResultSet2[]);
```

Coding ESQL to handle errors:

When you process messages in a message flow, errors can have a number of different causes and the message flow designer must decide how to handle those errors.

Introduction

When you process messages in message flows, errors can have the following causes:

- External causes; for example, the incoming message is syntactically invalid, a database used by the flow has been shut down, or the power supply to the machine on which the broker is running fails.
- Internal causes; for example, an attempt to insert a row into a database table fails because of a constraint check, or a character string that is read from a database cannot be converted to a number because it contains alphabetic characters.

  Internal errors can be caused by programs storing invalid data in the database, or by a flaw in the logic of a flow.

The message flow designer must decide how to handle errors.

Using default error-handling

The simplest strategy for handling ESQL errors is to do nothing, and use the broker's default behavior. The default behavior is to cut short the processing of the failing message, and to proceed to the next message. Input and output nodes provide options to control exactly what happens when processing is cut short.

If the input and output nodes are set to transactional mode, the broker restores the state before the message is processed:

1. The input message that has apparently been taken from the input queue is put back.
2. Any output messages that the flow has apparently written to output queues are discarded.

If the input and output nodes are not set to transactional mode:

1. The input message that was taken from the input queue is not put back.
2. Any output messages that the flow has written to output queues remain on the output queues.

Each of these strategies has its advantages. The transactional model preserves the consistency of data, while the non-transactional model maximizes the continuity of message processing. In the transactional model, the failing input message is put back onto the input queue, and the broker attempts to process it again. The most likely outcome of this scenario is that the message continues to fail until the retry limit is reached, at which point the message is placed on a dead letter queue. The reason for the failure to process the message is logged to the system event log (Windows) or syslog (UNIX). Therefore, the failing message holds up the processing of subsequent valid messages, and is left unprocessed by the broker.

Most databases operate transactionally so that all changes that are made to database tables are committed if the processing of the message succeeds, or rolled back if it fails, therefore maintaining the integrity of data. An exception to this situation is if the broker itself, or a database, fails (for example, the power to the

computers on which they are running is interrupted). In these cases, changes might be committed in some databases, but not in others, or the database changes might be committed but the input and output messages are not committed. If these possibilities concern you, make the flow coordinated and configure the databases that are involved.

Using customized error handling: The following list contains some general tips for creating customized error handlers.

- If you require something better than default error handling, the first step is to use a handler; see "DECLARE HANDLER statement" on page 5124. Create one handler per node to intercept all possible exceptions (or all those that you can predict).
- Having intercepted an error, the error handler can use whatever logic is appropriate to handle it. Alternatively, it can use a THROW statement or node to create an exception, which could be handled higher in the flow logic, or even reach the input node, causing the transaction to be rolled back; see "Throwing an exception" on page 2511.
- If a node generates an exception that is not caught by the handler, the flow is diverted to the Failure terminal, if one is connected, or handled by default error-handling if no Failure terminal is connected.

  Use Failure terminals to catch unhandled errors. Attach a simple logic flow to the Failure terminal. This logic flow could consist of a database or Compute node that writes a log record to a database (possibly including the message's bit stream), or writes a record to the event log. The flow could also contain an output node that writes the message to a special queue.

  The full exception tree is passed to any node that is connected to a Failure terminal; see "Exception list tree structure" on page 1066.
- Your error handlers are responsible for logging each error in an appropriate place, such as the system event log.

For a detailed description of the options that you can use to process errors in a message flow, see "Handling errors in message flows" on page 2823. For examples of what you can do, see "Throwing an exception" on page 2511 and "Capturing database state" on page 2512.

Writing code to detect errors

The following sections assume that the broker detects the error. It is possible, however, for the logic of the flow to detect an error. For example, when coding the flow logic, you could use the following elements:

- IF statements that are inserted specifically to detect situations that should not occur
- The ELSE clause of a case expression or statement to trap routes through the code that should not be possible

As an example of a flow logic-detected error, consider a field that has a range of possible integer values that indicate the type of message. It would not be good practice to leave to chance what would happen if a message were to arrive in which the field's value did not correspond to any known type of message. One way this situation could occur is if the system is upgraded to support extra types of message, but one part of the system is not upgraded.

Using your own logic to handle input messages that are not valid

Input messages that are syntactically invalid (and input messages that appear to be not valid because of erroneous message format information) are difficult to deal with, because the broker cannot determine the contents of the message. Typically, the best way to deal with these messages is to configure the input node to fully parse and validate the message. However, this configuration applies only to predefined messages; that is, MRM or IDoc.

If the input node is configured in this way, the following results are guaranteed if the input message cannot be parsed successfully:

- The input message never emerges from the node's normal output terminal (it goes to the Failure terminal).
- The input message never enters the main part of the message flow.
- The input message never causes any database updates.
- No messages are written to any output queues.

To deal with a failing message, connect a simple logic flow to the Failure terminal. The only disadvantage to this strategy is that if the normal flow does not require access to all of the message's fields, the forcing of complete parsing of the message affects performance.

Using your own logic to handle database errors

Database errors fall into three categories:

- The database is not working (for example, it is off line).
- The database is working but refuses your request (for example, a lock contention occurs).
- The database is working but it cannot do what you request (for example, read from a non-existent table).

If you require something better than default error handling, the first step is to use a handler (see "DECLARE HANDLER statement" on page 5124) to intercept the exception. The handler can determine the nature of the failure from the SQL state that is returned by the database.

A database is not working

If a database is not working at all, and is essential to the processing of messages, there is typically not much that you can do. The handler, having determined the cause, might complete one or more of the following actions:

- Use the RESIGNAL statement to re-throw the original error, therefore allowing the default error handler to take over
- Use a different database
- Write the message to a special output queue

  Be careful if you use an approach similar to this technique; the handler absorbs the exception, therefore all changes to other databases, or writes to queues, are committed.

A database refuses your request

The situation when a lock contention occurs is similar to the "Database not working" case because the database will have backed out *all* the database changes that you have made for the current message, not just the failing request. Therefore, unless you are sure that this was the only update, default error-handling is typically the best strategy, except possibly logging the error or passing the message to a special queue.

Impossible requests

An impossible request occurs when the database is working, but cannot complete the requested action. This type of error covers a wide variety of problems.

If, as discussed in the previous example, the database does not have a table of the name that the flow expects, default error-handling is typically the best strategy, except possibly logging the error or passing the message to a special queue.

Many other errors might be handled successfully, however. For example, an attempt to insert a row might fail because there is already such a row and the new row would be a duplicate. Or an attempt to update a row might fail because there is no such row (that is, the update action updated zero rows). In these cases, the handler can incorporate whatever logic you think appropriate. It might insert the missing row, or use the existing one (possibly making sure the values in it are suitable).

If you want an update of zero rows to be reported as an error, you must set the `Treat warnings as errors` property on the node to `true`, which is not the default setting.

Using your own logic to handle errors in output nodes

Errors that occur in MQOutput nodes report the nature of the error in the SQL state and give additional information in the *SQL native error* variable. Therefore, if something better than default error handling is required, the first step is to use a handler (see "DECLARE HANDLER statement" on page 5124) to intercept the exception. Such a handler typically surrounds only a single PROPAGATE statement.

Using your own logic to handle other errors

Besides those errors covered above, a variety of other errors can occur. For example, an arithmetic calculation might overflow, a cast might fail because of the unsuitability of the data, or an access to a message field might fail because of a type constraint. The broker offers two programming strategies for dealing with these types of error.

- The error causes an exception that is either handled or left to roll back the transaction.
- The failure is recorded as a special value that is tested for later.

In the absence of a type constraint, an attempt to access a non-existent message field results in the value null. Null values propagate through expressions, making the result null. Therefore, if an expression, however complex, does not return a null value, you know that all the values that it needed to calculate its result were not null.

Cast expressions can have a default clause. If there is a default clause, casts fail quietly; instead of throwing an exception, they simply return the default value. The default value could be an innocuous number (for example, zero for an integer), or a value that is clearly invalid in the context (for example, -1 for a customer number). Null might be particularly suitable because it is a value that is different from all others, and it will propagate through expressions without any possibility of the error condition being masked.

Handling errors in other nodes

Exceptions that occur in other nodes (that is, downstream of a PROPAGATE statement) might be caught by handlers in the normal way. Handling such errors intelligently, however, poses a problem: another node was involved in the original error, therefore another node, and not necessarily the originator of the exception, is likely to be involved in handling the error.

To help in these situations, the Database and Compute nodes have four terminals called Out1, Out2, Out3, and Out4. In addition, the syntax of the PROPAGATE statement includes target expression, message source, and control clauses to give more control over these terminals.

Throwing an exception:

If you detect an error or other situation in your message flow in which you want message processing to be ended, you can throw an exception in a message flow in two ways.

About this task

- Use the ESQL THROW EXCEPTION statement.

  Include the THROW statement anywhere in the ESQL module for a Compute, Database, or Filter node. Use the options on the statement to code your own data to be inserted into the exception.
- Include a THROW node in your message flow.

  Set the node properties to identify the source and content of the exception.

By using either statement options or node properties, you can specify a message identifier and values that are inserted into the message text to give additional information and identification to users who interpret the exception. You can specify any message in any catalog that is available to the broker. See "Using error logging from a user-defined extension" on page 3137 for more information.

The situations in which you might want to throw an exception are determined by the behavior of the message flow; decide when you design the message flow where this action might be appropriate. For example, you might want to examine the content of the input message to ensure that it meets criteria that cannot be detected by the input node (which might check that a particular message format is received).

The following example uses the "Example message" on page 5311 to show how you can use the ESQL THROW statement. To check that the invoice number is within a particular range, throw an exception for any invoice message received that does not fall in the valid range.

```
--Check for invoice number lower than permitted range
IF Body.Invoice.InvoiceNo < 100000 THEN
   THROW USER EXCEPTION CATALOG 'MyCatalog' MESSAGE 1234 VALUES
   ('Invoice number too low', Body.Invoice.InvoiceNo);

-- Check for invoice number higher than permitted range
ELSEIF Body.Invoice.InvoiceNo > 500000 THEN
      THROW USER EXCEPTION CATALOG 'MyCatalog' MESSAGE 1235 VALUES
   ('Invoice number too high', Body.Invoice.InvoiceNo);

ELSE DO
  -- invoice number is within permitted range
  -- complete normal processing
ENDIF;
```

Capturing database state:

If an error occurs when the broker accesses an external database, you can either let the broker throw an exception during node processing or use ESQL statements to process the exception within the node itself.

About this task

Letting the broker throw an exception during node processing is the default action; ESQL processing in the current node is abandoned. The exception is then propagated backwards through the message flow until an enclosing catch node, or the input node for this message flow, is reached. If the exception reaches the input node, an active transaction is rolled back.

Using ESQL statements to process the exception within the node itself requires an understanding of database return codes and a logical course of action to take when an error occurs. To enable this inline database error processing, you must clear the Filter, Database, or Compute node's `Throw Exception On Database Error` property. If you clear this property, the node sets the database state indicators SQLCODE, SQLSTATE, SQLNATIVEERROR, and SQLERRORTEXT, with appropriate information from the database manager instead of throwing an exception.

The indicators contain information only when an error (not a warning) occurs, unless you have selected the `Treat Warnings As Errors` property. If a database operation is successful, or returns success with information, the indicators contain their default success values.

You can use the values contained in these indicators in ESQL statements to make decisions about the action to take. You can access these indicators with the SQLCODE, SQLSTATE, SQLNATIVEERROR, and SQLERRORTEXT functions.

If you are attempting inline error processing, check the state indicators after each database statement is executed to ensure that you catch and assess all errors. When processing the indicators, if you meet an error that you cannot handle inline, you can raise a new exception either to deal with it upstream in a catch node, or to let it through to the input node so that the transaction is rolled back, for which you can use the ESQL THROW statement.

You might want to check for the special case in which a SELECT returns no data. This situation is not considered an error and SQLCODE is not set, therefore you must test explicitly for it; see “Checking returns to SELECT” on page 2500.

Using ESQL to access database state indicators

The following ESQL example shows how to use the four database state functions, and how to include the error information that is returned in an exception:

```
DECLARE SQLState1 CHARACTER;
DECLARE SQLErrorText1 CHARACTER;
DECLARE SQLCode1 INTEGER;
DECLARE SQLNativeError1 INTEGER;

-- Make a database insert to a table that does not exist --
INSERT INTO Database.DB2ADMIN.NONEXISTENTTABLE (KEY,QMGR,QNAME)
                              VALUES (45,'REG356','my TESTING 2');

--Retrieve the database return codes --
SET SQLState1 = SQLSTATE;
SET SQLCode1 = SQLCODE;
SET SQLErrorText1 = SQLERRORTEXT;
SET SQLNativeError1 = SQLNATIVEERROR;

--Use the THROW statement to back out the database and issue a user exception--
THROW USER EXCEPTION MESSAGE 2950 VALUES
( 'The SQL State' , SQLState1 , SQLCode1 , SQLNativeError1 ,
SQLErrorText1 );
```

You do not have to throw an exception when you detect a database error; you might prefer to save the error information returned in the local environment tree, and include a Filter node in your message flow that routes the message to error or success subflows according to the values saved.

The following sample program provides another example of ESQL that uses these database functions:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using the SELECT function:

The SELECT function is a convenient and powerful tool for accessing fields and transforming data in a message tree.

About this task

The following topics show by example how to use the SELECT function to transform a variety of messages. The examples are based on an XML input message that has been parsed in the XMLNS domain. However, the techniques shown in these topics can be applied to any message tree.

- "Transforming a simple message" on page 2516
- "Transforming a complex message" on page 2520
- "Returning a scalar value in a message" on page 2523

Transforming a simple message:

When you code the ESQL for a Compute node, use the SELECT function to transform simple messages.

About this task

This topic provides examples of simple message transformation. Review the examples and modify them for your own use. They are all based on the "Example message" on page 5311 as input.

Example

Consider the following ESQL:

```
SET OutputRoot.XMLNS.Data.Output[] =
   (SELECT R.Quantity, R.Author FROM InputRoot.XMLNS.Invoice.Purchases.Item[] AS R
   );
```

When this ESQL code processes the Invoice message, it produces the following output message:

```
<Data>
  <Output>
     <Quantity>2</Quantity>
     <Author>Neil Bradley</Author>
  </Output>
  <Output>
     <Quantity>1</Quantity>
     <Author>Don Chamberlin</Author>
  </Output>
  <Output>
     <Quantity>1</Quantity>
     <Author>Philip Heller, Simon Roberts</Author>
  </Output>
</Data>
```

Three Output fields are present, one for each Item field, because SELECT creates an item in its result list for each item described by its FROM list. Within each Output field, a Field is created for each field named in the SELECT clause. These fields are in the order in which they are specified within the SELECT clause, not in the order in which they appear in the incoming message.

The R that is introduced by the final AS keyword is known as a correlation name. It is a local variable that represents in turn each of the fields addressed by the FROM clause. The name chosen has no significance. In summary, this simple transform does two things:

1. It discards unwanted fields.
2. It guarantees the order of the fields.

You can perform the same transform with a procedural algorithm:

```
DECLARE i INTEGER 1;
DECLARE count INTEGER CARDINALITY(InputRoot.XMLNS.Invoice.Purchases.Item[]);

WHILE (i <= count)
   SET OutputRoot.XMLNS.Data.Output[i].Quantity = InputRoot.XMLNS.Invoice.Purchases.Item[i].Quantity;
   SET OutputRoot.XMLNS.Data.Output[i].Author   = InputRoot.XMLNS.Invoice.Purchases.Item[i].Author;
   SET i = i+1;
END WHILE;
```

These examples show that the SELECT version of the transform is much more concise. It also executes faster.

The following example shows a more advanced transformation:

```
SET OutputRoot.XMLNS.Data.Output[] =
    (SELECT R.Quantity AS Book.Quantity,
            R.Author   AS Book.Author
            FROM InputRoot.XMLNS.Invoice.Purchases.Item[] AS R
    );
```

In this transform, an AS clause is associated with each item in the SELECT clause. This clause gives each field in the result an explicit name rather than a field name that is inherited from the input. These names can be paths (that is, a dot-separated list of names), as shown in the example. The structure of the output message structure can be different from the input message. Using the same Invoice message, the result is:

```
<Data>
  <Output>
    <Book>
      <Quantity>2</Quantity>
      <Author>Neil Bradley</Author>
    </Book>
  </Output>
  <Output>
    <Book>
      <Quantity>1</Quantity>
      <Author>Don Chamberlin</Author>
    </Book>
  </Output>
  <Output>
    <Book>
      <Quantity>1</Quantity>
      <Author>Philip Heller, Simon Roberts</Author>
    </Book>
  </Output>
</Data>
```

The expressions in the SELECT clause can be of any complexity and there are no special restrictions. They can include operators, functions, and literals, and they can refer to variables or fields that are not related to the correlation name. The following example shows more complex expressions:

```
SET OutputRoot.XMLNS.Data.Output[] =
    (SELECT 'Start'                          AS Header,
            'Number of books:' || R.Quantity AS Book.Quantity,
            R.Author || ':Name and Surname'  AS Book.Author,
            'End'                            AS Trailer
            FROM InputRoot.XMLNS.Invoice.Purchases.Item[] AS R
    );
```

Using the same Invoice message, the result in this case is:

```
<Data>
 <Output>
  <Header>Start</Header>
  <Book>
   <Quantity>Number of books:2</Quantity>
   <Author>Neil Bradley:Name and Surname</Author>
  </Book>
  <Trailer>End</Trailer>
 </Output>
 <Output>
  <Header>Start</Header>
  <Book>
   <Quantity>Number of books:1</Quantity>
   <Author>Don Chamberlin:Name and Surname</Author>
  </Book>
  <Trailer>End</Trailer>
 </Output>
 <Output>
  <Header>Start</Header>
  <Book>
   <Quantity>Number of books:1</Quantity>
   <Author>Philip Heller, Simon Roberts:Name and Surname</Author>
  </Book>
  <Trailer>End</Trailer>
 </Output>
</Data>
```

As shown above, the AS clauses of the SELECT clause contain a path that describes the full name of the field that is to be created in the result. These paths can also specify (as is normal for paths) the type of field that is to be created. The following example transform specifies the field types. In this case, XML tagged data is transformed to XML attributes:

```
SET OutputRoot.XMLNS.Data.Output[] =
    (SELECT R.Quantity.* AS Book.(XML.Attribute)Quantity,
            R.Author.*   AS Book.(XML.Attribute)Author
            FROM InputRoot.XMLNS.Invoice.Purchases.Item[] AS R
    );
```

Using the same Invoice message, the result is:

```
<Data>
 <Output>
  <Book Quantity="2" Author="Neil Bradley"/>
 </Output>
 <Output>
  <Book Quantity="1" Author="Don Chamberlin"/>
 </Output>
 <Output>
  <Book Quantity="1" Author="Philip Heller, Simon Roberts"/>
 </Output>
</Data>
```

Finally, you can use a WHERE clause to eliminate some of the results. In the following example a WHERE clause is used to remove results in which a specific criterion is met. An entire result is either included or excluded:

```
SET OutputRoot.XMLNS.Data.Output[] =
    (SELECT R.Quantity AS Book.Quantity,
            R.Author   AS Book.Author
            FROM InputRoot.XMLNS.Invoice.Purchases.Item[] AS R
            WHERE R.Quantity = 2
    );
```

Using the same input message, the result is:

```
<Data>
 <Output>
  <Book>
   <Quantity>2</Quantity>
   <Author>Neil Bradley</Author>
  </Book>
 </Output>
</Data>
```

Transforming a complex message:

When you code the ESQL for a Compute node, use the SELECT function for complex message transformation.

About this task

This topic provides examples of complex message transformation. Review the examples and modify them for your own use. They are all based on the "Example message" on page 5311 as input.

Example

In this example, Invoice contains a variable number of Items. The transform is shown in the following example:

```
SET OutputRoot.XMLNS.Data.Statement[] =
    (SELECT I.Customer.Title                                    AS Customer.Title,
            I.Customer.FirstName || ' ' || I.Customer.LastName  AS Customer.Name,
            COALESCE(I.Customer.PhoneHome,'')                   AS Customer.Phone,
            (SELECT II.Title                          AS Desc,
                    CAST(II.UnitPrice AS FLOAT) * 1.6 AS Cost,
                    II.Quantity                       AS Qty
             FROM I.Purchases.Item[] AS II
             WHERE  II.UnitPrice> 0.0             )     AS Purchases.Article[],
            (SELECT SUM( CAST(II.UnitPrice AS FLOAT) *
                    CAST(II.Quantity  AS FLOAT) *
                    1.6                          )
             FROM I.Purchases.Item[] AS II      )       AS Amount,
            'Dollars'                                   AS Amount.(XML.Attribute)Currency

            FROM InputRoot.XMLNS.Invoice[] AS I
            WHERE I.Customer.LastName <> 'Brown'
    );
```

The output message that is generated is:

```
<Data>
 <Statement>
  <Customer>
   <Title>Mr</Title>
   <Name>Andrew Smith</Name>
   <Phone>01962818000</Phone>
  </Customer>
  <Purchases>
   <Article>
    <Desc Category="Computer" Form="Paperback" Edition="2">The XML Companion</Desc>
    <Cost>4.472E+1</Cost>
    <Qty>2</Qty>
   </Article>
   <Article>
    <Desc Category="Computer" Form="Paperback" Edition="2">
          A Complete Guide to DB2 Universal Database</Desc>
    <Cost>6.872E+1</Cost>
    <Qty>1</Qty>
   </Article>
   <Article>
    <Desc Category="Computer" Form="Hardcover" Edition="0">JAVA 2 Developers Handbook</Desc>
    <Cost>9.5984E+1</Cost>
    <Qty>1</Qty>
   </Article>
  </Purchases>
  <Amount Currency="Dollars">2.54144E+2</Amount>
 </Statement>
</Data>
```

This transform has nested SELECT clauses. The outer statement operates on the list of Invoices. The inner statement operates on the list of Items. The AS clause that is associated with the inner SELECT clause expects an array:

```
(SELECT II.Title                          AS Desc,
        CAST(II.UnitPrice AS FLOAT) * 1.6 AS Cost,
        II.Quantity                       AS Qty
 FROM I.Purchases.Item[] AS II
 WHERE  II.UnitPrice> 0.0             )
-- Note the use of [] in the next expression
   AS Purchases.Article[],
```

This statement tells the outer SELECT clause to expect a variable number of Items in each result. Each SELECT clause has its own correlation name: I for the outer SELECT clause and II for the inner one. Each SELECT clause typically uses its own correlation name, but the FROM clause in the inner SELECT clause refers to the correlation name of the outer SELECT clause:

```
(SELECT II.Title                          AS Desc,
        CAST(II.UnitPrice AS FLOAT) * 1.6 AS Cost,
        II.Quantity                       AS Qty
-- Note the use of I.Purchases.Item in the next expression
 FROM I.Purchases.Item[] AS II
 WHERE  II.UnitPrice> 0.0             ) AS Purchases.Article[],
```

This statement tells the inner SELECT clause to work with the current Invoice's Items. Both SELECT clauses contain WHERE clauses. The outer one uses one criterion to discard certain Customers, and the inner one uses a different criterion to discard certain Items. The example also shows the use of COALESCE to prevent missing input fields from causing the corresponding output field to be missing. Finally, it also uses the column function SUM to add together the value of all Items in each Invoice. Column functions are discussed in "Referencing columns in a database" on page 2489.

When the fields Desc are created, the whole of the input Title field is copied: the XML attributes and the field value. If you do not want these attributes in the output message, use the FIELDVALUE function to discard them; for example, code the following ESQL:

```
SET OutputRoot.XMLNS.Data.Statement[] =
    (SELECT I.Customer.Title                                  AS Customer.Title,
            I.Customer.FirstName || ' ' || I.Customer.LastName AS Customer.Name,
            COALESCE(I.Customer.PhoneHome,'')                 AS Customer.Phone,
            (SELECT FIELDVALUE(II.Title)                      AS Desc,
                    CAST(II.UnitPrice AS FLOAT) * 1.6 AS Cost,
                    II.Quantity                         AS Qty
             FROM I.Purchases.Item[] AS II
             WHERE  II.UnitPrice> 0.0             )      AS Purchases.Article[],
            (SELECT SUM( CAST(II.UnitPrice AS FLOAT) *
                    CAST(II.Quantity  AS FLOAT) *
                    1.6                           )
             FROM I.Purchases.Item[] AS II        ) AS Amount,
            'Dollars'                               AS Amount.(XML.Attribute)Currency

    FROM InputRoot.XMLNS.Invoice[] AS I
    WHERE I.Customer.LastName <> 'Brown'
    );
```

That code generates the following output message:

```
<Data>
 <Statement>
  <Customer>
   <Title>Mr</Title>
   <Name>Andrew Smith</Name>
   <Phone>01962818000</Phone>
  </Customer>

"Example message" on page 5311

Returning a scalar value in a message:

Use a SELECT statement to return a scalar value by including both the **THE** and **ITEM** keywords.

About this task

For example:

```
1 + THE(SELECT ITEM T.a FROM Body.Test.A[] AS T WHERE T.b = '123')
```

Use of the ITEM keyword:
About this task

The following example shows the use of the ITEM keyword to select one item and create a single value.

```
SET OutputRoot.MQMD = InputRoot.MQMD;

SET OutputRoot.XMLNS.Test.Result[] =
   (SELECT ITEM T.UnitPrice FROM InputBody.Invoice.Purchases.Item[] AS T);
```

When the Invoice message is received as input, the ESQL shown generates the following output message:

```
<Test>
  <Result>27.95</Result>
  <Result>42.95</Result>
  <Result>59.99</Result>
</Test>
```

When the ITEM keyword is specified, the output message includes a list of scalar values. Compare this message to the one that is produced if the ITEM keyword is omitted, in which a list of fields (name-value pairs) is generated:

```
<Test>
  <Result>
    <UnitPrice>27.95</UnitPrice>
  </Result>
  <Result>
    <UnitPrice>42.95</UnitPrice>
  </Result>
  <Result>
    <UnitPrice>59.99</UnitPrice>
  </Result>
</Test>
```

Effects of the THE keyword:
About this task

The THE keyword converts a list containing one item to the item itself.

The two previous examples both specified a list as the source of the SELECT in the FROM clause (the field reference has [] at the end to indicate an array), so typically the SELECT function generates a list of results. Because of this behavior, you must specify a list as the target of the assignment (thus the "Result[]" as the target of the assignment). However, you often know that the WHERE clause that you specify as part of the SELECT returns TRUE for only one item in the list. In this case use the THE keyword.

The following example shows the effect of using the THE keyword:

```
SET OutputRoot.MQMD = InputRoot.MQMD;

SET OutputRoot.XMLNS.Test.Result =
    THE (SELECT T.Publisher, T.Author FROM InputBody.Invoice.Purchases.Item[]
         AS T WHERE T.UnitPrice = 42.95);
```

The THE keyword means that the target of the assignment becomes `OutputRoot.XMLNS.Test.Result` (the "[]" is not permitted). Its use generates the

following output message:

```
<Test>
  <Result>
    <Publisher>Morgan Kaufmann Publishers</Publisher>
    <Author>Don Chamberlin</Author>
  </Result>
</Test>
```

Selecting from a list of scalars:
About this task

Consider the following sample input message:

```
<Test>
 <A>1</A>
 <A>2</A>
 <A>3</A>
 <A>4</A>
 <A>5</A>
</Test>
```

If you code the following ESQL statements to process this message:

```
SET OutputRoot.XMLNS.Test.A[] =
  (SELECT ITEM A from InputBody.Test.A[]
   WHERE CAST(A AS INTEGER) BETWEEN 2 AND 4);
```

the following output message is generated:

```
      <A>2</A>
      <A>3</A>
      <A>4</A>
```

Joining data in a message:

The FROM clause of a SELECT function is not restricted to having one item. Specifying multiple items in the FROM clause produces the typical Cartesian product joining effect, in which the result includes an item for all combinations of items in the two lists.

About this task

Using the FROM clause in this way produces the same joining effect as standard SQL.

The Invoice message includes a set of customer details, payment details, and details of the purchases that the customer makes. Code the following ESQL to process the input "Example message" on page 5311:

```
SET OutputRoot.XMLNS.Items.Item[] =
   (SELECT D.LastName, D.Billing,
           P.UnitPrice, P.Quantity
    FROM InputBody.Invoice.Customer[] AS D,
         InputBody.Invoice.Purchases.Item[] AS P);
```

The following output message is generated:

```
<Items>
 <Item>
  <LastName>Smith</LastName>
  <Billing>
   <Address>14 High Street</Address>
   <Address>Hursley Village</Address>
   <Address>Hampshire</Address>
   <PostCode>SO213JR</PostCode>
  </Billing>
  <UnitPrice>27.95</UnitPrice>
  <Quantity>2</Quantity>
 </Item>
 <Item>
  <LastName>Smith</LastName>
  <Billing>
   <Address>14 High Street</Address>
   <Address>Hursley Village</Address>
   <Address>Hampshire</Address>
   <PostCode>SO213JR</PostCode>
  </Billing>
  <UnitPrice>42.95</UnitPrice>
  <Quantity>1</Quantity>
 </Item>
 <Item>
  <LastName>Smith</LastName>
  <Billing>
   <Address>14 High Street</Address>
   <Address>Hursley Village</Address>
   <Address>Hampshire</Address>
   <PostCode>SO213JR</PostCode>
  </Billing>
  <UnitPrice>59.99</UnitPrice>
  <Quantity>1</Quantity>
 </Item>
</Items>
```

Three results are produced, giving the number of descriptions in the first list (one) multiplied by the number of prices in the second (three). The results systematically work through all the combinations of the two lists. You can see this by looking at the *LastName* and *UnitPrice* fields selected from each result:

```
LastName Smith   UnitPrice 27.95
LastName Smith   UnitPrice 42.95
LastName Smith   UnitPrice 59.99
```

You can join data that occurs in a list and a non-list, or in two non-lists, and so on. For example:

```
OutputRoot.XMLNS.Test.Result1[] =
  (SELECT ... FROM InputBody.Test.A[], InputBody.Test.b);
OutputRoot.XMLNS.Test.Result1 =
  (SELECT ... FROM InputBody.Test.A, InputBody.Test.b);
```

The location of the [] in each case is significant. Any number of items can be specified in the FROM clause, not just one or two. If any of the items specify [] to indicate a list of items, the SELECT function returns a list of results (the list might contain only one item, but the SELECT function can return a list of items).

The target of the assignment must specify a list (so must end in []), or you must use the "THE function" on page 5242 if you know that the WHERE clause guarantees that only one combination is matched.

"Example message" on page 5311

Translating data in a message:

You can translate data from one form to another.

About this task

A typical example of the requirement to translate data is if the items are known in one message by names, and in another message by numbers. For example:

```
Type Name          Type Code

Confectionary      2000
Newspapers         3000
Hardware           4000
```

Consider the following input message:

```
<Data>
  <Items>
    <Item>
      <Cat>1000</Cat>
      <Description>Milk Chocolate Bar</Description>
      <Type>Confectionary</Type>
    </Item>
    <Item>
      <Cat>1001</Cat>
      <Description>Daily Newspaper</Description>
      <Type>NewsPapers</Type>
    </Item>
    <Item>
      <Cat>1002</Cat>
      <Description>Kitchen Sink</Description>
      <Type>Hardware</Type>
    </Item>
  </Items>
  <TranslateTable>
    <Translate>
      <Name>Confectionary</Name>
      <Number>2000</Number>
    </Translate>
    <Translate>
      <Name>NewsPapers</Name>
      <Number>3000</Number>
    </Translate>
    <Translate>
      <Name>Hardware</Name>
      <Number>4000</Number>
    </Translate>
  </TranslateTable>
</Data>
```

This message has two sections; the first section is a list of items in which each item has a catalog number and a type; the second section is a table for translating between descriptive type names and numeric type codes. Include a Compute node with the following transform:

```
SET OutputRoot.XMLNS.Result.Items.Item[] =
   (SELECT M.Cat, M.Description, T.Number As Type
     FROM
       InputRoot.XMLNS.Data.Items.Item[]               As M,
       InputRoot.XMLNS.Data.TranslateTable.Translate[] As T
     WHERE M.Type = T.Name
   );
```

The following output message is generated:

```
<Result>
  <Items>
    <Item>
      <Cat>1000</Cat>
      <Description>Milk Chocolate Bar</Description>
      <Type>2000</Type>
    </Item>
    <Item>
      <Cat>1001</Cat>
      <Description>Daily Newspaper</Description>
      <Type>3000</Type>
    </Item>
    <Item>
      <Cat>1002</Cat>
      <Description>Kitchen Sink</Description>
      <Type>4000</Type>
    </Item>
  </Items>
</Result>
```

In the result, each type name has been converted to its corresponding code. In this example, both the data and the translate table were in the same message tree, although this is not a requirement. For example, the translate table could be coded in a database, or might have been set up in LocalEnvironment by a previous Compute node.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

Joining data from messages and database tables:

You can use SELECT functions that interact with both message data and databases.

About this task

You can also nest a SELECT function that interacts with one type of data within a SELECT clause that interacts with the other type.

Consider the following input message, which contains invoice information for two customers:

```
<Data>
  <Invoice>
    <CustomerNumber>1234</CustomerNumber>
    <Item>
      <PartNumber>1</PartNumber>
      <Quantity>9876</Quantity>
    </Item>
    <Item>
      <PartNumber>2</PartNumber>
      <Quantity>8765</Quantity>
    </Item>
</Invoice>
  <Invoice>
    <CustomerNumber>2345</CustomerNumber>
    <Item>
      <PartNumber>2</PartNumber>
      <Quantity>7654</Quantity>
    </Item>
    <Item>
      <PartNumber>1</PartNumber>
    <Quantity>6543</Quantity>
    </Item>
</Invoice>
</Data>
```

Consider the following database tables, Prices and Addresses, and their contents:

```
PARTNO      PRICE
----------- ----------------------
          1            +2.50000E+001
          2            +6.50000E+00

PARTNO      STREET               CITY             COUNTRY
------      ------------------   --------------   -------
1234        22 Railway Cuttings  East Cheam       England
2345        The Warren           Watership Down   England
```

If you code the following ESQL transform:

```
-- Create a valid output message
SET OutputRoot.MQMD = InputRoot.MQMD;

-- Select suitable invoices
SET OutputRoot.XMLNS.Data.Statement[] =
   (SELECT I.CustomerNumber                          AS Customer.Number,
           A.Street                                  AS Customer.Street,
           A.City                                    AS Customer.Town,
           A.Country                                 AS Customer.Country,

        -- Select suitable items
          (SELECT II.PartNumber AS PartNumber,
                  II.Quantity   AS Quantity,
                  PI.Price      AS Price
           FROM Database.db2admin.Prices AS PI,
               I.Item[]                 AS II
           WHERE II.PartNumber = PI.PartNo     )    AS Purchases.Item[]

    FROM Database.db2admin.Addresses  AS A,
         InputRoot.XMLNS.Data.Invoice[] AS I

    WHERE I.CustomerNumber = A.PartNo
    );
```

the following output message is generated. The input message is augmented with the price and address information from the database table:

```
<Data>
  <Statement>
    <Customer>
      <Number>1234</Number>
      <Street>22 Railway Cuttings</Street>
      <Town>East Cheam</Town>
      <Country>England</Country>
    </Customer>
    <Purchases>
      <Item>
        <PartNumber>1</PartNumber>
        <Quantity>9876</Quantity>
        <Price>2.5E+1</Price>
      </Item>
      <Item>
        <PartNumber>2</PartNumber>
        <Quantity>8765</Quantity>
        <Price>6.5E+1</Price>
      </Item>
    </Purchases>
  </Statement>
  <Statement>
    <Customer>
      <Number>2345</Number>
      <Street>The Warren</Street>
      <Town>Watership Down</Town>
      <Country>England</Country>
    </Customer>
    <Purchases>
      <Item>
        <PartNumber>1</PartNumber>
        <Quantity>6543</Quantity>
        <Price>2.5E+1</Price></Item>
      <Item>
        <PartNumber>2</PartNumber>
        <Quantity>7654</Quantity>
        <Price>6.5E+1</Price>
      </Item>
    </Purchases>
  </Statement>
</Data>
```

You can nest the database SELECT clause within the message SELECT clause. In most cases, the code is not as efficient as the previous example, but you might find that it is better if the messages are small and the database tables are large.

```
-- Create a valid output message
SET OutputRoot.MQMD = InputRoot.MQMD;

-- Select suitable invoices
SET OutputRoot.XMLNS.Data.Statement[] =
    (SELECT I.CustomerNumber                  AS Customer.Number,

        -- Look up the address
        THE ( SELECT
                  A.Street,
                  A.City    AS Town,
                  A.Country
                FROM Database.db2admin.Addresses AS A
                WHERE A.PartNo = I.CustomerNumber
            )                               AS Customer,

        -- Select suitable items
        (SELECT
            II.PartNumber AS PartNumber,
            II.Quantity   AS Quantity,

            -- Look up the price
            THE (SELECT ITEM P.Price
              FROM Database.db2admin.Prices AS P
              WHERE P.PartNo = II.PartNumber
            )             AS Price

          FROM I.Item[] AS II           ) AS Purchases.Item[]

    FROM InputRoot.XMLNS.Data.Invoice[] AS I
    );
```

Extended Structured Query Language (ESQL) is a programming language defined by WebSphere Message Broker to define and manipulate data within a message flow.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

"Managing ESQL files" on page 2390
In a message flow project, manage ESQL files that contain the ESQL code that you provide to modify or customize the behavior of Compute, Database, DatabaseInput, and Filter nodes.

"Compute node" on page 4340
Use the Compute node to construct one or more new output messages.

"Database node" on page 4354
Use the Database node to interact with a database in the specified ODBC data source.

"Filter node" on page 4452
Use the Filter node to route a message according to message content.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

"SELECT function" on page 5260
The SELECT function combines, filters, and transforms complex message and database data.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

Manipulating messages in the XML domains:

You can manipulate messages in the XML, XMLNS, and XMLNSC domains.

About this task

The following topics contain instructions about manipulating messages in the XMLNSC, XMLNS, and XML domains.

- "Working with XML messages"
- "Manipulating messages in the XMLNSC domain" on page 2546
- "Manipulating messages in the XMLNS domain" on page 2563
- "Manipulating messages in the XML domain" on page 2581

For information about dealing with MRM XML messages, see "Manipulating messages in the MRM domain" on page 2581.

Related concepts:

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

"Which XML parser should you use?" on page 1080
If your messages are general-purpose XML documents, you can use one of the dedicated XML domains (XMLNSC or XMLNS) to parse the message, or you can use the MRM domain to parse the message.

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

"XMLNS parser" on page 1104
The XMLNS parser is a flexible, general-purpose XML parser.

"XML parser" on page 1110
The XML domain is very similar to the XMLNS domain, but the XML domain has no support for XML namespaces or opaque parsing.

Working with XML messages:

The following topics provide information about typical tasks for processing XML messages.

About this task

Some of this information is available publicly in Web pages and online tutorials. If you are new to XML, you will find it useful to also read about the XML standard.

- "Constructing an XML message tree"
- "Working with namespaces" on page 2537
- "Working with binary data" on page 2538
- "XMLNSC: Working with CData" on page 2539
- "XMLNSC: Working with XML messages and bit streams" on page 2541
- "Working with large XML messages" on page 2543

For details about XML Schema, see XML Schema Part 0: Primer on the World Wide Web Consortium (W3C) Web site.

Constructing an XML message tree:

When constructing an XML message tree, consider the order of fields in the tree.

About this task

Order of fields in the message tree

When you create an XML output message in a Compute node, the order of your lines of ESQL code is important, because the message elements are created in the order that you code them.

Consider the following XML message:

```
<Order>
  <ItemNo>1</ItemNo>
  <Quantity>2</Quantity>
</Order>
```

If you want to add a DocType Declaration to this, insert the DocType Declaration before you copy the input message to the output message.

For example:

```
SET OutputRoot.XMLNS.(XML.XmlDecl) = '';
SET OutputRoot.XMLNS.(XML.XmlDecl).(XML.Version) = '1.0';
SET OutputRoot.XMLNS.(XML.DocTypeDecl)Order ='';
SET OutputRoot.XMLNS.(XML.DocTypeDecl).(XML.SystemId)   = 'NewDtdName.dtd';
SET OutputRoot = InputRoot;
  -- more ESQL --
```

If you put the last statement to copy the input message before the XML-specific statements, the following XML is generated for the output message.

```
<Order>
  <ItemNo>1</ItemNo>
  <Quantity>2</Quantity>
</Order>
<?xml version="1.0"?>
```

This is not well-formed XML and causes an error when it is written from the message tree to a bit stream in the output node.

Setting the field type

If you copy a message tree from input to output without changing the domain, most of the syntax elements will be created by the parser (XMLNSC or XMLNS) and their field types will be correct. However, if you construct your message tree from a database query, or from another parser's message tree, you must ensure that you identify each syntax element correctly by using its field type. You can find full details of the field type constants used by XMLNSC and XMLNS in the following topics:

- "XMLNSC: Using field types" on page 1094
- "XML constructs" on page 4257

Working with namespaces:

The following example shows how to use ESQL to work with namespaces.

About this task

Namespace constants are declared at the start of the main module so that you can use prefixes in the ESQL statements instead of the full URIs of the namespaces. The namespace constants affect only the ESQL; they do not control the prefixes that are generated in the output message. The prefixes in the generated output message are controlled by namespace declarations in the message tree. You can include namespace declarations in the tree using the XML.NamespaceDecl field type. These elements are then used to generate namespace declarations in the output message.

When the output message is generated, if the parser encounters a namespace for which it has no corresponding namespace declaration, a prefix is automatically generated using prefixes of the form NSn where n is a positive integer.

```
CREATE COMPUTE MODULE xmlns_doc_flow_Compute
CREATE FUNCTION Main() RETURNS BOOLEAN
BEGIN
CALL CopyMessageHeaders();
-- Declaration of namespace constants --
These are only used by ESQL

DECLARE sp1 NAMESPACE 'http://www.ibm.com/space1';
DECLARE sp2 NAMESPACE 'http://www.ibm.com/space2';
DECLARE sp3 NAMESPACE 'http://www.ibm.com/space3';

-- Namespace declaration for prefix 'space1'
SET OutputRoot.XMLNS.message.(XML.NamespaceDecl)xmlns:space1 = 'http://www.ibm.com/space1';
SET OutputRoot.XMLNS.message.sp1:data1 = 'Hello!';

-- Default namespace declaration ( empty prefix )
SET OutputRoot.XMLNS.message.sp2:data2.(XML.NamespaceDecl)xmlns = 'http://www.ibm.com/space2';
SET OutputRoot.XMLNS.message.sp2:data2.sp2:subData1 = 'Hola!';
SET OutputRoot.XMLNS.message.sp2:data2.sp2:subData2 = 'Guten Tag!';
SET OutputRoot.XMLNS.message.sp3:data3 = 'Bonjour!';
RETURN TRUE;
END;

CREATE PROCEDURE CopyMessageHeaders()
BEGIN
DECLARE I INTEGER 1;
DECLARE J INTEGER CARDINALITY(InputRoot.*[]);
WHILE I < J DO SET OutputRoot.*[I] = InputRoot.*[I];
  SET I = I + 1;
END WHILE;
END;
END MODULE;
```

When this ESQL is processed, the following output message is generated:

```
<message xmlns:space1="http://www.ibm.com/space1">
 <space1:data1>Hello!</space1:data1>
 <data2 xmlns="http://www.ibm.com/space2">
  <subData1>Hola!</subData1>
  <subData2>Guten Tag!</subData2>
 </data2>
 <NS1:data3 xmlns="http://www.ibm.com/space3>Bonjour!</NS1:data3>
</message>
```

Working with binary data:

If you need to include binary data or non-valid characters in your XML documents, the safest method is to encode the data as a binary string.

About this task

Binary encodings for XML

There are two methods of encoding binary data in an XML document.

```
hexBinary: <nonXMLChars>000102030405060708080C0E0F</nonXMLChars>

base64Binary: <nonXMLChars>AAECAwQFBgcICwwODw==</nonXMLChars>
```

The base64Binary encoding makes better use of the available XML characters, and on average a base64-encoded binary field is 2/3 the size of its hexBinary equivalent. Base64Binary is widely used by the MIME format and by various XML-based standards.

You might prefer to use the simpler hexBinary encoding if you are sending data to applications that cannot decode base64 data, and if the increase in message size is not important.

Parsing binary data

The most straightforward way to parse any binary data is to use the XMLNSC parser with a message set:

1. Locate or construct an XML Schema that describes your input XML.
2. Import the XML Schema to create a message definition file.
3. In your message flow, set the node properties as follows:
   - On the Default page, set *Message Domain* to XMLNSC and *Message Set* to the name of your message set.
   - On the Validation page, set *Validation* to Content and Value.
   - In the XMLNSC properties, select the check box option *Build tree using XML Schema types*.

The XMLNSC parser automatically decodes your hexBinary or base64Binary data, being guided by the simple type of the element or attribute that contains the binary data. The message tree will contain the decoded BLOB value.

If you are using the XMLNS domain, you must parse the binary data as a string. It appears in the message tree as a CHARACTER value. If the data is encoded as hexBinary, you can use the ESQL CAST function to convert it to a BLOB value. If the data is encoded as base64Binary, the easiest approach is to use the function BASE64DECODE. For more information, see “BASE64DECODE function” on page 5290.

Generating binary data

You can generate binary data in your output XML in either hexBinary or base64Binary encoding.

For hexBinary, use the ESQL CAST statement to convert your BLOB data to a hexBinary string.

For base64Binary, you have two options:

- Call the function BASE64ENCODE. For more information, see "BASE64ENCODE function" on page 5291.
- Use the XMLNSC parser, and modify the type field on the syntax element, as shown in this example:

```
-- ESQL code to generate base64-encoded binary data
DECLARE myBLOB BLOB;
-- Populate myBLOB with your binary data
CREATE LASTCHILD OF OutputRoot.XMLNSC.message
       TYPE BITOR(XMLNSC.Attribute, XMLNSC.base64Binary)
       NAME myBase64Element
       VALUE myBLOB;
```

  Note that setting the field type to XMLNSC.base64Binary does not change the logical value in the message tree. In your message flow, it is still a BLOB, and if you ask for its string representation, it is reported as a hexBinary string. However, when the message tree is converted to a bit stream (in an output node, or by a call to ASBITSTREAM) the base64 conversion is performed automatically, and the output XML contains the correct base64 string.

XMLNSC: Working with CData:

A CData section can be used to embed an XML document within another XML document.

About this task

What is a CData section?

An XML element can contain text content:

```
<element>text content</element>
```

However, some characters cannot appear in that content. In particular, '<' and '&' both have special meaning to an XML parser. If they are included in the text content of an element, they change the meaning of the XML document.

For example, this is a badly formed XML document:

```
<element><text><content></element>
```

There are two ways to make the XML well-formed:

1. Use character entities:

   ```
   <element>&lt;text&gt;&lt;content&gt;</element>
   ```

2. Use a CData section:

   ```
   <element><![CDATA[<text><content>]]></element>
   ```

What can you use a CData section for?

In a CData section, you can include XML markup in the value of an element. However, non-valid XML characters cannot be included. Binary data also cannot be included in a CData section.

The most common use for CData is to embed one XML document within another. For example:

```
<outer>
    <embedXML>
        <![CDATA[<innerMsg></innerMsg>]]>
    </embedXML>
</outer>
```

You can even embed a badly-formed XML document in this way, because the XML parser does not attempt to parse the content of a CData section.

```
<outer>
    <embedXML>
        <![CDATA[<badXML></wrongClosingTag>]]>
    </embedXML>
</outer>
```

The following items are not valid within a CData section:

- Non-valid XML characters (see http://www.w3.org/TR/2006/REC-xml-20060816/#charsets)
- The text string ']]>' (because this terminates the CData section)

Because of these restrictions, do not use a CData section to include arbitrary text in your XML document, and do not try to use a CData section to hold binary data (unless it is encoded as hexBinary or base64Binary).

How do you add a CData section to an output XML message?

Consider the following input message :

```
 <TestCase>
    <Folder>
       <Field1>Value1</Field1>
       <Field2>Value2</Field2>
       <Field3>Value3</Field3>
    </Folder>
 </TestCase>
```

The following ESQL shows how to serialize a whole message:

```
 DECLARE wholeMsgBlob BLOB
   ASBITSTREAM(InputRoot.XMLNSC,
               InputRoot.Properties.Encoding,
               InputRoot.Properties.CodedCharSetId );
  DECLARE wholeMsgChar CHAR
   CAST(wholeMsgBlob AS CHAR CCSID InputRoot.Properties.CodedCharSetId);
 SET OutputRoot.XMLNSC.Output.(XMLNSC.CDataField)Field1 = wholeMsgChar;
```

This example serializes the InputRoot.XMLNSC.TestCase.Folder portion of the message tree.

If the output message tree were examined before an MQOutput node, this would show :

```
(0x01000010):XML        = (
  (0x01000000):Output = (
    (0x01000000):Field1 = (
      (0x02000001): = '<TestCase><Folder><Field1>Value1</Field1><Field2>Value2</Field2>
                      <Field3>Value3</Field3></Folder><Folder2><Field1>Value1</Field1>
```

```
                        <Field2>Value2</Field2><Field3>Value3</Field3><Folder2></TestCase>'
       )
       )
   )
```

As can be seen, each CData section contains a single scalar value that is the character representation of the portion of the XML message that is required.

This tree produces the following XML output message :

```
<Output>
 <Field1><![CDATA[<TestCase><Folder><Field1>Value 1</Field1>
                                    <Field2>Value 2</Field2>
                                    <Field3>Value 3</Field3></Folder>
                             <Folder2><Field1>Value 1</Field1>
                                      <Field2>Value 2</Field2>
                                      <Field3>Value 3</Field3></Folder2>
                  </TestCase>]]</Field1>
 </Output>
```

XMLNSC: Working with XML messages and bit streams:

Use the ASBITSTREAM function and the CREATE statement to manage XML message content.

About this task

The ASBITSTREAM function

If you code the ASBITSTREAM function with the parser mode option set to RootBitStream to parse a message tree to a bit stream, the result is an XML document that is built from the children of the target element in the normal way. This algorithm is identical to that used to generate the normal output bit stream. Because the target element is not included in the output bit stream, you must ensure that the children of the element follow the constraints for an XML document.

One constraint is that there must be only one body element in the message. You can use a well-formed bit stream obtained in this way to re-create the original tree using a CREATE statement with a PARSE clause.

If you code the ASBITSTREAM function with the parser mode option set to FolderBitStream to parse a message tree to a bit stream, the generated bit stream is an XML document built from the target element and its children. Any DocTypeDecl or XmlDecl elements are ignored, and the target element itself is included in the generated bit stream.

The advantage of this mode is that the target element becomes the body element of the document, and that body element can have multiple elements nested within it. Use this mode to obtain a bit stream description of arbitrary sub-trees owned by an XML parser. You can use bit streams obtained in this way to re-create the original tree using a CREATE statement with a PARSE clause, and a mode of FolderBitStream.

For further information about the ASBITSTREAM function, and some examples of its use, see “ASBITSTREAM function” on page 5224.

The CREATE statement with a PARSE clause

If you code a CREATE statement with a PARSE clause with the parser mode option set to RootBitStream to parse a bit stream to a message tree, the expected bit stream is a normal XML document. A field in the tree is created for each field in the document. This algorithm is identical to that used when parsing a bit stream from an input node. In particular, an element named 'XML', 'XMLNS', or 'XMLNSC' is created as the root element of the tree, and all the content in the message is created as children of that root.

If you code a CREATE statement with a PARSE clause with the parser mode option set to FolderBitStream to parse a bit stream to a message tree, the expected bit stream is a normal XML document. Any content outside the body element (such as an XML declaration or doctype) is discarded. The first element created during the parse corresponds to the body of the XML document, and from there the parse proceeds as normal.

For further information about the CREATE statement, and examples of its use, see "CREATE statement" on page 5082.

The ASBITSTREAM field function generates a bit stream for the subtree of a given field according to the rules of the parser that owns the field.

Working with large XML messages:

The tree representation of an XML message is typically bigger than the input bit stream. Manipulating a large message tree can require much storage but you can code ESQL statements that help to reduce the storage load on the broker.

About this task

When an input bit stream is parsed and a logical tree is created, the tree representation of an XML message is typically bigger, and in some cases much bigger, than the corresponding bit stream.

The reasons for this expansion include the following factors:
- The addition of the pointers that link the objects together
- Translation of character data into Unicode, which can double the size
- The inclusion of field names that might have been implicit in the bit stream
- The presence of control data that is associated with operation of the broker

Manipulating a large message tree can require much storage. If you design a message flow that handles large messages that are made up of repeating structures, you can code ESQL statements that help to reduce the storage load on the broker. These statements support both random and sequential access to the message, but assume that you do not need access to the whole message at one time.

These ESQL statements cause the broker to perform limited parsing of the message, and to keep in storage at one time, only that part of the message tree that reflects a single record. If your processing requires you to retain information from record to record (for example, to calculate a total price from a repeating structure of items in an order), you can either declare, initialize, and maintain ESQL variables, or you can save values in another part of the message tree; for example, in the local environment.

This technique reduces the memory that is used by the broker to the memory that is needed to hold the full input and output bit streams, plus the memory that is needed for the message trees of just one record. This technique also provides memory savings when even a few repeats are encountered in the message. The broker uses partial parsing and the ability to parse specified parts of the message tree, to and from the corresponding part of the bit stream.

To use these techniques in your Compute node, take any of the following steps.
- Copy the body of the input message as a bit stream to a special folder in the output message. This action creates a modifiable copy of the input message that is not parsed and therefore uses a minimum amount of memory.
- Avoid any inspection of the input message, which avoids the need to parse the message.
- Use a loop and a reference variable to step through the message one record at a time. For each record, use the following processes:
  – Use normal transforms to build a corresponding output subtree in a second special folder.

- Use the ASBITSTREAM function to generate a bit stream for the output subtree. The generated bit stream is stored in a BitStream element that is placed in the position in the output subtree that corresponds to its required position in the final bit stream.
- Use the DELETE statement to delete both the current input and output record message trees when you have completed their manipulation.
- When you have completed the processing of all records, detach the special folders so that they do not appear in the output bit stream.

You can vary these techniques to suit the processing that is required for your messages.

The following ESQL code provides an example of one implementation, and is a modification of the ESQL example in "Transforming a complex message" on page 2520. It uses a single SET statement with nested SELECT functions to transform a message that contains nested, repeating structures.

```
-- Copy the MQMD header
  SET OutputRoot.MQMD = InputRoot.MQMD;

-- Create a special folder in the output message to hold the input tree
-- Note : SourceMessageTree is the root element of an XML parser
  CREATE LASTCHILD OF OutputRoot.XMLNS.Data DOMAIN 'XMLNS' NAME 'SourceMessageTree';

-- Copy the input message to a special folder in the output message
-- Note : This is a root to root copy which will therefore not build trees
  SET OutputRoot.XMLNS.Data.SourceMessageTree = InputRoot.XMLNS;

-- Create a special folder in the output message to hold the output tree
  CREATE FIELD OutputRoot.XMLNS.Data.TargetMessageTree;

-- Prepare to loop through the purchased items
  DECLARE sourceCursor REFERENCE TO OutputRoot.XMLNS.Data.SourceMessageTree.Invoice;
  DECLARE targetCursor REFERENCE TO OutputRoot.XMLNS.Data.TargetMessageTree;
  DECLARE resultCursor REFERENCE TO OutputRoot.XMLNS.Data;
  DECLARE grandTotal   FLOAT     0.0e0;

-- Create a block so that it's easy to abandon processing
  ProcessInvoice: BEGIN
  -- If there are no Invoices in the input message, there is nothing to do
    IF NOT LASTMOVE(sourceCursor) THEN
      LEAVE ProcessInvoice;
    END IF;

  -- Loop through the invoices in the source tree
  InvoiceLoop : LOOP
    -- Inspect the current invoice and create a matching Statement
    SET targetCursor.Statement = THE (SELECT 'Monthly' AS (XML.Attribute)Type,
                                            'Full' AS (0x03000000)Style[1],
                                            I.Customer.FirstName AS Customer.Name,
                                            I.Customer.LastName AS Customer.Surname,
                                            (SELECT
                                              FIELDVALUE(II.Title) AS Title,
                                              CAST(II.UnitPrice AS FLOAT) * 1.6 AS Cost,
                                              II.Quantity AS Qty
                                            FROM I.Purchases.Item[] AS II
                                            WHERE II.UnitPrice> 0.0) AS Purchases.Article[],
                                            (SELECT
                                              SUM( CAST(II.UnitPrice AS FLOAT) *
                                                   CAST(II.Quantity  AS FLOAT) *
                                                   1.6                         )
                                            FROM I.Purchases.Item[] AS II) AS Amount,
                                            'Dollars' AS Amount.(XML.Attribute)Currency
                                          FROM sourceCursor AS I
                                          WHERE I.Customer.LastName <> 'White');
```

```
   -- Turn the current Statement into a bit stream
   DECLARE StatementBitStream BLOB
   ASBITSTREAM(targetCursor.Statement OPTIONS FolderBitStream);
   -- If the SELECT produced a result
   -- (that is, it was not filtered out by the WHERE clause),
   -- process the Statement
   IF StatementBitStream IS NOT NULL THEN
   -- create a field to hold the bit stream in the result tree
      CREATE LASTCHILD OF resultCursor
         Type  XML.BitStream
         NAME  'StatementBitStream'
         VALUE StatementBitStream;

   -- Add the current Statement's Amount to the grand total
   -- Note that the cast is necessary because of the behavior
   -- of the XML syntax element
      SET grandTotal = grandTotal
       + CAST(targetCursor.Statement.Amount AS FLOAT);
   END IF;

   -- Delete the real Statement tree leaving only the bit stream version
   DELETE FIELD targetCursor.Statement;

   -- Step onto the next Invoice,
   -- removing the previous invoice and any
   -- text elements that might have been
   -- interspersed with the Invoices

   REPEAT
     MOVE sourceCursor NEXTSIBLING;
     DELETE PREVIOUSSIBLING OF sourceCursor;
     UNTIL (FIELDNAME(sourceCursor) = 'Invoice')
      OR (LASTMOVE(sourceCursor) = FALSE)
   END REPEAT;

   -- If there are no more invoices to process, abandon the loop
   IF NOT LASTMOVE(sourceCursor) THEN
    LEAVE InvoiceLoop;
   END IF;

  END LOOP InvoiceLoop;
END ProcessInvoice;

-- Remove the temporary source and target folders
DELETE FIELD OutputRoot.XMLNS.Data.SourceMessageTree;
DELETE FIELD OutputRoot.XMLNS.Data.TargetMessageTree;

-- Finally add the grand total
SET resultCursor.GrandTotal = grandTotal;
```

This ESQL code produces the following output message:

```
<Data>
 <Statement Type="Monthly" Style="Full">
  <Customer>
   <Name>Andrew</Name>
   <Surname>Smith</Surname>
   <Title>Mr</Title>
  </Customer>

The ASBITSTREAM field function generates a bit stream for the subtree of a given field according to the rules of the parser that owns the field.

Manipulating messages in the XMLNSC domain:

If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

About this task

The topics in this section provide information about how to write ESQL for processing messages that belong to the XMLNSC domain, and that are parsed by the XMLNSC parser. For background information, see "XMLNSC parser" on page 1090.

The following topics provide detailed information about the structure of the message tree that the XMLNSC parser builds, and the field types that it uses.

- "XMLNSC: The XML declaration" on page 2548
- "XMLNSC: The inline DTD" on page 2549
- "XMLNSC: The message body" on page 2549
- "XMLNSC: XML Schema support" on page 2559

If you are migrating from XML, XMLNS, or MRM XML, see "Migrating to XMLNSC" on page 2562.

For further information about processing XML messages, see "Working with XML messages" on page 2535.

Use the DECLARE statement to define a variable, the data type of the variable and, optionally, its initial value.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

XMLNSC: The XML declaration:

The XML declaration is represented in the message tree by a syntax element with field type XMLNSC.XMLDeclaration.

If an XML declaration is created by the XMLNSC parser, its name is 'XmlDeclaration'. However, when a message tree is being produced, the name is not important: the XMLNSC parser recognizes this syntax element by its field type only. The following example shows a typical declaration:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

The XML Declaration has three optional attributes; Version, Standalone, and Encoding. The XMLNSC parser does not define special field types for these attributes. Instead, they are identified by their name, and by their position as a child of the XML Declaration element.

ESQL example code to create an XML declaration

To construct the XML declaration that is shown in the previous example, code the following ESQL statements:

```
CREATE FIRSTCHILD OF OutputRoot.XMLNSC TYPE XMLNSC.XmlDeclaration NAME 'XmlDeclaration';
SET OutputRoot.XMLNSC.(XMLNSC.XmlDeclaration)*.(XMLNSC.Attribute)Version = '1.0';
SET OutputRoot.XMLNSC.(XMLNSC.XmlDeclaration)*.(XMLNSC.Attribute)Encoding = 'UTF-8';
SET OutputRoot.XMLNSC.(XMLNSC.XmlDeclaration)*.(XMLNSC.Attribute)StandAlone = 'yes';
```

The first line is optional; if it is omitted, the XMLNSC.XMLDeclaration element is automatically created when it is referenced by the second line.

Java example code to create an XML declaration

To construct the XML declaration that is shown in the previous example, write the following Java code:

```
//Create the XML domain root node
MBElement xmlRoot =
 root.createElementAsLastChild(MbXMLNSC.PARSER_NAME);
//Create the XML declaration parent node
MbElement xmlDecl =
 xmlRoot.createElementAsFirstChild(MbXMLNSC.XML_DECLARATION);

xmlDecl.setName("XmlDeclaration");

MbElement version =
 xmlDecl.CreateElementAsFirstChild(MbXMLNSC.ATTRIBUTE, "Version", "1.0");
MbElement encoding =
 xmlDecl.CreateElementAsFirstChild(MbXMLNSC.ATTRIBUTE, "Encoding", "utf-8");
MbElement standalone =
 xmlDecl.CreateElementAsFirstChild(MbXMLNSC.ATTRIBUTE, "Standalone", "yes");
```

Note: In both the ESQL example and the Java example, 'Version', 'StandAlone', and 'Encoding' can all be written in lowercase.

XMLNSC: The inline DTD:

When you parse an XML document that has an inline DTD, the XMLNSC parser does not put the DTD information into the message tree. However, by using ESQL code, you can add XML entity definitions to the message tree, and these definitions are used when the message tree is produced by the XMLNSC parser.

ESQL example code for entity definition and entity reference

This example assumes that InputRoot.XMLNSC has been created from the following XML message:

```
<BookInfo dtn="BookInfo" edn="author" edv="A.N.Other"/>
```

The following output message is generated:

```
<!DOCTYPE BookInfo [<!ENTITY author "A.N.Other">]>
<BookInfo><entref>&author;</entref></BookInfo>
```

The ESQL to create the output message is:

```
DECLARE cursor REFERENCE TO InputRoot.XMLNSC.BookInfo;
DECLARE docTypeName CHARACTER cursor.dtn;
DECLARE authorRef CHARACTER 'author';
-- Create <!DOCTYPE BOOKInfo ...
SET OutputRoot.XMLNSC.(XMLNSC.DocumentType)* NAME = docTypeName;
-- Create  <!ENTITY author "A.N.Other" > ...
SET OutputRoot.XMLNSC.(XMLNSC.DocumentType){docTypeName}.(XMLNSC.EntityDefinition) {authorRef} =
cursor.edv;
-- Create the entity reference
SET OutputRoot.XMLNSC.(XMLNSC.Folder){docTypeName}.(XMLNSC.EntityReference)entref = authorRef;
```

XMLNSC: The message body:

The XMLNSC parser builds a message tree from the body of an XML document.

The following topics describe how the XMLNSC parser builds a message tree from the body of an XML document:

- "XMLNSC: Using field types" on page 1094
- "XMLNSC: Attributes and elements" on page 2552
- "XMLNSC: Namespace declarations" on page 2554
- "XMLNSC: Element values and mixed content" on page 2556
- "XMLNSC: Comments and Processing Instructions" on page 2558

Related tasks:

"Manipulating messages in the XMLNSC domain" on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

XMLNSC: Using field types:

The XMLNSC parser sets the field type on every syntax element that it creates.

The field type indicates the type of XML construct that the element represents. The XMLNSC parser uses the field type when writing a message tree. The field type can be set by using ESQL or Java to control the output XML. The field types that are used by the XMLNSC parser must be referenced by using constants with names that are prefixed by 'XMLNSC.'

Tip: Field type constants that have the prefix 'XML.' are for use with the XMLNS and XML parsers only, and are not valid with the XMLNSC or MRM parsers.

Field types for creating syntax elements

Use the following field type constants to create syntax elements in the message tree. The XMLNSC parser uses these values when creating a message tree from an input message.

XML construct	XMLNSC Field Type constant	Value
Simple Element	XMLNSC.Field XMLNSC.CDataField	0x03000000 0x03000001
Attribute	XMLNSC.SingleAttribute XMLNSC.Attribute	0x03000101 0x03000100
Mixed content	XMLNSC.Value XMLNSC.CDataValue	0x02000000 0x02000001
Namespace Declaration	XMLNSC.SingleNamespaceDecl XMLNSC.NamespaceDecl	0x03000102 0x03000103
Complex element	XMLNSC.Folder	0x01000000
Inline DTD	XMLNSC.DocumentType	0x01000300
XML declaration	XMLNSC.XmlDeclaration	0x01000400
Entity reference	XMLNSC.EntityReference	0x02000100
Entity definition	XMLNSC.SingleEntityDefinition XMLNSC.EntityDefinition	0x03000301 0x03000300
Comment	XMLNSC.Comment	0x03000400
Processing Instruction	XMLNSC.ProcessingInstruction	0x03000401

Field types for path expressions (generic field types)

Use the following field type constants when querying the message tree by using a path expression; for example:

```
SET str = FIELDVALUE(InputRoot.e1.(XMLNSC.Attribute)attr1)
```

It is good practice to specify field types when querying a message tree built by the XMLNSC parser. This makes your ESQL code more specific and more readable, and it avoids incorrect results in some cases. However, care is required when choosing which field type constant to use. When you use the XMLNSC parser, use

a generic field type constant when querying the message tree. This allows your path expression to tolerate variations in the input XML.

The generic field type constants are listed in the following table:

XML construct	XMLNSC Field Type constant	Purpose
Tag	XMLNSC.Element	Matches any tag, whether it contains child tags (XMLNSC.Folder) or a value (XMLNSC.Field)
Element	XMLNSC.Field	Matches a tag which contains normal text, CData, or a mixture of both. Does not match tags which contain child tags.
Attribute	XMLNSC.Attribute	Matches single-quoted and double-quoted attributes
Mixed content	XMLNSC.Value	Matches normal text, CData, or a mixture of both
XML Declaration	XMLNSC.NamespaceDecl	Matches single- and double-quoted declarations

If you write

```
InputRoot.e1.(XMLNSC.DoubleAttribute)attrName
```

your path expression does not match a single-quoted attribute. If you use the generic field type constant *XMLNSC.Attribute*, your message flow works with either single-quoted or double-quoted attributes.

Note that you should always use the field type constants and not their numeric values.

Field types for controlling output format

The following field types are provided for XML Schema and base64 support. Do not use these field type constants in path expressions; use them in conjunction with XMLNSC.Attribute and XMLNSC.Field to indicate the required output format for DATE and BLOB values. See "XMLNSC: XML Schema support" on page 2559 for further information.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.gYear	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYear format.	0x00000010
XMLNSC.gYearMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gYearMonth format.	0x00000040
XMLNSC.gMonth	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonth format.	0x00000020
XMLNSC.gMonthDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gMonthDay format.	0x00000050

XMLNSC Field Type constant	Purpose	Value
XMLNSC.gDay	The value must be a DATE. If the field type includes this value, the DATE value is produced by using the XML Schema gDay format.	0x00000030
XMLNSC.base64Binary	The value must be a BLOB. The value is produced with base64 encoding.	0x00000060
XMLNSC.List	The element must be XMLNSC.Attribute or XMLNSC.Field. If the field type includes this value, the values of all child elements in the message tree are produced as a space-separated list.	0x00000070

Field types for direct output

Use the following field types to produce pre-constructed segments of an XML document. Character escaping is not done; therefore, take extra care not to construct a badly-formed output document. Use these constants only after carefully exploring alternative solutions.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.Bitstream	The value of this syntax element must be a BLOB. The value is written directly to the output bit stream. For more information about its usage, see "Working with large XML messages" on page 2543.	0x03000200
XMLNSC.AsisElementContent	The value of this syntax element must be CHARACTER. The value is written directly to the output bit stream. No character substitutions are performed. Use this element with care.	0x03000600

Related concepts:

"XMLNSC: The message body" on page 2549
The XMLNSC parser builds a message tree from the body of an XML document.

"XMLNSC: Element values and mixed content" on page 2556
The XMLNSC parser is a compact parser; therefore, an element with single content is parsed as a single syntax element. When an element has both child elements and some text, the text is called *mixed content*.

"XMLNSC: Comments and Processing Instructions" on page 2558
The XMLNSC parser discards comments and processing instructions because both comments and processing instructions are auxiliary information with no business meaning.

Related reference:

"XMLNSC: Attributes and elements"
The XMLNSC parser uses field types to represent attributes and elements.

"XMLNSC: Namespace declarations" on page 2554
The XMLNSC parser provides full support for namespaces.

XMLNSC: Attributes and elements:

The XMLNSC parser uses field types to represent attributes and elements.

Use the following field type constants when creating your own syntax elements in the message tree.

Table 25. Specific field type constants

XML Construct	XMLNSC Field Type constant	Value
Complex element	XMLNSC.Folder	0x01000000
Simple element	`XMLNSC.Field` `XMLNSC.CDataField`	`0x02000000` `0x02000001`
Attribute	`XMLNSC.SingleAttribute` `XMLNSC.Attribute`	`0x03000100` `0x03000101`

When accessing elements and attributes in the message tree, use generic field type constants which match all of the alternative values. Because there is only one type of Folder element, it is safe to use XMLNSC.Folder when querying the message tree.

Table 26. Generic field type constants

XML Construct	XMLNSC Field Type constant	Purpose
Element	XMLNSC.Field	Matches elements that contain normal text, CData, or a mixture of both
Attribute	XMLNSC.Attribute	Matches both single-quoted and double-quoted attributes

ESQL code examples

The following examples use this XML message:

```
<root id="12345">
    <id>ABCDE</id>
</root>
```

Note that the message contains an attribute and an element with the same name.

Example 1 : Query the value of an XML element

```
SET value = FIELDVALUE(InputRoot.XMLNSC.root.(XMLNSC.Field)id)
```

The result is that value is set to 'ABCDE'.

Example 2 : Query the value of an XML attribute

```
SET value = FIELDVALUE(InputRoot.XMLNSC.root.(XMLNSC.Attribute)id)
```

The result is that value is set to '12345'.

Example 3 : Create the example message by using ESQL

```
CREATE LASTCHILD OF OutputRoot.XMLNSC Type XMLNSC.Folder Name 'root';
-- Note : XMLNSC.Attribute could be used here as well.
SET OuputRoot.XMLNSC.root.(XMLNSC.Attribute)id = '12345';
SET OuputRoot.XMLNSC.root.(XMLNSC.Field)id = 'ABCDE';
```

The first line is optional because the element 'root' is created automatically by the following line if it does not already exist.

Related concepts:

"XMLNSC: The message body" on page 2549
The XMLNSC parser builds a message tree from the body of an XML document.

"XMLNSC: Element values and mixed content" on page 2556

Related reference:

"XMLNSC: Using field types" on page 1094
The XMLNSC parser sets the field type on every syntax element that it creates.

"XMLNSC: Namespace declarations"
The XMLNSC parser provides full support for namespaces.

XMLNSC: Namespace declarations:

The XMLNSC parser provides full support for namespaces.

The XMLNSC parser sets the correct namespace on every syntax element that it creates while parsing a message, and stores namespace declarations in the message tree. The parser uses the namespace declarations to select the appropriate prefixes when outputting the message tree.

The XMLNSC parser uses the following field types to represent namespace declarations. Use the field type constants that are listed in this table when you create namespace declarations in the message tree.

Table 27. Specific field type constants

XML construct	XMLNSC field type constant	Value
Namespace declaration	`XMLNSC.SingleNamespaceDecl` `XMLNSC.DoubleNamespaceDecl`	`0x03000102` `0x03000103`

When accessing elements and attributes in the message tree, do not use the constants that are listed in the previous table; instead, use the generic field type constant that matches both of the values in the table above.

Table 28. Generic field type constants

XML construct	XMLNSC field type constant	Purpose
Namespace declaration	XMLNSC.NamespaceDecl	Matches namespace declarations in both single and double quotation marks

ESQL code examples

Example 1: Declaring a non-empty prefix

```
DECLARE space1 NAMESPACE 'namespace1';
SET OutputRoot.XMLNSC.space1:root.(XMLNSC.NamespaceDecl)xmlns:ns1 = space1;
SET OutputRoot.XMLNSC.space1:root.space1:example = 'ABCDE';
```

This creates the following XML message:

```
<ns1:root xmlns:ns1="namespace1">
    <ns1:example>ABCDE</ns1:example>
</ns1:root>
```

Note that the NAMESPACE constant `space1` is just a local variable in the ESQL; it does not affect the namespace prefix `ns1` that is defined by the NameSpaceDecl element and appears in the output message.

However, as shown here, `space1` can be used to initialize the NameSpaceDecl for `ns1`. This avoids the need to duplicate the namespace URI ('namespace1' in this example), which in practice is typically a much longer string.

Example 2: Declaring an empty prefix

```
DECLARE space1 NAMESPACE 'namespace1';
SET OutputRoot.XMLNSC.space1:root.(XMLNSC.NamespaceDecl)xmlns = space1;
SET OutputRoot.XMLNSC.space1:root.space1:example = 'ABCDE';
```

This creates the following XML message:

```
<root xmlns="namespace1">
    <example>ABCDE</example>
</root>
```

Note that the syntax elements `root` and `example` must have a non-empty namespace. The default namespace declaration means that any child element without a prefix is in the namespace `namespace1`.

Example 3: Example of incorrect usage

```
DECLARE space1 NAMESPACE 'namespace1';
SET OutputRoot.XMLNSC.root.(XMLNSC.NamespaceDecl)xmlns = space1;
SET OutputRoot.XMLNSC.root.example = 'ABCDE';
```

This example causes the XMLNSC parser to issue the message BIP5014 when it attempts to create the message tree. The elements `root` and `example` are both within the scope of the default namespace declaration; therefore, in ESQL, these elements must be qualified by a namespace prefix bound to that namespace.

Example 4: Adding a namespace declaration with a prefix

```
SET OutputRoot.(XMLNSC.DoubleNamespaceDecl)xmlns:ns2 = space1;
```

This example of a SET statement creates a namespace declaration with the name ns2 in the namespace xmlns.

```
CREATE LASTCHILD OF OutputRoot IDENTITY (XMLNSC.DoubleNamespaceDecl)xmlns:ns2 VALUE space1;
CREATE LASTCHILD OF OutputRoot TYPE XMLNSC.DoubleNamespaceDecl NAMESPACE 'xmlns' NAME 'ns2' VALUE
```

These examples of a CREATE statement also create a namespace declaration with the name ns2 in the namespace xmlns.

However, be aware that the following example of a CREATE statement creates a namespace declaration with the name xmlns:ns2 in the default namespace:

```
CREATE LASTCHILD OF OutputRoot TYPE XMLNSC.DoubleNamespaceDecl NAME 'xmlns:ns2' VALUE space1;
```

Related concepts:

"XMLNSC: Attributes and elements" on page 2552
The XMLNSC parser uses field types to represent attributes and elements.

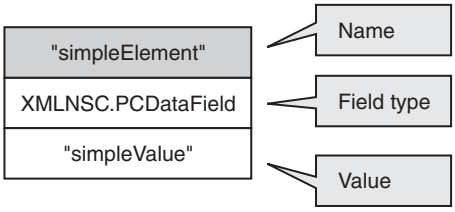
XMLNSC: Element values and mixed content:

The XMLNSC parser is a compact parser; therefore, an element with single content is parsed as a single syntax element. When an element has both child elements and some text, the text is called *mixed content*.

Element with simple content

The following XML fragment with a single content is parsed as a single syntax element:

```
<simpleElement>simpleValue</simpleElement>
```



The value of this element can be queried with this ESQL:

```
SET val = FIELDVALUE(InputRoot.XMLNSC.(XMLNSC.Field)simpleElement);
```

To generate an element with simple content in the output:

```
SET OutputRoot.XMLNSC.(PCDataField)simpleElement VALUE = 'simpleValue';
```

Note that XMLNSC.Field is used when querying the message tree, but XMLNSC.PCDataField is specified when constructing the output message. XMLNSC.PCDataField can be used to query the message tree; however, that would not work if the input message used a CData section, as shown in the following example:

```
<simpleElement><![CDATA[simpleValue]]></simpleElement>
```

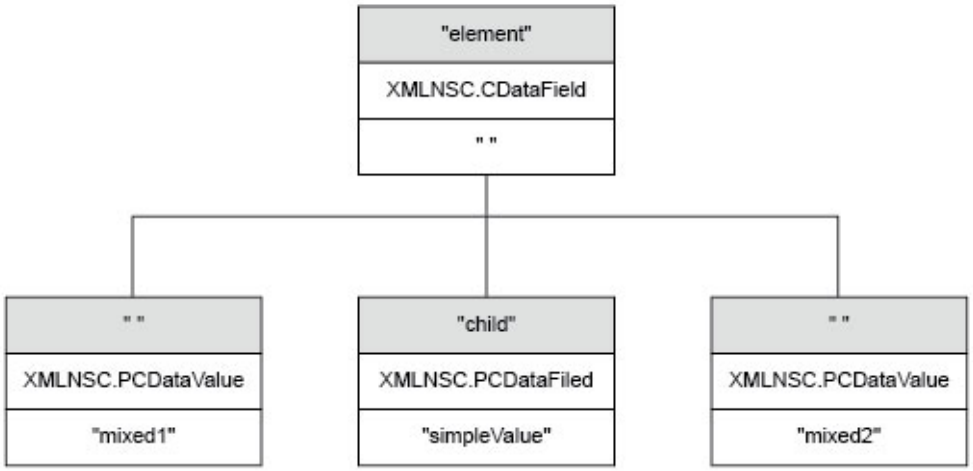
Element with mixed content

If an element has child elements, it is typically a 'folder', and does not have a value. When an element has both child elements and some text, the text is called 'mixed content'.

```
<element>mixed1<child>simpleValue</child>mixed2</element>
```

By default, mixed content is discarded because it is typically just formatting white space and has no business meaning. Mixed content can be preserved if you select the `Retain mixed content` check box on the Parser Options page of the node properties.

If mixed content is being preserved, the XMLNSC parser creates a Value child element for each distinct item of mixed content.



The mixed content can be queried with this ESQL:

```
SET mixed1 = FIELDVALUE(InputRoot.XMLNSC.(element).*[1];
```

The ESQL to construct the above XML fragment is:

```
CREATE ref REFERENCE TO OutputRoot.XMLNSC.element;
CREATE FIRSTCHILD OF ref TYPE XMLNSC.PCDataValue VALUE 'mixed1';
CREATE LASTCHILD OF ref NAME 'child' TYPE XMLNSC.PCDataField  VALUE 'simpleValue';
CREATE LASTSTCHILD OF ref TYPE XMLNSC.PCDataValue VALUE 'mixed2';
```

The following ESQL enables the *Retain mixed content* option:

```
DECLARE X BLOB;
-- assume that X contains an XML document
CREATE LASTCHILD OF OutputRoot
    PARSE(X OPTIONS XMLNSC.MixedContentRetainAll);
```

Element containing a CData section

A CData section is an XML notation that allows XML markup characters to be included in the content of an element.

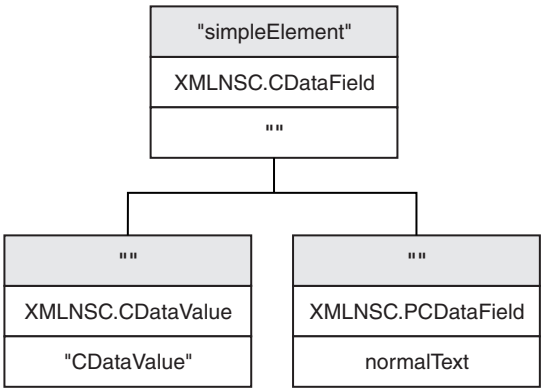
The following two XML fragments are identical in their meaning:

```
<simpleElement>simpleValue</simpleElement>
<simpleElement><![CDATA[simpleValue]]></simpleElement>
```

If the CData section is the only text content, the XMLNSC parser remembers that the input document contained a CData section by setting the field type to XMLNSC.CDataField instead of XMLNSC.PCDataField.

If the CData section is not the only text content, it is created as a child value element, with other child value elements representing the remaining text content. The following is an example of this:

```
<simpleElement><![CDATA[CDataValue]]>normalText</simpleElement>
```



See “XMLNSC: Working with CData” on page 2539 for more information about the correct use of CData in XML documents.

Related concepts:

The XMLNSC parser provides full support for namespaces.

XMLNSC: Comments and Processing Instructions:

The XMLNSC parser discards comments and processing instructions because both comments and processing instructions are auxiliary information with no business meaning.

Comments

Comments can be preserved if you select the *Retain comments* check box on the Parser Options page of the node properties.

If *Retain comments* is selected, each comment in the input document is represented by a single syntax element with field type XMLNSC.Comment. The *Retain comments* option can also be accessed by using the following ESQL:

```
DECLARE X BLOB;
-- assume that X contains an XML document
CREATE LASTCHILD OF OutputRoot.XMLNSC
```

```
    PARSE(X DOMAIN XMLNSC
          NAME preserveComments
          OPTIONS XMLNSC.CommentsRetainAll);

-- do it again, this time discarding comments
CREATE LASTCHILD OF OutputRoot.XMLNSC
    PARSE(X DOMAIN XMLNSC
          NAME discardComments
          OPTIONS XMLNSC.CommentsRetainNone);
```

Processing Instructions

Processing instructions can be preserved if you select the *Retain processing instructions* check box on the Parser Options page of the node properties.

If *Retain processing instructions* is selected, each processing instruction the input document is represented by a single syntax element with field type XMLNSC.ProcessingInstruction. The *Retain processing instructions* option can also be accessed by using the following ESQL:

```
DECLARE X BLOB;
-- assume that X contains an XML document
CREATE LASTCHILD OF OutputRoot.XMLNSC
    PARSE(X DOMAIN XMLNSC
          NAME preserveProcessingInstructions
          OPTIONS XMLNSC.ProcessingInstructionsRetainAll);

-- do it again, this time discarding processing instructions
CREATE LASTCHILD OF OutputRoot.XMLNSC
    PARSE(X DOMAIN XMLNSC
          NAME discardProcessingInstructions
          OPTIONS XMLNSC.ProcessingInstructionsRetainNone);
```

Related concepts:

"XMLNSC: The message body" on page 2549
The XMLNSC parser builds a message tree from the body of an XML document.

"XMLNSC: Element values and mixed content" on page 2556
The XMLNSC parser is a compact parser; therefore, an element with single content is parsed as a single syntax element. When an element has both child elements and some text, the text is called *mixed content*.

Related reference:

"XMLNSC: Using field types" on page 1094
The XMLNSC parser sets the field type on every syntax element that it creates.

"XMLNSC: Attributes and elements" on page 2552
The XMLNSC parser uses field types to represent attributes and elements.

"XMLNSC: Namespace declarations" on page 2554
The XMLNSC parser provides full support for namespaces.

XMLNSC: XML Schema support:

Use the XMLNSC parser to parse and validate by using an XML Schema.

For information about how to configure the XMLNSC parser to use an XML Schema, see "XMLNSC parser" on page 1090.

The following topics describe how the XMLNSC parser uses the field type to hold information about XML Schema simple types. This behavior enables the parser to write dates and binary elements in the same form in which they were parsed, and

according to the XML Schema specification. It also allows the message flow developer to write dates, lists, and binary data in the correct XML Schema format.

- "XMLNSC: base64 support"
- "XMLNSC: XML Schema date formatting"
- "XMLNSC: XML List type support" on page 2561

Related concepts:

"XMLNSC parser" on page 1090
The XMLNSC parser is a flexible, general-purpose XML parser that offers high performance XML parsing and optional XML Schema validation.

Related tasks:

"Manipulating messages in the XMLNSC domain" on page 2546
If you are writing ESQL to process messages in the XMLNSC domain, it is helpful to learn about the structure of the message tree that the XMLNSC parser builds.

XMLNSC: base64 support:

The XMLNSC parser can produce binary data in base64-encoded format.

If `Validation` is set to `Content and Value`, and `Build tree using schema types` is enabled, the XMLSNC parser automatically decodes base64 data and creates a BLOB value in the message tree. When producing a message tree, the XMLNSC parser will 'base64-encode' a BLOB if the field type includes the constant *XMLNSC.base64Binary*.

ESQL code example to output base64 data

```
DECLARE Base64Data BLOB '0102030405060708090A0B0C0D0E0F';
-- Add in the base64Binary field type
DECLARE base64FieldType INTEGER XMLNSC.Field + XMLNSC.base64Binary;
CREATE LASTCHILD OF OutputRoot DOMAIN 'XMLNSC' NAME 'XMLNSC';
CREATE LASTCHILD OF OutputRoot.XMLNSC TYPE base64FieldType NAME 'myBinaryData' VALUE Base64Data;
```

Result : <myBinaryData>AQIDBAUGBwgJCgsMDQ4P</myBinaryData>

Note that this example does not depend on validation. The XMLNSC parser can produce base64 binary data even if `Validation` is set to `None`.

Related concepts:

"XMLNSC: XML Schema support" on page 2559
Use the XMLNSC parser to parse and validate by using an XML Schema.

"XMLNSC: XML Schema date formatting"
The XMLNSC parser can parse and write all of the XML Schema simple types.

"XMLNSC: XML List type support" on page 2561
The XMLNSC parser can automatically parse a space-separated list of values into individual syntax elements in the message tree if you select certain options.

XMLNSC: XML Schema date formatting:

The XMLNSC parser can parse and write all of the XML Schema simple types.

The rarely used types gYear, gYearMonth, gMonth, gMonthDay, and gDay do not map directly to a message broker data type. For these simple types, the XMLNSC parser adds one of the following constant values to the field type. This behavior allows the parser to produce the data for output in the same format as it was received.

Field types for controlling date format

The following field types are provided for XML Schema date format support. Do not use these field type constants in path expressions. Use them in conjunction with constants XMLNSC.Attribute and XMLNSC.Field to indicate the required output format for DATE values.

XMLNSC Field Type constant	Purpose	Value
XMLNSC.gYear	Value must be a DATE. If the field type includes this value, the DATE value is written by using the XML Schema gYear format.	0x00000010
XMLNSC.gYearMonth	Value must be a DATE. If the field type includes this value, the DATE value is written by using the XML Schema gYearMonth format.	0x00000040
XMLNSC.gMonth	Value must be a DATE. If the field type includes this value, the DATE value is written by using the XML Schema gMonth format.	0x00000020
XMLNSC.gMonthDay	Value must be a DATE. If the field type includes this value, the DATE value is written by using the XML Schema gMonthDay format.	0x00000050
XMLNSC.gDay	Value must be a DATE. If the field type includes this value, the DATE value is written by using the XML Schema gDay format.	0x00000030

ESQL code example

```
DECLARE gYear DATE '2007-01-01';
-- Add in the gYear field type
DECLARE gYearFieldType INTEGER XMLNSC.Field + XMLNSC.gYear;
CREATE LASTCHILD OF OutputRoot DOMAIN 'XMLNSC' NAME 'XMLNSC';
CREATE LASTCHILD OF OutputRoot.XMLNSC TYPE gYearFieldType NAME 'gYear' VALUE gYear;
```

Result : <gYear>2007</gYear>

XMLNSC: XML List type support:

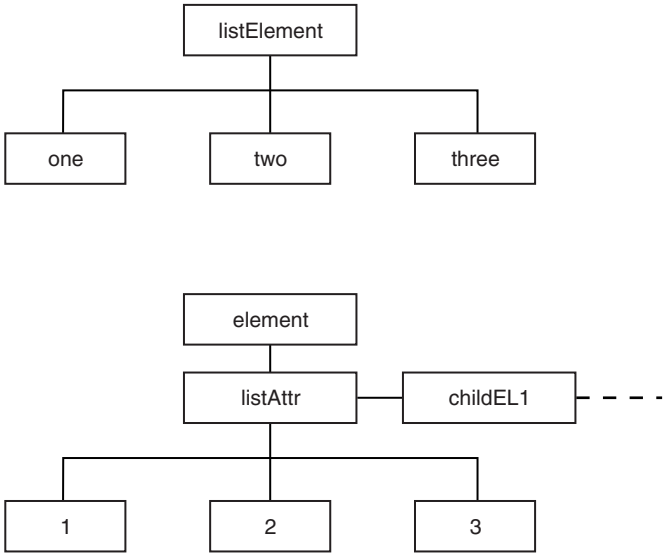
The XMLNSC parser can automatically parse a space-separated list of values into individual syntax elements in the message tree if you select certain options.

An element or an attribute can have multiple values separated by spaces, as shown in the following examples:

```
<listElement>one two three</listElement>
<element listAttribute="1 2 3"><childEL1/></element>
```

If your XML schema specifies a list type for an element or an attribute, and `Validation` is set to `Content and Value`, and `Build tree using schema types` is

enabled, the XMLNSC parser automatically parses the space-separated list of values into individual syntax elements in the message tree. The resulting message tree looks like this:
and for an attribute with a list value it looks like this:



ESQL code examples

Access the individual values in a list

```
SET val = InputRoot.XMLNSC.listElement.*[1];
```

Result : val = 'one'

```
SET val = InputRoot.XMLNSC.element.(XMLNSC.Attribute)listAttr.*[3];
```

Result : val='3'

Create a list element in the message tree

```
CREATE LASTCHILD OF OutputRoot.XMLNSC
   Name 'listElement'
   Type XMLNSC.List;
DECLARE listEl REFERENCE TO OutputRoot.XMLNSC.listElement;
DECLARE listValType INTEGER XMLNSC.PCDataValue;
CREATE LASTCHILD OF listEl TYPE listValType VALUE 'one';
CREATE LASTCHILD OF listEl TYPE listValType VALUE 'two';
CREATE LASTCHILD OF listEl TYPE listValType VALUE 'three';
```

Migrating to XMLNSC:

The XMLNSC parser offers the best combination of features and performance for most applications.

Reasons to migrate

If your message flow uses the XMLNS or XML domain, you might want to migrate a message flow to XMLNSC to take advantage of the XML schema validation. If your message flow uses the MRM domain, you might want to migrate to XMLNSC to obtain standards-compliant validation, and a large reduction in processor usage.

Migrating from the XMLNS or XML domain

The XMLNSC parser differs from the XMLNS parser in the following ways:

- The XMLNSC parser builds a compact message tree.
- It uses different field type constants.
- It discards inline DTDs

In most cases, the compact message tree has no effect on ESQL paths or XPath expressions. Typically, a simple message tree query produces the same results in XMLNSC as in the XMLNS or XML domain. Changing the correlation name from XMLNS to XMLNSC is often sufficient, but care must be taken with the following items:

- Empty elements and null values.

  The XMLNSC parser does not always handle empty elements and null values in the same way as XML and XMLNS.
- Complex XPath expressions that navigate to the value of an element, then to its parent in a single query.

  These expressions might produce different results in the XMLNSC domain.

The field type constants that are used by the XMLNSC parser are different from those constants used by XMLNS or XML. Every occurrence of XML.Attribute, XML.XmlDecl, for example, must be changed to use the equivalent XMLNSC field type constant.

The discarding of inline DTDs only affects message flows that process the DTD.

Migrating from MRM XML

The XMLNSC parser differs from the MRM XML parser in the following ways:

- The XMLNSC parser uses field types to identify the XML constructs in the message tree. The MRM parser distinguishes attributes from elements by matching the message tree against the message definition.
- When writing a message tree, the XMLNSC parser selects namespace prefixes by detecting and using xmlns attributes in the message tree. The MRM XML parser uses a table in the message set properties.
- The MRM parser does not include the root tag of the XML document in the message tree.

Migrating a message flow from MRM to XMLNSC typically requires extensive changes to your message flow. However, the migration usually delivers a large reduction in processor usage, and allows much more accurate control of the output XML.

Manipulating messages in the XMLNS domain:

When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

About this task

The topics in this section provide information about how to write ESQL for processing messages that belong to the XMLNS domain, and that are parsed by the XMLNS parser. Most of the information in these topics also applies to the XML domain, unless it refers to features that are not supported in the XML domain.

Refer to "XMLNS parser" on page 1104 for background information.

The following topics provided detailed information about the structure of the message tree that the XMLNS parser builds, and the field types that it uses.

- "XMLNS: The XML declaration" on page 2565
- "XMLNS: The DTD" on page 2568
- "XMLNS: The XML message body" on page 2569

You can find more information about processing XML messages in "Working with XML messages" on page 2535.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

Extended Structured Query Language (ESQL) is a programming language defined by WebSphere Message Broker to define and manipulate data within a message flow.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

"Manipulating messages in the XML domain" on page 2581
The XML parser is like the XMLNS parser, but the XML parser has no support for namespaces or opaque parsing.

"Working with XML messages" on page 2535
The following topics provide information about typical tasks for processing XML messages.

Related reference:

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

"DECLARE statement" on page 5117
Use the DECLARE statement to define a variable, the data type of the variable and, optionally, its initial value.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

XMLNS: The XML declaration:

The beginning of an XML message can contain an XML declaration.

The following is an example of a declaration:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

The XML Declaration is represented by the following types of syntax element:

- "XML.XMLDecl"
- "XML.version" on page 2566
- "XML.standalone" on page 2567

"XMLNS: XML declaration example" on page 2568 includes another example of an XML declaration and the tree structure that it forms.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

Related reference:

"XMLNS: XML declaration example" on page 2568
The XMLNS parser creates a tree that represents an XML declaration.

XML.XMLDecl:

The XML Declaration is represented in the message tree by a syntax element with field type 'XML.XMLDecl'.

If the XML declaration is created by the XMLNS parser its name is 'XMLDecl'. However, when a message tree is being written, the name is not important; only the field type is used by the parser.

The following shows an example of a declaration:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

"Manipulating messages in the XMLNS domain" on page 2563
When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XML.version:

The XML version attribute in the XML declaration is represented in the message tree by a syntax element with field type 'XML.version'.

The value of the XML version attribute is the value of the version attribute. It is always a child of an XML.XmlDecl syntaxelement. In the following example, the version element contains the string value 1.0:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

Related concepts:

"MRM XML physical format" on page 1247
The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"XML parsers and domains" on page 1084
You can use XML domains to parse and write messages that conform to the W3C XML standard.

Related tasks:

"Manipulating messages in the XMLNS domain" on page 2563
When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XML.encoding:

The encoding attribute is represented by a syntax element with field type 'XML.encoding', and is always a child of an XML.XmlDecl syntax element.

In the following example, the encoding attribute has a value of UTF-8.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

You cannot specify WebSphere MQ encodings in this element.

In your ESQL, (XML,"Encoding") must include quotation marks, because Encoding is a reserved word.

Related concepts:

"MRM XML physical format" on page 1247
The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XML.standalone:

The XML standalone element defines the existence of an externally-defined DTD. In the message tree it is represented by a syntax element with field type XML.standalone.

The value of the XML standalone element is the value of the standalone attribute in the XML declaration. It is always a child of an XML.XmlDecl syntax element. The only valid values for the standalone element are yes and no. The following is an example of this:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE s1 PUBLIC "http://www.ibm.com/example.dtd" "example.dtd">
<s1>........</s1>
```

A value of no indicates that this XML document is not standalone, and depends on an externally-defined DTD. A value of yes indicates that the XML document is self-contained. However, because the current release of WebSphere Message Broker does not resolve externally-defined DTDs, the setting of standalone is irrelevant, and is ignored.

Related concepts:

"MRM XML physical format" on page 1247
The MRM XML physical format describes the physical representation of an XML message for use by the MRM parser.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

XMLNS: The DTD:

The document type declaration (DTD) of an XML message is represented by a syntax element with field type XML.DocTypeDecl, and its children. These comprise the DOCTYPE construct.

Only internal (inline) DTD subsets are represented in the syntax element tree. An inline DTD is a DTD that is declared within the XML document itself. It can be a complete DTD definition, or it can extend the definition in an external DTD.

External DTD subsets (identified by the SystemID or PublicId elements described later in this section) can be referenced in the message, but those referenced are not resolved by the broker.

The following field type constants can be used to reference the various parts of a DTD in the message tree:

- "XML DocTypeDecl" on page 4272
- "XML NotationDecl" on page 4275
- "XML entities" on page 4275
- "XML ElementDef" on page 4281
- "XML AttributeList" on page 4281
- "XML AttributeDef" on page 4282
- "XML DocTypePI" on page 4286
- "XML WhiteSpace and DocTypeWhiteSpace" on page 4287
- "XML DocTypeComment" on page 4286

"XML DTD example" on page 4288 shows an example of an XML DTD.

See "XML document type declaration" on page 4271 for more information about handling an inline DTD.

"XMLNS: The XML message body"
Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XMLNS: The XML message body:

Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

The XMLNS parser assigns a field type to every syntax element that it creates. The value of the field type indicates the XML construct that it represents. In the following topics, each field type is discussed, with a series of example XML fragments.

The following common element types are discussed:

- "XML.element" on page 2573
- "XML.Attribute" on page 2573

"XML message body example" on page 2581 provides an example of an XML message body and the tree structure that is created from it using the syntax elements types that are listed above.

More complex XML messages might use some of the following syntax element types:

- "XML.CDataSection" on page 2575
- "XML.EntityReferenceStart and XML.EntityReferenceEnd" on page 2577
- "XML.comment" on page 2578
- "XML.ProcessingInstruction" on page 2578
- "XML.AsisElementContent" on page 2579

"XMLNS: The DTD" on page 2568
The document type declaration (DTD) of an XML message is represented by a syntax element with field type XML.DocTypeDecl, and its children. These comprise the DOCTYPE construct.

Accessing attributes and elements:

The XMLNS parser sets the field type on every message tree element that it creates.

The field type indicates the type of XML construct that the element represents. The field types used by the XMLNS parser can be referenced using constants with names prefixed with 'XML.' Field type constants with prefix 'XML.' are for use with the XMLNS and XML parsers only; they do not work with the XMLNSC or MRM parsers.

	XMLNS Field Type constant
Tag	XML.Element
Attribute	`XML.Attribute` `XML.Attr`

By using the field type in this way, the XMLNS parser can distinguish between an element and an attribute that have the same name.

Example XML

```
<parent id="12345">
    <id>ABCDE</id>
</parent>
```

Example ESQL

```
SET value = FIELDVALUE(InputRoot.XMLNS.parent.(XML.Element)id)
Result : value is 'ABCDE'

SET value = FIELDVALUE(InputRoot.XMLNS.parent.(XML.Attr)id)
Result : value is '12345'
```

Example using SELECT to access multiple attributes

In the "Example message" on page 5311, the element Title within each Item element has three attributes: Category, Form, and Edition. For example, the first Title element contains:

```
<Title Category="Computer" Form="Paperback" Edition="2">The XML Companion</Title>
```

The element `InputRoot.XML.Invoice.Purchases.Item[1].Title` has four children in the logical tree: Category, Form, Edition, and the element value, which is "The XML Companion".

If you want to access the attributes for this element, you can code the following ESQL. This extract of code retrieves the attributes from the input message and creates them as elements in the output message. It does not process the value of the element itself in this example.

```
-- Set the cursor to the first XML.Attribute of the Title.
-- Note the * after (XML.Attribute) meaning any name, because the name might not be known
DECLARE cursor REFERENCE TO InputRoot.XMLNS.Invoice.Purchases.Item[1].Title.(XML.Attribute)*;
WHILE LASTMOVE(cursor) DO
-- Create a field with the same name as the XML.Attribute
-- and set its value to the value of the XML.Attribute
  SET OutputRoot.XML.Data.Attributes.{FIELDNAME(cursor)} = FIELDVALUE(cursor);
-- Move to the next sibling of the same TYPE to avoid the Title value
-- which is not an XML.Attribute
  MOVE cursor NEXTSIBLING REPEAT TYPE;
END WHILE;
```

When this ESQL is processed by the Compute node, the following output message is generated:

```
<Data>
  <Attributes>
    <Category>Computer</Category>
    <Form>Paperback</Form>
    <Edition>2</Edition>
  </Attributes>
</Data>
```

You can also use a SELECT statement:

```
SET OutputRoot.XMLNS.Data.Attributes[] =
  (SELECT FIELDVALUE(I.Title) AS title,
          FIELDVALUE(I.Title.(XML.Attribute)Category) AS category,
          FIELDVALUE(I.Title.(XML.Attribute)Form) AS form,
          FIELDVALUE(I.Title.(XML.Attribute)Edition) AS edition
     FROM InputRoot.XML.Invoice.Purchases.Item[] AS I);
```

This statement generates the following output message:

```
<Data>
  <Attributes>
    <title>The XML Companion</title>
    <category>Computer</category>
    <form>Paperback</form>
    <edition>2</edition>
  </Attributes>
  <Attributes>
    <title>A Complete Guide to DB2 Universal Database</title>
    <category>Computer</category>
    <form>Paperback</form>
    <edition>2</edition>
  </Attributes>
  <Attributes>
    <title>JAVA 2 Developers Handbook</title>
    <category>Computer</category>
    <form>Hardcover</form>
    <edition>0</edition>
  </Attributes>
</Data>
```

You can qualify the SELECT with a WHERE statement to narrow down the results to obtain the same output message as the one that is generated by the WHILE statement. This second example shows that you can create the same results with less, and less complex, ESQL.

```
SET OutputRoot.XMLNS.Data.Attributes[] =
  (SELECT FIELDVALUE(I.Title.(XML.Attribute)Category) AS category,
          FIELDVALUE(I.Title.(XML.Attribute)Form) AS form,
          FIELDVALUE(I.Title.(XML.Attribute)Edition) AS edition
     FROM InputRoot.XML.Invoice.Purchases.Item[] AS I)
     WHERE I.Title = 'The XML Companion');
```

This statement generates the following output message:

```
<Data>
  <Attributes>
    <Category>Computer</Category>
    <Form>Paperback</Form>
    <Edition>2</Edition>
  </Attributes>
  </Data>
```

You can define message flow content by adding and configuring message flow

nodes and connecting them to form flows.

"Manipulating messages in the XMLNS domain" on page 2563
When you write ESQL for processing messages in the XMLNS domain, it is helpful to understand the structure of the message tree that the XMLNS parser builds.

"Working with XML messages" on page 2535
The following topics provide information about typical tasks for processing XML messages.

Related reference:

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

"DECLARE statement" on page 5117
Use the DECLARE statement to define a variable, the data type of the variable and, optionally, its initial value.

"SET statement" on page 5159
The SET statement assigns a value to a variable.

XML.element:

This syntax element represents an XML element (a tag).

The name of the syntax element corresponds to the name of the XML element in the message. This element can have many children in the message tree, including attributes, elements, and content.

XML.tag is supported as an alternative to XML.element for compatibility with earlier versions of WebSphere Message Broker. Use XML.element in any new message flows that you create.

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"XML.Attribute"
The XMLNS parser uses this field type for syntax elements that represent an XML attribute.

"XML message body example" on page 2581
The XMLNS parser creates a message tree that represents an XML document.

Related tasks:

Chapter 9, "Developing message flow applications," on page 1019
Develop message flows to process your business messages and data.

Related reference:

"XMLNS: The XML message body" on page 2569
Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.Attribute:

The XMLNS parser uses this field type for syntax elements that represent an XML attribute.

Parsing

The name and value of the syntax element correspond to the name and value of the XML attribute that is represented. Attribute elements have no children and must always be children of an element.

Writing

When the XMLNS parser generates a bit stream from a message tree, occurrences of ampersand (&), less than (<), greater than (>), double quotation mark ("), and apostrophe ('), within the attribute value, are replaced by the predefined XML entities &, <, >, ", and '.

The XML.attr field type constant is also supported for compatibility with earlier versions of WebSphere Message Broker.

Related concepts:

"Message flows overview" on page 1022

Related reference:

“XMLNS: The XML message body” on page 2569
Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.CDataSection:

CData sections in the XML message are represented by a syntax element with field type XML.CdataSection.

The content of the CDataSection element is the value of the CDataSection element without the `<![CDATA[` that marks its beginning, and the `]]>` that marks its end.

For example, the following CData section:

```
<![CDATA[<greeting>Hello, world!</greeting>]]>
```

is represented by a CDataSection element with a string value of:

```
"<greeting>Hello, world!</greeting>"
```

Unlike Content, occurrences of <,>, &, ", and ' are not translated to their XML character entities (<, >, and &) when the CDataSection is produced.

When to use XML.CDataSection

A CData section is often used to embed one XML message within another. By using a CData section, you ensure that the XML reserved characters (<, >, and &) are not replaced with XML character entities.

XML.AsisElementContent also allows the production of unmodified character data, but XML.CDataSection is typically a better choice because it protects the outer message from errors in the embedded message.

Parsing the contents of a CDataSection

A common requirement is to parse the contents of a CData section to create a message tree, which you can achieve by using the ESQL statement CREATE with the PARSE clause; see “XMLNSC: Working with XML messages and bit streams” on page 2541.

Related concepts:

“Message flows overview” on page 1022

Related reference:

"XMLNS: The XML message body" on page 2569
Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.NamespaceDecl:

A namespace declaration is represented by a syntax element with field type XML.NamespaceDecl.

Namespace declarations take one of two forms in the message tree:

- **Declaration using a namespace prefix**

  ```
  <ns1:e1 xmlns:ns1="namespace1"/>
  ```

  In the message tree, the syntax element for this namespace declaration is shown in the following table:

Namespace	`http://www.w3.org/2000/xmlns/`
Name	`ns1`
Value	`namespace1`

- **Declaration of a default namespace**

  A default namespace declaration is an xmlns attribute that defines an empty prefix

  ```
  <e1 xmlns="namespace1"/>
  ```

  In the message tree, the syntax element for this namespace declaration is shown in the following table:

Namespace	""
Name	`xmlns`
Value	`namespace1`

  Note that, in both cases, element 'e1' is in namespace 'namespace1'.

Related concepts:

Related reference:

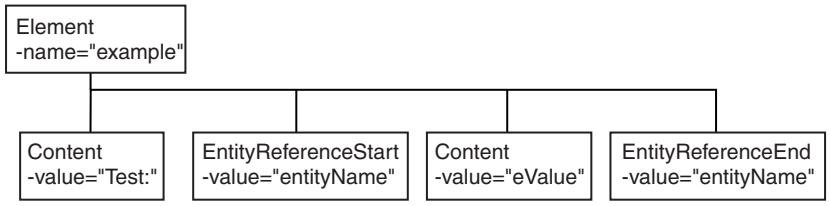
"XMLNS: The XML message body" on page 2569
Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.EntityReferenceStart and XML.EntityReferenceEnd:

When an entity reference is encountered in the XML message, both the expanded form and the original entity name are stored in the syntax element tree. The name of the entity is stored as the value of the EntityReferenceStart and EntityReferenceEnd syntax elements, and any syntax elements between contain the entity expansion.

The following examples show the XML entity references in an XML document, and in tree structure form.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<!DOCTYPE example [ <!ENTITY entityName "eValue"> ]>
<example>Test: &entityName;</example>
```



The XML declaration and the document type declaration are not shown here. Refer to "XMLNS: The XML declaration" on page 2565 and "XMLNS: The DTD" on page 2568 for details of those sections of the syntax element tree.

Related concepts:

Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

"XMLNS: The XML declaration" on page 2565
The beginning of an XML message can contain an XML declaration.

"XMLNS: The DTD" on page 2568
The document type declaration (DTD) of an XML message is represented by a syntax element with field type XML.DocTypeDecl, and its children. These comprise the DOCTYPE construct.

XML.comment:

An XML.comment that is encountered outside the document type declaration is represented by a syntax element with field type XML.comment. The value of the element is the comment text from the XML message.

If the value of the element contains the character sequence `-->`, the sequence is replaced with the text `-->`. This ensures that the contents of the comment cannot prematurely terminate the comment. Occurrences of the following characters are not translated to their escape sequences:

```
< > & " '
```

The following is an example of the XML comment in an XML document:

```
<example><!-- This is a comment --></example>
```

Related concepts:

"Message flows overview" on page 1022

"XMLNS: The DTD" on page 2568
The document type declaration (DTD) of an XML message is represented by a syntax element with field type XML.DocTypeDecl, and its children. These comprise the DOCTYPE construct.

XML.ProcessingInstruction:

A processing instruction that is encountered outside the document type declaration is represented by a syntax element with field type XML.ProcessingInstruction.

This is a name-value element; the name of the syntax element is the processing instruction target name, and the value of the syntax element is the character data of the processing instruction. The value of the syntax element must not be empty. The name cannot be `XML` in either uppercase or lowercase.

If the value of the element contains the character sequence `?>`, the sequence is replaced with the text `?>`. This ensures that the content of the processing instruction cannot prematurely terminate the processing instruction. Occurrences of the following characters are not translated to their escape sequences:

```
< > & " '
```

The following shows an example of the XML processing instruction in an XML document:

```
<example><?target This is a PI.?></example>
```

Related concepts:

"Message flows overview" on page 1022

Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.AsisElementContent:

Use the special field type XML.AsisElementContent to precisely control generated XML.

XML.AsisElementContent is a special field type. Use the field type in a message flow to precisely control the XML that is generated in an output message, without the safeguards of the Element, Attribute, and Content syntax elements. The XMLNS parser never creates elements with this field type.

Try to avoid using AsisElementContent; there is typically a safer alternative approach. If you do use AsisElementContent, it is your responsibility to ensure that the output message is well-formed XML.

You might choose to use AsisElementContent if, for example, you want to suppress the usual behavior in which occurrences of ampersand (&), less than (<), greater than (>), double quotation mark ("), and apostrophe (') are replaced by the predefined XML entities &, <, >, ", and '.

The following example illustrates the use of AsisElementContent. The statement:

```
Set OutputRoot.XMLNS.(XML.Element)Message.(XML.Content) = '<rawMarkup>';
```

generates the following XML in an output message:

```
<Message>&lt;rawMarkup&gt;</Message>
```

However, the statement:

```
Set OutputRoot.XMLNS.(XML.Element)Message.(XML.AsisElementContent) = '<rawMarkup>';
```

generates the following XML in an output message:

```
<Message><rawMarkup></Message>
```

This shows that the value of an AsisElementContent syntax element is not modified before it is written to the output message.

Every XML message must have a body. The body consists of a hierarchy of XML elements and other XML constructs that represent the message data.

XML.BitStream:

BitStream is a specialized element designed to aid the processing of very large messages.

XML.Bitstream is a special field type. When writing an XML message, the value of the BitStream element is written directly into the message, and the name is not important. The BitStream element might be the only element in the message tree.

The value of the element must be of type BLOB; any other data type generates an error when writing the element. Ensure that the content of the element is appropriate for use in the output message; pay special attention to the CCSID and the encoding of the XML text in the BLOB.

Use of the BitStream element is similar to the use of the AsisElementContent element, except that the AsisElementContent type converts its value into a string, whereas the BitStream element uses its BLOB value directly. This is a specialized element designed to aid the processing of very large messages.

The following ESQL excerpts demonstrate some typical use of this element. First, declare the element:

```
DECLARE StatementBitStream BLOB
```

Initialize the contents of StatementBitStream from an appropriate source, such as an input message. If the source field is not of type BLOB, use the CAST statement to convert the contents to BLOB. Then create the new field in the output message; for example:

```
CREATE LASTCHILD OF resultCursor
 Type XML.BitStream
 NAME 'StatementBitStream'
 VALUE StatementBitstream;
```

Manipulating messages in the XML domain:

The XML parser is like the XMLNS parser, but the XML parser has no support for namespaces or opaque parsing.

About this task

For information about how to work with the XML parser, see "Manipulating messages in the XMLNS domain" on page 2563.

Manipulating messages in the MRM domain:

How to use messages that have been modeled in the MRM domain, and that are parsed by the MRM parser.

About this task

The following topics show you how to deal with messages that have been modeled in the MRM domain, and that are parsed by the MRM parser. The physical formats associated with the message models do not affect this information unless

specifically stated. Use this information in conjunction with the information about manipulating message body content; see “Manipulating message body content” on page 2418.

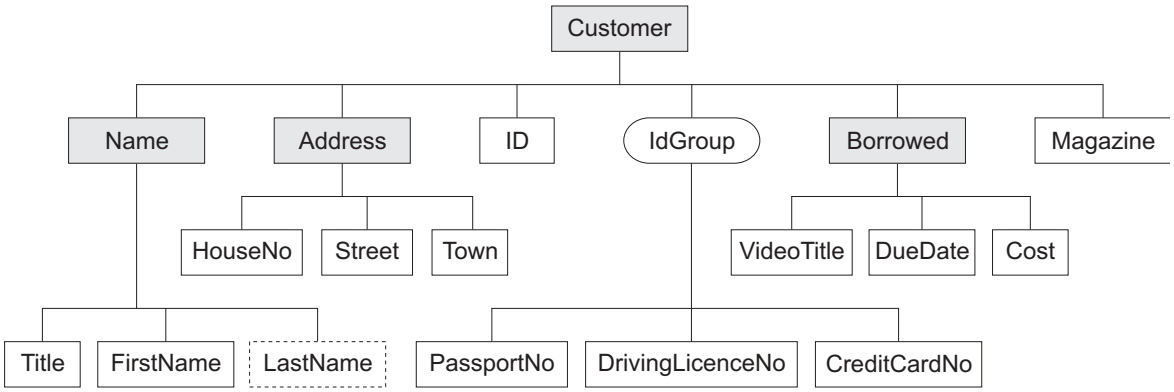
The structure of the "Customer" message is shown in the following sample:

- Video Rental

The message is used in the samples in the topics listed previously to show ESQL that manipulates the objects that can be defined in a message model.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.



The message includes a variety of structures that demonstrate how you can classify metadata to the MRM. Within an MRM message set, you can define the following objects: messages, types, groups, elements, and attributes. Folder icons that represent each of these types of objects are displayed for each message definition file in the Broker Application Development perspective.

Each message definition file can contribute to a namespace; in this sample, each namespace is completely defined by a single message definition file. You can combine several message definition files to form a complete message dictionary, which you can then deploy to a broker.

The video sample has three message definition files:

Customer.mxsd
Resides in the `no target` namespace

Address.mxsd
Resides in the namespace http://www.ibm.com/AddressDetails

Borrowed.mxsd
Resides in the namespace http://www.ibm.com/BorrowedDetails

Look at the video rental message structure sample for detailed information about the objects that are defined in this message model:

- Video Rental

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The message body is always the last child of root, and is identified by its parser name, for example XML or MRM. You can refer to, modify, and create message body data.

Related reference:

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Accessing elements in a message in the MRM domain:

You can use ESQL to manipulate the logical tree that represents a message in the message flow. This topic describes how to access data for elements in a message in the MRM domain.

About this task

You can populate an element with data with the SET statement:

```
SET OutputRoot.MRM.Name = UPPER(InputRoot.MRM.Name);
```

The field reference on the left hand side of the expression refers to the element called Name within the MRM message domain. This statement takes the input value for the Name field, converts it to uppercase, and assigns the result to the same element in the output message.

The Name element is defined in the noTarget namespace. No namespace prefix is specified in front of the Name part of the field reference in the example above. If you have defined an MRM element in a namespace other than the noTarget namespace, you must also specify a namespace prefix in the statement. For example:

```
DECLARE brw NAMESPACE 'http://www.ibm.com/Borrowed';

SET OutputRoot.MRM.brw:Borrowed.VideoTitle = 'MRM Greatest Hits';
```

For more information about using namespaces with messages in the MRM domain, see "Accessing the content of a message in the MRM domain with namespace support enabled" on page 2596.

SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Accessing multiple occurrences of an element in a message in the MRM domain:

You can use specific ESQL code to set the value of one occurrence of an element that has multiple occurrences in a message. You can also use arrow notation to indicate the direction of search when searching for multiple occurrences of an element.

About this task

You can access MRM domain elements following the general guidance given in "Accessing known multiple occurrences of an element" on page 2425 and "Accessing unknown multiple occurrences of an element" on page 2427. Further information specific to MRM domain messages is provided in this topic.

Consider the following statements:

```
DECLARE brw NAMESPACE 'http://www.ibm.com/Borrowed';

SET OutputRoot.MRM.brw:Borrowed[1].VideoTitle = 'MRM Greatest Hits Volume 1';
SET OutputRoot.MRM.brw:Borrowed[2].VideoTitle = 'MRM Greatest Hits Volume 2';
```

The above SET statements operate on two occurrences of the element Borrowed. Each statement sets the value of the child VideoTitle. The array index indicates which occurrence of the repeating element you are interested in.

When you define child elements of a complex type (which has its `Composition` property set to `Sequence`) in a message set, you can add the same element to the complex type more than once. These instances do not have to be contiguous, but you must use the same method (array notation) to refer to them in ESQL.

For example, if you create a complex type with a `Composition` of `Sequence` that contains the following elements:
- `StringElement1`
- `IntegerElement1`
- `StringElement1`

use the following ESQL to set the value of `StringElement1`:

```
SET OutputRoot.MRM.StringElement1[1] =
              'This is the first occurrence of StringElement1';
SET OutputRoot.MRM.StringElement1[2] =
              'This is the second occurrence of StringElement1';
```

You can also use the arrow notation (the greater than (>) and less than (<) symbols) to indicate the direction of search and the index to be specified:

```
SET OutputRoot.MRM.StringElement1[>] =
               'This is the first occurrence of StringElement1';
SET OutputRoot.MRM.StringElement1[<2] =
               'This is the last but one occurrence of
 StringElement1';
SET OutputRoot.MRM.StringElement1[<1] =
               'This is the last occurrence of StringElement1';
```

Refer to "Accessing known multiple occurrences of an element" on page 2425 and "Accessing unknown multiple occurrences of an element" on page 2427 for additional detail.

The SET statement assigns a value to a variable.

Accessing attributes in a message in the MRM domain:

When an MRM message is parsed into a logical tree, attributes and the data that they contain are created as name-value pairs in the same way that MRM elements are. The ESQL that you code to interrogate and update the data held in attributes refers to the attributes in a similar manner.

About this task

Consider the Video Rental sample MRM message. The attribute LastName is defined as a child of the Name element in the Customer message. Here is an example input XML message:

```
<Customer xmlns:addr="http://www.ibm.com/AddressDetails"

xmlns:brw="http://www.ibm.com/BorrowedDetails">
   <Name LastName="Bloggs">
      <Title>Mr</Title>
      <FirstName>Fred</FirstName>
   </Name>
   <addr:Address>
      <HouseNo>13</HouseNo>
      <Street>Oak Street</Street>
      <Town>Southampton</Town>
   </addr:Address>
             <ID>P</ID>
   <PassportNo>J123456TT</PassportNo>
   <brw:Borrowed>
      <VideoTitle>Fast Cars</VideoTitle>
      <DueDate>2003-05-23T01:00:00</DueDate>
      <Cost>3.50</Cost>
   </brw:Borrowed>
   <brw:Borrowed>
      <VideoTitle>Cut To The Chase</VideoTitle>
      <DueDate>2003-05-23T01:00:00</DueDate>
      <Cost>3.00</Cost>
   </brw:Borrowed>
   <Magazine>0</Magazine>
</Customer>
```

When the input message is parsed, values are stored in the logical tree as shown in the following section of user trace:

```
(0x0100001B):MRM = (
  (0x01000013):Name = (
    (0x0300000B):LastName = 'Bloggs'
    (0x0300000B):Title = 'Mr'
    (0x0300000B):FirstName = 'Fred'
  )
  (0x01000013)http://www.ibm.com/AddressDetails:Address = (
    (0x0300000B):HouseNo = 13
    (0x0300000B):Street = 'Oak Street'
    (0x0300000B):Town = 'Southampton'
  )
  (0x0300000B):ID = 'P'
  (0x0300000B):PassportNo = 'J123456TT'
  (0x01000013)http://www.ibm.com/BorrowedDetails:Borrowed = (
    (0x0300000B):VideoTitle = 'Fast Cars'
    (0x0300000B):DueDate = TIMESTAMP '2003-05-23 00:00:00'
    (0x0300000B):Cost = 3.50
  )
  (0x01000013)http://www.ibm.com/BorrowedDetails:Borrowed = (
    (0x0300000B):VideoTitle = 'Cut To The Chase '
    (0x0300000B):DueDate = TIMESTAMP '2003-05-23 00:00:00'
    (0x0300000B):Cost = 3.00
  )
  (0x0300000B):Magazine = FALSE
```

The following ESQL changes the value of the LastName attribute in the output message:

```
SET OutputRoot.MRM.Name.LastName = 'Smith';
```

Be aware of the ordering of attributes when you code ESQL. When attributes are parsed, the logical tree inserts the corresponding name-value before the MRM element's child elements. In the previous example, the child elements Title and FirstName appear in the logical message tree after the attribute LastName. In the Broker Application Development perspective, the Outline view displays attributes after the elements. When you code ESQL to construct output messages, you must define name-value pairs for attributes before any child elements.

The following sample shows the structure of the Customer message:

- Video Rental

SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Accessing elements within groups in a message in the MRM domain:

When an input message is parsed, structures that you have defined as groups in your message set are not represented in the logical tree, but its children are. If you want to refer to or update values for elements that are children of a groups, do not include the group in the ESQL statement. Groups do not have tags that appear in instance messages, and do not appear in user trace of the logical message tree.

About this task

Consider the following Video message:

```
<Customer xmlns:addr="http://www.ibm.com/AddressDetails"
xmlns:brw="http://www.ibm.com/BorrowedDetails">
   <Name LastName="Bloggs">
      <Title>Mr</Title>
      <FirstName>Fred</FirstName>
   </Name>
   <addr:Address>
      <HouseNo>13</HouseNo>
      <Street>Oak Street</Street>
      <Town>Southampton</Town>
   </addr:Address>
            <ID>P</ID>
   <PassportNo>J123456TT</PassportNo>
   <brw:Borrowed>
      <VideoTitle>Fast Cars</VideoTitle>

    (0x0300000B):VideoTitle = 'Cut To The Chase '
    (0x0300000B):DueDate = TIMESTAMP '2003-05-23 00:00:00'
    (0x0300000B):Cost = 3.00
  )
  (0x0300000B):Magazine = FALSE
```

Immediately following the element named ID, the MRM message definition uses a group which has a *Composition* of Choice. The group is defined with three children: PassportNo, DrivingLicenceNo, and CreditCardNo. The choice composition dictates that instance documents must use only one of these three possible alternatives. The example shown above uses the PassportNo element.

When you refer to this element in ESQL statements, you do not specify the group to which the element belongs. For example:

```
SET OutputRoot.MRM.PassportNo = 'J999999TT';
```

If you define messages within message sets that include XML and TDS physical formats, you can determine from the message data which option of a choice has been taken, because the tags in the message represent one of the choice's options. However, if your messages have CWF physical format, or are non-tagged TDS messages, it is not clear from the message data, and the application programs processing the message must determine which option of the choice has been selected. This is known as *unresolved choice handling*. For further information, see the description of the value of `Choice` in "Complex type logical properties" on page 5419.

"ESQL reference" on page 5019
SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Accessing mixed content in a message in the MRM domain:

When you define a complex type in a message model, you can optionally specify its content to be mixed. This setting, in support of mixed content in XML Schema, allows you to manipulate data that is included between elements in the message.

About this task

Consider the following example:

```
<MRM>
  <Mess1>
    abc
    <Elem1>def</Elem1>
    ghi
    <Elem2>jkl</Elem2>
    mno
    <Elem3>pqr</Elem3>
  </Mess1>
</MRM>
```

The strings abc, ghi, and mno do not represent the value of a particular element (unlike def, for example, which is the value of element Elem1). The presence of these strings means that you must model Mess1 with mixed content. You can model this XML message in the MRM using the following objects:

Message
The message *Name* property is set to `Mess1` to match the XML tag.

The *Type* property is set to `tMess1`.

Type The complex type *Name* property is set to `tMess1`.

The *Composition* property is set to `OrderedSet`.

The complex type has mixed content.

The complex type contains the following objects:

Element
The *Name* property is set to `Elem1` to match the XML tag.

The *Type* property is set to simple type `xsd:string`.

Element
The *Name* property is set to `Elem2` to match the XML tag.

The *Type* property is set to simple type `xsd:string`.

Element
The *Name* property is set to `Elem3` to match the XML tag.

The *Type* property is set to simple type `xsd:string`.

If you code the following ESQL:

```
SET OutputRoot.MRM.*[1] = InputBody.Elem3;
SET OutputRoot.MRM.Elem1 = InputBody.*[5];
SET OutputRoot.MRM.*[3] = InputBody.Elem2;
SET OutputRoot.MRM.Elem2 = InputBody.*[3];
SET OutputRoot.MRM.*[5] = InputBody.Elem1;
SET OutputRoot.MRM.Elem3 = InputBody*[1];
```

the mixed content is successfully mapped to the following output message:

```
<MRM>
  <Mess1>
    pqr
    <Elem1>mno</Elem1>
    jkl
    <Elem2>ghi</Elem2>
    def
    <Elem3>abc</Elem3>
  </Mess1>
</MRM>
```

Accessing embedded messages in the MRM domain:

If you have defined a multipart message, you have at least one message embedded within another. Within the overall complex type that represents the outer messages, you can model the inner message in two ways.

About this task

You can model the inner message in the following ways:

- An element (named E_outer1 in the following example) with its *Type* property set to a complex type that has been defined with its *Composition* property set to `Message`
- A complex type with its *Composition* property set to `Message` (named t_Embedded in the following example)

The ESQL that you need to write to manipulate the inner message varies depending on which of the above models you have used. For example, assume that you have defined:

- An outer message M_outer that has its *Type* property set to t_Outer.
- An inner message M_inner1 that has its *Type* set to t_Inner1
- An inner message M_inner2 that has its *Type* set to t_Inner2
- Type t_Outer that has its first child element named E_outer1 and its second child defined as a complex type named t_Embedded
- Type t_Embedded that has its *Composition* property set to `Message`
- Type t_Inner1 that has its first child element named E_inner11
- Type t_Inner2 that has its first child element named E_inner21
- Type t_outer1 that has its *Composition* property set to `Message`
- Element E_outer1 that has its *Type* property set to t_outer1

If you want to set the value of E_inner11, code the following ESQL:

```
SET OutputRoot.MRM.E_outer1.M_inner1.E_inner11 = 'FRED';
```

If you want to set the value of E_inner21, code the following ESQL:

```
SET OutputRoot.MRM.M_inner2.E_inner21 = 'FRED';
```

If you copy message headers from the input message to the output message, and your input message type contains a path, only the outermost name in the path is copied to the output message type.

When you configure a message flow to handle embedded messages, you can specify the path of a message type in either an MQRFH2 header (if one is present in the input message) or in the input node *Message Type* property in place of a name (for example, for the message modeled above, the path could be specified as M_Outer/M_Inner1/M_Inner2 instead of just M_Outer).

If you have specified that the input message has a physical format of either CWF or XML, any message type prefix is concatenated in front of the message type from the MQRFH2 or input node, giving a final path to use (for more information refer to "Multipart messages" on page 1191). The MRM uses the first item in the path as

the outermost message type, then progressively works inwards when it finds a complex type with its *Composition* property set to `Message`.

If you have specified that the input message has a physical format of TDS, a different process that uses message keys is implemented. This is described in "MRM TDS format: Multipart messages" on page 1241.

For more information about path concatenations, see "Message set properties" on page 5371.

Message sets have properties that you can set to define their characteristics and the way in which they are processed.

Accessing the content of a message in the MRM domain with namespace support enabled:

Use namespaces where appropriate for messages that are parsed by the MRM parser.

About this task

When you want to access elements of a message and namespaces are enabled, you must include the namespace when you code the ESQL reference to the element. If you do not do so, the broker searches the `no target` namespace. If the element is not found in the `no target` namespace, the broker searches all other known namespaces in the message dictionary (that is, within the deployed message set). For performance and integrity reasons, specify namespaces wherever they apply.

The most efficient way to refer to elements when namespaces are enabled is to define a namespace constant, and use this in the appropriate ESQL statements. This technique makes your ESQL code much easier to read and maintain.

Define a constant using the DECLARE NAMESPACE statement:

```
DECLARE ns01 NAMESPACE 'http://www.ns01.com'
.
.
SET OutputRoot.MRM.ns01:Element1 = InputBody.ns01:Element1;
```

`ns01` is interpreted correctly as a namespace because of the way that it is declared.

You can also use a CHARACTER variable to declare a namespace:

```
DECLARE ns02 CHARACTER 'http://www.ns02.com'
.
.
SET OutputRoot.MRM.{ns02}:Element2 = InputBody.{ns02}:Element2;
```

If you use this method, you must surround the declared variable with braces to ensure that it is interpreted as a namespace.

If you are concerned that a CHARACTER variable might get changed, you can use a CONSTANT CHARACTER declaration:

```
DECLARE ns03 CONSTANT CHARACTER 'http://www.ns03.com'
.
.
SET OutputRoot.MRM.{ns03}:Element3 = InputBody.{ns03}:Element3;
```

You can declare a namespace, constant, and variable within a schema, module, or function.

The following sample provides further examples of the use of namespaces:

- Video Rental

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The SET statement assigns a value to a variable.

Querying null values in a message in the MRM domain:

You can use an ESQL statement to compare an element to NULL.

About this task

If you want to compare an element to NULL, code the statement:

```
IF InputRoot.MRM.Elem2.Child1 IS NULL THEN
   DO:
    -- more ESQL --
END IF;
```

If nulls are permitted for this element, this statement tests whether the element exists in the input message, or whether it exists and contains the MRM-supplied null value. The behavior of this test depends on the physical format:

- For an XML element, if the XML tag or attribute is not in the bit stream, this test returns TRUE.
- For an XML element, if the XML tag or attribute is in the bit stream and contains the MRM null value, this test returns TRUE.
- For an XML element, if the XML tag or attribute is in the bit stream and does not contain the MRM null value, this test returns FALSE.
- For a delimited TDS element, if the element has no value between the previous delimiter and its delimiter, this test returns TRUE.
- For a delimited TDS element, if the element has a value between the previous delimiter and its delimiter that is the same as the MRM-defined null value for this element, this test returns TRUE.
- For a delimited TDS element, if the element has a value between the previous delimiter and its delimiter that is not the MRM-defined null value, this test returns FALSE.
- For a CWF or fixed length TDS element, if the element's value is the same as the MRM-defined null value for this element, this test returns TRUE.
- For a CWF or fixed length TDS element, if the element's value is not the same as the MRM-defined null value, this test returns FALSE.

If you want to determine if the field is missing, rather than present but with null value, you can use the ESQL CARDINALITY function.

Setting null values in a message in the MRM domain:

You can use implicit or explicit null processing to set the value of an element to NULL in an output message.

About this task

To set a value of an element in an output message, you normally code an ESQL statement similar to the following:

```
SET OutputRoot.MRM.Elem2.Child1 = 'xyz';
```

or its equivalent statement:

```
SET OutputRoot.MRM.Elem2.Child1 VALUE = 'xyz';
```

If you set the element to a non-null value, these two statements give identical results. However, if you want to set the value to null, these two statements do not give the same result:

Procedure

1. If you set the element to NULL using the following statement, the element is deleted from the message tree:

```
SET OutputRoot.MRM.Elem2.Child1 = NULL;
```

   The content of the output bit stream depends on the physical format:

   - For an XML element, neither the XML tag or attribute nor its value are included in the output bit stream.
   - For a Delimited TDS element, neither the tag (if appropriate) nor its value are included in the output bit stream. The absence of the element is typically conveyed by two adjacent delimiters.
   - For a CWF or Fixed Length TDS element, the content of the output bit stream depends on whether you have set the *Default Value* property for the element. If you have set this property, the default value is included in the bit stream. If you have not set the property, an exception is raised.

   This is called implicit null processing.
2. If you set the value of this element to NULL as follows:

```
SET OutputRoot.MRM.Elem2.Child1 VALUE = NULL;
```

   the element is not deleted from the message tree. Instead, a special value of NULL is assigned to the element. The content of the output bit stream depends on the settings of the physical format null-handling properties.

   This is called explicit null processing.

Results

Setting a complex element to NULL deletes that element and all its children.

Working with MRM messages and bit streams:

When you use the ASBITSTREAM function or the CREATE FIELD statement with a PARSE clause you must consider various restrictions.

About this task

The ASBITSTREAM function

If you code the ASBITSTREAM function with the parser mode option set to *RootBitStream*, to parse a message tree to a bit stream, the result is an MRM document in the format specified by the message format that is built from the children of the target element in the normal way.

The target element must be a predefined message defined within the message set, or can be a self-defined message if you are using an XML physical format. This algorithm is identical to that used to generate the normal output bit stream. A well-formed bit stream obtained in this way can be used to re-create the original tree by using a CREATE statement with a PARSE clause.

If you code the ASBITSTREAM function with the parser mode option set to *FolderBitStream*, to parse a message tree to a bit stream, the generated bit stream is an MRM element built from the target element and its children. Unlike *RootBitStream* mode the target element does not have to represent a message; it can represent a predefined element within a message or self-defined element within a message.

So that the MRM parser can correctly parse the message, the path from the message to the target element within the message must be specified in the *Message Type*. The format of the path is the same as that used by message paths except that the message type prefix is not used.

For example, suppose the following message structure is used:

```
Message
    elem1
         elem11
         elem12
```

To serialize the subtree representing element `elem12` and its children, specify the message path `'message/elem1/elem12'` in the *Message Type*.

If an element in the path is qualified by a namespace, specify the namespace URI between {} characters in the message path. For example if element `elem1` is qualified by namespace `'http://www.ibm.com/temp'`, specify the message path as `'message/{http://www.ibm.com/temp}elem1/elem12'`

This mode can be used to obtain a bit stream description of arbitrary sub-trees owned by an MRM parser. When in this mode, with a physical format of XML, the XML bit stream generated is not enclosed by the 'Root Tag Name' specified for the Message in the Message Set. No XML declaration is created, even if not suppressed in the message set properties.

Bit streams obtained in this way can be used to re-create the original tree by using a CREATE statement with a PARSE clause (by using a mode of *FolderBitStream*).

The CREATE statement with a PARSE clause

If you code a CREATE statement with a PARSE clause, with the parser mode option set to *RootBitStream*, to parse a bit stream to a message tree, the expected bit stream is a normal MRM document. A field in the tree is created for each field in the document. This algorithm is identical to that used when parsing a bit stream from an input node

If you code a CREATE statement with a PARSE clause, with the parser mode option set to *FolderBitStream*, to parse a bit stream to a message tree, the expected bit stream is a document in the format specified by the Message Format, which is either specified directly or inherited. Unlike *RootBitStream* mode the root of the document does not have to represent an MRM message; it can represent a predefined element within a message or self-defined element within a message.

So that the MRM parser can correctly parse the message the path from the message to the target element within the message must be specified in the *Message Type*. The format of the message path is the same as that used for the ASBITSTREAM function described above.

Example of using the ASBITSTREAM function and CREATE statement with a PARSE clause in FolderBitStream mode

The following ESQL uses the message definition described above. The ESQL serializes part of the input tree by using the ASBITSTREAM function, then uses the CREATE statement with a PARSE clause to re-create the subtree in the output tree. The Input message and corresponding Output message are shown below the ESQL.

```
CREATE COMPUTE MODULE DocSampleFlow_Compute
 CREATE FUNCTION Main() RETURNS BOOLEAN
 BEGIN
  CALL CopyMessageHeaders();

  -- Set the options to be used by ASBITSTREAM and CREATE ... PARSE
  -- to be FolderBitStream and enable validation
  DECLARE parseOptions INTEGER BITOR(FolderBitStream, ValidateContent,
                       ValidateValue, ValidateLocalError);

  -- Serialise the elem12 element and its children from the input bitstream
  -- into a variable
       DECLARE subBitStream BLOB
         ASBITSTREAM(InputRoot.MRM.elem1.elem12
           OPTIONS parseOptions
           SET 'DocSample'
           TYPE 'message/elem1/elem12'
           FORMAT 'XML1');

        -- Set the value of the first element in the output tree
        SET OutputRoot.MRM.elem1.elem11 = 'val11';

        -- Parse the serialized sub-tree into the output tree
        IF subBitStream IS NOT NULL THEN
            CREATE LASTCHILD OF OutputRoot.MRM.elem1
                PARSE ( subBitStream
                        OPTIONS parseOptions
                        SET 'DocSample'
                        TYPE 'message/elem1/elem12'
                        FORMAT 'XML1');
        END IF;

  -- Convert the children of elem12 in the output tree to uppercase
  SET OutputRoot.MRM.elem1.elem12.elem121 =
   UCASE(OutputRoot.MRM.elem1.elem12.elem121);

  SET OutputRoot.MRM.elem1.elem12.elem122 =
   UCASE(OutputRoot.MRM.elem1.elem12.elem122);

        -- Set the value of the last element in the output tree
        SET OutputRoot.MRM.elem1.elem13 = 'val13';

  RETURN TRUE;
 END;

 CREATE PROCEDURE CopyMessageHeaders() BEGIN
  DECLARE I INTEGER 1;
  DECLARE J INTEGER CARDINALITY(InputRoot.*[]);
  WHILE I < J DO
   SET OutputRoot.*[I] = InputRoot.*[I];
   SET I = I + 1;
  END WHILE;
 END;

END MODULE;
```

Input message :

```
<message>
    <elem1>
        <elem11>value11</elem11>
        <elem12>
            <elem121>value121</elem121>
            <elem122>value122</elem122>
        </elem12>

Handling large MRM messages:

When an input bit stream is parsed, and a logical tree created, the tree representation of an MRM message is typically larger, and in some cases much larger, than the corresponding bit stream.

About this task

The reasons for this large size include:

- The addition of the pointers that link the objects together
- Translation of character data into Unicode that can double the original size
- The inclusion of field names that can be contained implicitly within the bit stream
- The presence of control data that is associated with the broker's operation

Manipulation of a large message tree can, therefore, demand a great deal of storage. If you design a message flow that handles large messages made up of repeating structures, you can code specific ESQL statements that help to reduce the storage load on the broker. These statements support both random and sequential access to the message, but assume that you do not need access to the whole message at one time.

These ESQL statements cause the broker to perform limited parsing of the message, and to keep only that part of the message tree that reflects a single record in storage at a time. If your processing requires you to retain information from record to record (for example, to calculate a total price from a repeating structure of items in an order), you can either declare, initialize, and maintain ESQL variables, or you can save values in another part of the message tree, for example LocalEnvironment.

This technique reduces the memory used by the broker to that needed to hold the full input and output bit streams, plus that required for one record's trees. It provides memory savings when even a small number of repeats is encountered in the message. The broker makes use of partial parsing, and the ability to parse specified parts of the message tree, to and from the corresponding part of the bit stream.

To use these techniques in your Compute node apply these general techniques:

- Copy the body of the input message as a bit stream to a special folder in the output message. This creates a modifiable copy of the input message that is not parsed and which therefore uses a minimum amount of memory.

- Avoid any inspection of the input message; this avoids the need to parse the message.
- Use a loop and a reference variable to step through the message one record at a time. For each record:
  - Use normal transforms to build a corresponding output subtree in a second special folder.
  - Use the ASBITSTREAM function to generate a bit stream for the output subtree that is stored in a *BitStream* element, placed in the position in the tree, that corresponds to its required position in the final bit stream.
  - Use the DELETE statement to delete both the current input and the output record message trees when you complete their manipulation.
  - When you complete the processing of all records, detach the special folders so that they do not appear in the output bit stream.

You can vary these techniques to suit the processing that is required for your messages. The following ESQL provides an example of one implementation.

The ESQL is dependant on a message set called `LargeMessageExanple` that has been created to define messages for both the Invoice input format and the Statement output format. A message called `AllInvoices` has been created that contains a global element called `Invoice` that can repeat one or more times, and a message called `Data` that contains a global element called `Statement` that can repeat one or more times.

The definitions of the elements and attributes have been given the correct data types, therefore, the CAST statements used by the ESQL in the XML example are no longer required. An XML physical format with name `XML1` has been created in the message set which allows an XML message corresponding to these messages to be parsed by the MRM.

When the `Statement` tree is serialized using the ASBITSTREAM function the *Message Set*, *Message Type*, and *Message Format* are specified as parameters. The *Message Type* parameter contains the path from the message to the element being serialized which, in this case, is `Data/Statement` because the `Statement` element is a direct child of the `Data` message.

The input message to the flow is the same Invoice example message used in other parts of the documentation except that it is contained between the tags:

```
<AllInvoices> ....  </AllInvoices>
```

Example

```
CREATE COMPUTE MODULE LargeMessageExampleFlow_Compute
 CREATE FUNCTION Main() RETURNS BOOLEAN
 BEGIN
  CALL CopyMessageHeaders();
    -- Create a special folder in the output message to hold the input tree
    -- Note : SourceMessageTree is the root element of an MRM parser
    CREATE LASTCHILD OF OutputRoot.MRM DOMAIN 'MRM' NAME 'SourceMessageTree';

    -- Copy the input message to a special folder in the output message
    -- Note : This is a root to root copy which will therefore not build trees
    SET OutputRoot.MRM.SourceMessageTree = InputRoot.MRM;

    -- Create a special folder in the output message to hold the output tree
    CREATE FIELD OutputRoot.MRM.TargetMessageTree;

    -- Prepare to loop through the purchased items
```

```
DECLARE sourceCursor REFERENCE TO OutputRoot.MRM.SourceMessageTree.Invoice;
DECLARE targetCursor REFERENCE TO OutputRoot.MRM.TargetMessageTree;
DECLARE resultCursor REFERENCE TO OutputRoot.MRM;
DECLARE grandTotal   FLOAT     0.0e0;

-- Create a block so that it's easy to abandon processing
ProcessInvoice: BEGIN
 -- If there are no Invoices in the input message, there is nothing to do
 IF NOT LASTMOVE(sourceCursor) THEN
    LEAVE ProcessInvoice;
 END IF;

 -- Loop through the invoices in the source tree
 InvoiceLoop : LOOP
    -- Inspect the current invoice and create a matching Statement
    SET targetCursor.Statement =
      THE (
         SELECT
           'Monthly'                        AS Type,
           'Full'                           AS Style,
           I.Customer.FirstName             AS Customer.Name,
           I.Customer.LastName              AS Customer.Surname,
           I.Customer.Title                 AS Customer.Title,
           (SELECT
              FIELDVALUE(II.Title)    AS Title,
              II.UnitPrice * 1.6    AS Cost,
              II.Quantity                AS Qty
           FROM I.Purchases.Item[] AS II
           WHERE II.UnitPrice> 0.0               ) AS Purchases.Article[],
           (SELECT
              SUM( II.UnitPrice *
                       II.Quantity  *
                     1.6                          )
            FROM I.Purchases.Item[] AS II                    ) AS Amount,

Manipulating messages in the JMS domains:

This topic provides information specific to dealing with messages that belong to the JMSMap and JMSStream domains. These messages are parsed by the generic XML parser.

About this task

Messages that belong to the JMS domains are processed by the XML parser, so you can follow the guidance provided for XML messages in "Manipulating messages in the XML domain" on page 2581, in conjunction with the information in "Manipulating message body content" on page 2418.

The JMSMap and JMSStream domains support MapMessage and StreamMessage messages. Other kinds of JMS message are supported by other domains. For further information about using JMS messages with WebSphere Message Broker, see "WebSphere Broker JMS Transport" on page 1681.

SQL is the industry standard language for accessing and updating database data and ESQL is a language derived from SQL Version 3, particularly suited to manipulating both database and message data.

Manipulating messages in the IDOC domain:

Use ESQL from a Compute node to copy the incoming IDoc to the outgoing IDoc, and manipulate the message.

About this task

A valid IDoc message flows out of SAP and is sent to the MQSeries link for R/3.

When this IDoc has been committed successfully to the outbound WebSphere MQ queue, the input node of the message flow reads it from that queue and generates the syntax element tree.

The Compute node manipulates this syntax element tree and, when it has finished, passes the output message to subsequent nodes in the message flow. When the message reaches the output node, the IDOC parser is called to rebuild the bit stream from the tree.

The message flow must create an output message in a similar format to the input message.

See "Field names of the IDOC parser structures" on page 6333 for the field names in the DC (Control Structure) and DD (Data Structure) that are recognized by the IDOC parser

Procedure

Use the following ESQL example from a Compute node:

```
SET OutputRoot = InputRoot;
SET OutputRoot.IDOC.DC[1].tabnam = 'EDI_DC40  ';
SET OutputRoot.IDOC.DD[2].sdatatag.MRM.maktx = 'Buzzing all day';
```

Results

The first line of the code copies the incoming IDoc to the outgoing IDoc.

The second line sets the *tabname* of the first DC.

The third line uses the second DD segment, which in this example is of type `E2MAKTM001`, and sets the *maktx* field.

Accessing fields of the IDoc using ESQL:
About this task

Use the ESQL editor Content Assist to complete the SAP-defined fields of the IDoc.

After the `sdatatag` tag in an ESQL statement, the next tag is `MRM`, which you must enter manually, followed by the field name that is to be manipulated. Specify the name of the field within the message segment here, not the name of the message segment.

For example, the following code sets the segment name of the IDoc:

```
SET OutputRoot.IDOC.DD[I].segnam  = 'E2MAKTM001';
```

The following example sets the `msgfn` field within the `E2MAKTM001` segment:

```
SET OutputRoot.IDOC.DD[I].sdatatag.MRM.msgfn = '006';
```

Manipulating messages in the MIME domain:

A MIME message does not need to be received over a particular transport. For example, a message can be received over HTTP by using an HTTPInput node, or over WebSphere MQ by using an MQInput node. The MIME parser is used to process a message if the message domain is set to MIME in the input node properties, or if you are using WebSphere MQ, and the MQRFH2 header has a message domain of MIME.

This topic explains how to deal with messages that belong to the MIME domain, and are parsed by the MIME parser. Use this information in conjunction with the information in "Manipulating message body content" on page 2418.

You can manipulate the logical tree using ESQL before passing the message on to other nodes in the message flow. A message flow can also create a MIME domain tree using ESQL. When a MIME domain message reaches an output node, the MIME parser is called to rebuild the bit stream from the logical tree.

The following examples show how to manipulate MIME messages:
- "Creating a new MIME tree"
- "Modifying an existing MIME tree" on page 2613
- "Managing Content-Type" on page 2614

Creating a new MIME tree

A message flow often receives, modifies, and returns a MIME message. In this case, you can work with the valid MIME tree that is created when the input message is parsed. If a message flow receives input from another domain, such as XMLNS, and returns a MIME message, you must create a valid MIME tree. Use the following ESQL example in a Compute node to create the top-level structure for a single-part MIME tree:

```
CREATE FIELD OutputRoot.MIME TYPE Name;
DECLARE M REFERENCE TO OutputRoot.MIME;
CREATE LASTCHILD OF M TYPE Name NAME 'Data';
```

The message flow must also ensure that the MIME Content-Type is set correctly, as explained in "Managing Content-Type" on page 2614. The flow must then add the message data into the MIME tree. The following ESQL examples show how you can do this. In each case, a Data element is created with the domain BLOB.

- A bit stream from another part of the tree is used. This example shows how a bit stream could be created from an XML message that is received by the message flow. The flow then invokes the BLOB parser to store the data under the Data element.

```
DECLARE partData BLOB ASBITSTREAM(InputRoot.XMLNS);
CREATE LASTCHILD OF M.Data DOMAIN('BLOB') PARSE(partData);
```

- Instead of parsing the bit stream, create the new structure, then attach the data to it, as shown in this ESQL example:

```
DECLARE partData BLOB ASBITSTREAM(InputRoot.XMLNS);
CREATE LASTCHILD OF M.Data DOMAIN('BLOB') NAME 'BLOB';
CREATE LASTCHILD OF M.Data.BLOB NAME 'BLOB' VALUE partData;
```

Both of these approaches create the same tree structure. The first approach is better because explicit knowledge of the tree structure that the BLOB parser requires is not built into the flow.

More commonly, the Compute node must build a tree for a multipart MIME document. The following ESQL example shows how you can do this, including setting the top-level Content-Type property.

```
DECLARE part1Data BLOB ASBITSTREAM(InputRoot.XMLNS, InputProperties.Encoding, InputProperties.CodedCharSetId);

SET OutputRoot.Properties.ContentType = 'multipart/related; boundary=myBoundary';

CREATE FIELD OutputRoot.MIME TYPE Name;
DECLARE M REFERENCE TO OutputRoot.MIME;
CREATE LASTCHILD OF M TYPE Name NAME 'Parts';
CREATE LASTCHILD OF M.Parts TYPE Name NAME 'Part';
DECLARE P1 REFERENCE TO M.Parts.Part[1];
CREATE FIELD P1."Content-Type" TYPE NameValue VALUE 'text/plain';
CREATE FIELD P1."Content-Id"   TYPE NameValue VALUE 'part one';
CREATE LASTCHILD OF P1 TYPE Name NAME 'Data';
CREATE LASTCHILD OF P1.Data DOMAIN('BLOB') PARSE(part1Data);

CREATE LASTCHILD OF M.Parts TYPE Name NAME 'Part';
DECLARE P2 REFERENCE TO M.Parts.Part[2];
CREATE FIELD P2."Content-Type" TYPE NameValue VALUE 'text/plain';
CREATE FIELD P2."Content-Id"   TYPE NameValue VALUE 'part two';
CREATE LASTCHILD OF P2 TYPE Name NAME 'Data';
CREATE LASTCHILD OF P2.Data DOMAIN('BLOB') PARSE(part2Data);
```

Modifying an existing MIME tree

This ESQL example adds a new MIME part to an existing multipart MIME message. If the message is not multipart, it is not modified.

```
SET OutputRoot = InputRoot;

-- Check to see if the MIME message is multipart or not.
IF LOWER(InputProperties.ContentType) LIKE 'multipart/%'
THEN
  CREATE LASTCHILD OF OutputRoot.MIME.Parts NAME 'Part';

  DECLARE P REFERENCE TO OutputRoot.MIME.Parts.[<];
  CREATE FIELD P."Content-Type" TYPE NameValue VALUE 'text/xml';
  CREATE FIELD P."Content-ID"   TYPE NameValue VALUE 'new part';
  CREATE LASTCHILD OF P TYPE Name NAME 'Data';

  -- This is an artificial way of creating some BLOB data.
  DECLARE newBlob BLOB '4f6e652074776f2074687265650d0a';
  CREATE LASTCHILD OF P.Data DOMAIN('BLOB') PARSE(newBlob);
END IF;
```

If you receive a MIME message, for example; through an EmailInput node, and you know the format of your message, you might want to reparse the message. For example:

```
CREATE LASTCHILD OF OutputRoot.XMLNSC.emailData  DOMAIN('XMLNSC')
PARSE(InputRoot.MIME.Data.BLOB.BLOB,InputProperties.Encoding,
InputProperties.CodedCharSetId);
```

Managing Content-Type

When you create a new MIME message tree, or when you modify the value of the MIME boundary string, make sure that the MIME Content-Type header is set correctly by setting the ContentType value in the broker Properties subtree. The following example shows how to set the ContentType value for a MIME part with simple content:

```
SET OutputRoot.Properties.ContentType = 'text/plain';
```

Do not set the Content-Type value directly in the MIME tree or HTTP trees because the value is ignored or used inconsistently.

When you receive a MIME message, you can filter or route the message content based on the content-Type. The following example shows an XPath query that can be used in a Route node to filter the content based on whether the message contains an attachment or not:

```
starts-with($Root/MIME/Content-Type,"multipart")
```

Manipulating messages in the BLOB domain:

How to deal with messages that belong to the BLOB domain, and that are parsed by the BLOB parser.

About this task

You cannot manipulate the contents of a BLOB message, because it has no predefined structure. However, you can refer to its contents using its known position within the bit stream, and process the message with a minimum of knowledge about its contents.

The BLOB message body parser does not create a tree structure in the same way that other message body parsers do. It has a root element BLOB, that has a child element, also called BLOB, that contains the data.

You can refer to message content using substrings if you know the location of a particular piece of information within the BLOB data. For example, the following expression identifies the tenth byte of the message body:

```
InputBody.BLOB.BLOB[10]
```

The following expression references 10 bytes of the message data starting at offset 10:

```
SUBSTRING(InputBody.BLOB.BLOB from 10 for 10)
```

You can use the Mapping node to map to and from a predefined BLOB message, and to map to and from items of BLOB data.

Simple example to write a string in the output message:

About this task

The following simple example allows you to write some character data in your ESQL (for example, if you have read some character fields from a database) out as a BLOB:

```
CALL CopyMessageHeaders();
 -- CALL CopyEntireMessage();
 DECLARE mystring CHARACTER;
 SET mystring='hello';
 SET OutputRoot.BLOB.BLOB=CAST (mystring AS BLOB CCSID 1208);
```

Creating a JSON message:

You can create JSON message data containing JSON objects, JSON arrays, or both, by creating elements in the logical message tree, under the `Data` element that is owned by the JSON parser root.

A JSON message can have either an anonymous object or an anonymous array as the root of the data. When creating a JSON array in the logical message tree, the JSON array name is placed in a tree element that has its type set to the JSON parser element type `JSON.Array`.

The items in the JSON array are placed in the logical tree as `NameValue` elements, as children of the `JSON.Array` element, with the required value. The names of these array item elements are not used by the JSON serializer, because JSON array items are anonymous. However, for consistency with the name used by the JSON parser, use the name `Item` when you define the array item elements.

Creating a JSON object message

The following example shows how to create a JSON message that is formatted with an object at the root level, with the form:

```
{ --- }
```

This example shows how to create a simple JSON object message with one name-value pair:

```
{"Message":"Hello World"}
```

The following ESQL code can be used to create the message:

```
SET OutputRoot.JSON.Data.Message = 'Hello World';
```

The following Java code can also be used:

```
MbElement outRoot = outMessage.getRootElement();
MbElement outJsonRoot = outRoot.createElementAsLastChild(MbJSON.PARSER_NAME);
MbElement outJsonData = outJsonRoot.createElementAsLastChild(MbElement.TYPE_NAME, MbJSON.DATA_ELE
MbElement outJsonTest = outJsonData.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "Message"
```

The following PHP code can also be used:

```
$output_message->{MB_JSON_PARSER_NAME}->{MB_JSON_DATA_ELEMENT_NAME}->Message = 'Hello World';
```

The broker message tree produced from this example is:

```
Message: ( ['json' : 0xc552990]
  (0x01000000:Object   ):Data    = (
    (0x03000000:NameValue):Message = 'Hello World' (CHARACTER)
 )
```

Creating a JSON array message

The following example shows how to create a message that is formatted with an array at the root level, with the form:

```
[ --- ]
```

This example shows how to create a JSON array message:

```
["valueA","valueB"]
```

The following ESQL code can also be used to create the array:

```
CREATE FIELD OutputRoot.JSON.Data IDENTITY (JSON.Array)Data;
CREATE LASTCHILD OF OutputRoot.JSON.Data TYPE NameValue NAME 'Item' VALUE 'valueA';
CREATE LASTCHILD OF OutputRoot.JSON.Data TYPE NameValue NAME 'Item' VALUE 'valueB';
```

The following Java code can also be used:

```
MbElement outJsonRoot =
          outRoot.createElementAsLastChild("JSON");
MbElement outJsonData =
   outJsonRoot.createElementAsLastChild(MbJson.Array, "Data", null);
   outJsonData.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
                                        "Item", "valueA");
   outJsonData.createElementAsLastChild(MbElement.TYPE_NAME_VALUE,
                                        "Item", "valueB");
```

The following PHP code can also be used:

```
$output_assembly->JSON->Data[] = array("valueA","valueB");
```

For more information about PHP arrays, see "Using PHP arrays with JSON" on page 2685.

The message is created in the broker logical message tree with the form:

```
Message: ( ['json' : 0xc552990]
  (0x01001000:Array     ):Data    = (
    (0x03000000:NameValue):Item = 'valueA' (CHARACTER)
    (0x03000000:NameValue):Item = 'valueB' (CHARACTER)
 )
```

Creating a JSON object array message

The following example shows how to create a message that is formatted with an array of objects at the root level, with the form:

```
[{--},{--},...]
```

This example shows how to create the JSON object array message:

```
[{"Nam1":"val1","Num1":1},{"Nam2":"val2","Num2":"}]
```

The following ESQL code can also be used to create the array:

```
CREATE FIELD OutputRoot.JSON.Data IDENTITY(JSON.Array)Data;
SET OutputRoot.JSON.Data.Item[1].Nam1 = 'val1';
SET OutputRoot.JSON.Data.Item[1].Nam1 = 1;
SET OutputRoot.JSON.Data.Item[2].Nam2 = 'val2';
SET OutputRoot.JSON.Data.Item[2].Nam2 = 2;
```

The following Java code can also be used:

```
MbElement jsonData = outMessage.getRootElement().createElementAsLastChild(MbJSON.PARSER_NAME);
MbElement jsonRootArray = jsonData.createElementAsLastChild(MbJSON.DATA_ELEMENT_NAME,null);

MbElement jsonFirstArrayItem = jsonRootArray.createElementAsLastChild(MbElement.TYPE_NAME, MbJSON.
```

```
jsonFirstArrayItem.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "nam1", "val1");
jsonFirstArrayItem.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "num1", new Integer(1));

MbElement jsonSecondArrayItem = jsonRootArray.createElementAsLastChild(MbElement.TYPE_NAME, MbJSON.AR
jsonSecondArrayItem.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "nam2", "val2");
jsonSecondArrayItem.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "num2", new Integer(2));
```

The message is created in the broker logical message tree with the form:

```
Message: ( ['json' : 0xc673900]
  (0x01001000:Array):Data = (
    (0x01000000:Object):Item = (
      (0x03000000:NameValue):nam1 = 'val1' (CHARACTER)
      (0x03000000:NameValue):num1 = 1 (INTEGER)
    )(0x01000000:Object):Item = (
      (0x03000000:NameValue):nam2 = 'val2' (CHARACTER)
      (0x03000000:NameValue):num2 = 2 (INTEGER)
    )
  )
)
```

"Managing ESQL files" on page 2390
In a message flow project, manage ESQL files that contain the ESQL code that you provide to modify or customize the behavior of Compute, Database, DatabaseInput, and Filter nodes.

Modifying a JSON message:

You can modify JSON objects and JSON arrays.

JSON data streams are parsed into the logical message tree and placed under the `Data` element that is owned by the `JSON` parser root. The JSON data objects and arrays can be accessed and modified from each supported language as follows:

- ESQL as `OutputRoot.JSON.Data.`*`path to required object or array`*
- Java as `/JSON/Data/`*`path to required object or array`*
- PHP as `output_assembly->JSON->Data->`*`path to required object or array`*

The following example shows a possible JSON message:

```
{
    "name" : "John Doe",
    "age" : -1,
    "known" : false,
    "address" : { "street" : null,
                  "city" : "unknown" },
    "belongings" : ["this", "that", "the other"]
}
```

The JSON parser parses the input JSON bit stream, to produce the following broker logical message tree:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
    (0x01000000:Object):Data      = (
      (0x03000000:NameValue): name    = 'John Doe' (CHARACTER)
      (0x03000000:NameValue): age     = -1 (INTEGER)
      (0x03000000:NameValue): known   = FALSE (BOOLEAN)
      (0x01000000:Object     ): address = (
        (0x03000000:NameValue): street = NULL (UNKNOWN)
        (0x03000000:NameValue): city = 'unknown' (CHARACTER)
      )
      (0x01001000:Array     ): belongings = (
        (0x03000000:NameValue): Item = 'this' (CHARACTER)
        (0x03000000:NameValue): Item = 'that' (CHARACTER)
        (0x03000000:NameValue): Item = 'the other' (CHARACTER)
      )
    )
  )
```

This message tree can be modified through ESQL as:

```
SET OutputRoot.JSON.Data.age =  InputRoot.JSON.Data.age + 22;   -- Set age to 21
SET OutputRoot.JSON.Data.belongings.Item[4] = 'an other';
SET OutputRoot.JSON.Data.belongings.Item[5] = 'and another';
```

The message tree can be modified through PHP as:

```
$output_assembly->JSON->Data->address->age = $input_assembly->JSON->Data->address->age + 22; // Se
$output_assembly->JSON->Data->belongings[2] = 'an other';
$output_assembly->JSON->Data->belongings[3] = 'and another';
```

For more information about PHP arrays, including multidimensional arrays, see "Using PHP arrays with JSON" on page 2685.

The message tree can be modified through Java as:

```
MbElement ageEl = message.getRootElement().getLastChild().getFirstElementByPath("/JSON/Data/age");
int age = ((Integer)ageEl.getValue()).intValue();
ageEl.setValue(age + 22);       // Set age to 21
inMessage.getRootElement().getLastChild().getFirstElementByPath("/JSON/Data/belongings/Item[3]").set
```

JSON with a multidimensional array

The following example shows JSON input containing a multidimensional array:

```
{
    "customer" : "Joe",
    "orders" : [ [ "thing1", 1, 10.1 ],
                 [ "thing2", 2, 20.2 ]  ]
}
```

The following broker message tree is produced:

```
(Message):JSON   = ( ['json' : 0xhhhhhh]
    (0x01000000:Object):Data   = (
      (0x03000000:NameValue):customer = 'Joe' (CHARACTER)
      (0x01001000:Array):orders = (
        (0x01001000:Array):Item   = (
          (0x03000000:NameValue):Item = 'thing1' (CHARACTER)
          (0x03000000:NameValue):Item = 1 (INTEGER)
          (0x03000000:NameValue):Item = 1.01E+1 (FLOAT)
        )
        (0x01001000:Array):Item   = (
          (0x03000000:NameValue):Item = 'thing2' (CHARACTER)
          (0x03000000:NameValue):Item = 2 (INTEGER)
          (0x03000000:NameValue):Item = 2.02E+1 (FLOAT)
        )
      )
    )
  )
```

This message tree is accessed through ESQL in the following way (you can use either the name *Item* or an asterisk (*) as a wildcard):

```
InputRoot.JSON.Data.orders.Item[1].Item[1]   -- 'thing1'
InputRoot.JSON.Data.orders.*[2].*[3]         -- 2.02E+1
```

The message tree is accessed through PHP as:

```
 $output_assembly->JSON->Data.orders[0][0]   // "thing1"
 $output_assembly->JSON->Data.orders[1][2]   // 2.02E+1
```

The message tree is accessed through Java in the following way (you can use either the name *Item*, which the JSON parser gives to array items, or an asterisk (*) as a wildcard):

```
inMessage.getRootElement().getFirstElementByPath("/JSON/Data/orders/Item[1]/Item[1]");  // 'thing1'
inMessage.getRootElement().getFirstElementByPath("/JSON/Data/orders/*[2]/*[3]");  // '2.02'
```

"Managing ESQL files" on page 2390
In a message flow project, manage ESQL files that contain the ESQL code that you provide to modify or customize the behavior of Compute, Database, DatabaseInput, and Filter nodes.

Using the CALL statement to call a user-written routine:

The ESQL CALL statement calls routines that have been created and implemented in different ways.

About this task

A routine is a user-defined function or procedure that has been defined by one of the following statements:
- CREATE FUNCTION
- CREATE PROCEDURE

You can use the CALL statement to call a routine that has been implemented in any of the following ways:
- ESQL
- Java
- As a stored procedure in a database
- As a built-in (broker-provided) function

  You can use CALL to call built-in (broker-provided) functions and user-defined SQL functions, but typically you would use their names directly in expressions .

For details of the syntax and parameters of the CALL statement, see "CALL statement" on page 5077. For an example of the use of CALL, see the examples in

“CREATE PROCEDURE statement” on page 5103.

Calling an ESQL routine:
About this task

A routine is called as an ESQL method if the routine's definition specifies a LANGUAGE clause of ESQL or if the routine is a built-in function. An exact one-to-one matching of the data types and directions of each parameter, between the definition and the CALL, is required. An ESQL routine is allowed to return any ESQL data type, excluding List and Row.

Calling a Java routine:
About this task

A routine is called as a Java method if the routine's definition specifies a LANGUAGE clause of JAVA. An exact one-to-one matching of the data types and directions of each parameter, between the definition and the CALL, is required. If the Java method has a void return type, the INTO clause cannot be used because no value exists to return.

A Java routine can return any data type in the “ESQL-to-Java data-type mapping table” on page 5043, excluding List and Row.

Calling a database stored procedure:
About this task

A routine is called as a database stored procedure if the routine's definition has a LANGUAGE clause of DATABASE.

When a call is made to a database stored procedure, the broker searches for a definition (created by a CREATE PROCEDURE statement) that matches the procedure's local name. The broker then uses the following sequence to resolve the name by which the procedure is known in the database and the database schema to which it belongs:

1. If the CALL statement specifies an IN clause, the name of the data source, the database schema, or both, is taken from the IN clause.
2. If the name of the data source is not provided by an IN clause on the CALL statement, it is taken from the DATASOURCE attribute of the node.
3. If the database schema is not provided by an IN clause on the CALL statement, but is specified on the EXTERNAL NAME clause of the CREATE PROCEDURE statement, it is taken from the EXTERNAL NAME clause.
4. If no database schema is specified on the EXTERNAL NAME clause of the CREATE PROCEDURE statement, the database's user name is used as the schema name. If a matching procedure is found, the routine is called.

The chief use of the CALL statement's IN clause is that it allows the data source, the database schema, or both, to be chosen dynamically at run time. (The EXTERNAL SCHEMA clause also allows the database schema which contains the stored procedure to be chosen dynamically, but it is not as flexible as the IN clause and is retained only for compatibility with earlier versions. Its use in new applications is deprecated.)

If the called routine has any DYNAMIC RESULT SETS specified in its definition, the number of expressions in the CALL statement's *ParameterList* must match the number of parameters to the routine, plus the number of DYNAMIC RESULT

SETS. For example, if the routine has three parameters and two DYNAMIC RESULT SETS, the CALL statement must pass five parameters to the called routine. The parameters passed for the two DYNAMIC RESULT SETS must be list parameters; that is, they must be field references qualified with array brackets [ ]; for example, Environment.ResultSet1[].

A database stored procedure is allowed to return any ESQL data type, excluding Interval, List, and Row.

Accessing broker properties from ESQL:

You can access broker properties, at run time, from the ESQL modules in your message flow nodes.

About this task

You can use broker properties on the right side of regular SET statements. For example:

```
DECLARE mybroker CHARACTER;
SET mybroker = BrokerName;
```

where `BrokerName` is the broker property that contains the name of the broker on which the message flow is running. However, you cannot use broker properties on the left side of SET statements. This restriction exists because, at run time, broker properties are constants: they cannot be modified, therefore their values cannot be changed by SET statements. If a program tries to change the value of a broker property, the error message `Cannot assign to a symbolic constant` is issued.

Broker properties:

- Are grouped by broker, execution group, flow, and node.
- Are case sensitive. Their names always start with an uppercase letter.

- Return NULL if they do not contain a value.

If your ESQL code already contains a variable with the same name as one of the broker properties, your variable takes precedence; that is, your variable masks the broker property. To access the broker property, use the form `SQL.<broker_property_name>`. For example: `SQL.BrokerName`.

"Broker properties that are accessible from ESQL and Java" on page 5302 shows the broker, flow, and node properties that are accessible from ESQL and indicates which properties are also accessible from Java.

Related concepts:

"Broker properties" on page 1144
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

Related tasks:

"Accessing broker properties from the JavaCompute node" on page 2658
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your Java programs. It can be useful, during the run time of your code, to have real-time access to details of a specific node, flow, or broker.

You can access broker, message flow, and node properties from ESQL and Java.

Configuring a message flow at deployment time with user-defined properties:

Use user-defined properties (UDPs) to configure message flows at deployment and run time, without modifying program code. You can give a UDP an initial value when you declare it in your program, or when you use the Message Flow editor to create or modify a message flow.

Before you begin

Before you start:

For an overview of user-defined properties, see "User-defined properties" on page 1147.

For an example of how to code a UDP statement, see "DECLARE statement" on page 5117.

About this task

In ESQL, you can define UDPs at the module or schema level. After a UDP has been defined in the Message Flow editor, you can modify the value before you deploy it.

To configure UDPs, complete the following steps.

Procedure

1. Open the broker archive (BAR) file. The contents of the BAR file are shown in the **Manage** page of the Broker Archive editor. On this page, you can expand a flow to show the individual nodes that it contains.
2. Click the message flow in which you are interested (not the `.cmf` compiled message flow file). The UDPs that are defined in that flow are displayed with their values in the **Properties** view.
3. If the value of the UDP is unsuitable for your current environment or task, change it to an appropriate value. The value of the UDP is set at the flow level, and is the same for all eligible nodes that are contained in the flow. If a subflow includes a UDP that has the same name as a UDP in the main flow, the value of the UDP in the subflow is not changed.
4. Save your BAR file.

Results

Next:

Deploy the message flow by following the instructions in "Deploying a broker archive file" on page 3235.

These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

Developing Java

When you use the JavaCompute node, you customize it to determine the exact processing that it provides.

About this task

To tailor the behavior of each node, create a Java class file that provides the processing that you want. You manage Java files through the Java perspective.

You can add any valid Java code to a JavaCompute node, making full use of the Java user-defined node API to process an incoming message. You can use the Java editing facilities of the Eclipse platform to develop your Java code. These facilities include:

- Code completion
- Integrated Javadoc documentation
- Automatic compilation

The Java user-defined node API includes some extra methods that simplify tasks that involve message routing and transformation. These tasks include accessing named elements in a message tree, setting their values, and creating elements, without the need to navigate the tree explicitly.

Use the Debug perspective to debug a message flow that contains a JavaCompute node. When control passes to a JavaCompute node during debugging, the perspective opens the Java debugger, and you can step through the Java class code for the node.

This section provides the following information on developing Java:

- "Managing Java Files" on page 2629

Creating Java code for a JavaCompute node:

Use these instructions to associate Java code with your JavaCompute node.

Before you begin

Before you start

To complete this task, you must have already created a JavaCompute node in your message flow.

About this task

To associate Java code with a JavaCompute node, use one of the following methods:

Procedure

- Use the New Java Compute Node Class wizard to create template code. This is a preferred method.
  1. Right-click the node and click **Open Java**.
  2. Navigate the New Java Compute Node Class wizard until you reach the Java Compute Node Class Template page. On the Java Compute Node Class Template page, choose one of the following options:
     - For a filter node template code, select **Filtering message class**.
     - To change an incoming message, select **Modifying message class**.
     - To create a new message, select **Creating message class**.
  3. Click **Finish**.

  You have created template code for your JavaCompute node.
- Associate a JavaCompute node with an existing Java class that the wizard has previously generated; this is the safest way in which you can share the same Java code between multiple nodes. To associate a JavaCompute nodes with an existing Java class, perform the following steps:
  1. Right-click the JavaCompute node and click **Properties**.
  2. Enter the name of the Java class in the **Java Class** field.
  3. Click **OK**.

  You have associated your JavaCompute node with an existing Java class.
- Create a Java project from scratch. Before you add one or more classes to the project, you must perform the following steps:
  1. Open the `.project` file in the text editor, and ensure that the following builders and natures are set:

```
<buildSpec>
  <buildCommand>
   <name>org.eclipse.jdt.core.javabuilder</name>
   <arguments>
   </arguments>
  </buildCommand>
  <buildCommand>
   <name>com.ibm.etools.mft.java.builder.javabuilder</name>
   <arguments>
   </arguments>
  </buildCommand>
  <buildCommand>
   <name>com.ibm.etools.mft.jcn.jcnbuilder</name>
   <arguments>
   </arguments>
  </buildCommand>
  <buildCommand>
   <name>com.ibm.etools.mft.bar.barbuilder</name>
   <arguments>
   </arguments>
  </buildCommand>
 </buildSpec>
 <natures>
  <nature>org.eclipse.jdt.core.javanature</nature>
  <nature>com.ibm.etools.mft.bar.barnature</nature>
  <nature>com.ibm.etools.mft.jcn.jcnnature</nature>
 </natures>
```

2. Add the following plug-ins to the build path of the Java project:
   a. Open the properties of the Java project.
   b. Select **Java Build Path** and open the **Libraries** tab.
   c. Click **Add Variable**.
   d. Select the variable `JCN_HOME` and click **OK**.
   e. Double-click the variable you added to open the **Edit Variable Entry** dialog.
   f. Click **Extension** and select `javacompute.jar`.
   g. Repeat the previous four steps to add the variable `JCN_HOME/jplugin2.jar`.
3. Create the appropriate Java class and ensure that it extends from `com.ibm.broker.javacompute.MbJavaComputeNode`.

You have created your Java project.

What to do next

You can now perform the following tasks:

Opening an existing Java file:

You can add to and modify Java code that you have created in a Java project.

Before you begin

Before you start

Before you start this task, complete the following tasks:

- Add a "JavaCompute node" on page 4514 to your message flow.
- "Creating Java code for a JavaCompute node" on page 2629

About this task

To open an existing Java file:

Procedure

1. Switch to the Java perspective.
2. In the Package Explorer view, double-click the Java file that you want to open. The file is opened in the editor view.
3. Work with the contents of the file to make your changes.

Results

You can also open a Java file when you have a message flow open in the editor view. Right-click the JavaCompute node, then select **Open Java**.

What to do next

Next:

You can now perform the following tasks:

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Adding Java code dependencies:

When you write Java code for a JavaCompute node, you can include references to other Java projects and JAR files.

Before you begin

Before you start

To complete this task, you must have completed the following tasks:
- Add a "JavaCompute node" on page 4514 to your message flow.
- Create Java code for a JavaCompute node.

About this task

The Java code in a JavaCompute node might contain references to other Java projects in the Eclipse workspace (internal dependencies), or to external JAR files, for example the JavaMail API (external dependencies), or a set of JAXB Java object classes (internal or external). If other JAR files are referenced, you must add the files to the project class path.

Procedure

1. Right-click the project folder for the project on which you are working, and click **Properties**.
2. Click **Java Build Path** in the left pane.
3. Click the **Libraries** tab.
4. Complete one of the following steps:
   - To add an internal dependency, click **Add JARs**, select the JAR file that you want to add, then click **OK**.
   - To add an external dependency, click **Add External JARs**, select the JAR file that you want to add, then click **Open**. Copy the JAR file to the `shared-classes` directory required. For more details of the `shared-classes` directories available and the effects of each, see "Java shared classloader" on page 2637. If you do not copy the JAR file to a valid `shared-classes` directory, `ClassNotFoundException` exceptions are generated at run time.

Results

You have now added a code dependency.

Related tasks:

If the message processing requires it, you can include other nodes after the input node that are customized in Java to complete the actions that your applications need.

"Changing the location of the work path" on page 1011
The work path directory is the location where a component stores internal data, such as installation logs, component details, and trace output. The shared-classes directory is also located in the work path directory and is used for deployed Java code. If the work path directory does not have enough capacity, redirect the directory to another file system that has enough capacity.

"Java shared classloader" on page 2637
Loads all the JAR files located within the shared-classes directories. The precedence order of loading is dictated by the directories the JAR files are located in.

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Deploying JavaCompute node code:

The WebSphere Message Broker Toolkit handles the deploying of JavaCompute node code automatically. When you create a BAR file and add the message flow, the WebSphere Message Broker Toolkit packages the compiled Java code and its dependencies into the BAR file.

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

JavaCompute node classloading:

Details the default Java classloader options and the precedence order of each type.

The JavaCompute node loads and runs a Java class defined as the `Java class` property on the node. Normally, this class is deployed, along with any other required classes, in a Java archive (JAR) file contained in the broker archive (BAR) file that is used to deploy the flow containing the JavaCompute node.

Any Java classes deployed in this way are loaded by an execution group-wide classloader. Whenever a new or changed JAR file is deployed, the execution group-wide classloader is deleted and recreated with all the currently deployed JAR files. At the same time all JavaCompute nodes refresh the Java classes being used within them, as well as recreating all the Java static variables. It is possible to modify this behavior by using the `JavaClassLoader configurable service` property on the node, which allows alternative classloaders to be used. For more details, see "JavaCompute node classloading using a configurable service" on page 2636.

The execution group-wide classloader first searches all the deployed JAR files for a required class. If a required class cannot be found, it defers to the shared classloader. The shared classloader looks in a set of directories on the broker machine and loads any JAR files found. It can be used to install any required JAR files that do not need to be repeatedly deployed, such as client libraries that the JavaCompute nodes need to use. For more details, see "Java shared classloader" on page 2637.

If the required class cannot be found in any of the deployed JAR files, or in the JAR files installed in the shared classes directories, a classloader containing all of the broker supplied classes is checked (for example: this classloader contains the `jplugin2.jar`), followed by the classpath, and then finally the Java virtual machine (JVM) system classloader.

Two key points must be considered when deciding which of the above mechanisms are used to load a class:

- Isolation between different applications (for example: adding classes to the classpath makes them available to every part of WebSphere Message Broker and can cause conflicts). `JavaClassLoader configurable service` can also be used to isolate JavaCompute nodes in the same execution group.
- Delegation from one classloader to another can only occur in one direction. If a class is resolved in the shared classloader, then it cannot directly create classes in the execution group-wide classloader.

JavaCompute node classloading using a configurable service:

Details alternative configurable Java classloader options and the precedence order of each type.

The JavaCompute node loads and runs a Java class defined as the `Java class` property on the node. Normally, this class is deployed, along with any other required classes, in a Java archive (JAR) file contained in the broker archive (BAR) file that is used to deploy the flow containing the JavaCompute node.

Any Java classes deployed in this way are loaded by an execution group-wide classloader. It is possible to override this behavior by using the `JavaClassLoader configurable service` property on the node.

The classloader defined by the `JavaClassLoader configurable service` has a list of JAR files, defined by the `includedDeployedJars` property, which it will own and use. Whenever these JAR files are deployed, the configurable service classloader receives the JAR files and uses them for resolving classes. The JAR files are no longer available to the execution group classloader, and any node using that classloader will not have access to any classes contained in those JAR files.

The configurable service classloader first searches all the deployed JAR files it has received for a required class. If a required class cannot be found, it defers to the shared classloader. The shared classloader looks in a set of directories on the broker machine and loads any JAR files found. It can be used to install any required JAR files that do not need to be repeatedly deployed, such as client libraries that the JavaCompute nodes need to use. For more details, see "Java shared classloader" on page 2637. This mechanism can be overridden by setting the `sharedJarPath` property on the configurable service in order to use a specified directory to find installed JAR files, rather than the shared classes directories.

If the required class cannot be found in any of the deployed JAR files, or in the JAR files installed in the shared classes directories, a classloader containing all of the broker supplied classes is checked (for example: this classloader contains the `jplugin2.jar`), followed by the classpath, and then finally the Java virtual machine (JVM) system classloader.

For information about how to create a `JavaClassLoader configurable service`, see "**mqsicreateconfigurableservice** command" on page 3849. Properties of the `JavaClassLoader configurable service` are defined in "JavaClassLoader configurable service" on page 3777.

Java shared classloader:

Loads all the JAR files located within the shared-classes directories. The precedence order of loading is dictated by the directories the JAR files are located in.

Before you begin

Before you start

Determine the broker *workpath* to use by running the **mqsireportbroker** command as follows:

```
mqsireportbroker <my_broker_name>
```

See the "**mqsireportbroker** command" on page 3919 for an example output from the command. On z/OS the *workpath* is usually referred to as the *component* directory.

About this task

JAR files are loaded in the following precedence order:

Procedure

1. JAR files placed in the execution group `shared-classes` directory allow only a single defined execution group to access them. Files placed in here are loaded first. No other execution groups can use them.

   Add the JAR files to the following directory:

   - For Windows

workpath\config\<*my_broker_name*>\<*my_eg_label*>\shared-classes

- For Linux, UNIX, and z/OS

  workpath/config/<*my_broker_name*>/<*my_eg_label*>/shared-classes

Ensure that the broker name, and any execution groups created, contain only characters that are valid on your file system. You may also need to create the required directory structure.

All files placed into the execution group `shared-classes` directory that have a `.jar` extension, are loaded and made available in the broker Java environment for that execution group. JAR files in this directory take precedence over JAR files in the top level `shared-classes` directory.

Note: The execution group `shared-classes` directory is not automatically removed when the execution group is deleted. Manually delete the directory if no longer required.

2. JAR files placed in the top level `shared-classes` directory are made available to all brokers and all execution groups. Files placed in here are loaded after any files placed in the execution group `shared-classes` directory.

   Add the JAR files to the following directory:

   - For Windows

     workpath\shared-classes

   - For Linux, UNIX and z/OS

     workpath/shared-classes

Writing Java

When you create a message flow, you include input nodes that receive messages and, optionally, output nodes that send out new or updated messages. If the message processing requires it, you can include other nodes after the input node that are customized in Java to complete the actions that your applications need.

About this task

You can customize the processing that some of the built-in nodes provide. In a JavaCompute node, you can provide Java code that controls precisely the behavior of the node. This set of topics discusses how you can use Java to customize the JavaCompute node.

You can use a JavaCompute node to check and manipulate message content. The node can read the contents of the input message, then construct new output messages that are created from all, part, or none of the input message.

Use the Debug perspective to debug a message flow that contains a JavaCompute node. When control passes to a JavaCompute node during debugging, the perspective opens the Java debugger, allowing you to step through the Java class code for the node.

This section provides more information about writing Java:

Accessing elements in a message tree from a JavaCompute node:

Access the contents of a message, for reading or writing, using the structure and arrangement of the elements in the tree that the parser creates from the input bit stream.

About this task

Follow the relevant parent and child relationships from the top of the tree downwards until you reach the required element.

The message tree is passed to a JavaCompute node as an argument of the evaluate method. The argument is an MbMessageAssembly object. MbMessageAssembly contains four message objects:

- Message
- Local Environment
- Global Environment
- Exception List

These objects are read-only, except for Global Environment. If you try to write to the read-only objects, an MbReadOnlyException is issued.

This topic contains the following information about accessing elements in a message tree:

- "Traversing the element tree"
- "Accessing information about an element" on page 2642

Traversing the element tree:
About this task

The following table shows the Java methods that you can use to access element trees, and the equivalent ESQL field type constant for each point in the tree.

Java accessor from MbMessageAssembly	ESQL field type constant
getMessage().getRootElement()	InputRoot
getMessage().getRootElement().getLastChild()	InputBody
getLocalEnvironment().getRootElement()	InputLocalEnvironment
getGlobalEnvironment().getRootElement()	Environment
getExceptionList().getRootElement()	InputExceptionList

Use the following methods to traverse a message tree from an element of type MbElement:

getParent()
returns the parent of the current element

getPreviousSibling()
returns the previous sibling of the current element

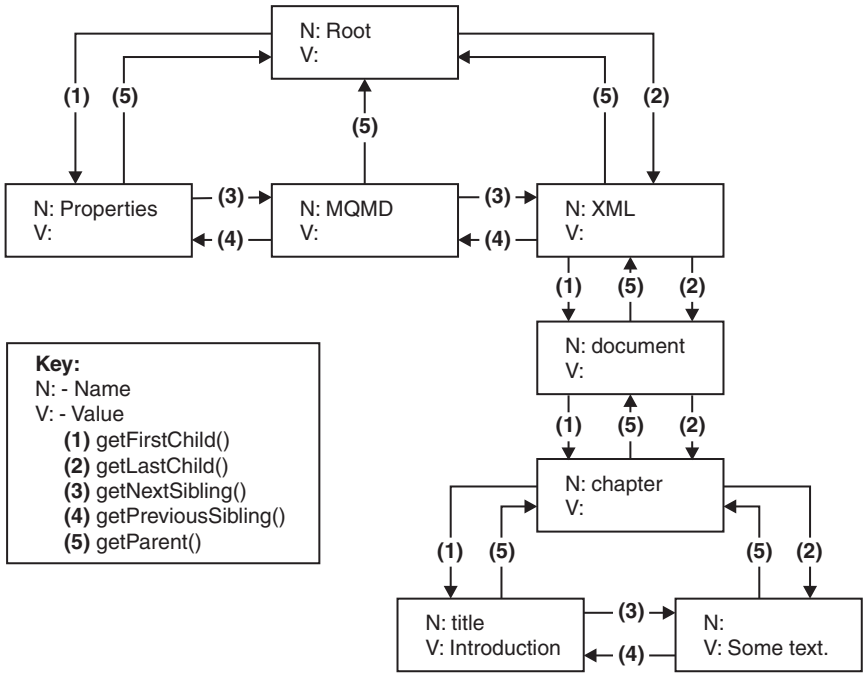
getNextSibling()
returns the next sibling of the current element

getFirstChild()
returns the first child of the current element

getLastChild()
returns the last child of the current element

The following example shows a simple XML message and the logical tree that would be created from the message. The message has been sent using WebSphere MQ. The logical tree diagram also shows the methods to call in order to navigate around the tree.

```
<document>
  <chapter title='Introduction'>
    Some text
  </chapter>
</document>
```



The tree used in this diagram is the one that is created by parsing the previous XML example.

- From the Root part of the tree, calling **getFirstChild()** navigates to Properties. Also from Root, calling **getLastChild()** returns XML.
- From Properties, calling **getParent()** returns Root, and calling **getNextSibling()** returns MQMD.

- From MQMD, calling **getPreviousSibling()** returns Properties, calling **getParent()** returns Root, and calling **getNextSibling()** returns XML.
- From XML, calling **getPreviousSibling()** returns MQMD, calling **getParent()** returns Root, calling **getFirstChild()** returns document, and calling **getLastChild()** also returns document.
- From document, calling **getParent()** returns XML, calling **getFirstChild()** returns chapter, and calling **getLastChild()** also returns chapter.
- From chapter, calling **getParent()** returns document, calling **getFirstChild()** returns title, and calling **getLastChild()** returns the child that contains the message data "Some text.".

The following Java code accesses the chapter element in the logical tree for an XML message that does not contain white spaces. The XML parser retains white space in the parsed tree, but the XMLNS and XMLNSC parsers do not.

```
MbElement root = assembly.getMessage().getRootElement();
MbElement chapter = root.getLastChild().getFirstChild().getFirstChild();
```

Accessing information about an element:
About this task

Use the following methods to return information about the referenced element:

getName()
returns the element name as a java.lang.String

getValue()
returns the element value

getType()
returns the generic type, which is one of the following types:
- NAME: an element of this type has a name, but no value.
- VALUE: an element of this type has a value, but no name.
- NAME/VALUE: an element of this type has both a value and a name.

getSpecificType()
returns the parser-specific type of the element

getNamespace()
returns the namespace URI of this element

Java user-defined extensions API

Transforming a message by using a JavaCompute node:

You can transform a message by using the JavaCompute node.

The following topics describe how to transform messages by using the JavaCompute node:

- "Creating a new message by using a JavaCompute node"
- "Copying a message by using a JavaCompute node" on page 2644
- "Setting, copying, and moving message elements by using a JavaCompute node" on page 2644
- "Creating new elements by using a JavaCompute node" on page 2646

Creating a new message by using a JavaCompute node:

Many message transformation scenarios require a new outgoing message to be built. The *Create Message Class* template in the JavaCompute node wizard generates template code for this.

About this task

In the template code, the default constructor of MbMessage is called to create a blank message, as shown in the following Java code:

```
MbMessage outMessage = new MbMessage();
```

The headers can be copied from the incoming message by using the supplied utility method, copyMessageHeaders(), as shown in this Java code:

```
copyMessageHeaders(inMessage, outMessage);
```

The new message body can now be created. First, add the top level parser element. For XML, this is:

```
MbElement outRoot = outMessage.getRootElement();
MbElement outBody = outRoot.createElementAsLastChild(MbXMLNSC.PARSER_NAME);
```

The remainder of the message can then be built up by using the **createElement** methods and the extended syntax of the broker XPath implementation.

When you want to create a BLOB message, that is handled as a single byte string by using the BLOB parser domain. The message data is added as a byte array to the single element named "BLOB" under the parser level element, described as follows:

```
String myMsg = "The Message Data";
MbElement outRoot = outMessage.getRootElement();
// Create the Broker Blob Parser element
MbElement outParser = outRoot.createElementAsLastChild(MbBLOB.PARSER_NAME);
// Create the BLOB element in the Blob parser domain with the required text
MbElement outBody = outParser.createElementAsLastChild(MbElement.TYPE_NAME_VALUE, "BLOB", myMsg.getBytes());
```

You can use the following code to create a BLOB message in a JavaCompute node:

```
MbElement outMsgRootEl = outMessage.getRootElement();

String parserName = MbBLOB.PARSER_NAME;
String messageType = "";
String messageSet = "";
String messageFormat = "";
int encoding = 0;
int ccsid = 0;
int options = 0;
outMsgRootEl.createElementAsLastChildFromBitstream(responseBodyXmlData,
  parserName, messageType, messageSet, messageFormat, encoding, ccsid,
  options);
```

To add a JSON message in a JavaCompute node, see “Creating a JSON message” on page 2618.

Use the JavaCompute node to work with messages by using the Java language.

Copying a message by using a JavaCompute node:

You can copy a message by using a JavaCompute node.

About this task

The incoming message and message assembly are read-only. To modify a message, a copy of the incoming message must be made. The *Modifying Message Class* template in the JavaCompute node wizard generates this copy. The following copy constructors are called:

```
MbMessage outMessage = new MbMessage(inAssembly.getMessage());
MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly, outMessage);
```

The new outAssembly object is propagated to the next node.

Setting, copying, and moving message elements by using a JavaCompute node:

Transform elements in the message as it passes through a JavaCompute node in the message flow.

Before you begin

Before you start:

The incoming message and message assembly are read-only. Therefore, to modify a message, you must make a copy of it first. For more information, see “Copying a message by using a JavaCompute node.”

About this task

- “Setting information about an element” on page 2645
- “Moving and copying elements” on page 2645

The Java API reference information provides details about each of the methods used in the following sections:

Setting information about an element:
About this task

Use these methods to set information about the referenced element:

setName()
Sets the name of the element

setValue()
Sets the value of the element

setSpecificType()
Sets the parser-specific type of the element

setNamespace()
Sets the namespace URI of the element

Moving and copying elements:
About this task

Use a JavaCompute node to copy or detach an element from a message tree by using the following methods:

`detach()`
The element is detached from its parent and siblings, but any child elements are left attached

`copy()` A copy of the element and its attached children is created

Use one of four methods to attach an element or subtree that you have copied on to another tree:

`addAsFirstChild(`*element*`)`
Adds an unattached element as the first child of *element*

`addAsLastChild(`*element*`)`
Adds an unattached element as the last child of *element*

`addBefore(`*element*`)`
Adds an unattached element as the previous sibling of *element*

`addAfter(`*element*`)`
Adds an unattached element as the next sibling of *element*

Creating new elements by using a JavaCompute node:

You can use a JavaCompute node to create new elements.

About this task

Use the following methods in a JavaCompute node to create new elements in a message tree:

- createElementAsFirstChild()
- createElementAsLastChild()
- createElementBefore()
- createElementAfter()

The method returns a reference to the newly-created element. Each method has three overloaded forms:

createElement...(int type)
Creates a blank element of the specified type. Valid generic types are:

- MbElement.TYPE_NAME. This type of element has only a name, for example an XML element.
- MbElement.TYPE_VALUE. This type of element has only a value, for example XML text that is not contained in an XML element.
- MbElement.TYPE_NAME_VALUE. This type of element has both a name and a value, for example an XML attribute.

Specific type values can also be assigned. The meaning of this type information is dependent on the parser. Element name and value information must be assigned by using the setName() and setValue() methods.

createElement...(int type, String name, Object value)
Method for setting the name and value of the element at creation time.

createElement...(String parserName)
A special form of createElement...() that is only used to create top-level parser elements.

This example Java code adds a new chapter element to the XML example given in "Accessing elements in a message tree from a JavaCompute node" on page 2640:

```
MbElement root = outMessage.getRootElement();
MbElement document = root.getLastChild().getFirstChild();
MbElement chapter2 = document.createElementAsLastChild(MbElement.TYPE_NAME,"Chapter",null);

// add title attribute
MbElement title2 = chapter2.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE,
 "title", "Message Flows");
```

This produces the following XML output:

```
<document>
 <chapter title="Introduction">
  Some text.
 </chapter>
 <chapter title="Message Flows"/>
</document>
```

Related tasks:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Creating a simple filter by using a JavaCompute node:

The JavaCompute node has two output terminals: Out and Alternate. To use the JavaCompute node as a filter node, propagate a message to either the Out or Alternate terminal based on the message content.

Before you begin

Before you start

To complete this task, you must have added a "JavaCompute node" on page 4514 to your message flow.

About this task

Use the JavaCompute node creation wizard to generate template code for a filter node:

Procedure

Select the *Filtering Message Class* template in the JavaCompute node creation wizard to create a filter node.
The following template code is produced. It passes the input message to the Out terminal without doing any processing on the message.

```
public class jcn2 extends MbJavaComputeNode {

  public void evaluate(MbMessageAssembly assembly) throws MbException {
    MbOutputTerminal out = getOutputTerminal("out");
    MbOutputTerminal alt = getOutputTerminal("alternate");

    MbMessage message = assembly.getMessage();

    // ----------------------------------------------------------
    // Add user code below

    // End of user code
    // ----------------------------------------------------------

    // The following should only be changed
    // if not propagating message to the 'out' terminal

    out.propagate(assembly);
  }
}
```

The template produces a partial implementation of a method called evaluate(). The broker calls evaluate() once for each message that passes through the node. The parameter that is passed to evaluate() is the message assembly. The message assembly encapsulates the message that is passed on from the previous node in the message flow.
Add custom code to the template, and propagate messages to both the Out and Alternate terminals to create a message filter.

Related tasks:

"Propagating a message to the JavaCompute node Out and Alternate terminals"
The JavaCompute node has two output terminals, Out and Alternate. Therefore, you can use the node both as a filter node and as a message transformation node. After you have processed the message, propagate the message to an output terminal by using a propagate() method.

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Propagating a message to the JavaCompute node Out and Alternate terminals:

The JavaCompute node has two output terminals, Out and Alternate. Therefore, you can use the node both as a filter node and as a message transformation node. After you have processed the message, propagate the message to an output terminal by using a propagate() method.

About this task

To propagate the message assembly to the Out terminal use the following method:

```
out.propagate(assembly);
```

To propagate the message assembly to the Alternate terminal, use the following method:

```
alt.propagate(assembly);
```

To propagate the same MbMessage object multiple times, call the finalizeMessage() method on the MBMessage object, so that any changes made to the message are reflected in the bit stream that is generated downstream of the JavaCompute node; for example:

```
MbMessage outMessage = new MbMessage(inMessage);
MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly, outMessage);
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(outAssembly);
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(outAssembly);
```

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Extracting information from a message by using XPath 1.0 and a JavaCompute node:

XPath is a query language designed for use with XML documents, but you can use it with any tree structure to query contents.

WebSphere Message Broker uses XPath to select elements from the logical message tree regardless of the format of the bit stream. The terminology used in this topic is based on the terminology used in the W3C definition of XPath 1.0. For more information about XPath, see "Using XPath" on page 1506; and for more information about the W3C definition of the XPath 1.0 standard, see W3C XPath 1.0 Specification. For examples of XPath use, see the MbXPath topic in the "Java user-defined node API" on page 5312 documentation.

This topic contains the following information:

Using the evaluateXPath method to extract message information

The evaluateXPath() method is included in the Java user-defined node API. It supports XPath 1.0, with the following exceptions:

- Namespace axis and namespace node type. The namespace axis returns the actual XML namespace declaration nodes for a particular element. You can therefore manipulate XML prefix or URI declarations within an XPath expression. This axis returns an empty node set for bit streams that are not XML.
- If you use the **id()** function, it throws an MbRecoverableException.

The evaluateXPath() method can be called on a MbMessage object (for absolute paths), or on a MbElement object (for relative paths). The XPath expression is passed to the method as a string parameter. A second form of this method is provided that takes an MbXPath object. This object encapsulates an XPath expression along with variable bindings and namespace mappings, if these are required.

The evaluateXPath() method returns an object of one of these four types, depending on the expression return type:

- java.lang.Boolean, representing the XPath Boolean type
- java.lang.Double, representing the XPath number type
- java.lang.String, representing the XPath string type
- java.util.List, representing the XPath node set. The List interface represents an ordered sequence of objects, in this case MbElements. It allows direct access to the elements, or the ability to get an Iterator or an MbElement array.

XPath variable binding

XPath 1.0 supports the ability to refer to variables that have been assigned before the expression that contains them is evaluated. The MbXPath class has three methods for assigning and removing these variable bindings from user Java code. The value must be one of the four XPath 1.0 supported types:

- Boolean
- node set
- number
- string

XPath namespace support

For XML messages, namespaces are referred to by using a mapping from an abbreviated namespace prefix to the full namespace URI, as shown in the following XML example:

```
<ns1:aaa xmlns:ns1='http://mydomain.com/namespace1'
         xmlns:ns2='http://mydomain.com/namespace2'>
  <ns2:aaa>
    <ns1:bbb/>
  </ns2:aaa>
</ns1:aaa>
```

The namespace prefix is convenient for representing the namespace, but is meaningful only within the document that defines that mapping. The namespace URI defines the global meaning. Also, the concept of a namespace prefix is not meaningful for documents that are generated in a message flow, because a namespace URI can be assigned to a syntax element without an XMLNS mapping having been defined.

For this reason, the XMLNSC and MRM parsers expose only the namespace URI to the broker and to user code (ESQL or user-defined code). By using ESQL, you can set up your own mappings to create abbreviations to these potentially long URIs. These mappings are not related in any way to the prefixes that are defined in the XML document (although they can be the same name).

By using the XPath processor you can map namespace abbreviations on to URIs that are expanded at evaluation time. The MbXPath class contains methods to assign and remove these namespace mappings. For example:

```
MbXPath xp = new MbXPath("/aaa/other:aaa/bbb");
xp.addNamespacePrefix("other", "http://mydomain.com/namespace2");
xp.setDefaultNamespace("http://mydomain.com/namespace2");
List nodeset = (List)message.evaluateXPath(xp);
```

Updating a message by using XPath extensions

The XPath implementation in WebSphere Message Broker provides the following extra functions for modifying the message tree:

set-local-name(*object*)
: Sets the local part of the expanded name of the context node to the value specified in the argument. *object* can be any valid expression, and is converted to a string as if a call to the string function is used.

set-namespace-uri(*object*)
: Sets the namespace URI part of the expanded name of the context node to the value specified in the argument. *object* can be any valid expression, and is converted to a string as if a call to the string function is used.

set-value(*object*)
: This function sets the string value of the context node to the value specified in the argument. *object* can be any valid expression, and is converted to a string as if a call to the string function is used.

To allow for syntax element trees to be built as well as modified, the following axis is available in addition to the 13 that are defined in the XPath 1.0 specification:

select-or-create::*name* or ?*name*
: ?*name* is equivalent to select-or-create::*name*. If *name* is @name, an attribute

is created or selected. This selects child nodes matching the specified name, or creates new nodes according to the following rules:

- ?*name* selects children called *name* if they exist. If a child called *name* does not exist, ?*name* creates it as the last child, then selects it.
- ?$*name* creates *name* as the last child, then selects it.
- ?^*name* creates *name* as the first child, then selects it.
- ?>*name* creates *name* as the next sibling, then selects it.
- ?<*name* creates *name* as the previous sibling, then selects it.

Manipulating other parts of the message tree by using a JavaCompute node:

You can access parts of the message tree other than the message body data. These parts of the logical tree are independent of the domain in which the message exists, and all these topics apply to messages in all supported domains, including the BLOB domain. You can access all parts of the message tree by using a JavaCompute node.

About this task

Elements of the message tree can be accessed in the same way as the message body data, by using a JavaCompute node.

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Accessing headers by using a JavaCompute node:

You can access headers by using a JavaCompute node.

About this task

If an input node receives an input message that includes message headers that the input node recognizes, the node starts the correct parser for each header. Parsers are supplied for most WebSphere MQ headers. The following topics provide guidance for accessing the information in the MQMD and MQRFH2 headers that you can follow when accessing other headers that are present in your messages.

- "Copying message headers by using a JavaCompute node"
- "Accessing the MQMD header by using a JavaCompute node" on page 2653
- "Accessing the MQRFH2 header by using a JavaCompute node" on page 2654

For further details of the contents of these and other WebSphere MQ headers for which WebSphere Message Broker provides a parser, see "Element definitions for message parsers" on page 4237.

Copying message headers by using a JavaCompute node:

You can copy message headers by using a JavaCompute node.

The *Modifying Message Class* template in the JavaCompute node wizard generates the following code to copy message headers using a JavaCompute node:

```
public void copyMessageHeaders(MbMessage inMessage, MbMessage outMessage) throws MbException
{
 MbElement outRoot = outMessage.getRootElement();
 MbElement header = inMessage.getRootElement().getFirstChild();

 while(header != null && header.getNextSibling() != null)
 {
  outRoot.addAsLastChild(header.copy());
  header = header.getNextSibling();
 }
}
```

Use the JavaCompute node to work with messages by using the Java language.

Accessing the MQMD header by using a JavaCompute node:

WebSphere MQ and WebSphere MQ Everyplace messages include an MQMD header. You can use a JavaCompute node to refer to the fields in the MQMD, and to update them.

About this task

The following Java code shows how to add an MQMD header to your message:

```
public void addMqmd(MbMessage msg) throws MbException
{
 MbElement root = msg.getRootElement();

 // create a top level 'parser' element with parser class name
 MbElement mqmd = root.createElementAsFirstChild("MQHMD");

 // specify next parser in chain
 mqmd.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE,
  "Format",
  "XMLNS");
}
```

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Accessing the MQRFH2 header by using a JavaCompute node:

You can use a JavaCompute node to add an MQRFH2 header to an outgoing message.

About this task

When you construct MQRFH2 headers in a JavaCompute node, two types of field exist:

- Fields in the MQRFH2 header structure (for example, Format and NameValueCCSID)
- Fields in the MQRFH2 NameValue buffer (for example mcd and psc)

The following code adds an MQRFH2 header to an outgoing message that is to be used to make a subscription request:

```
public void addRfh2(MbMessage msg) throws MbException
{
 MbElement root = msg.getRootElement();
 MbElement body = root.getLastChild();

 // insert new header before the message body
 MbElement rfh2 = body.createElementBefore("MQHRF2");

 rfh2.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "Version", new Integer(2));
 rfh2.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "Format", "MQSTR");
 rfh2.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "NameValueCCSID", new Integer(1208));

 MbElement psc = rfh2.createElementAsFirstChild(MbElement.TYPE_NAME, "psc", null);
 psc.createElementAsFirstChild(MbElement.TYPE_NAME, "Command", "RegSub");
 psc.createElementAsFirstChild(MbElement.TYPE_NAME, "Topic", "department");
 psc.createElementAsFirstChild(MbElement.TYPE_NAME, "QMgrName", "QM1");
 psc.createElementAsFirstChild(MbElement.TYPE_NAME, "QName", "PUBOUT");
 psc.createElementAsFirstChild(MbElement.TYPE_NAME, "RegOpt", "PersAsPub");

 MbXPath xp = new MbXPath("/MQMD/Format" + "[set-value(´MQHRF2´)]", root);
 root.evaluateXPath(xp);
}
```

In this example, the `MQHRF2` parameter is the parser class name, which is different from the parser element name (MQRFH2). For a list of the parsers, root element names, and class names for different headers, see "Available parsers" on page 6689.

Updating the local environment with the JavaCompute node:

The local environment tree is part of the logical message tree in which you can store information while the message flow processes the message.

About this task

The following information shows how to update the local environment:

Procedure

1. Make a new copy of the local environment to update it. Use the full version of the copy constructor to create a new MbMessageAssembly object, as shown in the following example:

```
MbMessage env = assembly.getLocalEnvironment();
MbMessage newEnv = new MbMessage(env);

newEnv.getRootElement().createElementAsFirstChild(
  MbElement.TYPE_NAME_VALUE,
  "Status",
  "Success");

MbMessageAssembly outAssembly = new MbMessageAssembly(
  assembly,
  newEnv,
  assembly.getExceptionList(),
  assembly.getMessage());

getOutputTerminal("out").propagate(outAssembly);
```

2. Edit the copy to update the local environment.

Related concepts:

Updating the Global Environment with the JavaCompute node:

The Global Environment tree is always created when the logical tree is created for an input message. However, the message flow neither populates it nor uses its contents. You can use this tree for your own purposes, for example to pass information from one node to another. You can use the whole tree as a scratchpad or working area.

About this task

The Global Environment can be altered across the message flow, therefore do not make a copy of it to alter. The following Java code shows how to alter the Global Environment:

```
MbMessage env = assembly.getGlobalEnvironment();
env.getRootElement().createElementAsFirstChild(MbElement.TYPE_NAME_VALUE, "Status", "Success");

getOutputTerminal("out").propagate(assembly);
```

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Accessing the ExceptionList tree using Java:

The ExceptionList tree is created with the logical tree when an input message is parsed.

About this task

The tree is initially empty, and is only populated if an exception occurs during message flow processing. It is possible that more than one exception can occur; if more than one exception occurs, the ExceptionList tree contains a subtree for each exception.

You can access the ExceptionList tree in JavaCompute nodes from the `MbMessageAssembly` parameter of your `evaluate()` method.

You can access the ExceptionList tree in a node in an error handling procedure. For example, you might want to route the message to a different path based on the type of exception.

You can use the querying capabilities within XPath to carry out this task. The descendant axis (//) of XPath gives you the ability to search for an element by name regardless of its depth in the tree. For example:

```
//ParserException
```

returns all elements in the tree named `ParserException`.

If you are specifically interested in a particular message, you can use a predicate (see predicates for further information) to narrow down the result set. For example:

```
//ParserException[Number=5016]
```

returns only the exception that contains `Number=5016`.

If you only want to extract the text message associated with this exception, the following XPath expression returns this as a `java.lang.String`:

```
string(//ParserException[Number=5016]/Text)
```

The following Java code extracts this text from your code:

```
String text =
(String)inAssembly.getExceptionList().evaluateXPath("string(//ParserException[Number=5016]/Text)");
```

For information on accessing the ExceptionList tree using ESQL, see "Accessing the ExceptionList tree using ESQL" on page 2471

An exception list contains information about exceptions, such as error numbers, the name of the node that generated the exception, and the reason for the exception.

Accessing broker properties from the JavaCompute node:

For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your Java programs. It can be useful, during the run time of your code, to have real-time access to details of a specific node, flow, or broker.

About this task

Broker properties are divided into four categories:

- Properties that relate to a specific node
- Properties that relate to nodes in general
- Properties that relate to a message flow
- Properties that relate to the execution group

"Broker properties that are accessible from ESQL and Java" on page 5302 includes a table that shows the groups of properties that are accessible from Java. The table also indicates if the properties are accessible from ESQL.

Broker properties have the following characteristics.

- They are grouped by broker, execution group, flow, and node.
- They are case sensitive. Their names always start with an uppercase letter.
- They return NULL if they do not contain a value.

To access broker properties in a JavaCompute node, call methods on the following classes:

- MbBroker
- MbExecutionGroup
- MbMessageFlow
- MbNode

For example:

```
String brokerName = getBroker().getName();
```

Related concepts:

"Broker properties" on page 1144
For each broker, WebSphere Message Broker maintains a set of properties. You can access some of these properties from your ESQL programs. A subset of the properties is also accessible from Java programs. It can be useful, at run time, to have real-time access to details of a specific node, flow, or broker.

"User-defined properties in ESQL" on page 2376
Access user-defined properties (UDPs) as variables in your ESQL program by specifying the EXTERNAL keyword on a DECLARE statement. For example, the ESQL statement `DECLARE today EXTERNAL CHARACTER 'monday'` defines a user-defined property called today with an initial value monday.

Related tasks:

"Accessing broker properties from ESQL" on page 2625
You can access broker properties, at run time, from the ESQL modules in your message flow nodes.

"Managing Java Files" on page 2629
The Java code that you provide to modify or customize the behavior of a JavaCompute node is stored in a Java project. WebSphere Message Broker uses the Eclipse Java perspective for developing and administering Java files.

"Writing Java" on page 2638
When you create a message flow, you include input nodes that receive messages and, optionally, output nodes that send out new or updated messages. If the message processing requires it, you can include other nodes after the input node that are customized in Java to complete the actions that your applications need.

Related reference:

"Broker properties that are accessible from ESQL and Java" on page 5302
You can access broker, message flow, and node properties from ESQL and Java.

Accessing message flow user-defined properties from a JavaCompute node:

Customize a JavaCompute node to access properties that you have associated with the message flow in which the node is included.

About this task

To access these properties from a JavaCompute node, use the `getUserDefinedAttribute(`*name*`)` method, where *name* is the name of the property that you are accessing. The type of the object that is returned depends on the type of the property that you are accessing. The object has one of a set of types:

- MbDate
- MbTime
- MbTimestamp
- Boolean
- byte[]
- String
- Integer 32-bit values
- Long 64-bit values
- Double
- BigDecimal
- BitSet

You cannot access user-defined properties in the constructor. To access them at initialization time, implement the following method, and use it to access the user-defined properties.

```
public void onInitialize() throws MbException
{
   // access the user-defined properties here
}
```

You can use the Administration API for WebSphere Message Broker (also known as the CMP API) to change the value of user-defined properties. Use the getUserDefinedPropertyNames(), getUserDefinedProperty(), and setUserDefinedProperty() methods to query, discover, and set user-defined properties, as described in "Setting message flow user-defined properties at run time in a CMP application" on page 985.

Related concepts:

"User-defined properties" on page 1147
A user-defined property (UDP) is a property that is defined when you construct a message flow by using the Message Flow editor. This property can be used by the ESQL or Java program inside message flow nodes, such as a Compute node.

"The Administration API for WebSphere Message Broker" on page 54
The Administration API for WebSphere Message Broker is a programming interface that your applications can use to control brokers and their resources through a remote interface.

Related tasks:

"Setting message flow user-defined properties at run time in a CMP application" on page 985
Use the CMP API to query, discover, and set message flow user-defined properties dynamically at run time. You can use the CMP API to set properties with a data type of character.

Related reference:

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Adding keywords to JAR files:

If a BAR file contains JAR files, you can associate keywords with the JAR files.

Before you begin

Before you start:

Read about keywords in "Message flow version and keywords" on page 1445.

About this task

To add keywords to a JAR file:

Procedure

1. Add a file called `META-INF/keywords.txt` to the root of the JAR file.
2. Add your keywords to the `META-INF/keywords.txt` file, because this file is parsed for keywords when it is deployed. Keywords have this format:
   `$MQSI keyword = value MQSI$`

Example

For example, a deployed BAR file contains *compute.jar*, and *compute.jar* contains the file `META-INF/keywords.txt` with the following contents:

```
# META-INF/keywords.txt
$MQSI modified date = 3 Nov MQSI$
$MQSI author = john MQSI$
```

This content means that the keywords "modified date" and "author" are associated with the deployed file *compute.jar* in Administration API (also known as the CMP API) applications, including the WebSphere Message Broker Toolkit.

What to do next

You have now added keywords to your JAR file.

Next:

When you have added keywords to your JAR file, you can display them in the BAR file editor; for more information, see "Version and keyword information for deployable objects" on page 1443.

Related concepts:

"Message flow version and keywords" on page 1445
When you are developing a message flow, you can define the version of the message flow as well as other key information that you want to be associated with it.

"Version and keyword information for deployable objects" on page 1443
Use the Broker Archive editor to view the version and keyword information of deployable objects.

Related reference:

"Guidance for defining keywords" on page 4017
You can add extra information to an object in the form of one or more keywords.

Interacting with databases by using the JavaCompute node:

Access databases from Java code included in the JavaCompute node.

About this task

Choose from the following options for database interaction:

- Broker JDBCProvider for type 4 connections
- MbSQLStatement
- JDBC API in an unmanaged environment
- SQLJ

If you use JDBCProvider for type 4 connections or MbSQLStatement, the databases that you access can participate in globally coordinated transactions. In all other cases, database access cannot be globally coordinated.

Broker JDBCProvider for type 4 connections:
About this task

You can establish JDBC type 4 connections to interact with databases from your JavaCompute nodes. The broker supports type 4 drivers, but does not supply them. You must obtain these drivers from your database vendor; for information about supported drivers, see "Supported databases" on page 3591.

Use the broker JDBCProvider for type 4 connections to benefit from the following advantages:

- Use broker configuration facilities to define the connection, and to provide optional security, in preference to coding these actions.
- Configure the broker and the databases to coordinate access and updates with other resources that you access from your message flows, except when the broker is running on z/OS.

- Use the broker Java API getJDBCType4Connection to initiate the connection, then perform SQL operations by using the standard JDBC APIs. The broker manages the connections, thread affinity, connection pooling, and lifecycle. If a connection is idle for approximately 1 minute, or if the message flow completes, the broker closes the connection.

If the broker is running on a distributed system, you can configure the databases and the connections to be coordinated with other resource activity. Global coordination on distributed systems is provided by WebSphere MQ, and can include interactions with local or remote databases, including remote databases that are defined on z/OS systems. If you establish a JDBC type 4 connection to a database from a broker that is running on z/OS, coordination is not provided. For information about setting up connections and coordination, see "Enabling JDBC connections to the databases" on page 683.

Before you can include this function in the code that you write for the node, you must configure the required environment. Decide whether your database requires security of access, and whether you want the database updates to participate in globally coordinated transactions. For the required and optional tasks, see "Enabling JDBC connections to the databases" on page 683.

When you have configured the JDBCProvider, you can establish a JDBC type 4 connection to the database by using the getJDBCType4Connection call on the MbNode interface. The following code provides an example of its use:

```
public class MyJavaCompute extends MbJavaComputeNode {
    public void evaluate(MbMessageAssembly inAssembly) throws MbException {
      MbOutputTerminal out = getOutputTerminal("out");
      MbMessage inMessage = inAssembly.getMessage();

      // create new message
      MbMessage outMessage = new MbMessage(inMessage);
      MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly,outMessage);

      try {
        // Obtain a java.sql.Connection using a JDBC Type4 datasource - in this example for a
        // JDBC broker configurable service called "MyDB2"

        Connection conn = getJDBCType4Connection("MyDB2",
                    JDBC_TransactionType.MB_TRANSACTION_AUTO);

        // Example of using the Connection to create a java.sql.Statement
        Statement stmt = conn.createStatement(ResultSet.TYPE_SCROLL_INSENSITIVE,
                    ResultSet.CONCUR_READ_ONLY);
        ResultSet srs0 = stmt.executeQuery("SELECT NAME, CITY FROM MySchema.MyTable");

        stmt.executeUpdate("UPDATE MySchema.MyTable SET CITY = \"Springfield\" WHERE Name = \"Bart\"");
        .
        // Perform other database updates
        .

      } catch (SQLException sqx ){
        sqx.printStackTrace();
      } finally {
        // Clear the outMessage
        outMessage.clearMessage();
      }
    }
  }
```

In this example:

- *MyDB2* is the name of the JDBCProvider configurable service. Use the name of the service that you have created to connect to your database.
- *MySchema* is the name of the database schema (not the name of the database).
- MB_TRANSACTION_AUTO defines the level of transaction coordination that is required by the node. Only this value is supported, and indicates that the coordination in the node is inherited from the coordination configured at message flow level.

To indicate a failure (and roll back a transaction), issue an exception from the JavaCompute node and the broker will handle the rollback.

The primary use of the getJDBCType4Connection call is in the `evaluate()` method of a JavaCompute node, where it is used to obtain a JDBC connection that is managed by the broker.

WebSphere Message Broker manages JDBC connections in the following ways:

- Non-pooled connections:
  - WebSphere Message Broker creates a JDBC connection on demand for each message flow instance that requires one.
  - Each JDBC connection is associated with the message flow instance for which it was created. This association is maintained until the connection is closed.
  - Each JDBC connection that is idle for 60 seconds is closed, and is no longer associated with a message flow instance.
  - After a JDBC connection that was associated with a message flow instance is closed, if the same message flow instance requires a JDBC connection, WebSphere Message Broker creates a new JDBC connection on demand.
- Pooled connections:
  - When a message flow instance requires a JDBC connection, WebSphere Message Broker assigns an unused connection from the pool.
  - If all pooled JDBC connections are being used, and the maximum pool size has not been reached, WebSphere Message Broker creates a new pooled JDBC connection. The maximum pool size is specified in the `maxConnectionPoolSize` property of the "JDBCProviders configurable service" on page 3778.
  - Each pooled JDBC connection remains associated with a message flow instance only for the processing of one input message.
  - When a message flow instance completes the processing of an input message, the association with a JDBC connection is removed, and the JDBC connection is returned to the pool.
  - Each pooled JDBC connection that is idle for 15 minutes is closed, and is removed from the pool.
  - Pooled JDBC connections are not applicable to the DatabaseRetrieve and DatabaseRoute nodes.

When using the getJDBCType4Connection call, your code must comply with the following restrictions:

- Do not include code that makes explicit transaction calls such as COMMIT or ROLLBACK. This restriction includes explicit transaction calls in a database stored procedure.
- Do not close a connection, or cache a connection in the JavaCompute node.

A secondary use of the getJDBCType4Connection call is in the `onitialize()` method of a JavaCompute node. The `onitialize()` method is called once, either

during deployment or on broker startup, before the message flow starts processing input. You can use the getJDBCType4Connection call in the `onitialize()` method to complete work with a database before the message flow starts; for example:

- To create an in-memory cache of read-only data that is retrieved from a database, to reduce the need to query the database in the message flow
- To prime a database with data before the message flow starts

When using the getJDBCType4Connection in the `onitialize()` method, ensure that any exceptions that might occur in this processing are handled. Any unhanded exception causes the deployment or startup of the message flow to fail. For more information, see "JavaCompute node" on page 4514.

MbSQLStatement:
About this task

The MbSQLStatement class provides full transactional database access by using ESQL and ODBC. The broker resource manager coordinates database access when using MbSQLStatement. Global coordination is provided by WebSphere MQ on distributed systems, and by RRS on z/OS. For information about how to set up the ODBC resources that are required, see "Enabling ODBC connections to the databases" on page 668.

Create instances of the MbSQLStatement class by using the createSQLStatement() method of MbNode, passing to the method the ODBC data source, a broker EQSL statement, and, optionally, the transaction mode.

- Calling select() on this object returns the results of the query.
- Calling execute() on this object runs a query where no results are returned, such as updating a table.

The following Java code shows how to access a database by using MbSQLStatement:

```
MbMessage newMsg = new MbMessage(assembly.getMessage());
MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);

String table = "dbTable";

MbSQLStatement state = createSQLStatement( "dbName",
 "SET OutputRoot.XMLNS.integer[] = PASSTHRU('SELECT * FROM " + table + "');" );

state.setThrowExceptionOnDatabaseError(false);
state.setTreatWarningsAsErrors(true);
state.select( assembly, newAssembly );

int sqlCode = state.getSQLCode();
if(sqlCode != 0)
{
 // Do error handling here
}

getOutputTerminal("out").propagate(assembly);
```

JDBC API in an unmanaged environment:
About this task

You can access standard Java APIs in the code that you write for your JavaCompute nodes, including JDBC calls. You can therefore use JDBC APIs to connect to a database, write to or read from the database, and disconnect from the database. On operating systems other than z/OS, the broker supports your JDBC

connection code calling both type 2 and type 4 JDBC drivers in this environment, but does not supply them. You must obtain these drivers from your database vendor. On z/OS, type 2 drivers are not supported.

If you choose this method to access databases, the broker does not support managing the transactions; your code must manage the local commit and rollback of database changes. Your code must also manage the connection lifecycle, connection thread affinity, and connection pooling. You must also monitor the access to databases when you use this technique to ensure that these connections do not cause interference with connections made by the broker. In particular, be aware that type 2 drivers bridge to an ODBC connection that might be in use in message flows that access databases from ESQL.

SQLJ:
About this task

SQLJ is a Java extension that you can use to embed static SQL statements within Java code. Create SQLJ files by using the WebSphere Message Broker Toolkit. The broker resource manager does not coordinate database access when using SQLJ.

Procedure

1. Enable SQLJ capability in the WebSphere Message Broker Toolkit:
   a. Select **Window** > **Preferences**.
   b. Expand **General**.
   c. Select **Capabilities**.
   d. Select **Data**.
   e. Click **OK**.
2. Create an SQLJ file within a Java project:
   a. Right-click the ***Java project*** in which you want to create the file.
   b. Select **New** > **Other**.
   c. Expand **Data**.
   d. Expand **SQLJ Applications**.
   e. Select **SQLJ File**.
   f. Click **Next**.
   g. Follow the directions given by the New SQLJ File wizard to generate the SQLJ file.

Results

You can now reference the class in this SQLJ file from a JavaCompute node class in this project or in another referenced project.

Related concepts:

"Project references" on page 44
When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

Java user-defined extensions API

Calling an Enterprise Java Bean:

You can call an Enterprise Java Bean (EJB) from a JavaCompute node.

Before you begin

Before you start:

- Ensure that all required Java classes are in WebSphere Message Broker shared-classes directories, or are referenced in the CLASSPATH environment variable. You can use the wildcard character (*) at the end of a directory path specifier to load all JARs in that directory path.
- Ensure that the user JAR files that are needed for EJB access are referenced in CLASSPATH. For more information, see the documentation for the application server that is hosting the EJB.
- If you are using a version of WebSphere Message Broker before Version 6.0 Fix Pack 3, you must set the context loader by including the following statement in the node's Java code before the InitialContext is set:

  ```
  Thread currentThread().setContextClassLoader(this.getClass().getClassLoader());
  ```

Example

The following example shows how to call an EJB from a JavaCompute node:

```
public class CallAckNoAckEJB_JavaCompute extends MbJavaComputeNode {

   public void evaluate(MbMessageAssembly inAssembly) throws MbException {
                MbOutputTerminal out = getOutputTerminal("out");
                MbOutputTerminal alt = getOutputTerminal("alternate");

                MbMessage inMessage = inAssembly.getMessage();

                // create new message
                MbMessage outMessage = new MbMessage(inMessage);
                MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly,outMessage);

                try {
                        // ----------------------------------------------------------
                        // Add user code below
```

```
                        String response = null;
                        String responseMessage = null;

                        Properties properties = new Properties();
                        properties.put(Context.PROVIDER_URL, "iiop://localhost:2809");
                        properties.put(Context.INITIAL_CONTEXT_FACTORY, "com.ibm.websphere.naming.
WsnInitialContextFactory");

                        try {

                           Context initialContext = new InitialContext(properties);
                                Object obj = initialContext.lookup("ejb/com/acme/ejbs/AckNoAckHome");
                                AckNoAckHome ejbHome = (AckNoAckHome)javax.rmi.PortableRemoteObject.
narrow(obj,AckNoAckHome.class);

                                AckNoAck ackNoAck = ejbHome.create();
                                responseMessage = ackNoAck.getAck();
                                response = "Ack";
                        } catch(Exception e) {
                                responseMessage = e.getMessage();
                                response = "NoAck";
                        }

                        MbElement cursor = outMessage.getRootElement().getFirstElementByPath("/XML/AckNoAck");
                        cursor.createElementAsLastChild(MbElement.TYPE_NAME,"Response",null);
                        cursor.getLastChild().createElementAsLastChild(MbElement.TYPE_NAME,response,null);
                        cursor.getLastChild().getLastChild().createElementAsLastChild(MbElement.TYPE_VALUE,null,
responseMessage);

                        // End of user code
                        // ------------------------------------------------------------

                        // The following should only be changed
                        // if not propagating message to the 'out' terminal
                        out.propagate(outAssembly);

                } finally {
                        // clear the outMessage
                        outMessage.clearMessage();
                }
        }
}
```

JavaCompute node exception handling:

The `evaluate()` method throws an `MbException`.

If your code throws other classes of checked exceptions, they must be caught and rethrown as `MbException`. Typically, you use the `MbUserException` class. `MbUserException` is a subclass of `MbException`, and has a public constructor. WebSphere Message Broker utility functions can throw other subclasses of MbException that have private constructors.

For information about what happens after the `evaluate()` method is processed, see "Default error handling" on page 1280.

About this task

Exceptions can occur during message flow processing (during the `evaluate()` method) and during the `onInitialize()` method. If you have implemented the `onInitialize()` method, and you detect an unrecoverable error in the node configuration, an exception of class `MBException` is issued and the flow fails to initialize. Either your flow fails to deploy, and error message BIP4157 is issued, or the flow does not start and does not appear in the list of running flows.

Do not run code in an `onInitialize()` method that depends on another external resource that might not be there because the broker will not retry calls to that method. If you need to initialize an external connection, for example, initialize it during the first call to the `evaluate()` method. If the initialization does not work, you can throw an exception that will be handled like any other flow exception.

Logging errors with the JavaCompute node:

The MbService class contains a number of static methods for writing to the Administration log or syslog. Define message catalogs by using Java resource bundles to store the message text.

About this task

Three levels of severity are supported:
- Information
- Warning
- Error

The following sample demonstrates the use of resource bundles and logging:
- JavaCompute Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Using XSL Transform

Use the XSLTransform node to transform an XML message to another form of message, according to the rules provided by an XSL (Extensible Stylesheet Language) style sheet.

About this task

Use the XSLTransform node to transform an input XML message into another format using XSLT style sheets and to set the message domain, message set, message type, and message format for the generated message. It is imperative that the data can be parsed into a XML message. The style sheet, using the rules that are defined within it, can perform the following actions:

- Sort the data
- Select data elements to include or exclude based on some criteria
- Transform the data into another format

The Xalan-Java transformation engine (Apache Xalan-java XSLT processor) is used as the underlying transformation engine. For more information about XML Transformations, the W3C specification of the syntax, and semantics of the XSL Transformations language for transforming XML documents into other XML documents, see W3C XSL Transformations.

You can deploy style sheets and XML files to broker execution groups, to help with style sheet and XML file maintenance.

You can specify the location of the style sheet to apply to this transformation in three ways:

- Use the content of the XML data within the message itself to transform the message according to a style sheet that the message itself defines.
- Set a value in the LocalEnvironment folder. You must set this value in a node that precedes the XSLTransform node (for example, a Compute node). You can therefore use various inputs to determine which style sheet to use for this message, such as the content of the message data, or a value in a database.
- Use node properties to ensure that the transformation that is defined by this single style sheet is applied to every message that is processed by this node.

An XSLT (Extensible Stylesheet Language for Transformations) compiler is used for the transformation if the style sheet is not embedded within the message, and the node cache level (node property Stylesheet Cache Level) is greater than zero. If the XSLT is cached, the performance is improved because the XSLT is not parsed every time it is used.

If the prologue of the input message body contains an XML encoding declaration, the XSLTransform node ignores the encoding, and always uses the CodedCharSetId in the message property folder to decode the message.

The XSLT capability that is provided by the XSLTransform node requires XML processing APIs that are included in Xalan-Java and Xerces JAR files. The XSLTransform node provides Xalan-Java and Xerces JAR files that work correctly with the node. The Java JRE also includes Xalan-Java and Xerces JAR files, but you might experience unpredictable results when these Java XML processing methods are invoked by using an external Java method from a style sheet. Therefore, the calling of Java methods from a style sheet that directly or indirectly reference Java JRE XML processing methods is unsupported.

To find out more about the XSLTransform node and how to configure it, refer to the following topics:
- "XSLTransform node" on page 4968
- "Adding keywords to XSL style sheets" on page 4975
- "Using local environment variables to set properties" on page 4976
- "Deployed and non-deployed style sheets" on page 4978

Using PHP

You can use the PHP scripting language for message routing and transformation.

About this task

Support for the PHP scripting language is available on all operating systems on which WebSphere Message Broker is supported.

When you use the PHPCompute node, you can customize it to determine the exact processing that it provides. To tailor the behavior of each node, create a PHP file that provides the processing that you require. You can edit your PHP files by using a text editor such as the default Eclipse text editor.

The PHP API simplifies tasks that involve message routing and transformation tasks. These tasks include accessing named elements in a message tree, setting their values, and creating elements, without the need to navigate the message tree explicitly.

The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

PHP overview

WebSphere Message Broker provides support for the PHP scripting language.

WebSphere Message Broker provides a PHPCompute node, which is a programmable node that supports message transformation and routing by using the PHP scripting language. For example:

```
$output_assembly->XMLNSC->doc->item =
$input_assembly->MRM->structure->field;
```

This PHP code generates the following XML code:

```
<doc>
    <item>
           ... deep copy of field element from input tree
    </item>
</doc>
```

The PHPCompute node builds on this syntax to produce a powerful syntax for accessing WebSphere Message Broker trees.

Standard output and standard error messages from the PHP engine are written to the console log for the broker. For information about reading the console log, see "Standard system logs" on page 6866.

z/OS On z/OS, all PHP scripts must be encoded in UTF-8 format. All string literals in PHP scripts, and all character data that is passed to scripts from the message assembly, are in UTF-8 encoding. Typically, scripts that interact with the message assembly in PHP work in the same way on z/OS as they do on other operating systems. If a script uses byte streams in PHP (such as file access), the Multibyte String functions can be used to detect the code page and convert character data as required.

UTF-8 might not be the default code page of the broker, which means that any function that requires the broker to have a UTF-8 default code page might need to

be modified. For example, the asBitstream and addElementFromBitstream methods on the MbsElement object use the default code page of the broker as their default code page, rather than the code page of PHP.

The PHPCompute node provides support for Simple Network Management Protocol (SNMP). The Management Information Base (MIB) files are installed during the installation of WebSphere Message Broker, and their location is specified by the **MIBDIRS** environment variable.

For information about the PHP functions supported by WebSphere Message Broker, see "PHP extensions" on page 5324.

For more information about the PHP scripting language, see the PHP: Hypertext Preprocessor web site.

Creating PHP code for a PHPCompute node

Use these instructions to create your PHP code and associate it with your PHPCompute node.

About this task

To create your PHP code and associate it with a PHPCompute node, follow these steps:

Procedure

1. Ensure that your PHP code is in a PHP script file, with an extension of `.php`:
   - If the required PHP code exists, import the PHP script file into the workspace (see "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931). Alternatively, ensure that the PHP script file is stored in the file system, so that the PHPCompute node can point to it directly.
   - If the required PHP code does not exist, create it by following the instructions in "Writing PHP code" on page 2673.
2. Associate the PHP code with a PHPCompute node in your message flow. Follow the instructions in "Associating PHP code with a PHPCompute node" on page 2675.

Related concepts:

"PHP overview" on page 2671

"PHP API" on page 5313
The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

Writing PHP code:

Use these instructions to create your PHP code.

About this task

Procedure

1. In the Broker Application Development perspective, click **File** > **New** > **Other**. The Select a wizard pane is displayed.
2. Select **File** from the list of resources, then click **Next**.
3. Select the required parent folder from the list, then type the name of your new PHP script file in the **File Name** field. Ensure that the file you specify has an extension of `.php` (for example, `Hello.php`). The Eclipse text editor opens, with an empty pane in which you can type your PHP code.
4. Type your PHP code into your new PHP script file, by using the Eclipse text editor. The PHP script must be contained within the `<?php` and `?>` tags:

   ```
   <?php

   // Body of the script

   ?>
   ```

   You can create a PHP script with or without a class and evaluate method. The option you choose affects both the content of the script and the setting of the PHPCompute node's `Invoke evaluate method` property:

   - Create a script including a class and evaluate method:

     The `Invoke evaluate method` property of the PHPCompute node is selected by default, therefore a class and evaluate method are expected in the PHP script.

     The PHP code must contain a class with the same name as the PHP file (`Hello`, for example), and this class must contain a function called evaluate, with parameters for the input and output message assemblies:

```
<?php

class Hello {

  /**
   * An example of MessageBrokerSimpleTransform
   * @MessageBrokerSimpleTransform
   */
  function evaluate($output_assembly, $input_assembly) {
   // transformation code here
   // $output_assembly ->XMLNSC->... = $input_assembly->XMLNSC->...
  }

}

?>
```

For more information about the @MessageBrokerSimpleTransform annotation shown in this example, see "Using annotations" on page 2676.

- Create a script without a class and evaluate method:

  The global variable *$assembly* makes the incoming message assembly available to the script. The incoming message and message assembly are read only. As a result, for message transformation, you must make a new copy of the message and the assembly containing the new message:

```
<?php

$output_message = new MbsMessage();

// transformation code here
// $output_message->XMLNSC->... = $assembly->XMLNSC->...

$output_assembly = new MbsMessageAssembly($assembly, $output_message);
$output_assembly->propagate("out");

?>
```

  The `Invoke evaluate method` property of the PHPCompute node is selected by default, therefore a class and evaluate method are expected in the PHP script. If you use a PHP script without a class and evaluate method, remember to clear the **`Invoke evaluate method`** property of the PHPCompute node.

  You must explicitly propagate the message assembly to one of the output terminals before the end of the script.

What to do next

When you have created your PHP code, associate it with the PHPCompute node by following the instructions in "Associating PHP code with a PHPCompute node" on page 2675.

For information about the PHP scripting language, see the PHP: Hypertext Preprocessor Web site.

Related concepts:

"Using annotations" on page 2676
Annotations alter the behavior of the evaluate method when using the PHP class structure, and remove the need to repeat commonly used code (for transforming message trees) in each PHP script.

Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

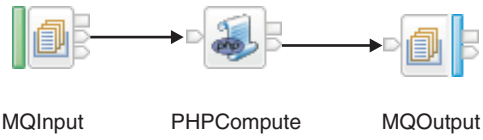
Associating PHP code with a PHPCompute node:

Use these instructions to associate your PHP code with a PHPCompute node.

About this task

Procedure

1. Create a message flow containing a PHPCompute node. For example, create a message flow containing an MQInput node, a PHPCompute node, and an MQOutput node. For information, see "Creating a message flow" on page 1431.
2. Connect the Out terminal of the MQInput node to the In terminal of the PHPCompute node.
3. Connect the Out terminal of the PHPCompute node to the In terminal of the MQOutput node.



4. On the MQInput node, set the `Queue name` property (on the **Basic** tab) to `InQueue`.
5. On the PHPCompute node, set the `PHP script` property (on the **Basic** tab) to `Hello.php`. You can either type the name of the PHP file into the field, or select **Browse** to navigate to the PHP files stored in your workspace. If you select **Browse**, the PHP files in the current message flow project are displayed, together with PHP files in any referenced projects. To add project references, right-click the message flow project, select **Properties**, then select the **Project references** category.
6. Set the following properties of the MQOutput node:
   a. On the **Basic** tab, set the `Queue name` property to `OutputQueue`
   b. On the **Validation** tab, set the `Validate` property to `Inherit`.
7. Save the message flow.

Results

You can display the PHP script file associated with the PHPCompute node by double-clicking the node in the message flow. The file `Hello.php` is opened in the Eclipse text editor.

"PHP API" on page 5313
The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

Using annotations:

Annotations alter the behavior of the evaluate method when using the PHP class structure, and remove the need to repeat commonly used code (for transforming message trees) in each PHP script.

When you use the PHP class structure with WebSphere Message Broker, the class must have the same name as the PHP file and it must implement a method called evaluate. The PHPCompute node instantiates the class and calls the evaluate method. For more information about developing PHP code, see "Creating PHP code for a PHPCompute node" on page 2672.

The following annotations are supported by the broker:

- "@MessageBrokerSimpleTransform" on page 2677
- "@MessageBrokerCopyTransform" on page 2678
- "@MessageBrokerRouter" on page 2679
- "@MessageBrokerLocalEnvironmentTransform" on page 2680

You can specify multiple annotations for an evaluate method. If the MessageBrokerCopyTransform and MessageBrokerSimpleTransform annotations are specified together, the MessageBrokerCopyTransform annotation takes precedence. The input assembly is available with both the MessageBrokerSimpleTransform and MessageBrokerCopyTransform annotations.

If no annotations are specified, the first argument to the evaluate method is a read-only assembly. Annotation names are case-sensitive, and annotations that are not recognized are ignored.

When you use an annotation, the output assembly is passed to the evaluate method as the first parameter, and the input assembly is passed as the second parameter. The second parameter is optional and is passed in if you have specified it in your evaluate method declaration.

Related concepts:

"Local environment tree structure" on page 1056
The local environment tree is a part of the logical message tree in which you can store information while the message flow processes the message.

"PHP API" on page 5313
The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

@MessageBrokerSimpleTransform:

Use the @MessageBrokerSimpleTransform annotation to alter the behavior of the evaluate method in a PHP class.

The @MessageBrokerSimpleTransform annotation causes two parameters to be passed to the evaluate method. The first parameter is a reference to the output assembly, and the second parameter is a reference to the input assembly. The second parameter is optional.

If the MessageBrokerSimpleTransform and MessageBrokerCopyTransform annotations are specified together, the MessageBrokerCopyTransform annotation takes precedence.

The following example copies the subtree under element *aaa* into the output tree under element *bbb*:

```
<?php

class SimpleTransform {

/**

     * An example of MessageBrokerSimpleTransform
     * @MessageBrokerSimpleTransform

     */

    function evaluate($output_assembly, $input_assembly) {

        $output_assembly->XMLNSC->bbb = $input_assembly->XMLNSC->aaa;
    }

}

?>
```

Related concepts:

You can use the PHP scripting language for message routing and transformation.

Related reference:

"PHPCompute node" on page 4639
Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language.

@MessageBrokerCopyTransform:

Use the @MessageBrokerCopyTransform annotation to alter the behavior of the evaluate method in a PHP class.

The @MessageBrokerCopyTransform annotation causes one parameter to be passed to the evaluate method. This parameter is a reference to the output assembly with the contents of the input assembly already copied into it. The input assembly is available with the @MessageBrokerCopyTransform. If you declare a second parameter (which is optional) the input assembly is passed to it.

If the @MessageBrokerCopy Transform and @MessageBrokerSimpleTransform annotations are specified together, the @MessageBrokerCopyTransform annotation takes precedence.

The following example modifies the original XML message by adding an element called *Greeting* with the value *Hello World*:

```
<?php

class CopyTest {

    /**

     * An example of MessageBrokerCopyTransform

     *

     * @MessageBrokerCopyTransform

     */

    function evaluate($assembly) {
        $assembly->XMLNSC->doc->Greeting = "Hello World";
    }
```

```
}

?>
```

You can use the PHP scripting language for message routing and transformation.

Related reference:

"PHPCompute node" on page 4639
Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language.

@MessageBrokerRouter:

Use the @MessageBrokerRouter annotation to alter the behavior of the evaluate method in a PHP class.

The @MessageBrokerRouter annotation causes the return value of the evaluate method to be used to specify the terminal through which the message is to be propagated. The terminal can be either the Out terminal (defined on the node) or a dynamic terminal that you have created. You can add output terminals dynamically to your node instance in the Message Flow editor. The string that is returned from the evaluate method must match either the name of the dynamic terminal that you have defined or the Out terminal. If no return value is specified, the output assembly is not propagated to the next node after the evaluate method returns.

The following example routes the message to the Out terminal if the value of the *threshold* element is greater than 10; otherwise the message is routed to the *other* terminal:

```
<?php
class RouteTest {
```

```
    /**
     * Basic routing of a message.
     *
     * @MessageBrokerRouter
     */
    function evaluate($assembly) {
 // Simple filter
 if ($assembly->XMLNSC->doc->threshold->getValue() > 10) {
       return 'out';
 } else {
  return 'other';
  }
 }
}
?>
```

For information about dynamic terminals, see "Using dynamic terminals" on page 1518.

You can use the PHP scripting language for message routing and transformation.

Related reference:

"PHPCompute node" on page 4639
Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language.

@MessageBrokerLocalEnvironmentTransform:

Use the @MessageBrokerLocalEnvironmentTransform annotation to alter the behavior of the evaluate method in a PHP class.

The @MessageBrokerLocalEnvironmentTransform is similar to the @MessageBrokerSimpleTransform annotation but creates a copy of the local environment tree in the output assembly.

If the @MessageBrokerLocalEnvironmentTransform is used, nodes downstream of the PHPCompute node see changes to the local environment. If the @MessageBrokerLocalEnvironmentTransform is not used, the node can still modify the local environment, and all nodes in the flow (including upstream nodes) can see the changes.

The following example populates two new folders in the local environment tree, and copies the *Wildcard* subtree from the local environment into the output message:

```
<?php

class LocalEnvironmentTest {

    /**

     * Test local environment messages.

     *

     * @MessageBrokerSimpleTransform

     * @MessageBrokerLocalEnvironmentTransform

     */

    function evaluate($output_assembly, $input_assembly) {

        $output_assembly[MB_LOCAL_ENVIRONMENT]->Folder1 = 'some string';

        $output_assembly[MB_LOCAL_ENVIRONMENT]->Folder2->SubFolder =
          'another string';

        $output_assembly->XMLNSC->Message->InputLocalEnvironment =
          $input_assembly[MB_LOCAL_ENVIRONMENT]->Wildcard;

    }

}

?>
```

Using PHP arrays with XML

PHP arrays are associative arrays (maps) but you can treat them as lists by adding values without keys.

PHP supports the following syntax for building arrays:

```
$array[] = "aaa";
$array[] = "bbb";
```

PHP allows an object to function as an array, and you can use this capability to create repeating elements in a tree. For example:

```
$output_root->XMLNSC->a->b->c[] = $input_root->XMLNSC->a->b;
$output_root->XMLNSC->a->b->c[] = $input_root->XMLNSC->a->c;
```

The code shown above creates the following elements:

```
<a>
 <b>
  <c>
   ... // contents of $input_root->XMLNSC->a->b
  </c>
  <c>
   ... // contents of $input_root->XMLNSC->a->c
  </c>
 </b>
</a>
```

You can use the array operator in the path, as shown in the following example:

```
$output_root->XMLNSC->a->b[]->c = $input_root->XMLNSC->a->b;
$output_root->XMLNSC->a->b[]->c = $input_root->XMLNSC->a->c;
```

to create the following elements:

```
<a>
 <b>
  <c>
   ... // contents of $input_root->XMLNSC->a->b
  </c>
 </b>
 <b>
  <c>
   ... // contents of $input_root->XMLNSC->a->c
  </c>
 </b>
</a>
```

The following example uses no array operators:

```
$output_root->XMLNSC->a->b->c = $input_root->XMLNSC->a->b;
$output_root->XMLNSC->a->b->c = $input_root->XMLNSC->a->c;
```

The example above produces the following XML code:

```
<a>
 <b>
  <c>
   ... // contents of $input_root->XMLNSC->a->c (overwriting previous)
  </c>
 </b>
</a>
```

You can also iterate a set of repeating elements by using a *foreach* loop, as shown in the following example:

```
foreach ($input_root->XMLNSC->doc->item as $item) {
   $output_root->XMLNSC->msg->bit[] = $this->transformItem($item);
}
```

This example builds an output message with a repeating *bit* element, one for each *item* element in the input message. The content of each *bit* element is determined by the *transformItem* function, which refers to the *item* element as its parameter. The following sample shows an example of this syntax being used for message transformation:

- PHPCompute Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

You can assign standard PHP arrays into an element tree as a way of building subtrees by using a very compact syntax. The following example shows how to build a repeating element from an array of values:

```
$output_root->XMLNSC->doc->item[] = array('aaa', 'bbb', 'ccc');
```

This code builds a tree with three item elements:

```
<doc>
 <item>aaa</item>
 <item>bbb</item>
 <item>ccc</item>
</doc>
```

Although the PHP array looks like a list, it is an associative array with the keys *0*, *1*, and *2*. The following example shows how to assign key/value pairs into the element tree:

```
$output_root->XMLNSC->doc->item = array('book'  => 'PHP',
                                        'fruit' => 'apple',
                                        'dog'   => 'Spaniel'   );
```

Without the [] operator on the item element, the keys in the array are used to name the child elements:

```
<doc>
 <item>
  <book>PHP</book>
  <fruit>apple</fruit>
  <dog>Spaniel</dog>
 </item>
</doc>
```

You can also nest arrays to represent more complex structures. For example:

```
output_root->XMLNSC->doc->items =
             array('book'  => array('title'  => 'PHP',
                                    'author' => 'A N Other'),
                   'fruit' => 'apple',
                   'dog'   => array('breed'  => 'Spaniel',
                                    'ears'   => 'long') );
```

The preceding example produces the following XML code:

```
<doc>
 <items>
  <book>
   <title>PHP</title>
   <author>A N Other</author>
  </book>
  <fruit>apple</fruit>
  <dog>
   <breed>Spaniel</breed>
   <ears>long</ears>
  </dog>
 </items>
</doc>
```

MbsElement arrays:

When an array of MbsElement objects is assigned to an element tree, the array acts as an associative array.

For example:

```
$output_assembly->XMLNSC->doc->folder = $input_assembly->xpath("//item");
```

This example generates the following result:

```
<doc>
 <folder>
  <item>
   ... deep copy of 1st item element
  </item>
  <item>
   ... deep copy of 2nd item element
  </item>
  <item>
```

```
   ... deep copy of 3rd item element
  </item>
 </folder>
</doc>
```

The name of each element on the right side (in this example, *item*) becomes the name of the child element in the target tree. However, if the [] operator is used on the left side, *item* is replaced with *folder*, as shown in the following example:

```
$output_assembly->XMLNSC->doc->folder[] = $input_assembly->xpath("//item");
```

The example shown above generates the following result:

```
<doc>
 <folder>
  ... deep copy of 1st item element
 </folder>
 <folder>
  ... deep copy of 2nd item element
 </folder>
 <folder>
  ... deep copy of 3rd item element
 </folder>
</doc>
```

Using PHP arrays with JSON

PHP arrays are associative maps, in which the key can be an integer or a string.

Integer keys can be allocated automatically in ascending sequential order, to work in the same way as a traditional integer indexed array. PHP supports an empty index operator ([]), which can be used on the left side of an assignment to add an item to the array, using an integer index with the value of the highest current index plus 1.

PHP associative arrays are modeled as JSON object structures, because JSON arrays are anonymous.

Values in a JSON logical tree can be set using any of the PHP native types, including arrays. The type of array determines the resulting JSON logical tree shape:

- A JSON array is produced by assigning a contiguous integer-indexed PHP array into a JSON domain tree path. A PHP array variable is contiguous integer-indexed if it contains only integer keys that are sequenced from `0` to *n*`-1` (where *n* is the total number of items in the array). The tree elements have their type set automatically to `JSON.Array`, which produces a JSON array format in the bit stream when the tree is serialized.
- A JSON object is produced by assigning an associative PHP array into a JSON domain tree path. A PHP array is associative if it contains one or more string keys, or if it has integer keys that are not contiguously sequenced from `0` to *n*`-1`.

When a multidimensional PHP array variable is assigned to a JSON domain tree path, these rules are applied to each dimension of the array variable, so that an appropriate JSON array or object is formed in the message tree to model each dimension of the PHP array.

When you create a JSON message tree in PHP using individual value assignments, you can create JSON array items by appending the target path with the PHP array append operator (`[]`) in the assignment. You can use the `[]` operator on a path in the following ways:

- To create a JSON array and add the first item into it
- To append an item to the end of an existing JSON array

If you try to create an array item using a target path with the `[]` operator, and the path resolves to an existing JSON object element in the tree, an exception is thrown.

The PHPCompute node supports the PHP constant `MB_JSON_ARRAY`, which you can use in the MbElement `setType()` method to change an existing JSON object element into a JSON array. This method is typically used when elements have been created by copying from a tree owned by another parser domain.

To access or change an existing value of a JSON array item in a tree, you can use an array index (`[index]`) to select the required item. JSON array items cannot be created in the JSON tree by using the `[index]` form; attempts to do so result in an exception being thrown.

You can also access non-array elements in the JSON domain tree, as if the tree were an associative array, by using an index key name. For example, to select an element called `street`, which is a child of an element called `address`, use the following path construct:

```
->address['street']
```

The following examples demonstrate how you can use PHP arrays with JSON:

- "Creating a JSON array message from individual PHP variables" on page 2687
- "Creating a JSON array message from a PHP indexed array" on page 2687
- "Creating a JSON object message from a PHP associative array" on page 2688
- "Creating a JSON message from a PHP integer index multidimensional array" on page 2688

- "Creating a JSON message from a PHP mixed associative and integer indexed multidimensional array" on page 2688
- "Updating a JSON array in the logical tree" on page 2689
- "Copying an XML domain message subtree with repeating elements to a JSON domain tree and converting it to a JSON array using PHP" on page 2689
- "Working with a JSON object with a repeating name" on page 2690

Creating a JSON array message from individual PHP variables

You can create a JSON array and append items to it by using a target path with an array append index operator ([]):

```
$strVar = "this";
$boolVar = true;
$output_assembly->JSON->Data[] = $strVar;
$output_assembly->JSON->Data[] = $boolVar;
```

You must use the array append index operator ([]) to append to an array; you cannot use the [index] form.

The following broker message tree is produced:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
     (0x01001000:Array     ): Data = (
       (0x03000000:NameValue): Item = 'this' (CHARACTER)
       (0x03000000:NameValue): Item = TRUE (BOOLEAN)
     )
 )
```

This message tree is serialized to the following JSON bit stream:

```
["this",true]
```

You can extend this example to build a multidimensional JSON array:

```
$output_assembly->JSON->Data[][] = '00';
$data = $output_assembly->JSON->Data;
$data[0][] = '01';
$data[][]  = '10';
$data[1][] = '11';
```

The resulting message tree is serialized to the following JSON bit stream:

```
[["00","01"],["10","11"]]
```

Creating a JSON array message from a PHP indexed array

You can create a PHP array with contiguous integer keys, and assign it to the message tree element that you want to form the JSON array:

```
$arr = array("this", "that");
$output_assembly->JSON->Data = $arr;
```

The following broker message tree is produced:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
     (0x01001000:Array     ): Data = (
       (0x03000000:NameValue): 0 = 'this' (CHARACTER)
       (0x03000000:NameValue): 1 = 'that' (CHARACTER)
     )
 )
```

This message tree is serialized to the following JSON bit stream:

```
["this", "that" ]
```

Creating a JSON object message from a PHP associative array

This example shows how to create a PHP array with named keys, and assign it to the message tree element that you want to form the JSON object:

```
$arr = array('first' => "1st", 'second' => "2nd");
$output_assembly->JSON->Data = $arr;
```

The following broker message tree is produced:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
    (0x01000000:Object  ): Data = (
      (0x03000000:NameValue): first = '1st' (CHARACTER)
      (0x03000000:NameValue): second = '2nd' (CHARACTER)
    )
)
```

You can access the array elements using the key name in the array index:

```
$var1 = $output_assembly->JSON->Data['second']; // 2nd
$var2 = $output_assembly->JSON->Data['none'];   // null
```

This is serialized to the following JSON bit stream:

```
{"first":"1st","second":"2nd"}
```

Creating a JSON message from a PHP integer index multidimensional array

You can assign the array to the element that is to hold the data. The top level and the nested level of the PHP array are integer indexed arrays, so both are created as JSON arrays, resulting in a multidimensional JSON array:

```
$arr = array(array("a1","a2"),array("b1","b2"));
$output_assembly->JSON->Data = $arr;
```

The following broker message tree is produced:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
     (0x01001000:Array     ): Data = (
       (0x01001000:Array     ): 1 = (
         (0x03000000:NameValue): 1 = 'a1' (CHARACTER)
         (0x03000000:NameValue): 2 = 'a2' (CHARACTER)
       )
       (0x01001000:Array     ): 2 = (
         (0x03000000:NameValue): 1 = 'b1' (CHARACTER)
         (0x03000000:NameValue): 2 = 'b2' (CHARACTER)
       )
     )
)
```

This message tree is serialized to the following JSON bit stream:

```
[["a1","a2"],["b1","b2"]]
```

Creating a JSON message from a PHP mixed associative and integer indexed multidimensional array

You can assign the array to the element that is to hold the data. The top level of the PHP array is associative, with string key names, and so becomes a JSON object. The nested level of the PHP array is using integer indexed arrays, and is created as a JSON array.

```
$arr = array("top1" => array("a1","a2"), "top2" => array("b1","b2"));
$output_assembly->JSON->Data = $arr;
```

The following broker message tree is produced from the example shown above:

```
 (Message):JSON     = ( ['json' : 0xhhhhhh]
      (0x01000000:Object     ): Data = (
        (0x01001000:Array     ):top1 = (
          (0x03000000:NameValue): 1 = 'a1' (CHARACTER)
          (0x03000000:NameValue): 2 = 'a2' (CHARACTER)
        )
        (0x01001000:Array     ):top2 = (
          (0x03000000:NameValue): 1 = 'b1' (CHARACTER)
          (0x03000000:NameValue): 2 = 'b2' (CHARACTER)
        )
      )
  )
```

This message tree is serialized to the following JSON bit stream:

```
{"top1":["a1","a2"],"top2":["b1","b2"]}
```

Updating a JSON array in the logical tree

```
[["a1","a2"],["b1","b2"]]
```

The following broker message tree is produced from the JSON input shown above:

```
 (Message):JSON     = ( ['json' : 0xhhhhhh]
      (0x01001000:Array     ): Data = (
        (0x01001000:Array     ): Item = (
          (0x03000000:NameValue): Item = 'a1' (CHARACTER)
          (0x03000000:NameValue): Item = 'a2' (CHARACTER)
        )
        (0x01001000:Array     ): Item = (
          (0x03000000:NameValue): Item = 'b1' (CHARACTER)
          (0x03000000:NameValue): Item = 'b2' (CHARACTER)
        )
      )
  )
```

You can update this message with PHP, using `[index]` on the element that is holding the array to access existing elements, and the `[]` form to create additional elements:

```
output_assembly->JSON->Data[0][0] = "A1";
output_assembly->JSON->Data[1][1] = "B2";
output_assembly->JSON->Data[1][] = "New3";
```

This example produces the following JSON output:

```
[["A1","a2"],["b1","B2","new3"]]
```

Copying an XML domain message subtree with repeating elements to a JSON domain tree and converting it to a JSON array using PHP

You can use the PHP constant MB_JSON_ARRAY to explicitly test and set the Array type of a message tree element. For example, you can use MB_JSON_ARRAY if you are copying message tree data from an XML domain to a JSON domain, or from a JSON domain to an XML domain. The following XML input contains repeating elements:

```
<doc>
      <cats>
        <cat>thing1</cat>
        <cat>thing2</cat>
      </cats>
</doc>
```

The following broker message tree is produced by the XMLNSC parser:

```
(0x01000000:Folder):XMLNSC     = ( ['xmlnsc' : 0xhhhhhh]
      (0x01001000:Folder     ): doc = (
        (0x01001000:Folder     ): cats = (
          (0x03000000:NameValue): cat = 'thing1' (CHARACTER)
          (0x03000000:NameValue): cat = 'thing2' (CHARACTER)
        )
      )
 )
```

The message flow can convert this broker message tree into a JSON message, to be serialized in the following way:

```
{"cats":["thing1","thing2"]}
```

You can transform the message using PHP, as shown in the following example:

```
$output_assembly->JSON->Data = $input_assembly->XMLNSC->doc;
$output_assembly->JSON->Data->cats->setType(MB_JSON_ARRAY);
```

This transformation produces the following message tree, which serializes to JSON format:

```
(Message):JSON     = ( ['json' : 0xhhhhhh]
    (0x01000000:Obejct):Data     = (
        (0x01001000:Array     ): cats = (
          (0x03000000:NameValue): cat = 'thing1' (CHARACTER)
          (0x03000000:NameValue): cat = 'thing2' (CHARACTER)
        )
     )
 )
```

Working with a JSON object with a repeating name

The JSON specification states that JSON objects should not have duplicate names. However, it is possible for a message to contain this format; for example, in the following JSON message the name `cat` is repeated:

```
{"cat":"thing1","cat":"thing2" }
```

The JSON parser produces the following broker message tree from the JSON input shown above:

```
 (Message):JSON     = ( ['json' : 0xhhhhhh]
      (0x01001000:Object     ): Data = (
        (0x03000000:NameValue): cat = 'thing1' (CHARACTER)
        (0x03000000:NameValue): cat = 'thing2' (CHARACTER)
      )
  )
```

This is an invalid PHP data structure because it has a duplicate key, which cannot exist in an associative array. As a result, this form of JSON data cannot be accessed, created, or modified from a PHPCompute node. To process this type of JSON data, the message flow must use either ESQL or Java.

Deploying code in a PHPCompute node

The WebSphere Message Broker Toolkit deploys the PHPCompute node code automatically.

About this task

When you create a broker archive (BAR) file and add the message flow, the WebSphere Message Broker Toolkit packages the PHP code and its dependencies into the BAR file.

PHP files referenced by a PHPCompute node are added to the BAR file automatically when it is built, but you can also add additional PHP files to the BAR file by using the Broker Archive editor:

Accessing elements in the message tree from a PHPCompute node

Access the contents of a message, for reading or writing, by using the structure and arrangement of the elements in the tree that the parser creates from the input bit stream.

You can extract information from a message by using the PHPCompute node path syntax, or by using the MbsElement API methods. XPath 1.0 is supported as a means of accessing parts of the message.

Follow the relevant parent and child relationships from the top of the tree downwards until you reach the required element.

The following topics provide more information about accessing, extracting, and updating information in the message tree:

Traversing the element tree:

Use PHP methods to access element trees.

About this task

Use the following statements to traverse a message tree from an element:

getParent()
Returns the parent of the current element.

getPreviousSibling()
Returns the previous sibling of the current element.

getNextSibling()
Returns the next sibling of the current element.

getChild()
Returns the first child of the current element, whose name is given by the first parameter. The n^{th} occurrence of that child element can be returned by specifying the second optional parameter.

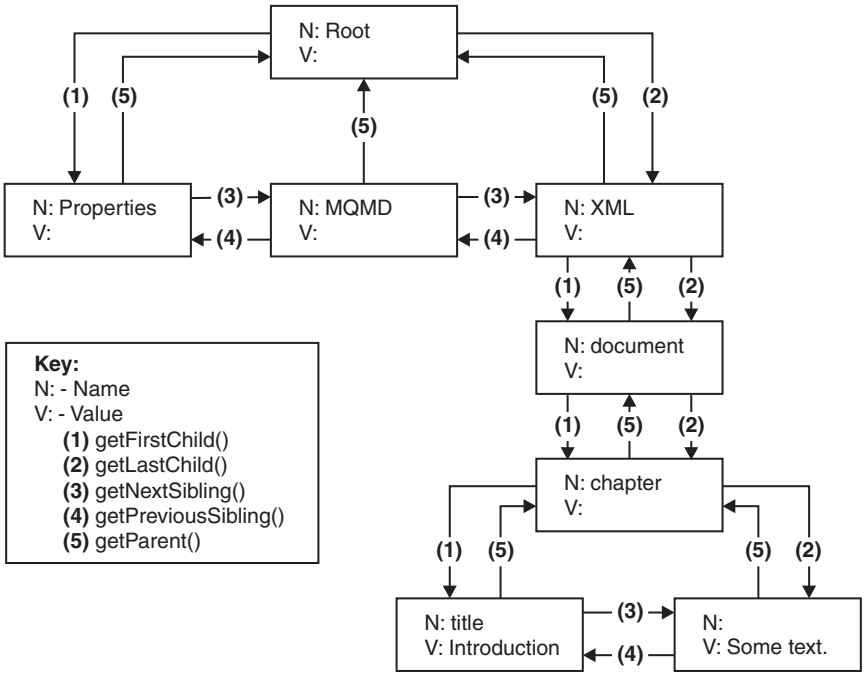
getChildren()
Returns all the child elements of the current element as an array of MbsElements. If the **namespace** parameter is specified, the array contains only the child elements with that namespace URI.

getFirstChild()
Returns the first child of the current element.

getLastChild()
Returns the last child of the current element.

The following example shows a simple XML message and the logical tree that is created from the message. The message has been sent by using WebSphere MQ. The logical tree diagram also shows the methods to call to navigate around the tree:

```
<document>
  <chapter title='Introduction'>
    Some text
  </chapter>
</document>
```



The tree used in this diagram is the one that is created by parsing the XML example given in this topic.

- From the Root part of the tree, calling **getFirstChild()** navigates to Properties. Also from Root, calling **getLastChild()** returns XML.
- From Properties, calling **getParent()** returns Root, and calling **getNextSibling()** returns MQMD.
- From MQMD, calling **getPreviousSibling()** returns Properties, calling **getParent()** returns Root, and calling **getNextSibling()** returns XML.
- From XML, calling **getPreviousSibling()** returns MQMD, calling **getParent()** returns Root, calling **getFirstChild()** returns document, and calling **getLastChild()** also returns document.
- From document, calling **getParent()** returns XML, calling **getFirstChild()** returns chapter, and calling **getLastChild()** also returns chapter.
- From chapter, calling **getParent()** returns document, calling **getFirstChild()** returns title, and calling **getLastChild()** returns the child that contains the message data "Some text.".

The following example shows how to use the MbsElement methods to navigate to the chapter element:

```
$chapter = $input_assembly->getLastChild()->getFirstChild()->getFirstChild();
```

The following example shows how to navigate to the chapter element by using the path syntax:

```
$chapter = $input_assembly->XML->document->chapter;
```

Using SPL iterators with PHP:

The PHPCompute node provides support for the Standard PHP Library (SPL) syntax, which provides iterators that can be used in PHP code.

SPL iterators are classes that allow you to traverse a collection of data, processing each element of the collection in a specific way. A collection might be a simple serial list of elements, or a complex tree structure.

An SPL iterator, called MbsElementIterator, enables you to iterate over WebSphere Message Broker messages, and provides support for filtering and recursion.

For more information about the MbsElementIterator class, see "MbsElementIterator" on page 5316.

The following topics provide more information about iterating over elements in the message tree:

- "Iterating over elements" on page 2696
- "Recursive iterators" on page 2697

Iterating over elements:

Use the MbsElementIterator class to provide sequential iteration over elements in the message tree.

You can use an MbsElementIterator in a `foreach()` statement to iterate over the children of an MbsElement. The `foreach()` statement automatically calls methods on the iterator object to step through all the elements.

The following example shows how you can use MbsElementIterator to iterate over elements:

```
$it = new MbsElementIterator($input_assembly->XMLNSC->getFirstChild());

echo "\nIterating using an MbsElementIterator in a foreach loop\n";
foreach($it as $key=>$value)
{
  echo $key.'='.$value."\n";
}
```

For more information about the MbsElementIterator class, see "MbsElementIterator" on page 5316.

Related concepts:

Recursive iterators:

You can use a RecursiveIteratorIterator to iterate over a whole message tree, by using it to wrap around an MbsElementIterator.

The following example creates an MbsElementIterator and wraps it in a RecursiveIteratorIterator:

```
$it  = new MbsElementIterator($input_assembly->XMLNSC->getFirstChild());
$rii = new RecursiveIteratorIterator($it, RecursiveIteratorIterator::CHILD_FIRST);

foreach($rii as $key=>$value)
{
  echo $key.'='.$value."\n";
}
```

For more information about the MbsElementIterator class, see "MbsElementIterator" on page 5316.

Iterating with a filter:

Use a FilterIterator to filter elements in the message tree.

The following example shows how to use a FilterIterator to iterate over a message tree, extracting only the *Toughened Steel* components:

```
class ToughenedSteelPartsIterator extends FilterIterator
{
  public function __construct(Iterator $it)
  {
    parent::__construct($it);
  }

  function accept()
  {
    /*** only check components ***/
    if (!strcmp($this->key(),"component"))
    {
      /*** Return true for Toughened Steel ***/
      if (!strcmp($this->current()->material,"Toughened Steel"))
      {
        return true;
      }
    }
    return false;
  }
}

class PhpComputeNode_Iterator_Filter
{
  /**
   * @MessageBrokerSimpleTransform
   */
  function evaluate($output_assembly, $input_assembly)
```

```
  {
    ob_start();
    echo "\nIterating over parts which have a material name of Toughened Steel\n";

    $it  = new MbsElementIterator($input_assembly->XMLNSC->getFirstChild());
    $rii = new ToughenedSteelPartsIterator(new RecursiveIteratorIterator($it, RecursiveIteratorIte

    foreach($rii as $key=>$value)
    {
      echo $key.' = '.$value->name." ".$value->price." ".$value->material."\n";
    }

    $output_assembly->XMLNSC->results->contents = ob_get_contents();
    ob_end_clean();
  }
}
```

The following message is used as input to the FilterIterator shown above:

```
<machine>
 <assembly name="Engine Block Top End">
  <assembly name="Cylinder Head">
   <assembly name="Tappet Assembly">
     <component name="Tappet" price="3.50" material="Toughened Steel"/>
     <component name="Coil String" price="1.50" material="Spring Steel"/>
     <component name="Circlip" price="1.50"  material="Spring Steel"/>
     <component name="Circlip" price="1.50"  material="Spring Steel"/>
     <component name="Seat" price="3.50" material="Toughened Steel"/>
   </assembly>
   <assembly name="Cam Shaft">
     <component name="Shaft" price="3.50" material="Mild Steel"/>
     <component name="Cam" price="1.50" material="Toughened Steel" />
     <component name="Cam" price="1.50" material="Toughened Steel" />
     <component name="Cam" price="1.50" material="Toughened Steel" />
     <component name="Cam" price="1.50" material="Toughened Steel" />
     <component name="Bearing" price="1.00" material="Toughened Steel" />
     <component name="Bearing" price="1.00" material="Toughened Steel" />
     <component name="Cam Chain Sprocket" price="4.20" material="Toughened Steel" />
     <component name="Cam Chain" price="4.20" material="Toughened Steel" />
     <component name="Tensioner" price="0.50" material="Plastic" />
   </assembly>
   <component name="Head" price="12.40" material="Alloy" />
   <component name="Plug" price="3.00"  material="Bakelite/Steel" />
  </assembly>
  <assembly name="Cylinder Block">
   <component name="Cylinder" price="20.00"  material="Alloy" />
   <component name="Sleeve" price="10.00"  material="Toughened Steel" />
  </assembly>
  <assembly name="Carburetor">
  <assembly name="Piston Assembly"/>
   <component name="Piston" price="20.00" material="Toughened Steel" />
   <component name="Ring" price="10.00" material="Spring Steel" />
   <component name="Ring" price="10.00"  material="Spring Steel" />
   <component name="Con Rod" price="10.00" material="Toughened Steel" />
  </assembly>
 </assembly>
</machine>
```

The resulting output shows only the parts whose material is *Toughened Steel*:

```
<results><contents>
Iterating Over parts which have a material name of Toughened Steel
component = Tappet 3.50 Toughened Steel
component = Seat 3.50 Toughened Steel
component = Cam 1.50 Toughened Steel
component = Cam 1.50 Toughened Steel
component = Cam 1.50 Toughened Steel
component = Cam 1.50 Toughened Steel
```

```
component = Bearing 1.00 Toughened Steel
component = Bearing 1.00 Toughened Steel
component = Cam Chain Sprocket 4.20 Toughened Steel
component = Cam Chain 4.20 Toughened Steel
component = Sleeve 10.00 Toughened Steel
component = Piston 20.00 Toughened Steel
component = Con Rod 10.00 Toughened Steel
</contents></results>
```

Creating and transforming messages using a PHPCompute node

You can use the PHPCompute node to create and copy messages, and to create and manipulate message elements.

About this task

These topics describe how to transform messages by using a PHPCompute node:

- "Creating a new message using a PHPCompute node"
- "Copying a message using a PHPCompute node" on page 2703
- "Setting and moving message elements using a PHPCompute node" on page 2704
- "Creating new elements using a PHPCompute node" on page 2706

Related concepts:

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Message modeling" on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

"Defining message flow content" on page 1488
You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Related reference:

"PHPCompute node" on page 4639
Use the PHPCompute node to route and transform an incoming message, using the PHP scripting language.

Creating a new message using a PHPCompute node:

Create a new output message by using the PHPCompute node.

About this task

When you use a PHPCompute node to create a new output message, the code required depends on whether the annotated evaluate method is defined in the PHP script.

If you use the @MessageBrokerSimpleTransform annotation, the new output message and message assembly objects are created automatically. For example:

```
<?php

class MyNode {

 /**
  * @MessageBrokerSimpleTransform
  */
 function evaluate($output_assembly, $input_assembly) {
  // $output_assembly refers to the new message
 }
}

?>
```

If you use a plain script without an annotated evaluate method, you must create the output message and message assembly objects explicitly:

```
<?php

// the output message must be created explicitly
$output_message = new MbsMessage();

// a new output message assembly must be created to hold this new message
$output_assembly = new MbsMessageAssembly($assembly, $output_message);

?>
```

Copying a message using a PHPCompute node:

Copy an existing message using the PHPCompute node.

About this task

When you use a PHPCompute node to copy an existing message, the code required depends on whether or not the annotated evaluate method is defined in the PHP script.

If you use the @MessageBrokerCopyTransform annotation, the new output message and message assembly objects are created automatically. For example:

```
<?php

class MyNode {

 /**
```

```
  * @MessageBrokerCopyTransform
  */
 function evaluate($output_assembly, $input_assembly) {
  // $output_assembly refers to the new message
 }
}

?>
```

If you use a plain script without an annotated evaluate method, you must create the output message and message assembly objects explicitly:

```
<?php

// create a copy of the input message
$output_message = new MbsMessage($assembly[MB_MESSAGE]);

// a new output message assembly must be created to hold this new message
$output_assembly = new MbsMessageAssembly($assembly, $output_message);

?>
```

Setting and moving message elements using a PHPCompute node:

You can transform elements in the message as it passes through a PHPCompute node in the message flow.

About this task

The following sections show the methods that you can use to modify, move, and remove elements:

- "Setting information about an element"
- "Moving elements"
- "Removing elements"

The "PHP API" on page 5313 reference information provides details about each of the methods used in the following sections.

Setting information about an element:
About this task

Use these methods to set information about the referenced element:

setName()
Sets the name of the current element

setValue()
Sets the value of the current element

setType()
Sets the specific type of the current element. For a full list of type values, see:

- "PHP constants for type values" on page 5343

setNamespace()
Sets the namespace URI of the current element

You can also set the value of an element by using the assignment operator. For example, `$element = 'text';` is equivalent to `$element.setValue('text');`.

Moving elements:
About this task

Use a PHPCompute node to copy or detach an element from a message tree by using the following methods:

`detach()`
Detaches the current element from the tree

`detachAllChildren()`
Detaches all children of the current element from the tree

Use one of the following methods to attach an element or subtree that you have copied on to another tree:

`addElement(`*element*`)`
Adds an element as the last child (by default) of the current element

`addAttribute(`*attribute*`)`
Adds an attribute to the current element

Removing elements:
About this task

Use these methods to remove elements from the message tree:

detach()
Detaches the current element from the tree

detachAllChildren()
Detaches all children of the current element from the tree

You can also remove elements from the message tree by using the PHP unset() function. For example:

```
unset($output_assembly->XMLNSC->doc->folder->item);
$output_assembly->XMLNSC->doc->folder->item->detach();
```

You can use type values to create syntax elements in your message tree.

Creating new elements using a PHPCompute node:

Use the PHPCompute node to create new elements in a message tree.

About this task

You can create new elements in a message tree in several ways:

- By using the MbsElement addElement method. By default this creates an element as the last child of the current element. This method has the following parameters:
  - **name**
  - **value**
  - **namespace**

- **type** (optional)
- **position** (optional)

The **type** parameter is the parser-specific type of the new node, which defaults to the XML element type for XML parsers. For a full list of values for the **type** parameter, see:

- "PHP constants for type values" on page 5343

The **position** parameter can have one of the following values:
- *MB_FIRST_CHILD*
- *MB_LAST_CHILD*
- *MB_NEXT_SIBLING*
- *MB_PREVIOUS_SIBLING*

- By using the path syntax. Elements on the left side of an assignment expression are created (if they do not exist already) when they are referenced in a path. For example, the following code navigates the elements in the XMLNSC tree, creating them if necessary:

```
$output_assembly->XMLNSC->doc->folder->item = 'book';
```

- By using an MbsElement constructor. To create a PHP function that creates and returns a subtree (part of a message), you can instantiate an element, build extra elements (using either of the previous two methods described), and return the result. You can then assign the result into the output message. For example:

```
$output_assembly->XMLNSC->doc->part = create_subtree();

function create_subtree() {
 $element = new MbsElement();
 $element->folder->item = 'some value';
 return $element;
}
```

You can also use the MbsElement addElementFromBitstream method to create an element tree from a string containing an unparsed bit stream. Use this method to defer until run time the decision about which parser to use.

You can use type values to create syntax elements in your message tree.

"PHP API" on page 5313
The WebSphere Message Broker PHP API provides classes to represent the message, the message assembly, and the element tree.

XML support

The PHP capability in WebSphere Message Broker provides support for XML.

XML namespaces

The path navigation syntax in the PHPCompute node is not namespace aware. As a result, the expression shown in the following example navigates through the catalogue and entry elements regardless of the namespace URI of the elements:

```
$ref->catalogue->entry
```

If you generate an output message that requires namespace elements, set the namespace URI after you create the path:

```
$table->entry = $ref->catalogue->entry;
$table->entry->setNamespace('http://www.ibm.com/namespaceURI');
```

Alternatively, you can create the entry element by using the addElement API method:

```
$value = $ref->catalogue->entry;
$table->addElement('entry', $value, 'http://www.ibm.com/namespaceURI');
```

XML attributes

XML attributes are stored in the element tree as MbsElements with a *type* value that identifies them as attributes. The path syntax supports addressing an attribute of an element, by using the array operator with the attribute name as the key; therefore, attributes function as map arrays on the element. For example, the following code returns the *name* attribute of the **folder** element:

```
$attr = $input->XMLNSC->doc->folder['name']
```

You can create attributes in a similar way; for example:

```
$output->XMLNSC->doc->folder['name'] = 'PHP';
```

This example generates the following XML code:

```
<doc>
 <folder name='PHP'/>
</doc>
```

the PHP scripting language.

Routing a message using a PHPCompute node

Route a message by using the PHPCompute node as a filter node.

Before you begin

Before you start:

Add a "PHPCompute node" on page 4639 to your message flow.

About this task

By default, the output message assembly is propagated to the Out terminal after the evaluate method in the PHP script has been processed. However, the PHPCompute node also has dynamic output terminals, so that you can use it as a filter node by propagating a message to the appropriate terminal, based on the message content.

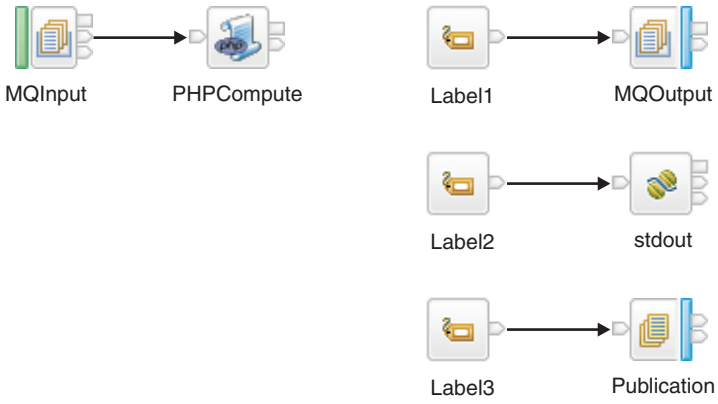
You can use the @MessageBrokerRouter annotation in your PHP code to route the message to a terminal specified by the string return value of the evaluate method. If no string is returned, the message is not propagated.

The following example shows the @MessageBrokerRouter annotation in a PHP script file:

```
/**
   * @MessageBrokerRouter
   */
  function evaluate($message) {
    if ($message->XMLNSC->doc->threshold->getValue() > 10) {
      return 'out';
    } else {
      return 'other';
    }
  }
```

For more information about using the @MessageBrokerRouter annotation for message routing, see "@MessageBrokerRouter" on page 2679.

Alternatively, you can propagate a message directly to a Label node. When you use this method, you do not need to use a RouteToLabel node, and you do not need to propagate messages to output terminals.



The following example shows the PHP code associated with the PHPCompute node in the message flow shown above. The PHP code specifies that the message is to be routed to the node called *Label2*:

```
...
$output->routeToLabel('Label2');
```

Accessing other parts of the message tree using the PHPCompute node

You can use the PHPCompute node to access headers, broker properties, user-defined properties, the local environment, and the global environment.

About this task

The message tree is passed to a PHPCompute node as an argument of the evaluate method. The argument is an MbsMessageAssembly object. The message assembly contains four message objects:

- Parsed message
- LocalEnvironment
- GlobalEnvironment
- ExceptionList

The following constants are provided for accessing the different trees:

- MB_MESSAGE (default)
- MB_LOCAL_ENVIRONMENT
- MB_GLOBAL_ENVIRONMENT
- MB_EXCEPTION_LIST

The following topics describe how to access parts of the message tree:

- "Accessing headers with a PHPCompute node"

Accessing headers with a PHPCompute node:

Access MQMD and MQRFH2 headers by using a PHPCompute node.

About this task

If an input node receives an input message that includes message headers that the input node recognizes, the node invokes the correct parser for each header. Parsers are supplied for most WebSphere MQ headers. This topic provides guidance for accessing the information in the MQMD and MQRFH2 headers that you can follow when accessing other headers that are present in your messages.

For more information about the contents of these and other WebSphere MQ headers for which WebSphere Message Broker provides a parser, see "Element definitions for message parsers" on page 4237.

Accessing the MQMD header:
About this task

WebSphere MQ messages include an MQMD header. You can use a PHPCompute node to refer to the fields within the MQMD, and to update them.

The following PHP code shows how to add an MQMD header to your message:

```
$output_assembly->MQMD->Version = 2;
```

Accessing the MQRFH2 header:
About this task

The following PHP code adds an MQRFH2 header to an outgoing message that is to be used to make a subscription request:

```
$output_assembly->MQRFH2->psc->Topic = 'department/sales';
```

Updating the local environment with the PHPCompute node:

The local environment tree is part of the logical message tree in which you can store information while the message flow processes the message.

About this task

Follow these steps to update the local environment:

Procedure

1. Make a copy of the local environment to update.
2. Use the following PHP code to alter the copy of the local environment:

```
<?php

class LocalEnv {

  /**
   * @MessageBrokerLocalEnvironmentTransform
   */
  function evaluate($output_assembly, $input_assembly) {

    $output_assembly [MB_LOCAL_ENVIRONMENT] = $input_assembly->XMLNSC->Message;
    $output_assembly [MB_LOCAL_ENVIRONMENT]->Folder1 = 'some data';
    $output_assembly [MB_LOCAL_ENVIRONMENT]->Folder2->SubFolder = 'more data';
    }
}

?>
```

Updating the global environment with the PHPCompute node:

Use PHP code associated with a PHPCompute to modify the global environment.

About this task

The Global Environment tree is always created when the logical tree is created for an input message. You can use this tree for your own purposes, for example to pass information from one node to another. You can use the whole tree as a scratchpad or working area.

The global environment can be altered across the message flow. The following PHP code shows how to alter the global environment:

```
<?php
class GlobalEnv {

  /**
   *    */
  function evaluate($output_assembly, $input_assembly) {

    $output_assembly [MB_GLOBAL_ENVIRONMENT] = $input_assembly->XMLNSC->Message;
    $output_assembly [MB_GLOBAL_ENVIRONMENT]->Folder1 = 'some data';
    $output_assembly [MB_GLOBAL_ENVIRONMENT]->Folder2->SubFolder = 'more data';
    }
}

?>
```

Accessing broker properties from the PHPCompute node:

For each broker, WebSphere Message Broker maintains a set of properties, and you can access some of these properties from the PHP code associated with a PHPCompute node. You can have real-time access to details of a specific node, flow, or broker.

About this task

Four categories of broker property exist, which relate to:

- A specific node
- Nodes in general
- A message flow
- An execution group

Broker properties:

- Are grouped by broker, execution group, flow, and node
- Are case sensitive. Their names always start with an uppercase letter
- Return NULL if they do not contain a value

The use of the MB_* array indexes in the $_ENV array is deprecated. Use the $_MB array instead:

Broker property	**PHP variable**
Work Path	*$_MB['WORK_PATH']*
Broker Name (label)	*$_MB['BROKER_NAME']*
Execution Group Name (label)	*$_MB['EXECUTION_GROUP_NAME']*
Node Name (label)	*$_MB['NODE_NAME']*
Message Flow Name (label)	*$_MB['MESSAGE_FLOW_NAME']*
Script Name	*$_MB['SCRIPT_NAME']*

Related concepts:

Accessing user-defined properties from a PHPCompute node:

Customize a PHPCompute node to access properties that you have associated with the message flow in which the node is included.

About this task

To access these properties from a PHPCompute node, use the mb_get_user_defined_property(*name*) method, where *name* is the name of the property that you are accessing. This method returns a PHP datatype equivalent to the ESQL broker type in the property definition.

For more information about the ESQL to PHP mappings, see "PHP data types" on page 5323.

You can use the Administration API for WebSphere Message Broker (also known as the CMP API) to change the value of user-defined properties. Use the getUserDefinedPropertyNames(), getUserDefinedProperty(), and setUserDefinedProperty() methods to query, discover, and set user-defined properties, as described in "Setting message flow user-defined properties at run time in a CMP application" on page 985.

Calling Java from PHP

The IBM sMash Runtime for PHP provides access to Java classes and functionality from PHP. This Java Bridge can instantiate Java classes and call their methods.

You can manipulate values in an MRM or XMLNSC tree with xsd types that do not map directly to PHP types:

- xsd:decimal type java.math.BigDecimal
- xsd:dateTime com.ibm.broker.plugin.MbTimestamp

For example:

```
/**
* @MessageBrokerSimpleTransform
*/
function evaluate ($output, $input) {
 $number = $input->XMLNSC-doc->number->getValue();
 $signature = new JavaSignature (JAVA_STRING);
 $decimal = new Java("java.math.BigDecimal", $signature, "654.321");
 $sum = $number->add($decimal);
 $output->XMLNSC->doc->number = $sum;

 $timestamp = $input->XMLNSC->doc->date->getValue();
 $now = new Java("java.util.Date");
 $timestamp->setTime($now);
 $output->XMLNSC->doc->date = $timestamp;
}
```

Message flow aggregation

Aggregation is the generation and fan-out of related requests that are derived from a single input message, and the fan-in of the corresponding replies to produce a single aggregated reply message.

The initial request that is received by the message flow, representing a collection of related request items, is split into the appropriate number of individual requests to satisfy the subtasks of the initial request. This process is known as *fan-out*, and it is provided by a message flow that includes aggregation nodes.

Replies from the subtasks are combined and merged into a single reply, which is returned to the original requester (or another target application) to indicate completion of the processing. This process is known as *fan-in*, and it is also provided by a message flow that includes aggregation nodes.

A message aggregation is initiated by a message flow that contains the AggregateControl node followed by an AggregateRequest node. The responses are aggregated back together using a flow that contains the AggregateReply node. The aggregation nodes work correctly only for transports that use a request/reply model; for example, WebSphere MQ Enterprise Transport.

WebSphere Message Broker provides three message flow nodes that support aggregation:

- The AggregateControl node
- The AggregateRequest node
- The AggregateReply node

When you include these nodes in your message flows, the multiple fan-out requests are issued in sequence from one thread in the execution group process.

If you use WebSphere MQ Enterprise Transport, the responses that are received by the fan-in flow must be valid reply messages that contain the reply identifier. You must set the reply identifier to the value of the message in the request message's message descriptor (MQMD), then store the reply identifier in the correlation

identifier field (CorrelId) of the MQMD. If the CorrelId is set to MQCI_NONE, the AggregateReply node issues an error because the reply message is not valid, and cannot be matched to a request message.

You can also use these aggregation nodes to issue requests to applications outside the broker environment. Messages can be sent asynchronously to external applications or services; the responses are retrieved from those applications, and the responses are combined to provide a single response to the original request message.

These nodes can help to improve response time because slow requests can be performed in parallel, and they do not need to follow each other sequentially. If the subtasks can be processed independently, and they do not need to be handled as part of a single unit of work, they can be processed by separate message flows.

You can design and configure a message flow that provides a similar function without using the aggregation nodes, by issuing the subtask requests to another application (for example, using the HTTPRequest node), and recording the results of each request in the local environment. After each subtask has completed, merge the results from the LocalEnvironment in a Compute node, and create the combined response message for propagating to the target application. However, all the subtasks are performed sequentially, and they do not provide the performance benefits of parallel operation that you can achieve if you use the aggregation nodes.

Examples of aggregation flows that use the aggregation nodes are provided in the following samples:

- Aggregation
- Airline Reservations

The Aggregation sample demonstrates a simple four-way aggregation, and the Airline Reservations sample simulates requests that are related to an airline reservation service, and illustrates the techniques that are associated with aggregation flows.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The aggregation nodes store state for aggregations on WebSphere MQ queues. By default, the following storage queues are used:

- SYSTEM.BROKER.AGGR.CONTROL
- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST
- SYSTEM.BROKER.AGGR.UNKNOWN
- SYSTEM.BROKER.AGGR.TIMEOUT

However, you can create alternative storage queues and use an aggregation configurable service to specify which queues are to be used by the node. For more information, see “Configuring the storage of events for aggregation nodes” on page 753.

By default, the timeout on the AggregateControl node is set to 0. If you do not specify a timeout (or if you leave it set to 0), aggregation requests that WebSphere

MQ stores are never deleted unless all reply messages are returned. This situation might lead to a gradual build up of messages on the internal queues. Set the timeout to a value greater than zero to ensure that requests are removed and that queues do not fill up with redundant requests. It is good practice to set the timeout value to a large value, for example, 86400 seconds (24 hours), so that the queues clear old aggregation messages even if timeouts are not required or expected.

You can set the timeout either by setting the `Timeout` property on the AggregateControl node, or by using an Aggregation configurable service and specifying the `timeoutSeconds` property. For more information, see "Setting timeout values for aggregation" on page 2736.

The aggregation nodes use WebSphere MQ message expiry to manage timeout of messages. For message expiry to work, the aggregation nodes must browse the message queues. The aggregation nodes browse the queues automatically to ensure that expired messages are processed.

z/OS On z/OS, you can configure WebSphere MQ to run a scavenger process that browses the queues instead of the aggregation nodes. To enable the scavenger, set the broker's queue manager property EXPRYINT to a value of 5 seconds. If you do not set EXPRYINT, or set it to a value higher than 10 seconds, the aggregation nodes revert to browsing the aggregation queues automatically.

Configuring aggregation flows

Use aggregation message flows to generate and fan-out a number of related requests, fan-in the corresponding replies, and compile those replies into a single aggregated reply message, by using the AggregateControl, AggregateRequest, and AggregateReply nodes.

Before you begin

Before you start:

Read the following concept topic:

- "Message flow aggregation" on page 2718

About this task

By default, the messages are put onto a set of default storage queues (beginning SYSTEM.BROKER.AGGR) for processing, but you can use an Aggregation configurable service to specify alternative queues. You can also use the Aggregation configurable service to set a timeout for the aggregation.

For an overview of using aggregation in message flows, see "Message flow aggregation" on page 2718.

To configure aggregation flows see the following topics:

- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728
- "Associating fan-out and fan-in aggregation flows" on page 2733

Creating the aggregation fan-out flow:

The aggregation fan-out flow receives the initial input message and restructures it to present a number of requests to a number of target applications.

Before you begin

Before you start:

- For background information, see "Message flow aggregation" on page 2718.
- Create a message flow project, as described in "Creating a message flow project" on page 1425.

About this task

You can include the fan-out and fan-in flow in the same message flow. However, you might prefer to create two separate flows. For more information about the benefits of configuring separate message flows, see "Associating fan-out and fan-in aggregation flows" on page 2733.

To review an example of a fan-out flow that is supplied with WebSphere Message Broker, see the following sample:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create the fan-out flow:

Procedure

1. Create a message flow to provide the fan-out processing. For more information, see "Creating a message flow" on page 1431.
2. Add the following nodes to the message flow, then configure and connect them as described.

   Input node

   The input node receives an input message from which multiple request messages are generated. This node can be any one of the built-in nodes, or a user-defined input node.

   a. Select the input node to open the Properties view. The node properties are displayed.
   b. Specify the source of input messages for this node. For example, specify the name of a WebSphere MQ queue in the `Queue name` property. The MQInput node retrieves messages from this queue.
   c. Optional: set values for any other properties that you want to configure for this node. For example, to ensure that aggregate request messages are put under sync point, set the `Transaction mode` property to `Yes`. This option avoids the situation where the AggregateReply node receives response messages before it has received the control message that informs it of the aggregation instance. Putting the fan-out flow under transactional control ensures that the fan-out flow completes before any response messages get to the AggregateReply.
   d. Connect the input node's Out terminal to the In terminal of an AggregateControl node. This option represents the simplest configuration; if appropriate, you can include other nodes between the input node and the AggregateControl node. For example, store the request for audit purposes (in a DatabaseWarehouse node), or add a unique identifier to the message (in a Compute node).
   e. Optional: if your fan-out and fan-in flows are combined in one message flow, modify the `Order mode` property on the `Advanced` tab. Select the `By Queue Order` option and ensure that the `Logical Order` property is also selected. These options force the input node to be single threaded to maintain the logical order of the messages that arrive on the queue. Any additional instance threads that you make available are then shared among only the fan-in input nodes to improve the performance of aggregation. If your fan-in and fan-out flows are in separate message flows this step is not required because you can make additional threads available specifically to the fan-in flow.

   AggregateControl node

   The AggregateControl node updates the local environment that is associated with the input message with information required by the AggregateRequest node. The AggregateControl node creates the `LocalEnvironment.ComIbmAggregateControlNode` folder. This folder and

the fields in it are for internal use by WebSphere Message Broker and you should not rely on their existence or values when developing your message flows.

a. Select the AggregateControl node to open the Properties view. The node properties are displayed.
b. Set the `Aggregate name` property of the AggregateControl node to identify this particular aggregation. It is used later to associate this AggregateControl node with a specific AggregateReply node. The `Aggregate name` that you specify must be contextually unique in a broker.
c. Optional: set the `Timeout` property to specify how long the broker waits for replies to arrive before taking action (described in "Setting timeout values for aggregation" on page 2736). If a timeout is not set on the AggregateControl node then aggregate requests stored internally will not be removed unless all aggregate reply messages return. This situation might lead to a gradual build-up of messages on the internal queues. To avoid this situation, set the timeout to a value other than zero (zero means that a timeout never occurs) so that when the timeout is reached the requests are removed and the queues do not fill up with redundant requests. Even if timeouts are not required or expected, it is good practice to set the timeout value to a large value; for example, 86400 seconds (24 hours) so that the queues occasionally get cleared of old aggregations.
d. Connect the Out terminal of the AggregateControl node to the In terminal of one or more Compute nodes that provide the analysis and breakdown of the request in the input message that is propagated on this terminal.

Attention: The Control terminal of the AggregateControl node was deprecated at Version 6.0 and by default any connections from this terminal to the AggregateReply node (either direct or indirect) are ignored. This configuration maximizes the efficiency of aggregation flows and does not damage the reliability of aggregations. This configuration is the optimum configuration.

However, if you do want a control message to be sent from the AggregateControl node to the AggregateReply node, you must connect the Control terminal to the corresponding AggregateReply node on the fan-in flow (either directly or indirectly, as described in "Associating fan-out and fan-in aggregation flows" on page 2733). If you connect it indirectly to the AggregateReply node, for example through an MQOutput node, you must include a Compute node to add the appropriate headers to the message to ensure that it can be safely transmitted.

In addition, for the Control terminal and connections from it to be recognized, you must enable the environment variable MQSI_AGGR_COMPAT_MODE. However, choosing this option has implications regarding the performance and behavior of message aggregations. For a full description of these implications and the environment variable, see "Using control messages in aggregation flows" on page 2745.

Compute node

The Compute node extracts information from the input message and constructs a new output message.

If the target applications that handle the subtask requests can extract the information that they require from the single input message, you do not need to include a Compute node to split the message. You can pass the whole input message to all target applications.

If your target applications expect to receive an individual request, not the whole input message, you must include a Compute node to generate each individual subtask output message from the input message. Configure each Compute node in the following way, copying the appropriate subset of the input message to each output message:

a. Select the Compute node to open the Properties view. The node properties are displayed.

b. Select a value for the Basic property `Compute mode`. This property specifies which sections of the message tree are modified by the node. The AggregateControl node inserts elements into the local environment tree in the input message that the AggregateRequest node reads when the message reaches it. Ensure that the local environment is copied from the input message to the output message in the Compute node. This configuration happens automatically unless you specify a value that includes local environment (one of All, LocalEnvironment, LocalEnvironment and Message, or Exception and LocalEnvironment).

   If you specify one of these values, the broker assumes that you are customizing the Compute node with ESQL that writes to local environment, and that you are copying any elements in that tree that are required in the output message.

   To modify the local environment, add the following statement to copy the required aggregate information from input message to output message:

```
SET OutputLocalEnvironment.ComIbmAggregateControlNode =
           InputLocalEnvironment.ComIbmAggregateControlNode;
```

c. Optional: set values for any other properties that you want to configure for this node.

d. Connect the Out terminal of each Compute node to the In terminal of the output node that represents the destination of the output request message that you have created from the input message in this node.

Output node

Include an output node for each output message that you generate in your fan-out flow. Configure each node, as described later in this section, with the appropriate modifications for each destination.

The output node must be an output node that supports the request/reply model, such as an MQOutput node, or a mixture of these nodes (depending on the requirements of the target applications).

a. Select the output node to open the Properties view. The node properties are displayed.

b. Specify the destination for the output messages for this node. For example, specify the name of a WebSphere MQ queue in the `Queue name` property to which the MQOutput node sends messages. The

target application must process its request, and send the response to the reply destination indicated in its input message (for example the WebSphere MQ ReplyToQueue).

c. Click **Request** in the left view and set values for these properties to specify that replies are sent to the input queue of the fan-in flow.

d. Optional: set values for any other properties that you want to configure for this node.

e. Connect the Out terminal of the output node to the In terminal of an AggregateRequest node. When the message is propagated through the output node's Out terminal, the built-in output node updates the WrittenDestination folder in the associated local environment with additional information required by the AggregateRequest node.

The information written by the built-in nodes is queue name, queue manager name, message ID, and correlation ID (from the MQMD), and message reply identifier (set to the same value as message ID).

AggregateRequest node

Include an AggregateRequest node for each output message that you generate in your fan-out flow.

a. Select the AggregateRequest node to open the Properties view. The node properties are displayed.

b. Set the Basic property `Folder name` to a value that identifies the type of request that has been sent out. This value is used by the AggregateReply node to match up with the reply message when it is received in the fan-in flow. The folder name that you specify for each request that the fan-out flow generates must be unique.

The AggregateRequest node writes a record in WebSphere MQ for each message that it processes. This record enables the AggregateReply node to identify which request each response is associated with. If your output nodes are non-transactional, the response message might arrive at the fan-in flow before this database update is committed. For details on how you can use timeouts to avoid this situation, see "Setting timeout values for aggregation" on page 2736.

CAUTION:
Although the use of timeouts can help to avoid this situation described previously, configure your fan-out flow to be transactional. Therefore, response messages cannot get to the fan-in flow before the corresponding AggregateRequest nodes have committed their database updates.

3. To save the message flow and validate its configuration, press **Ctrl-S** or click **File** > **Save**.

What to do next

To collect the aggregation responses initiated by your fan-out flow, create a fan-in flow, as described in "Creating the aggregation fan-in flow" on page 2728.

Related concepts:

"Local environment tree structure" on page 1056
The local environment tree is a part of the logical message tree in which you can store information while the message flow processes the message.

Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

Creating the aggregation fan-in flow:

The aggregation fan-in flow receives the responses to the request messages that are sent out by the fan-out flow, and constructs a combined response message containing all the responses received.

Before you begin

Before you start:

- Read an overview of aggregation in "Message flow aggregation" on page 2718.
- Create a message flow project, as described in "Creating a message flow project" on page 1425.

About this task

You can include the fan-out and fan-in flow within the same message flow. However, you might prefer to create two separate flows. For more information about the benefits of configuring separate message flows, see "Associating fan-out and fan-in aggregation flows" on page 2733. Do not deploy multiple copies of the same fan-in flow either to the same or to different execution groups.

If you do not configure the fan-out flow to be transactional, the timeout values that you have specified might result in the combined response message being generated before the fan-in flow has received all the replies. For more information, see "Creating the aggregation fan-out flow" on page 2722.

To review an example of a fan-in flow see the following sample:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create the fan-in flow:

Procedure

1. Create a message flow to provide the fan-in processing.
2. Add the following nodes in the editor view and configure and connect them as described:

   Input node
   The input node receives the responses to the multiple request messages that are generated from the fan-out flow.

   This node must be an input node that supports the request/reply model, such as an MQInput node, or a mixture of these nodes

(depending on the requirements of the applications that send these responses). The response that is received by each input node must be sent across the same protocol as the request to which it corresponds. For example, if you include an MQOutput node in the fan-out flow, the response to that request must be received by an MQInput node in this fan-in flow.

a. Select the input node to open the Properties view. The node properties are displayed.
b. Specify the source of input messages for this node; for example, specify the name of a WebSphere MQ queue in the Basic property Queue name from which the MQInput node retrieves messages.
c. Optional: specify values for any other properties that you want to configure for this node.
d. Connect the Out terminal of the input node to the In terminal of an AggregateReply node.

   Connect the terminals in this way to create the simplest configuration; if appropriate, you can include other nodes between the input node and the AggregateReply node; for example, you might want to store the replies for audit purposes (in a Warehouse node).

Include just one input node that receives all the aggregation response messages at the beginnings of the fan-in flow as described previously. If you include multiple input nodes, threads that are started by a specific reply input node might complete the aggregation and execution of the message flow while other threads are sending their response messages to the AggregateReply node and becoming eligible to timeout. Use a single input node to enable sequential processing of replies for each aggregation. Specify additional instances to provide greater processing throughput in this single node, see "Configurable message flow properties" on page 4020.

AggregateReply node

The AggregateReply node receives the inbound responses from the input node through its In terminal. The AggregateReply node stores each reply message for subsequent processing.

When all the replies for a particular group of aggregation requests have been collected, the AggregateReply node creates an aggregated reply message, and propagates it through the Out terminal.

a. Select the AggregateReply node to open the Properties view. The node properties are displayed.
b. Set the Aggregate name property of the AggregateReply node to identify this aggregation. Set this value to be the same value that you set for the Aggregate name property in the corresponding AggregateControl node in the fan-out flow.
c. Optional: to retain an unrecognized message before propagating it to the Unknown terminal, set a value for the Unknown message timeout property. If you are using separate fan-out and fan-in flows, set this value to a non-zero number if the control message might be delayed.
d. Optional: to explicitly handle unrecognized messages, connect the Unknown terminal to another node, or sequence of nodes. If you do not connect this terminal to another node in the message flow, messages propagated through this terminal are discarded.

e. Optional: if you have specified a timeout value for this aggregation in the AggregateControl node, and you want to explicitly handle timeouts that expire before all replies are received, connect the Timeout terminal to another node, or sequence of nodes. Partially complete aggregated replies are sent to the Timeout terminal if the timer expires. If you do not connect this terminal to another node in the message flow, messages propagated through this terminal are discarded.

f. Optional: specify values for any other properties that you want to configure for this node.

g. Connect the Out terminal of the AggregateReply node to the In terminal of a Compute node.

Attention: The Control terminal of the AggregateReply node was deprecated at Version 6.0, and by default any connections to this terminal (either direct or indirect) are ignored. This change maximizes the efficiency of aggregation flows and does not damage the reliability of aggregations. This configuration provides the optimum content.

However, if you want the AggregateReply node to receive, on its Control terminal, the control message that was sent by the corresponding AggregateControl node on the fan-out flow, you must make the necessary connections as described in "Creating the aggregation fan-out flow" on page 2722. Keep the path from the AggregateReply node to the output node as direct as possible to maximize the performance of aggregations. Do not modify the content of this control message.

In addition, for the Control terminal and connections to it to be recognized, you must enable the environment variable MQSI_AGGR_COMPAT_MODE. If you choose this option, the performance and behavior of message aggregations might be affected; for a full description of these implications and the environment variable, see "Using control messages in aggregation flows" on page 2745.

Aggregated messages which are sent from the AggregateReply node output terminals (Out and Timeout) are not validated. Validation of data must be done before messages are sent to the AggregateReply node, because it ignores validation options when reconstructing the stored messages.

Compute node

The Compute node receives the message that contains the combined responses. Typically, the format of this combined message is not valid for output, because the aggregated reply message has an unusual structure and cannot be parsed into the bit stream required by some nodes, for example the MQOutput node. The Out and Timeout terminals always propagate an aggregated reply message, which always requires further processing before it can be propagated to an MQOutput node. Therefore you must include a Compute node and configure this node to create a valid output message.

a. Select the Compute node to open the Properties view. The node properties are displayed.

b. Specify in the Basic property ESQL module the name of the ESQL module that customizes the function of this node.
c. Right-click the node and click **Open ESQL** to open the ESQL file that contains the module for this node. The module is highlighted in the ESQL editor view.
d. Code the ESQL to create a single output message from the aggregated replies in the input message.

   The aggregated reply message is propagated through the Out terminal. Information about how you can access its contents is provided in "Accessing the combined message contents."
e. Optional: specify values for any other properties that you want to configure for this node.
f. Connect the Out terminal of the Compute node to the In terminal of the output node that represents the destination of the single response message.

Output node

Include an output node for your fan-in flow. This node can be any of the built-in nodes, or a user-defined output node.

a. Select the output node to open the Properties view. The node properties are displayed.
b. Specify the destination for the output message for this node; for example, specify in the Basic property Queue name the name of a WebSphere MQ queue to which the MQOutput node sends messages.
c. Optional: specify values for any other properties that you want to configure for this node.

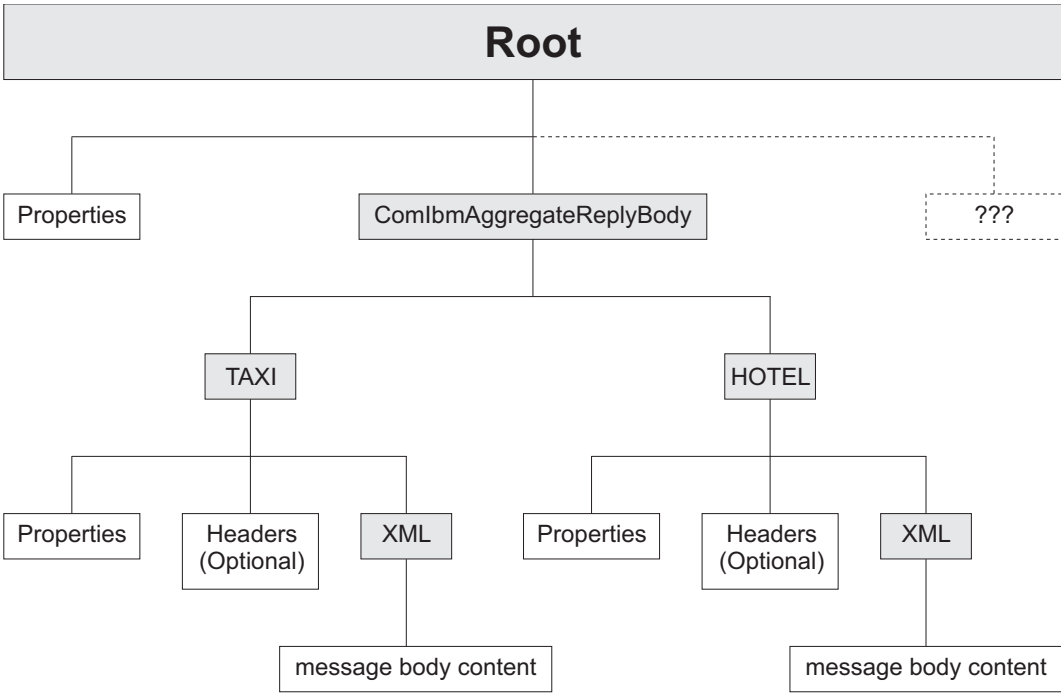
3. To save the message flow and validate its configuration, press Ctrl-S or click **File** > **Save**.

Accessing the combined message contents:
About this task

The AggregateReply node creates a folder in the combined message tree below Root, called ComIbmAggregateReplyBody. Below this folder, the node creates a number of subfolders using the names that you set in the AggregateRequest nodes. These subfolders are populated with the associated reply messages.

For example, the request messages might have folder names:
- TAXI
- HOTEL

The resulting aggregated reply message created by the AggregateReply node might have a structure like the following example:



Use ESQL within a Compute node to access the reply from the taxi company using the following correlation name:

```
InputRoot.ComIbmAggregateReplyBody.TAXI.xyz
```

The folder name does not have to be unique. If you have multiple requests with the folder name TAXI, you can access the separate replies using the array subscript notation, for example:

```
InputRoot.ComIbmAggregateReplyBody.TAXI[1].xyz
InputRoot.ComIbmAggregateReplyBody.TAXI[2].xyz
```

Associating fan-out and fan-in aggregation flows:

Associate the fan-out message flow processing with its corresponding fan-in message flow processing by setting the `Aggregate Name` property of the AggregateControl and AggregateReply nodes in your aggregation flow to the same value.

Before you begin

If you did not configure this property when you created your fan-in and fan-out flows, you must complete this task.

Before you start:

You must have completed the following tasks:
- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728

About this task

The `Aggregate Name` must be contextually unique within a broker. You can have only one AggregateControl node and one AggregateReply node with a particular `Aggregate Name`, although you can have more than one AggregateControl node with the same `Aggregate Name`, see "Using multiple AggregateControl nodes" on page 2741. Do not deploy a fan-in flow to multiple execution groups on the same broker; results are unpredictable.

You can either create the fan-out and fan-in flows in the same message flow, or in two different message flows. In either case, the two parts of the aggregation are associated when you set the `Aggregate Name` property.

How you configure your aggregation flow depends on a number of factors:

- The design of your message flow.
- The hardware on which the broker is running.
- The timeout values that you choose, see "Setting timeout values for aggregation" on page 2736.
- How you expect to maintain the message flows.

You can include the fan-out and fan-in flow within the same message flow. However, you might prefer to create two separate flows. The advantages of creating separate fan-out and fan-in flows are:

- You can modify the two flows independently.
- You can start and stop the two flows independently.
- You can deploy the two flows to separate execution groups to take advantage of multiprocessor systems, or to provide data segregation for security or integrity purposes.
- You can allocate different numbers of additional threads to the two flows, as appropriate, to maintain a suitable processing ratio.

The following sample shows the use of two flows for aggregation:

- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To associate the fan-out flow with the fan-in flow:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow that contains your fan-out flow.
3. Select the AggregateControl node to open the Properties view. The node properties are displayed.
4. Set the `Aggregate Name` property of the AggregateControl node to identify this aggregation. The `Aggregate Name` that you specify must be contextually unique within a broker.
5. `If you have separate fan-out and fan-in flows:`

a. Press Ctrl-S or click **File** > **Save** ***name*** on the taskbar menu (where *name* is the name of this message flow) to save the message flow and validate its configuration.
b. Open the message flow that contains your fan-in flow.

6. Select the AggregateControl node to open the Properties view. The node properties are displayed.
7. Set the `Aggregate Name` property of the AggregateReply node to the same value that you set for the `Aggregate Name` property in the corresponding AggregateControl node in the fan-out flow.
8. Press Ctrl-S or click **File** > **Save** ***name*** to save the message flow and validate its configuration.

What to do next

In WebSphere Message Broker, fan-out and fan-in flows were also associated by sending control messages from the AggregateControl node to the AggregateReply node. This facility is no longer available. For optimum performance, do not connect the AggregateControl and AggregateReply node. However, if you do want to use control messages in your aggregations, and you want to connect these two nodes, see "Using control messages in aggregation flows" on page 2745.

Setting timeout values for aggregation:

You can use two properties of the aggregation nodes to set timeout values for aggregated message processing.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:
- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728

About this task

Two situations might require the use of timeouts:
- The need to receive an aggregated reply message within a specified time. For this situation, you set the `Timeout` property of the AggregateControl node.
- The need to wait before propagating an unrecognized message to the Unknown terminal. For this situation, you set the `Unknown Message Timeout` property on the AggregateReply node.

The following sections describe each situation in more detail.

To receive an aggregated reply message within a specified time:
About this task

In some situations you might need to receive an aggregated reply message within a specified time. Some reply messages might be slow to return, or might never arrive. For these situations, complete the following steps.

1. Open the fan-out message flow.
2. Set the `Timeout` property of the AggregateControl node to specify how long (in seconds) the broker must wait for replies. By default, this property is set to 0 (zero), which means that there is no timeout and the broker waits indefinitely.

By default, timeout polling occurs every 5 seconds. Therefore, if you set the `Timeout` property to a value that is not a multiple of 5, an extra delay occurs. For example, if you set the `Timeout` property to 7 seconds, you see a delay of 3 seconds until timeout polling next occurs. You can change the default timeout polling interval by using the environment variable MQSI_AGGR_WAIT_TIMEOUT. Valid values are between 1000 and 5000 milliseconds. To change the default polling

interval, stop the broker, then restart the broker in an environment where you have set the MQSI_AGGR_WAIT_TIMEOUT environment variable.

You can also use an Aggregation configurable service to specify the timeout interval. You can create an Aggregation configurable service with the same name as the `Aggregate name` property of the AggregateControl node, and specify the timeout value in the `timeoutSeconds` property of the configurable service. Alternatively, you can create an Aggregation configurable service with the same name as the execution group. Values from Aggregation configurable services are taken in the following order:

1. If an Aggregation configurable service exists with the same name as the aggregation (defined in the `Aggregate name` property), that configurable service is used.
2. If no configurable service exists with the same name as aggregation, but a configurable service exists with the same name as the execution group, that configurable service is used.

If an Aggregation configurable service exists with the same name as an execution group, it can be used for every aggregation in the execution group. However, if a configurable service exists with the same name as an aggregation in the execution group, it is used for that specific aggregation. In each case, the value of the `timeoutSeconds` property of the configurable service overrides the `Timeout` property of the AggregateControl node.

Alternatively, you can use the `Timeout location` property of the AggregateControl node to specify the location of a timeout value in the incoming message. Any timeout value specified in this way overrides the values specified by the AggregateControl node and the Aggregation configurable service.

The timeout is determined by values in the message, the configurable service, or the node, in the following order:

1. If a timeout value is specified in the incoming message (in the location specified by the `Timeout location` property of the AggregateControl node) this value is used.
2. If no location is specified by the `Timeout location` property, or if the location in the message is empty or does not exist, the value specified by the `timeoutSeconds` property of the Aggregation configurable service is used (if one exists).
3. If no Aggregation configurable service has been defined, or if the `timeoutSeconds` property of the configurable service is not set, the value set in the `Timeout` property of the AggregateControl node is used.

For more information about the Aggregation configurable service, see "Configurable services properties" on page 3766.

If the timeout interval passes without all the replies arriving, the replies that have arrived are turned into an aggregated reply message by the corresponding AggregateReply node, and propagated to its Timeout terminal. You can process this partial response message in the same way as a complete aggregated reply message. If you prefer, you can provide special processing for incomplete aggregated replies.

To wait before propagating an unrecognized message to the Unknown terminal:

About this task

When a message arrives at the In terminal of an AggregateReply node, it is examined to see if it is an expected reply message. If it is not recognized, the message is propagated to the Unknown terminal. You might want the broker to wait for a specified period of time before propagating the message for the following reasons:

- The reply message might arrive before the work completed by the AggregateRequest node has been transactionally committed. This situation can be avoided by configuring the `Transaction mode` property of the input node, as described in "Creating the aggregation fan-out flow" on page 2722.
- The reply message might arrive before the control message. This situation can be avoided by leaving the Control terminal of the AggregateControl node unconnected. For further information about the implications of connecting the Control terminal, see "Using control messages in aggregation flows" on page 2745.

These situations are most likely to happen if you send the request messages out of syncpoint, and might result in valid replies being sent to the Unknown terminal. To reduce the likelihood of this event, complete the following steps.

1. Open the fan-in message flow.
2. Set the `Unknown Message Timeout` property of the AggregateReply node.

   When you set this property, a message that cannot be recognized immediately as a valid reply is held persistently in the broker for the number of seconds that you specify for this property.

If the unknown timeout interval expires, and the message is recognized, it is processed. The node also checks to see if this previously unknown message is the last reply needed to make an aggregation complete. If it is, the aggregated reply message is constructed and propagated.

If the unknown timeout interval expires and the message is still not recognized, the message is propagated to the Unknown terminal.

Processing timed out aggregation messages:

Assign additional processing threads to enable processing of timed out aggregation messages in the AggregateReply node.

Before you begin

Before you start:

To complete this task, the following conditions must be met:

- The AggregateReply node must be using an Aggregation configurable service.
- The associated Aggregation configurable service must have a queue prefix set that is unique across all Aggregation configurable services.
- The set of aggregation queues referred to by the associated Aggregation configurable service must only be used by a single execution group on a single broker.

About this task

By default the AggregateReply node uses a single thread to process timed out aggregation messages. In scenarios where a high volume of messages are expected to timeout, a backlog of messages can accumulate on the SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT queue. Follow this task to assign additional processing threads for timeout processing in the AggregateReply node.

You can configure the number of threads that are used to process timeout messages by setting the `timeoutThreads` property of the associated Aggregation configurable service. For example, use the following command:

```
mqsichangeproperties MYBROKER -c Aggregation -o myAggregationService -n timeoutThreads -v 10
```

This command sets the timeout threads of an aggregation to 10 for all nodes that are configured to use the myAggregationService configurable service.

Using multiple AggregateControl nodes:

You might find it useful to design a fan-out flow with multiple AggregateControl nodes, all with the same value set for the property `Aggregate Name`, but with different values for the `Timeout` property. You can reuse an aggregate name in only this situation.

Before you begin

Before you start:

For background information, see "Message flow aggregation" on page 2718.

To complete this task, you must have created a message flow project by following the instructions in "Creating a message flow project" on page 1425.

About this task

You might want to use multiple AggregateControl nodes if, for example, you have created an aggregation flow that books a business trip, and you might have some requests that need a reply within two days. However, other, more urgent requests, need a reply within two hours.

To configure an aggregation flow that uses multiple AggregateControl nodes, complete the following steps.

Procedure

1. Create or open the fan-out message flow.

2. Configure the required number of AggregateControl nodes. Set the Basic property `Aggregate Name` of each node to the same value. For example, include two nodes and enter the name `JOURNEY` as the `Aggregate Name` for both.
3. Set the value for the `Timeout` property in each node to a different value. For example, set the `Timeout` in one node to two hours; set the `Timeout` in the second node to two days.
4. Configure a Filter node to receive incoming requests, check their content, and route them to the correct AggregateControl node.
5. Connect the nodes together to achieve the required result. For example, if you have configured the Filter node to test for requests with a priority field set to urgent, connect the true terminal to the AggregateControl node with the short timeout. Connect the false terminal to the AggregateControl node with the longer timeout. Connect the out terminals of the AggregateControl nodes to the following nodes in the fan-out flow.

   You must connect the two AggregateControl nodes in parallel, not in sequence. This means that you must connect both to the Filter node (one to the true terminal, one to the false), and both to the downstream nodes that handle the requests for the fan-out. Each input message must pass through only one of the AggregateControl nodes. If you connect the nodes such that a single message is processed by more than one AggregateControl node, duplicate records are created in the database by the AggregateRequest node and subsequent processing results are unpredictable.

Results

The following diagram shows an example fan-out message flow that uses this technique.

Correlating input request and output response aggregation messages:

If you want to correlate initial request messages with their combined response messages, you can do so using the ReplyIdentifier in the Properties folder of the response message.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:
- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728

About this task

In some cases you might want to correlate aggregation request messages with the combined response message produced by your fan-in flow, there are two ways of doing this:

- Store some correlation information in one of the requests sent out as part of the aggregation.
- Send the original request message directly back to the AggregateReply node as one of the aggregation requests. To do this, the CorrelId must be set to the MsgId, and the MQOutput node must have its MessageContext set to 'Pass all'.

Using control messages in aggregation flows:

The default behavior is that connections between AggregateControl and AggregateReply nodes for sending control messages are ignored. This configuration optimizes performance and removes the possibility that response messages will be received by the AggregateReply node before the control message.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:
- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728

About this task

Control messages are not required to make aggregations work correctly. However, you can send control messages in your aggregation flows if you want. To send control messages in a message flow, see "Configuring message flows to send control messages" and "Configuring a broker environment to send control messages" on page 2746.

For a working example of aggregation (without the use of control messages), see the following sample:
- Airline Reservations

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Configuring message flows to send control messages:
About this task

To configure message flows to send control messages from an AggregateControl node to an AggregateReply node:

Procedure

1. If you have created the fan-out and fan-in flows in a single message flow:
   a. Open the aggregation message flow.
   b. Connect the Control terminal of the AggregateControl node to the Control terminal of the AggregateReply node to make the association.

   This connection is referred to as a direct connection between the two aggregation nodes.
2. If you have created separate fan-out and fan-in message flows:

a. Open the fan-out message flow.
b. Configure the AggregateControl node, see "Creating the aggregation fan-out flow" on page 2722.
c. At this stage, you can configure a Compute node that creates a valid output message that contains the control message. For example, to pass the control message to an MQOutput node, configure the Compute node to add an MQMD to the message and complete the required fields in that header. For example, you can code the following ESQL:

```
SET OutputRoot.MQMD.Version = MQMD_CURRENT_VERSION;
SET OutputRoot.MQMD.Format = MQFMT_STRING;
```

d. Configure an output node that represents the intermediate destination for the control message. For example, to send the control message to an intermediate WebSphere MQ queue, include an MQOutput node and identify the target queue in the Basic properties `Queue Manager Name` and `Queue Name`.
e. Connect the Control terminal of the AggregateControl node to the In terminal of the Compute node, and connect the Out terminal of the Compute node to the In terminal of the output node that represents the intermediate destination for the control message.
f. Open the fan-in message flow.
g. Configure one input node to receive the reply messages, see "Creating the aggregation fan-in flow" on page 2728. This input node also receives the control information from the AggregateControl node. For example, set the Basic property `Queue Name` of the MQInput node to receive the response and control message from an intermediate WebSphere MQ queue.
h. Add a Filter node to your fan-in flow after the input node and before the AggregateReply node, see "Avoiding thread starvation on fan-in flows" on page 2748.
i. Connect the Out terminal of the input node to the In terminal of the Filter node.
j. Connect the Out terminals of the Filter node to the Control terminal and in terminal of the AggregateReply node.

This connection is referred to as an indirect connection between the two aggregation nodes.

Configuring a broker environment to send control messages:
About this task

By default, in WebSphere Message Broker Version 7.0, all connections from the Control terminal of the AggregateRequest node to the AggregateReply node are ignored. For these connections to be active, create the MQSI_AGGR_COMPAT_MODE environment variable in the broker environment. By default, the environment variable does not exist. The existence of the environment variable means that connections from the AggregateControl node are active, regardless of the value to which the environment variable is set.

When the MQSI_AGGR_COMPAT_MODE environment variable has not been created, the default behavior for aggregation fan-out flows is used. If the Control terminal of the AggregateControl node is connected, either directly or indirectly, to the In terminal of the AggregateReply node, this connection is ignored and no control message is sent.

If the MQSI_AGGR_COMPAT_MODE environment variable is created, the default behavior for aggregation fan-out flows is not used, allowing you to send control messages from the AggregateControl node to the AggregateReply node. If the Control terminal of the AggregateControl node is connected, either directly or indirectly, to the In terminal of the AggregateReply node, see "Creating the aggregation fan-out flow" on page 2722, this connection is recognized and a control message is sent. Be aware that this configuration is not the optimal configuration and might affect performance.

To create the MQSI_AGGR_COMPAT_MODE variable to support connections between AggregateControl and AggregateReply nodes to be recognized:

- Windows On Windows:
  1. Open System Properties by clicking **Start** > **Control Panel** > **System**.
  2. Click the **Advanced** tab.
  3. Click **Environment Variables**.
  4. In the System variables pane, click **New**.
  5. Under **Variable name** type `MQSI_AGGR_COMPAT_MODE`.
  6. (Optional) You can type in the **Variable value** or leave it blank.
  7. For the environment variable to take effect, restart the computer.
- Linux UNIX z/OS On Linux, UNIX and z/OS:
  1. Edit the profile of the broker userid and include the following code:
     ```
     export MQSI_AGGR_COMPAT_MODE=
     ```
  2. Reload the profile.
  3. Restart the broker.

Avoiding thread starvation on fan-in flows:

Follow this guidance to avoid thread starvation on fan-in flows if the Control terminal of the AggregateControl node in your fan-out flow is connected to output control messages to a queue.

About this task

By not connecting the Control terminal, you can overcome the issues that are discussed here. For further information about connecting the Control terminal of the AggregateControl node, see "Using control messages in aggregation flows" on page 2745.

The Aggregate Reply node has two input terminals: In and Control. The use of the Control terminal is optional. If you use both of these terminals, the MQInput nodes that supply the two terminals must not use threads from the message flow additional instance pool. If the nodes do use these threads, they compete for resources, and the Control terminal's MQInput node typically takes all available threads because it is activated before the In terminal.

Configure each MQInput node to use additional instances that are defined on the node, not at the message flow level.

Handling exceptions in aggregation flows:

When you use aggregation flows, exceptions might occur.

Before you begin

Before you start:

Complete the following tasks:
- "Creating the aggregation fan-out flow" on page 2722
- "Creating the aggregation fan-in flow" on page 2728

Dealing with exceptions:
About this task

If an error is detected downstream of an AggregateReply node, the broker issues an exception. Another node in the message flow might also issue an exception using the ESQL THROW statement. In either case, when an exception occurs, it is caught in one of two places:
- The input node on which the replies arrive
- The AggregateReply node

The following table lists events and describes what happens to an exception that occurs downstream of the AggregateReply node.

Event	Message propagated	Output terminal	Exception caught at
An expected reply arrives at the input node and is passed to the In terminal of the AggregateReply node. The reply is the last one that is needed to make an aggregation complete.	An aggregated reply message that contains all the replies	Out	Input node
An unexpected reply arrives at the input node and is passed to the AggregateReply node. The reply is not recognized as a valid reply, and the `Unknown Message Timeout` property is set to `0`.	Message received	Unknown	Input node
A timeout occurs because all the replies for an aggregation have not yet arrived.	An aggregated reply message that contains all the replies that have been received	Timeout	AggregateReply node
An unknown timeout occurs because a retained message is not identified as a valid reply.	Retained message	Unknown	AggregateReply node
An aggregation is discovered to be complete at some time other than when the last reply arrived.	An aggregated reply message that contains all the replies	Out	AggregateReply node

To handle errors that occur in aggregation flows, you must catch these exceptions at all instances of each of these nodes in the message flow.

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the message flow with which you want to work.

3. To handle these exceptions yourself, connect the Catch terminal of each input and AggregateReply node to a sequence of nodes that handles the error that has occurred.

   For a unified approach to error handling, connect the Catch terminals of all these nodes to a single sequence of nodes, or create a subflow that handles errors in a single consistent manner, and connect that subflow to each Catch terminal.
4. If you want the broker to handle these exceptions using default error handling, do not connect the Catch terminals of these nodes.

Results

If you connect the Catch terminal of the AggregateReply node, and want to send the message that is propagated through this terminal to a destination from which it can be retrieved for later processing, include a Compute node in the catch flow to provide any transport-specific processing. For example, you must add an MQMD header if you want to put the message to a WebSphere MQ queue from an MQOutput node.

The following ESQL example shows you how to add an MQMD header and pass on the replies that are received by the AggregateReply node:

```
-- Add MQMD
SET OutputRoot.MQMD.Version = 2;
.
-- Include consolidated replies in the output message
SET OutputRoot.XMLNS.Data.Parsed = InputRoot.ComIbmAggregateReplyBody;
.
```

To propagate the information about the exception in the output message, set the `Compute mode` property of the Compute node to a value that includes `Exception`.

Exceptions when dealing with unknown and timeout messages:

When timeout messages or unknown messages from unknown timeout processing are produced from an AggregateReply node, they originate from an internal queue and not from an MQInput node. This behavior affects how the error handling should be performed.

If a message that is sent down the timeout thread causes an exception, the message rolls back to the AggregateReply node and is sent to the Catch terminal. If this terminal is unattached or an exception occurs while processing the message, the timeout is rolled back onto the internal queue and is reprocessed. Potentially, this behavior can lead to an infinite loop, which can be stopped by deploying a version of the message flow that fixes the problem.

To avoid this infinite loop, take the following actions.

- Connect the Catch terminal to a set of nodes that handle errors.
- Ensure that the error-handling nodes cannot throw an exception by ensuring that they perform very simple operations; for example, converting the message to a BLOB, then writing it to a queue, or adding extra TryCatch nodes.

The failure terminal of the AggregateReply node is not used currently and messages are not passed to this terminal.

Configuring the storage of events for aggregation nodes:

You can use an Aggregation configurable service to control the storage of events for AggregateControl and AggregateReply nodes.

About this task

By default, the storage queues used by all aggregation nodes are:

- SYSTEM.BROKER.AGGR.CONTROL
- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST

- SYSTEM.BROKER.AGGR.UNKNOWN
- SYSTEM.BROKER.AGGR.TIMEOUT

However, you can control the queues that are used by different aggregation nodes by creating alternative queues containing a *QueuePrefix*, and using an Aggregation configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry time of an aggregation:

Procedure

1. Create the storage queues to be used by the aggregation nodes. The following queues are required:
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.CONTROL
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REPLY
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.REQUEST
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.UNKNOWN
   - SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create an Aggregation configurable service. You can create a configurable service to be used with either a specific aggregation or with all aggregations in an execution group.
   a. If the configurable service is to be used with a specific aggregation, ensure that the name of the configurable service is the same as the name that you specify in the `Aggregate name` property on the AggregateControl and AggregateReply nodes. If the configurable service is to be used with all aggregations in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Timeout** property to control the expiry time of an aggregation.

   For example, create a configurable service called `myAggregation`, which specifies queues prefixed with SYSTEM.BROKER.AGGR.SET1 and a timeout of 60 seconds:

   ```
   mqsicreateconfigurableservice MYBROKER -c Aggregation -o myAggregation
   -n queuePrefix,timeoutSeconds -v SET1,60
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Aggregation configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see "Configurable services properties" on page 3766
3. In the AggregateControl and AggregateReply nodes:
   a. Ensure that the name of the Aggregation configurable service is the same as the name specified in the `Aggregate name` property on the **Basic** tab; for example, `myAggregation`. If no Aggregation configurable service exists with

the same name as the `Aggregate name` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.

b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Using message collections

A message collection is a single message that contains multiple messages derived from one or more sources. You can use a Collector node to group together messages from one or more sources into a message collection, so that they can be processed together by downstream nodes.

About this task

The topics in this section describe how message collection works, and how you can configure your message flow to process message collections.

Message collections

A message collection is a single message that contains multiple messages derived from one or more sources.

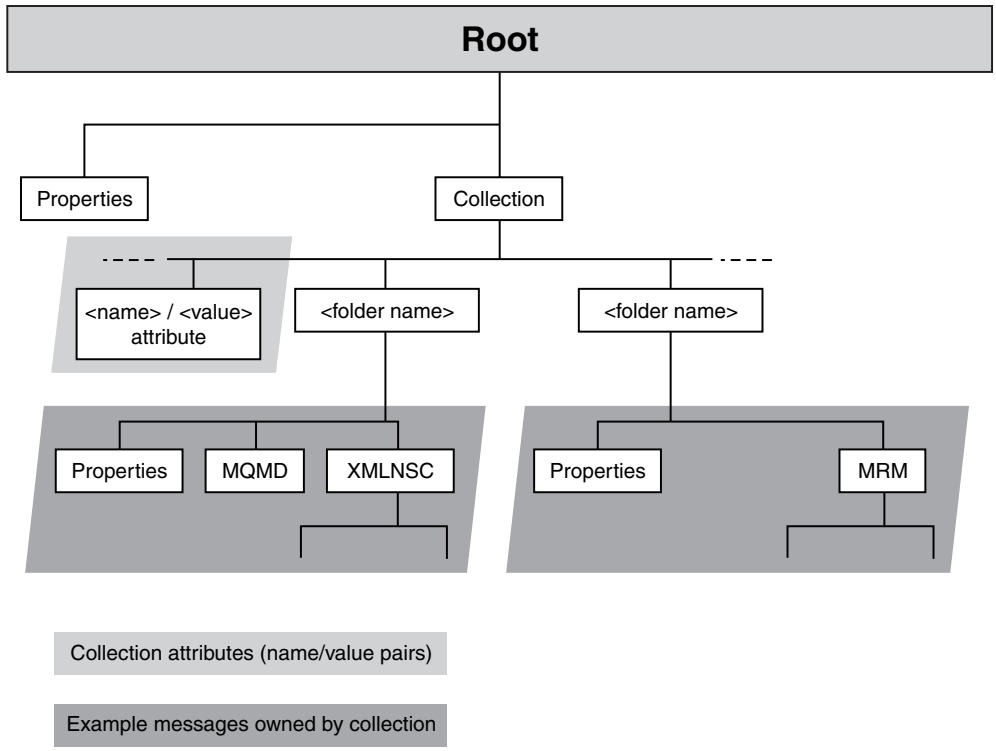
You can use a Collector node to group together messages from one or more sources into a message collection, so that they can be processed together by downstream nodes. You can also manually build a message collection using a Compute node.

Structure of a message collection

A message collection tree contains sub-trees that hold the content of the individual messages received by the Collector node. The message assembly that is propagated from the Collector node to other nodes in your message flow contains the following four components:

- Message (including transport headers)
- Local environment
- Global environment
- Exception list

The following figure shows an example of the message tree structure of a message collection.



The message collection in this example contains two messages, one received from WebSphere MQ, and one from a file input source.

A message collection has a Properties header and a single folder element named Collection. A message collection can also have zero or more attributes that are name/value pairs; the name of an attribute must be unique within a message collection. These are shown as `<name> / <value>` in the figure. A standard attribute for the message collection is an attribute called *`CollectionName`*. If you use a Collector node to generate a message collection, the value for the collection name is generated based on the values you configure in the node. The collection name attribute is not compulsory.

Within the Collection folder in the message collection tree structure are folders, shown as `<folder name>` in the diagram. These folders contain the message tree of each message added to the message collection. Each of these folders has a name, but this name does not have to be unique within the message collection. The value for the `<folder name>` is derived from the source of the input message.

Nested message collections are not permitted. You cannot therefore use a message collection as a source message for another message collection. For example, If you attempt to pass a message collection to a input terminal on a Collector node, an error is generated.

The LocalEnvironment, Environment and ExceptionList trees are not included in the structure, but are instead carried separately as a part of the message assembly. There is no concept of a LocalEnvironment associated with each message in a message collection.

Generating a message collection using a Collector node

You can use the Collector node to make multiple synchronous or asynchronous requests in parallel. The results of these requests can be joined together downstream if required. This is different from the behavior of the aggregation nodes where there is a fixed pattern of request/response and where reply messages are grouped by request id. In contrast, the collector node does not need an initial fan-out stage and can group together unrelated input messages by correlating their content. You can configure dynamic input terminals on a Collector node to receive messages from different sources. You can also configure properties on the Collector node, known as event handlers, to determine how messages are added to a message collection, and when a message collection is complete.

Processing a message collection

A message collection is supported by the following nodes only:

- Compute
- JavaCompute

Errors are generated by other nodes if they receive a message collection.

You can use ESQL or XPath expressions to access the content of messages in a message collection by referencing the folder names preceded by `InputRoot.Collection`. To access the contents of a message in a message collection using ESQL you can use code similar to the following ESQL:

```
InputRoot.Collection.folder1.XMLNSC
```

In XPath, the root element is the body of the message. The root element for a message collection is the Collection element. Therefore, to access the contents of a message in a message collection using XPath, you must use an expression similar to the following XPath:

```
/folder1/XMLNSC
```

Examples of XPath expressions that you can use to access the message collection are:

- `/*`: returns a list of all the messages in the message collection.
- `/@*`: returns a list of all the attributes of the message collection.
- `/@Name`: returns the value of the attribute `Name`.

You might not be able to determine the order of the messages within a message collection. If you generate a message collection using the Collector node, the messages are arranged in the same order as the messages arrived at the node.

"Using message collections" on page 2755
A message collection is a single message that contains multiple messages derived from one or more sources. You can use a Collector node to group together messages from one or more sources into a message collection, so that they can be processed together by downstream nodes.

Related reference:

"Built-in nodes" on page 4293
WebSphere Message Broker supplies built-in nodes that you can use to define your message flows.

"Collector node" on page 4333
Use the Collector node to create message collections based on rules that you configure in the node.

Creating a message collection by using ESQL

A message collection can be constructed by using ESQL. Using a message collection is useful if messages must be grouped together for parsing, or if the message collection must be constructed to represent a particular data structure, such as a CICS Transaction Server for z/OS channel data structure.

Before you begin

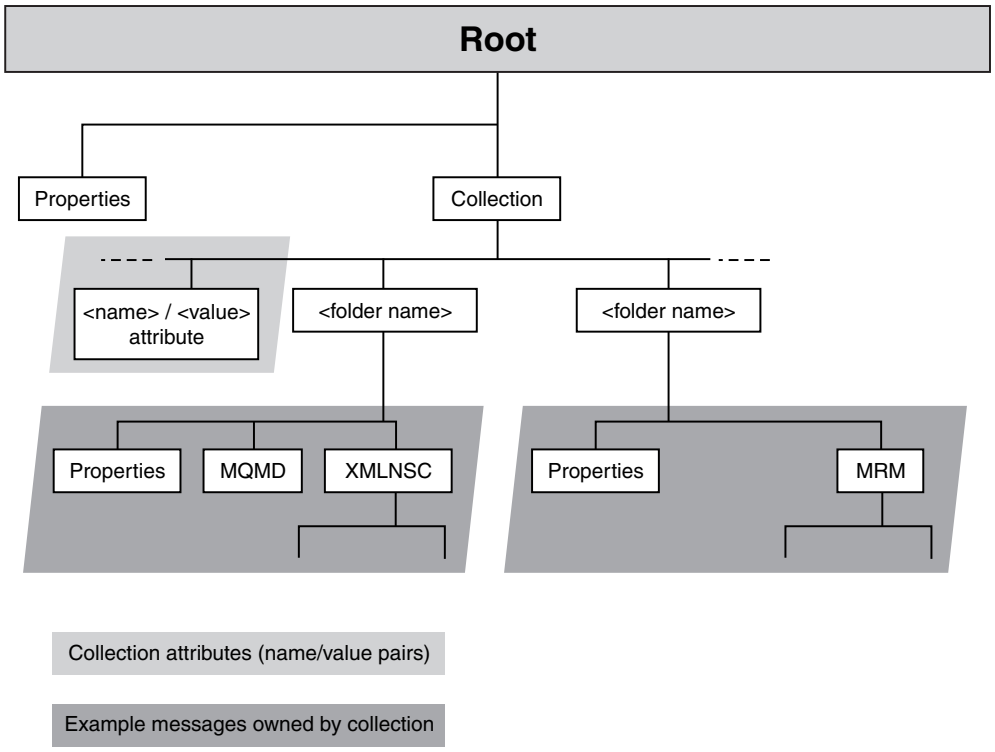
Before you start:

- Create a message flow project and a message set project, as described in "Creating a message flow project" on page 1425 and "Working with a message set project" on page 2838.
- For background information, read "Message collections" on page 2755.

About this task

A message collection is a message that consists of a `Properties` header and a single domain element named `Collection`. The `Collection` folder contains a number of child messages, each of which can contain a `Properties` folder, a number of headers (such as MQMD), and a body. A message collection can also have zero or more attributes that are name/value pairs. The name of an attribute must be unique within a message collection. A standard attribute for the message collection is an attribute called `CollectionName`.

The following figure shows an example of a message collection structure.



You can create a message collection by using ESQL to group messages together for parsing, or create a message collection that must be constructed to represent a particular data structure, such as a CICS channel data structure.

To configure a message collection by using ESQL, complete the following steps:

Procedure

1. Create a `Properties` folder for the collection by using the following ESQL statement:

   ```
   CREATE FIRSTCHILD of OutputRoot domain 'Properties' NAME 'Properties';
   ```

2. Create the `Collection` domain element by using the following statement:

   ```
   CREATE LASTCHILD OF OutputRoot DOMAIN 'Collection';
   ```

   As with message folders, the domain element is always the last child of the message.

3. Use the following statement to set an attribute in the collection called `CollectionName`:

   ```
   SET OutputRoot.Collection.CollectionName = 'myCollectionName';
   ```

4. The following ESQL shows an example procedure to create a message within the collection:

   ```
   SET OutputRoot.Collection.foldername.Properties.MessageSet     = set;
   SET OutputRoot.Collection.foldername.Properties.MessageType    = type;
   SET OutputRoot.Collection.foldername.Properties.MessageFormat  = format;
   SET OutputRoot.Collection.foldername.Properties.Encoding       = encoding;
   SET OutputRoot.Collection.foldername.Properties.CodedCharSetId = ccsid;

   SET OutputRoot.Collection.foldername.domain.content=some data;
   ```

Creating a message collection by using Java

A message collection can be constructed by using Java and the MbMessageCollection class. Using a message collection is useful if messages must be grouped together for parsing, or if the message collection must be constructed to represent a particular data structure, such as a CICS Transaction Server for z/OS channel data structure.

Before you begin

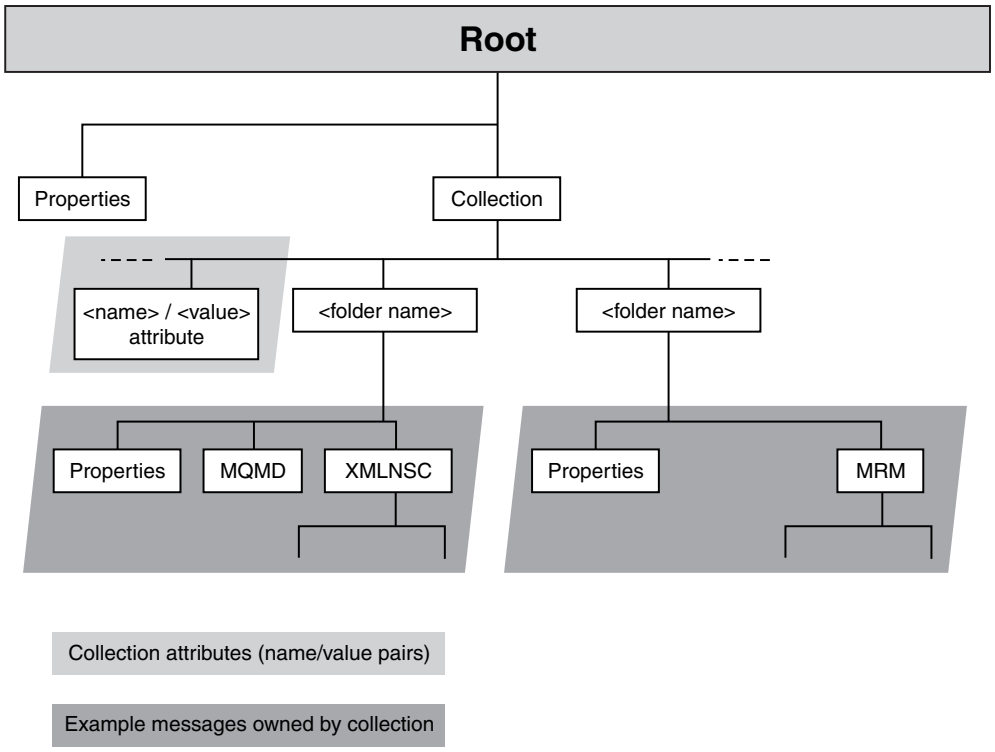
Before you start:

- Create a message flow project and a message set project. For more information, see "Creating a message flow project" on page 1425 and "Working with a message set project" on page 2838.
- For background information, read "Message collections" on page 2755.

About this task

A message collection is a message that consists of a `Properties` header and a single domain element named `Collection`. The `Collection` folder contains a number of child messages, each of which can contain a `Properties` folder, a number of headers (such as MQMD), and a body. A message collection can also have zero or more attributes that are name/value pairs. The name of an attribute must be unique within a message collection. A standard attribute for the message collection is an attribute called *`CollectionName`*.

The following figure shows an example of a message collection structure.



You can create a message collection by using Java, and the MbMessageCollection class, to group messages together for parsing, or create a message collection that must be constructed to represent a particular data structure, such as a CICS channel data structure.

To configure a message collection by using Java, complete the following steps:

Procedure

1. Create a new message by using the following example:

```
// create new message
MbMessageCollection outMessage = new MbMessageCollection();
MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly,
 outMessage);
```

2. Create a `Properties` folder for the collection by using the following example:

```
// create top level Properties folder and data
MbElement omroot = outMessage.getRootElement();
MbElement properties = omroot.createElementAsFirstChild("Properties");
MbElement property1 = properties.createElementAsLastChild(
 MbElement.TYPE_NAME_VALUE, "myProperty1", "propertyData1");
MbElement property2 = properties.createElementAsLastChild(
 MbElement.TYPE_NAME_VALUE, "myProperty2", "propertyData2");
```

3. Create the name value pairs by using the following example:

```
// create collection attributes (name/value pairs)
MbElement cn  = outMessage.createNameValue("CollectionName", "myCollectionName");
MbElement nv1 = outMessage.createNameValue("NAME1", "Value1");
MbElement nv2 = outMessage.createNameValue("NAME2", 12345);
```

   As with message folders, the domain element is always the last child of the message property.

4. The following example shows the procedure to create a message within the collection. Steps one, two, and three are repeated.

```
public void evaluate(MbMessageAssembly inAssembly) throws MbException {
 MbOutputTerminal out = getOutputTerminal("out");

 // create new message
 MbMessageCollection outMessage = new MbMessageCollection();
 MbMessageAssembly outAssembly = new MbMessageAssembly(inAssembly,
  outMessage);

 // create top level Properties folder and data
 MbElement omroot = outMessage.getRootElement();
 MbElement properties = omroot.createElementAsFirstChild("Properties");
 MbElement property1 = properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myProperty1", "propertyData1");
 MbElement property2 = properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myProperty2", "propertyData2");

 // create collection attributes (name/value pairs)
 MbElement cn  = outMessage.createNameValue("CollectionName", "myCollectionName");
 MbElement nv1 = outMessage.createNameValue("NAME1", "Value1");
 MbElement nv2 = outMessage.createNameValue("NAME2", 12345);

 // create folder 1
 MbElement folder1 = outMessage.createFolder("folder1");

 // create properties for folder 1
 MbElement folder1properties = folder1.createElementAsFirstChild("Properties");
 MbElement folder1property1 = folder1properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myFolder1Property1", "folder1propertyData1");
 MbElement folder1property2 = folder1properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myFolder1Property2", "folder1propertyData2");

 // create body of folder 1
 MbElement mrm = folder1.createElementAsLastChild("MRM");

 // create message domain element of folder 1
 MbElement msg = mrm.createElementAsLastChild(MbElement.TYPE_NAME,
  "msg", null);

 // create data within the message body for folder 1
 MbElement data = msg.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "data", "myData");

 // create folder 2
 MbElement folder2 = outMessage.createFolder("Folder2");

 // create properties for folder 2
 MbElement folder2properties = folder2.createElementAsFirstChild("Properties");
 MbElement folder2property1 = folder2properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myFolder2Property1", "folder2propertyData1");
 MbElement folder2property2 = folder2properties.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myFolder2Property2", "folder2propertyData2");

 // create body of folder 2
 MbElement xmlnsc = folder2.createElementAsLastChild("XMLNSC");

 // create message domain element of folder 2
 MbElement msg2 = xmlnsc.createElementAsLastChild(
  MbElement.TYPE_NAME, "msg2", null);

 // create data within the message body for folder 2
 MbElement data2 = msg2.createElementAsLastChild(
  MbElement.TYPE_NAME_VALUE, "myData2", "myXMLData");

 try {
```

```
     out.propagate(outAssembly);
    } finally {
     // clear the outMessage even if there's an exception
     outMessage.clearMessage();
    }
   }
```

Results

The following example output from a Trace node shows the message structure built by this Java code:

```
TraceOutput:  Root ( ['MQROOT' : 0xee3a90]
 (0x01000000:Name):Properties = ( ['MQPROPERTYPARSER' : 0xae4370]
  (0x03000000:NameValue):myProperty1 = 'propertyData1' (CHARACTER)
  (0x03000000:NameValue):myProperty2 = 'propertyData2' (CHARACTER)
 )
 (0x01000000:Name):Collection = ( ['COLLECTION' : 0x58d0b08]
  (0x03000000:NameValue):CollectionName = 'myCollectionName' (CHARACTER)
  (0x03000000:NameValue):NAME1          = 'Value1' (CHARACTER)
  (0x03000000:NameValue):NAME2          = 12345 (INTEGER)
  (0x01000000:Name     ):Folder1     = ( ['COLLECTIONFOLDER' : 0xee42e8]
   (0x01000000:Name ):Properties = ( ['MQPROPERTYPARSER' : 0xae39e8]
    (0x03000000:NameValue):myFolder1Property1 = 'folder1propertyData1' (CHARACTER)
    (0x03000000:NameValue):myFolder1Property2 = 'folder1propertyData2' (CHARACTER)
   )

You can define message flow content by adding and configuring message flow nodes and connecting them to form flows.

Creating a flow that uses message collections

Use a Collector node in your message flow to group messages from one or more sources into a message collection. You can add dynamic input terminals to your Collector node for each message source that you want to configure for your message flow.

Before you begin

Before you start:

Complete the following tasks.

- For background information, read "Message collections" on page 2755.
- Create a message flow project, as described in "Creating a message flow project" on page 1425.

About this task

You can also use a Compute node to create a message collection by using ESQL, which is useful if messages must be grouped together for parsing, or if the message collection must be constructed to represent a particular data structure, such as a CICS Transaction Server for z/OS channel data structure. For more information about using ESQL to create a message collection, see "Creating a message collection by using ESQL" on page 2758.

Look at the following sample to see how to use the Collector node for message collection:

- Collector Node

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create a message flow to generate and process message collections:

Procedure

1. Create a new message flow.
2. Add the input nodes in the editor view. The input nodes receive the messages from which message collections are generated. You can use any of the built-in nodes, or user-defined input nodes. Configure and connect them as described.
   a. Add an input node for each source of input messages for your message flow, for example an MQInput node and a JMSInput node.
   b. Select each input node in turn to display its properties in the Properties view.
   c. Specify the source of input messages for each node. For example, specify the name of a WebSphere MQ queue in the Basic property `Queue Name` from which the MQInput node retrieves messages.
   d. Optional: Specify values for any other properties that you want to configure for each node.

3. Add the Collector node in the editor view. The Collector node receives messages from input nodes or other nodes in the message flow. You must add a dynamic input terminal to the Collector node for each input message source before you can connect the input nodes or any upstream nodes to the Collector node. Configure and connect them as described.
   a. Add a Collector node to your message flow.
   b. Right-click the Collector node and click **Add Input Terminal** to add a new dynamic input terminal to the Collector node. Add a new input terminal for each input source that you plan to add to your message flow; for more information about adding dynamic input see "Adding an input terminal to a Collector node for each input source" on page 2768.
   c. Connect the out terminal of each input node to a different dynamic input terminal of the Collector node. This represents the simplest configuration; if appropriate, you can include other nodes between the input node and the Collector node. For example, you might want to store the request for audit purposes (in a Warehouse node), or add a unique identifier to the message (in a Compute node).
4. Add processing nodes to your message flow. You can process message collections from a Collector node using the following nodes only:
   - Compute
   - JavaCompute

   You must connect either a Compute node or a JavaCompute node to the Collector node in your message flow. Use these nodes to process the message collection and propagate other messages. You can use ESQL or XPATH to access the contents of the individual messages in the message collection for processing. To process a message collection:
   a. Add a Compute node or a JavaCompute node to your message flow.
   b. Code your ESQL or Java to create single output messages from the message collection.
   c. Optional: Specify values for any other properties that you want to configure for this processing node.
   d. Connect the out terminal of the processing node to the in terminal of an output node or other processing node.
   e. Optional: Add other nodes to your message flow for further processing.
5. Include one or more output nodes for your message flow. These can be any of the built-in nodes, or a user-defined output node. An output node cannot process a message collection, therefore ensure that you connect the output node to a processing node that propagates single output messages. To configure an output node:
   a. Select each output node in turn to display its properties in the Properties view.
   b. Specify the destination properties for each node. For example, specify the name of a WebSphere MQ queue in the Basic property `Queue Name` to which the MQOutput node sends messages.
   c. Optional: Specify values for any other properties that you want to configure for each node.
6. Include processing for handling errors and expired message collections:
   a. Optional: Add processing nodes to your message flow to handle expired message collections. Connect these nodes to the Expire terminal of the Collector node.

b. Optional: Add processing or error handling nodes to handle any exceptions in your message flow. Connect these nodes to the Catch terminal of the Collector node

   If an error is detected downstream of the Collector node, the broker throws an exception. The message collection is propagated to the Collector node's Catch terminal. Connect the Catch terminal to a sequence of nodes that handles the errors, to avoid losing any data, and ensure that no further exceptions can be generated during error processing. The node connected to the Catch terminal must be either a Compute node or a JavaCompute node to handle the message collection.

7. Press Ctrl-S or click **File** > **Save** ***name*** on the taskbar menu (where *name* is the name of this message flow) to save the message flow and validate its configuration.

Results

If you want to control when complete message collections are propagated, you must also add additional nodes to your message flow. For more information, see "Using control messages with the Collector node" on page 2779.

What to do next

Next: Configure the Collector node.

Adding an input terminal to a Collector node for each input source:

Add new dynamic input terminals to the Collector node for all of the sources of messages for your message collections.

Before you begin

Before you start:

This task assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

To add a dynamic input terminal to the Collector node for each message source, complete the following steps.

Procedure

1. Right-click the Collector node and select **Add Input Terminal**.
2. In the dialog box that is displayed, enter a name of your choice for the terminal, and click **OK**. The name that you give to the input terminal is used as the folder name in the message collection.
3. Repeat steps 1 and 2 to add further input terminals.

What to do next

Next:

When you have created all the required input terminals on the Collector node, you can set the event handler properties. For more information see, "Setting event handler properties" on page 2769.

Related concepts:

Setting event handler properties:

You can configure event handler properties for each dynamic input terminal on a Collector node. These event handler properties determine how the messages received by each terminal are added to message collections.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:
- "Creating a flow that uses message collections" on page 2764
- "Adding an input terminal to a Collector node for each input source" on page 2768

About this task

You can use one or more of the event handler properties to control the way that messages are added to message collections for each input terminal that you added to the Collector node. Incomplete message collections are stored on a WebSphere MQ queue. The message collections are stored in the order that they are generated by the Collector node (first in, first out). Each message collection has an event handler instance for each of the input terminals. The event handler determines whether an incoming message on that terminal is added to a message collection. The event handler instance maintains information about the state of the collection, the number of messages received, the timer, and the correlation string. When a new message is received on an input terminal, it is offered to the event handler for each message collection waiting on the queue in turn. When the message is accepted by one of the event handlers, it is added to the message collection. The accepted message is not offered to any other message collections. If all the event handlers reject the message, it is added to a new message collection, which is added to the end of the queue.

The first message accepted into a collection determines the correlation string for that message collection, if it is configured. Subsequent messages offered to that message collection are only accepted if their correlation string matches that of the collection. The first message accepted by each event handler starts the timeout timer, if it is configured. Each message accepted by each event handler increments the quantity count. An event handler becomes satisfied when the number of messages accepted equals the configured quantity, or when the timeout value is reached. When an event handler is satisfied, the event handler does not accept any more messages. A message collection is complete only when all of the message collection's event handlers are satisfied. The message collection is then ready for propagation.

You can configure the event handler properties by using the **Collection Definition** table, on the **Basic** tab of the Properties view.

To configure the event handler properties on the Collector node:

Procedure

1. Open the message flow with the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Basic** tab.
4. Use the following instructions to configure the event handler properties that you want to set for each input terminal:
   - If you want to add a set number of messages to each message collection from one or more of the terminals, you must enter a value for `Quantity` in the Collection Definition table. This value is used to specify the number of messages that each configured input terminal accepts to complete a collection. For example, if you have set `Quantity` to wait for 2 messages on three of the input terminals, the message collection is not complete until 2 messages have been received on each of the three input terminals. The complete message collection contains 6 messages, 2 from each of the three terminals. As soon as more than 2 messages are received on one of the input terminals, the next message is added to a new message collection.
     a. In the Collection Definition table, click the row for the selected input terminal within the `Quantity` column.
     b. Enter a value for the number of input messages that you want to add to a message collection. If you select `Zero` or choose not to set this property, there is no limit to the number of messages accepted. In this case the value set on the `Timeout` property must be greater than zero. If you accept the default value of `1`; only one message from the selected terminal is added to a collection.

     You must enter a value for `Quantity` if `Timeout` is not set.
   - If you want to collect messages for a set amount of time before the message collection is propagated you must enter a value for `Timeout`. This value is used to specify the maximum time in seconds for which the selected input terminal accepts messages before completing a message collection. The timeout interval starts when the first message has arrived at the selected terminal. Any subsequent messages are added to the same message collection. When the timeout interval ends, no more messages are added to the message collection from this terminal. When the conditions on all the terminals are satisfied, the message collection is ready for propagation. When the next message reaches the selected input terminal, a new message collection is created and the timeout interval starts again. If a timeout is set on multiple input terminals, each terminal collects messages for the configured amount of time. During the timeout messages from all of the terminals are added to the same message collection.
     a. In the Collection Definition table, click the row for the selected input terminal within the `Timeout` column.
     b. Enter a value for the length of time in seconds that you want to wait to add messages to a message collection. For example, to wait for messages to add to a message collection for an hour, enter a value of `3600`. If you accept the default value `Zero`, timeout is not enabled and there is no limit on the time to wait for messages. In this case the value set on the `Quantity` property must be greater than zero.

     You must enter a value for `Timeout` if `Quantity` is not set.
   - If you want to add messages to different message collections based on the content of the message you must enter an XPath value for the `Correlation path`. This value is used to specify the path in the incoming message from which to extract the correlation string. The correlation string is the value that is extracted by the correlation path. If a correlation pattern is specified, the

correlation string is matched against the correlation pattern. Messages are only accepted into a message collection with the same correlation string. If you specify an asterisk (*) in the name of the message collection, it is replaced by the correlation string.

a. In the Collection Definition table, click the row for the selected input terminal within the `Correlation path` column.

b. Either select a predefined correlation path from the list, or enter your own correlation path using XPath. The correlation path must begin with a correlation name, which can be followed by zero or more path fields. For example, in the following message the correlation string is `xxx` in the name field:

```
<library>
 <name>xxx</name>
 <more>
  ...
 </more>
</library>
```

In this example, the correlation path using XPath is `$Body/library/name`.

The variables `$Root`, `$LocalEnvironment`, and `$Environment` are available to allow the path to start at the roots of the message, local environment, environment trees, and message body.

If the correlation path evaluates to an empty string the unmatched message is added to a default unnamed message collection.

If you define a value for `Correlation path`, you can optionally configure a `Correlation pattern`.

- If you want to match a substring of the message content from the `Correlation path`, you can define a pattern to match in the message by using `Correlation pattern`. The `Correlation pattern` contains a single wildcard character and optional text. The correlation string, used for the name of the message collection, is the part of the substring that matches the wildcard. For example, if the correlation path contains the filename `part1.dat` in a file header, and the correlation pattern is specified as `*.dat`, the correlation string is `part1`.

  If this property is set, only messages that have the same correlation string are added to the same message collection. The first message added to a message collection determines the correlation string that must be matched by all other messages in that message collection.

  a. In the Collection Definition table, click the row for the selected input terminal within the `Correlation pattern` column.

  b. Enter a value for the correlation pattern. The `Correlation pattern` must contain a single wildcard character: *. This wildcard character can optionally be surrounded by other text.

  If the correlation pattern fails to match the wildcard to a substring, the unmatched message is added to a default unnamed message collection.

5. Repeat step 4 on page 2770 for each of the input terminals that you added to your Collector node. You can configure different event handlers for different input sources.

What to do next

Note: Ensure that you set the event handler properties across different terminals carefully to match the expected delivery of messages to the terminals on the Collector node.

You can now configure the collection expiry, see “Setting the collection expiry.”

Related reference:

“Collector node” on page 4333
Use the Collector node to create message collections based on rules that you configure in the node.

Setting the collection expiry:

The collection expiry is a property on the Collector node to set a maximum timeout for adding messages to a message collection.

Before you begin

Before you start:

This topic assumes that you have already created a message flow that contains a Collector node. For more information, see “Creating a flow that uses message collections” on page 2764.

About this task

When messages are added to a message collection, the incomplete message collection is stored on a queue. If the message collection's event handlers are not satisfied, the incomplete message collection is stored on the queue indefinitely, and not propagated for further processing. If a Collector node has 2 input terminals,

and one of the terminals stops receiving messages, for example if the source application is not running, there is the potential for the queue of incomplete message collections to grow indefinitely. To ensure that these incomplete message collections are released after an appropriate amount of time, configure the *Collection Expiry* property. You can configure this timeout, as a value in seconds, in the *Collection Expiry* property on the Collector node. The collection expiry timeout starts when the first message is accepted into a message collection. The collection expiry overrides any individual event handler timers. When the collection expiry timeout has passed for a message collection, the incomplete message collection is propagated to the **Expire** terminal. Connect appropriate processing nodes to the **Expire** terminal, to handle any expired message collections in your message flow.

To configure a collection expiry:

Procedure

1. Open the message flow with the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Basic** tab.
4. In `Collection Expiry`, enter a time in seconds for the collection expiry timeout.

What to do next

Next: Configure the collection name.

Use the Collector node to create message collections based on rules that you configure in the node.

Setting the collection name:

You can set a default name, or use a correlation string, for the name of your message collections, by using the `Collection name` property on the Collector node.

Before you begin

Before you start:

This task assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

Each message collection that is produced by the Collector node has a name. The collection name is the value that is associated with the CollectionName attribute in the message collection tree structure. Each message collection has only one name.

You can either use `Collection name` to set a default name to be used for each message collection, or you can use the event handler properties to create a correlation string to use for the message collection name. You can use the correlation string to generate a unique name for the message collection, based on the content of the input messages. To use the correlation string for the collection name, you must enter the wildcard symbol `*`. If you leave `Collection name` blank, or if it is set to `*` and the value of the correlation string is empty, the CollectionName attribute of the message collection is set to an empty value.

Any `*` characters in the collection name are replaced with the correlation string. The correlation string for each message collection is also copied into the local environment message that is associated with the propagated message collection. The location of the correlation string in the local environment is `Wildcard/WildcardMatch`.

To configure the message collection name:

Procedure

1. Open the message flow that contains the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Basic** tab.
4. For the `Collection name` property, enter a name for the message collections that are generated by the Collector node. If you have set a value for `Correlation path` on your input terminals, you can use the `*` for the `Collection name` property to substitute the correlation string into the collection name value. Leave the collection name blank if you want to set your message collection name to an empty value.

"Collector node" on page 4333
Use the Collector node to create message collections based on rules that you configure in the node.

Setting the event coordination property:

Use the `Event coordination` property for controlling how message collections are propagated from the Collector node.

Before you begin

Before you start:

This topic assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

In addition to the dynamic input terminals that you can add to the Collector node, there is a static input terminal called **Control**. The purpose of this terminal is to allow an external resource to trigger the output from the collector node. Details are controlled through the Event coordination property settings.

Incomplete message collections that have exceeded the value for the *`Collection expiry`* timeout are immediately propagated to the Expire terminal, regardless of how you configure the *`Event coordination`* property.

To configure *`Event coordination`*:

Procedure

1. Open the message flow that contains the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Advanced** tab.

4. Set the *Event coordination* property on the Collector node. Select from the following options:
   - If you select `Disabled`, messages to the **Control** terminal are ignored and message collections are propagated when they are complete.
   - If you select `All complete collections`, complete message collections are held on a queue. When a message is received on the **Control** terminal, all message collections on the queue are propagated to the **Out** terminal.
   - If you select `First complete collection`, complete message collections are held on a queue. When a message is received on the **Control** terminal, the first message collection on the queue is propagated to the **Out** terminal. If the queue is empty when a message arrives on the **Control** terminal, the next message collection that is completed is propagated to the **Out** terminal.

Results

You have completed configuration of the Collector node.

What to do next

Next: if you have configured your Collector node to use control messages, see "Using control messages with the Collector node" on page 2779.

"Collector node" on page 4333
Use the Collector node to create message collections based on rules that you configure in the node.

Setting the persistence mode property:

Use the `Persistence Mode` property to control whether incomplete message collections are stored persistently on the queues of a Collector node.

Before you begin

Before you start:

This topic assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

The storage of incoming messages and the Collector node state is handled internally by using WebSphere MQ queues. By default, incomplete message collections are stored non-persistently, which means that incomplete message collections persist if you restart your broker, but not if you restart your queue manager.

You can use the `Persistence Mode` property on the Collector node to store incomplete message collections on a queue persistently. If you set the `Persistence Mode` property to `Persistent`, incomplete message collections are not lost if you restart your queue manager. However, if you do set the property to `Persistent`, the overall performance of the Collector node might be affected.

To configure the `Persistence Mode`:

Procedure

1. Open the message flow that contains the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Advanced** tab.
4. Set the `Persistence Mode` property on the Collector node to one of the following values.
   - If you select `Non Persistent`, messages and collection state are stored by the broker queue manager as non-persistent messages.
   - If you select `Persistent`, messages and collection state are stored by the broker queue manager as persistent messages.

Results

You have completed configuration of the Collector node.

Setting the configurable service property:

Use the `Configurable service` property on the Collector node to specify a Collector configurable service that sets the values of properties at run time.

Before you begin

Before you start:

This task assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

You can use the `Configurable service` property on the Collector node to specify the name of a Collector configurable service to be used by the node. The Collector configurable service has the following properties:

`queuePrefix`
The identifier used to specify the names of queues in which events and collections are stored.

`collectionExpirySeconds`
The expiry time (in seconds) of a collection. This property overrides the value specified by the `Collection expiry` property on the Collector node.

To configure the `Configurable service` property, complete the following steps.

Procedure

1. Open the message flow that contains the Collector node.
2. Right-click the Collector node and select **Properties**.
3. Click the **Advanced** tab.
4. Specify the name of the Collector configurable service in the `Configurable service` field.

Using control messages with the Collector node

You can send control messages to the Collector node in order to control how complete message collections are propagated to other nodes in your message flow.

Before you begin

Before you start:

This task assumes that you have already created a message flow that contains a Collector node. For more information, see "Creating a flow that uses message collections" on page 2764.

About this task

You can control when complete message collections are propagated to other nodes for processing, using messages sent to the **Control** terminal. The exact behavior depends on the settings that you have chosen for the *Event coordination* property on the Collector node. If you want to use control messages to propagate completed messages collections you must set the *Event coordination* property to one of the following:

- `All complete collections`
- `First complete collection`

In these cases, the complete message collections are held on a queue until a control message is received. If you set *Event coordination* to `All complete collections`, all the message collections held on the queue are propagated to the **Out** terminal. If you set *Event coordination* to `First complete collection`, only the first message collection on the queue is propagated to the **Out** terminal. If there are no complete message collections on the queue, the next message collection to complete is immediately propagated to the **Out** terminal.

Incomplete message collections that have exceeded the value for *Collection expiry* are immediately propagated to the **Expire** terminal regardless of the setting of *Event coordination*.

If you want to propagate any complete message collections after a set amount of time for further processing, connect a TimeoutNotification node to the **Control** terminal of the Collector node. You can use the TimeoutNotification node to send a control message to propagate the message collections to ensure that messages are processing within a reasonable time, or to schedule processing tasks.

For more information about driving a message flow using the TimeoutNotification node, see "Automatically generating messages to drive a flow" on page 2817.

Alternatively, you can propagate complete message collections using a message from another application or message flow by connecting an input node to the **Control** terminal of the Collector node.

You can send any message to the **Control** terminal of the Collector node. The message received on the **Control** terminal is not examined by the broker and is discarded on receipt.

Configuring the storage of events for Collector nodes

You can use a Collector configurable service to control the storage of events for Collector nodes.

About this task

By default, the storage queues used by all Collector nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Resequence node.

However, you can control the queues that are used by different Collector nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Collector configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry for the collection:

Procedure

1. Create the storage queues to be used by the Collector node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Collector configurable service. You can create a configurable service to be used with either a specific collection or with all collections in an execution group.
   a. If you are creating a configurable service to be used with a specific collection, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Collector node. If you are creating a configurable service to be used with all collections in the execution group, ensure that the configurable service has the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Collection expiry** property.

   For example, create a Collector configurable service called `myCollectorService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, and with a collection expiry of 60 seconds:

```
mqsicreateconfigurableservice MYBROKER -c Collector -o myCollectorService
-n queuePrefix,collectionExpirySeconds -v SET1,60
```

You can use the **mqsideleteconfigurableservice** command to delete the Collector configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.

For more information, see "Configurable services properties" on page 3766

3. In the Collector node:
   a. If the configurable service is to be used for a specific collection, specify the name of the configurable service in the `Configurable service` property on the **Advanced** tab; for example, `myCollectorService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Using message sequences

You can maintain or change the sequence of messages in a message flow based on the sequence number and group ID contained in each message.

Before you begin

Before you start:

Read the following concept topics, which contain information that you need to understand before you can use message sequences:

- "Message sequencing" on page 2784
- "Sequence groups" on page 2786
- "Starting a message sequence" on page 2787
- "Ending a message sequence" on page 2790
- "Duplicate message processing" on page 2793

About this task

WebSphere Message Broker enables you to configure the sequence of messages in a message flow by using the following nodes:

- "Sequence node" on page 4736
- "Resequence node" on page 4651

The following topics describe the tasks involved in configuring message sequences:

- "Adding sequence numbers to messages" on page 2794
- "Reordering messages in a message flow" on page 2797
- "Maintaining the sequential order of messages" on page 2799
- "Handling missing messages" on page 2806
- "Configuring the storage of events for Resequence nodes" on page 758

These topics provide examples of how to use a Resequence node, and show how the node processes messages in a message flow:

- "Message sequencing scenario 1" on page 2800
- "Message sequencing scenario 2" on page 2803

Related concepts:

Message sequencing

Use message sequencing to ensure that messages are delivered to the receiving application in a particular order.

WebSphere Message Broker provides support for adding sequence numbers to messages, and for reordering messages in the message flow based on their sequence number. Messages can arrive in any order and you can use the Sequence and Resequence nodes to reorder the messages into the required sequence.

In some applications, the ability to process messages in a specific order is important for maintaining the integrity of the workflow. For example, a series of debits and credits against a bank account must be processed in the order in which they took place, and patient records that are received, processed, and forwarded must be sent on in the order in which they arrived.

Messages arriving in the message flow might or might not contain sequence numbers. If messages without sequence numbers are received from an input source, you can preserve the order in which the messages are received by using a Sequence node to generate a monotonically increasing sequence number for each message in the sequence group. When each message arrives at the Sequence node, the sequence number is incremented and stored with the message in a location specified on the node. The current sequence numbers for each active sequence group are stored on the following WebSphere MQ queues:

- SYSTEM.BROKER.SEQ.GROUP
- SYSTEM.BROKER.SEQ.NUMBER

For more information, see "Sequence node" on page 4736.

When the input messages contain sequence numbers, whether they were added by the Sequence node or already defined in an integer field in the message, you can use a Resequence node to change the order of the messages in the message flow.

When messages arrive at the Resequence node, they are held in a storage queue until all previous messages in the sequence have been propagated and committed. When each message becomes the next one in the sequence, it is taken off the queue and propagated down the Out terminal. This sequence of events ensures that messages are kept in the correct order even when message processing fails.

By default, the storage queues used by the Resequence node are:

- SYSTEM.BROKER.EDA.COLLECTIONS
- SYSTEM.BROKER.EDA.EVENTS

However, you can use a Resequence configurable service to specify alternative queues to be used by the Resequence node. For more information about using the Resequence configurable service, see “Configuring the storage of events for Resequence nodes” on page 758.

You can configure the Resequence node to time out if a message in the sequence fails to arrive in a specified period of time, and you can specify how subsequent messages are processed if a message is missing. For example, you can configure the node so that:

- The message sequence must always be maintained
- Gaps are allowed in the message sequence but all other messages must remain in sequence
- Occasional out-of-sequence messages are allowed

For information about how to configure the Resequence node for these scenarios, see “Handling missing messages” on page 2806.

You can divide messages into sequence groups, which can be processed independently, allowing multiple sequences to be processed at the same time. For more information about sequence groups and duplicate message processing, see “Sequence groups” on page 2786.

For more information about the way in which the beginning and end of sequences are controlled, see “Starting a message sequence” on page 2787.

Sequence groups

Use sequence groups to control the way in which messages are grouped together for processing by Sequence and Resequence nodes.

By default, all messages arriving at the Sequence and Resequence nodes are ordered as part of a single sequence group. However, you can divide messages into multiple sequence groups, based on a sequence group identifier in the message, and order each sequence group independently. For example, you might have a message flow that receives, processes, and forwards patient records. It is important that the order of records is maintained for each individual patient, but ordering between patients is not necessary. In this case, the sequence group identifier would be the name or ID of the patient.

The group to which a message belongs is determined by the group identifier that is specified in the message. You can use the **Path to sequence group identifier** property on the Sequence and Resequence nodes to specify the location of the sequence group identifier in the message.

Messages that have the same group identifier are considered part of the same sequence group. If no sequence group is specified, a single default sequence group is used for all messages. However, if the **Path to sequence group identifier** property specifies a location in the message that does not exist, an error occurs.

Each sequence group can be associated with only one Sequence node. Multiple nodes can have a sequence group with the same name, but each of those sequence groups is associated with only one node and is separate from other groups with the same name on different nodes. For example, SequenceNode1 might have a sequence group called GroupA, and SequenceNode2 might also have a sequence group called GroupA, but they are separate groups.

Although you can reuse sequence groups when they have been closed, there is a risk that two occurrences of the same sequence group could overlap, with unpredictable results.

For example, if you have a sequence group including the numbers 1-10 and the group is used twice in close succession, it is possible for the second occurrence of sequence number *1* to arrive before sequence number *10* of the first occurrence. If this happens, a duplicate message exception occurs. For this reason, it is advisable to use a group name for only one set of sequence numbers, rather than reusing it in a Resequence node. If you do decide to reuse a sequence group, ensure that you reuse it only when you can be certain that the preceding use has been finished for a significant amount of time.

Even if all the numbers have been received by the first occurrence of the group, it can be difficult to know for certain exactly when the group is closed because it closes only when the final message has completely finished processing; this includes any processing that is required downstream of the node. Any message from the second occurrence fails as a duplicate unless all processing is complete. When a sequence group has started overlapping, it is very difficult to recover all the messages (in both uses of the group) in the correct order, although no messages are lost).

Use the Collector node to create message collections based on rules that you configure in the node.

Starting a message sequence

The start of a message sequence is determined by the `Start of sequence definition` property on the Resequence and Sequence nodes.

Using a Resequence node

When you use the Resequence node to reorder messages in a message flow, you use the `Start of sequence definition` property on the Resequence node to define how the reordered message sequence will start. You can specify the starting sequence number in one of the following ways:

As a literal number

Select `Literal` to specify a literal sequence number, which can be any positive or negative numeric value in the range -9223372036854775807 to 9223372036854775807. When a message with the specified sequence number arrives, it is identified as the first message in the sequence and the messages are propagated.

Using the smallest number received

Select `Automatic` and specify the length of time (in seconds) during which the node collects messages, before it identifies the message that contains the smallest sequence number. When the smallest number has been determined, that sequence number becomes the first in the message sequence.

For example, assume that you have a Resequence node with the following properties:

- `Path to sequence number` property with a value of `/doc/seq`
- `Path to sequence group identifier` property with a value of `/doc/grp`
- `Start of sequence definition` property set to `Automatic` with a value of `5`. This value means that, for any new group, the Resequence node collects messages for 5 seconds before determining the starting sequence number.
- `End of sequence definition` property set to `Automatic` with a value of `60`. This value means that, for any new group, the Resequence node waits for 60 seconds before determining the ending sequence number.

The following messages are received by the Resequence node:

```
<doc><grp>a<grp><seq>5</seq></doc>
<doc><grp>a<grp><seq>4</seq></doc>
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>b<grp><seq>0</seq></doc>
<doc><grp>b<grp><seq>2</seq></doc>
```

At this point, the automatic period for the start of sequence expires (5 seconds), then the following messages are received:

```
<doc><grp>a<grp><seq>6</seq></doc>
<doc><grp>b<grp><seq>3</seq></doc>
```

For group *a*, the following messages are propagated to the Out terminal after 5 seconds:

```
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>4</seq></doc>
<doc><grp>a<grp><seq>5</seq></doc>
<doc><grp>a<grp><seq>6</seq></doc>
```

For group *b*, the following message is propagated to the Out terminal after 5 seconds:

```
<doc><grp>b<grp><seq>0</seq></doc>
```

No more messages are received before a missing message timeout occurs, at which point the following messages are propagated to the Expire terminal:

```
<doc><grp>b<grp><seq>2</seq></doc>
<doc><grp>b<grp><seq>3</seq></doc>
```

Using predicate set on the Resequence node

Select `Predicate` and specify an XPath expression to calculate whether the message is the first in the sequence. The predicate evaluates to either True or False, and messages continue to be collected while the expression evaluates to False. When the expression of a message is evaluated to True, it indicates that the message is the first in the sequence.

For example, you might specify the following XPath expression:

```
/Employee/EmpStartSeq="10"
```

When the input message field *EmpStartSeq* contains the value *10*, the start of sequence predicate is evaluated to True, and the message is identified as the first in the sequence:

```
<Employee>
 <EmpStartSeq>10</EmpStartSeq>
</Employee>
```

Typically, the XPath expression evaluates to a Boolean; however, if other data types are returned, the predicate is determined in the following way:

Table 29.

Returned data type	True	False
Boolean	True	False
Numeric	Any non-zero value	0 or 0.0
String	Any string matching `true` (case-insensitive)	Any string not matching `true` (case insensitive)
NodeSet	Never	Always

When a message evaluates the expression to True (and is therefore identified as the start of the sequence), the node checks that the message has the smallest sequence number collected up to that point. If messages are found with lower sequence numbers, an exception is thrown.

When the first message that evaluates to true has been processed successfully, the XPath expressions of subsequent messages are not checked. If a message arrives with a lower sequence number than the message that was identified as the start of the sequence, an exception is thrown.

Using a Sequence node

When you use the Sequence node to add sequence numbers to messages in the message flow, you use the `Start of sequence definition` property to specify a literal number that is to be used as the starting sequence number. The value can be any positive or negative integer in the range -9223372036854775807 to 9223372036854775807.

The Sequence node allocates a monotonically increasing sequence number for each input message that arrives at the node, starting with the sequence number that you define in the `Start of sequence definition` property. However, this value can be overridden by the value of the *StartOfSequenceNumber* field in the *LocalEnvironment* of the incoming message. For example:
`InputLocalEnvironment.Sequence.StartOfSequenceNumber = 10`.

Ending a message sequence

The end of a message sequence is determined by the `End of sequence definition` property on the Resequence and Sequence nodes.

Using a Resequence node

When you use the Resequence node to reorder messages in a message flow, you use the `End of sequence definition` property on the Resequence node to define how the reordered message sequence will end. You can specify the end sequence number in the Resequence node in one of the following ways:

As a literal number

Select `Literal` to specify a literal sequence number as the end of the sequence. This value can be any positive or negative numeric value in the range -9223372036854775807 to 9223372036854775807. When a message with the specified sequence number arrives, the sequence group is closed. If there are any messages missing from the sequence, the sequence group remains open for the period of time specified by the `Missing message timeout` property.

For example, assume that you have a Resequence node with the following properties:

- `Path to sequence number` property with a value of `/doc/seq`
- `Path to sequence group identifier` property with a value of `/doc/grp`
- `Start of sequence definition` property set to `Literal` with a value of `0`.
- `End of sequence definition` property set to `Literal` with a value of `6`. This value means that the group will be closed when a message with the sequence number 6 is received and when all earlier messages in the sequence have been received (or the missing message timeout expires).

The following messages are received by the Resequence node:

```
<doc><grp>a<grp><seq>6</seq></doc>
<doc><grp>a<grp><seq>5</seq></doc>
<doc><grp>a<grp><seq>4</seq></doc>
```

```
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>0</seq></doc>
```

The following messages are propagated to the Out terminal:

```
<doc><grp>a<grp><seq>0</seq></doc>
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>4</seq></doc>
<doc><grp>a<grp><seq>5</seq></doc>
<doc><grp>a<grp><seq>6</seq></doc>
```

When the sequence group has closed, any further messages arriving at the node for that sequence group are processed as part of a new instance of the group.

By an automatic timeout

Select `Automatic` and specify the length of time (in seconds) during which the node waits for new messages to arrive onto an empty queue. Each time the queue of messages waiting to be propagated is empty, the Resequence node starts a timer, which expires after the specified number of seconds. If no new messages arrive within the specified time, the sequence group is closed, and any new messages that arrive subsequently are treated as part of a new group. If new messages arrive at the node within the specified time limit, the timer is reset.

Using predicate set on the Resequence node

Select `Predicate` and specify an XPath expression to calculate whether the message is the last in the sequence. The predicate evaluates to either True or False, and messages continue to be collected while the expression evaluates to False. When the expression of a message is evaluated to True, it indicates that the message is the last in the sequence and the sequence group is closed. However, if earlier messages are missing from the sequence group, the sequence group remains open for the period of time specified by the `Missing message timeout` property.

When the sequence group has closed, any further messages arriving at the node for that sequence group are processed as part of a new instance of the group.

Typically, the XPath expression evaluates to a Boolean; however, if other data types are returned, the predicate is determined in the following way:

Table 30.

Returned data type	True	False
Boolean	True	False
Numeric	Any non-zero value	0 or 0.0
String	Any string matching `true` (case-insensitive)	Any string not matching `true` (case insensitive)
NodeSet	Never	Always

When a message evaluates the expression to True (and is therefore identified as the last message in the sequence), the node checks that the message has the highest sequence number collected up to that point. If messages are found with higher sequence numbers, an exception is thrown.

Using a Sequence node

When you use the Sequence node to add sequence numbers to messages, you use the `End of sequence definition` property to define how the message sequence will end. The Sequence node allocates a monotonically increasing sequence number for each input message that arrives at the node, ending with the sequence number that you define in the `End of sequence definition` property.

You can specify the end sequence number in the Sequence node in one of the following ways:

As a literal number
: Select `Literal` and specify a positive or negative numeric value as the end of sequence number (for example, 15). The value must be in the range -9223372036854775807 to 9223372036854775807. The monotonically increasing sequence ends when it reaches the end of sequence number specified by this property.

Using predicate set on the Sequence node
: Select `Predicate` to specify that the sequence ends when the XPath expression evaluates to True. For more information, see the table above.

By an automatic timeout
: Select `Automatic` and specify the length of time (in seconds) during which the node waits for new messages after a message for the sequence group has been propagated. If a new message arrives, the timer is canceled and reset when the message is propagated. If no new messages arrive within the specified time, the sequence group is closed, and any new messages that arrive subsequently are treated as part of a new group.

Duplicate message processing

Each sequence number within a sequence group must be unique.

If a Resequence node receives a message containing a sequence number that has already been processed in the current sequence group, an exception is thrown (BIP4821) and the duplicate message is propagated to the Failure terminal. An exception occurs only if the duplicate message arrives after the first message with that sequence number has arrived and before the sequence group closes.

For example, assume that you have a Resequence node with the following properties:

- `Path to sequence number` property with a value of `/doc/seq`
- `Path to sequence group identifier` property with a value of `/doc/grp`
- `Start of sequence definition` property set to `Literal` with a value of `1`
- `End of sequence definition` property set to `Literal` with a value of `3`

The following messages arrive at the Resequence node:

```
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>2</seq>/doc>
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>3</seq></doc>
```

The following messages are propagated to the Out terminal:

```
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>2</seq></doc>
<doc><grp>a<grp><seq>3</seq></doc>
<doc><grp>a<grp><seq>1</seq></doc>
<doc><grp>a<grp><seq>2</seq>/doc>
<doc><grp>a<grp><seq>3</seq></doc>
```

The second occurrence of the input message with sequence number 2 causes an exception to be thrown and is propagated to the Failure terminal:

```
<doc><grp>a<grp><seq>2</seq>/doc>
```

Adding sequence numbers to messages

You can add sequence numbers to messages entering a message flow by using the Sequence node.

Before you begin

Before you start:

Read the concept topic about "Message sequencing" on page 2784.

About this task

The Sequence node allocates a monotonically increasing sequence number for each input message that arrives at the node. As each message arrives at the Sequence node, the sequence number is incremented and stored with the message in the location specified by the `Path to store sequence number` property. The allocation of sequence numbers continues until the sequence ends, as specified by the `End of sequence definition` property.

You can divide input messages into independent sequence groups, based on an identifier defined in the message. Each group has a separate group identifier, and the sequence of messages within each group is managed independently.

The Sequence node allocates a sequence number to each message in the sequence group, and the next sequence number in the group is not allocated until the current message in the group has finished processing (either by being committed or rolled back). This ensures that sequencing is maintained for the group when there are multiple threads in the message flow.

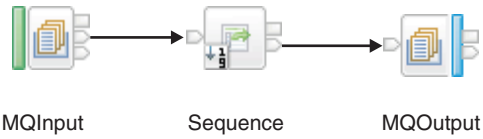
If you need to save the message with the newly assigned sequence number (for example, if you need to save the message to WebSphere MQ for processing by another flow), and if there is no convenient place in the message to save the sequence number, you can add an MQRFH2 header to the message before the Sequence node, and set the sequence number in a field in the `usr` folder.

Multiple sequence groups can be managed independently, in parallel, and sequence group state is preserved when the broker is restarted.

The following steps show how to create a message flow that adds a sequence number to each message in a sequence group.

Procedure

1. Create a message flow containing an MQInput node, a Sequence node, and an MQOutput node.
2. Connect the Out terminal of the MQInput node to the In terminal of the Sequence node.
3. Connect the Out terminal of the Sequence node to the In terminal of the MQOutput node.



4. On the MQInput node, specify the source of input messages for the node by setting the `Queue name` property (on the **Basic** tab) to the name of a WebSphere MQ queue, from which the MQInput node retrieves messages. For example: `SEQ.TASK1.IN1`.
5. Set the following properties of the Sequence node:
   a. On the **Basic** tab, set the following properties:
      - Set the `Path to store sequence number` property to the location in the message where the sequence number is to be set. For example, `$OutputBody/doc/seq`. The sequence number is also set in the local environment, with the *LocalEnvironment.Sequence.Number* variable.
      - Set the `Path to sequence group identifier` property to the location of the sequence group identifier in the message. For example, `$InputBody/doc/grp`. The sequence group identifier is also copied to the local environment, with the *LocalEnvironment.Sequence.Group* variable.
      - Set the `Start of sequence definition` property to `Literal` with the required starting value; for example, `0`.

        Although the starting sequence number must be specified by a literal number, the value can be overridden in the local environment by the *LocalEnvironment.Sequence.StartOfSequenceNumber* variable.

        The start of sequence message is indicated in the local environment by the *LocalEnvironment.Sequence.Start* variable, which takes a Boolean value.
      - Set the `End of sequence definition` property to one of the following values:
        – `Automatic` with the required timeout value; for example, `60`. This value specifies that the sequence group is closed automatically when the message queue in the node has been empty for 60 seconds.

- `Literal` with the required end value; for example, `100`. This value specifies that the sequence group is closed when the message with the sequence number `100` is processed.
- `Predicate` with the required XPATH expression; for example, `$InputBody/doc/endFlag`. This value specifies that the sequence group is closed when the `$InputBody/doc/endFlag` predicate evaluates to True (`$InputBody/doc/endFlag=True`).

The end of sequence message is indicated in the local environment by the *LocalEnvironment.Sequence.End* variable, which takes a Boolean value.

b. On the **Advanced** tab, set the `Persistence mode` property to `Non-persistent`. Select `Persistent` if you want the sequence to be preserved if the queue manager is restarted.

6. On the MQOutput node, set the `Queue name` property (on the **Basic** tab) to the name of a WebSphere MQ queue to which the MQOutput node sends messages. For example: `SEQ.TASK1.OUT1`.
7. Save your message flow.

Reordering messages in a message flow

When messages entering a message flow contain sequence numbers and a group ID, you can use the Resequence node to re-establish the sequential order of the messages before propagating them through the message flow.

Before you begin

Before you start:

Read the concept topic about "Message sequencing" on page 2784.

Ensure that each message contains a monotonically increasing sequence number.

About this task

The sequence number might have been added to the message by the Sequence node or it might be another integer field in the message.

When the Resequence node receives an input message, it propagates the message only if it is the next one in the sequence. If the message is not next in the sequence, the Resequence node stores it until further messages arrive that allow the node to correct the sequence, at which point the node propagates the stored message. If a message fails to arrive, preventing the Resequence node from completing the sequence, the remaining messages are processed according to the way in which the Resequence node has been configured. For more information about this configuration, see "Handling missing messages" on page 2806.

A transaction break occurs at the Resequence node. When a message is delivered to the Resequence node, control is returned to the previous node in the message flow. All messages that are propagated from the Resequence node are propagated in a new transaction, even if the sequence is complete. For more information, see "Resequence node" on page 4651.

The message sequence is preserved when the broker is restarted. If the `Persistent` option is selected on the **Advanced** tab of the Resequence node, the sequence is also preserved when the queue manager is restarted.

The following steps show how to create a message flow that enables you to re-establish the sequential order of the messages in a sequence group:

Procedure

1. Switch to the Broker Application Development perspective.
2. Create a message flow containing an MQInput node, a Resequence node, and an MQOutput node.
3. Connect the Out terminal of the MQInput node to the In terminal of the Resequence node.
4. Connect the Out terminal of the Resequence node to the In terminal of the MQOutput node.

5. On the MQInput node, specify the source of input messages for the node by setting the `Queue name` property (on the **Basic** tab) to the name of a WebSphere MQ queue, from which the MQInput node retrieves messages. For example: `RESEQ.TASK1.IN1`.
6. Set the following properties of the Resequence node:
   a. On the **Basic** tab, set the following properties:
      - Set the `Path to sequence number` property to the location of the sequence number in the message. For example, `$InputBody/doc/seq`. The sequence number is also set in the local environment, with the *LocalEnvironment.Sequence.Number* variable.
      - Set the `Path to sequence group identifier` property to the location of the sequence group identifier in the message. For example, `$InputBody/doc/grp`. The sequence group identifier is also copied to the local environment, with the *LocalEnvironment.Sequence.Group* variable.
      - Set the `Start of sequence definition` property to the first sequence number in the group. For example, select `Literal` with a value of `0`.
      - Set the `End of sequence definition` property to `Automatic` with the required timeout value; for example, `60`. This value specifies that the sequence group is closed automatically when the message queue in the node has been empty for 60 seconds. The end of sequence message is indicated in the local environment by the *LocalEnvironment.Sequence.End* variable, which takes a Boolean value.
      - Set the `Missing message timeout` property to `10`. This value specifies that the Resequence node will wait for a missing message for 10 seconds before propagating subsequent messages in the sequence group to the Expire terminal. When the subsequent message is propagated, the sequence numbers of any missing (timed-out) messages are copied to the local environment, as *LocalEnvironment.Sequence.Missing* variables.
7. On the MQOutput node, set the `Queue name` property (on the **Basic** tab) to the name of a WebSphere MQ queue to which the MQOutput node sends messages. For example: `SEQ.TASK1.OUT1`.
8. Save your message flow.

Maintaining the sequential order of messages

You can maintain the order in which messages enter a message flow by using the Sequence and Resequence nodes.

Before you begin

Before you start:

Read the concept topic about “Message sequencing” on page 2784.

About this task

When messages have been processed in a message flow, they might be propagated in a different order to the order in which they arrived at the input node, so the original message sequence can be altered. You can use the Sequence and Resequence nodes to rearrange the messages into sequential order based on a sequence number in the message, restoring the original sequence in which they entered the input node.

If the messages contain sequence numbers, you can use the Resequence node to re-establish the order in which they arrived at the input node. If the messages do not contain sequence numbers, you can use a Sequence node to apply sequence numbers to the messages, before reordering them into sequential order using the Resequence node.

Procedure

- If the messages contain sequence numbers, rearrange the messages into sequential order by creating a message flow containing a Resequence node. See “Reordering messages in a message flow” on page 2797.
- If the messages do not contain sequence numbers, establish the sequential order of the messages by completing the following steps:
  1. Create a message flow containing a Sequence node, which you can use to apply sequence numbers to the messages. See “Adding sequence numbers to messages” on page 2794.

2. Create a message flow containing a Resequence node, which you can use to re-establish the sequential order of the messages. See “Reordering messages in a message flow” on page 2797.

Message sequencing scenario 1

Change the sequence of messages received from WebSphere MQ, so that they are propagated in the correct order using a sequence number defined in an XML message.

Before you begin

Before you start:

Read the concept topic about “Message sequencing” on page 2784.

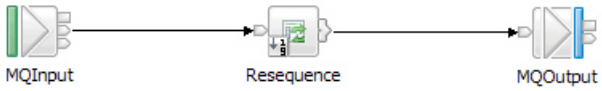
About this task

In this example task, the sequence is defined as starting at sequence number 0 (which is the default) and finishing at sequence number 8. The message flow is configured so that messages can arrive out of order but cannot be propagated out of order, even if one of the sequence numbers never arrives.

The following steps show how to write a message flow that can receive the XML document from WebSphere MQ, reorder the messages based on a sequence number in an XML message (in this example the path `$Root/XMLNSC/Doc/SeqNo` is used) and write it to a WebSphere MQ queue:

Procedure

1. Create a message flow called Resequence_Task1, containing an MQInput node, a Resequence node, and an MQOutput node. For more information about how to do this, see "Creating a message flow" on page 1431.
2. Connect the Out terminal of the MQInput node to the In terminal of the Resequence node.
3. Connect the Out terminal of the Resequence node to the In terminal of the MQOutput node.



4. Set the following properties of the MQInput node:
   a. On the **Basic** tab, set the `Queue name` property to `RESEQUENCE_TASK1_IN1`
   b. On the **Input Message Parsing** tab, set the `Message domain` property to `XMLNSC`.
5. On the Resequence node, set the following properties on the **Basic** tab:
   a. Set the `Path to sequence number` property to `$Root/XMLNSC/Doc/SeqNo`
   b. Set the `End of sequence definition` property to `Literal` with a value of 8.
6. On the MQOutput node, set the `Queue name` property (on the **Basic** tab) to `RESEQUENCE_TASK1_OUT1`.
7. Save the message flow.

Results

Message processing in the message flow:

This section describes the way in which the Resequence node processes the messages that enter the message flow.

1. The following messages arrive on the WebSphere MQ queue RESEQUENCE_TASK1_IN1:

```
<Doc><SeqNo>0</SeqNo></Doc>,<Doc><SeqNo>1</SeqNo></Doc>,<Doc><SeqNo>2</SeqNo></Doc>,
<Doc><SeqNo>3</SeqNo></Doc>,<Doc><SeqNo>4</SeqNo></Doc>,<Doc><SeqNo>5</SeqNo></Doc>,
<Doc><SeqNo>6</SeqNo></Doc>,<Doc><SeqNo>7</SeqNo></Doc>,<Doc><SeqNo>8</SeqNo></Doc>,
```

2. The Resequence node first receives the message with sequence number 0. The Resequence node creates a new sequence group to manage the reordering process; the new sequence group is a default group because no sequence group has been defined in the message. The message (with sequence number 0) is the first one in the sequence, so it is propagated to the Out terminal.
3. The Resequence node then receives the rest of the messages up to and including sequence number 8, and propagates them in the order in which they arrived. Each message is stored before it is propagated, and a different transaction is used for propagating the messages downstream from the Resequence node.
4. When the message containing sequence number 8 is processed, the sequence group is closed. Any new message in the same group that arrives later causes a new group to be created.
5. The next messages arrive on the RESEQUENCE_TASK1_IN1 queue:

```
<Doc><SeqNo>8</SeqNo></Doc>,<Doc><SeqNo>7</SeqNo></Doc>,<Doc><SeqNo>6</SeqNo></Doc>,
<Doc><SeqNo>5</SeqNo></Doc>,<Doc><SeqNo>4</SeqNo></Doc>,<Doc><SeqNo>3</SeqNo></Doc>,
<Doc><SeqNo>2</SeqNo></Doc>,<Doc><SeqNo>1</SeqNo></Doc>,<Doc><SeqNo>0</SeqNo></Doc>,
```

6. The Resequence node first receives the message containing sequence number 8. At this point, the Resequence node creates a new (default) sequence group. The message is the last one in the sequence so it is not propagated but is stored internally.
7. The Resequence node then receives the rest of the messages up to and including sequence number 0. All the messages are stored and none are propagated until the first number in the sequence is received (in this case, sequence number 0).
8. When the message with sequence number 0 is received, it is propagated down the message flow, followed by each of the other messages, in order, until the final message (sequence number 8) is propagated. At this point, the sequence group is closed again.

Message sequencing scenario 2

Change the sequence of messages received from WebSphere MQ, so that they are propagated in the correct order using a sequence number defined in an XML message.

Before you begin

Before you start:

Read the concept topic about "Message sequencing" on page 2784.

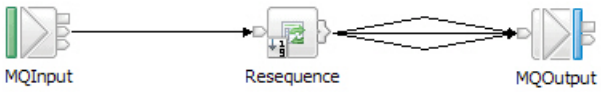
About this task

In this example task, the sequence is defined as starting at sequence number 0 (which is the default) and finishing when it has received no new messages in the group for 60 seconds. The message flow is configured so that messages can arrive out of order but the Resequence node attempts to propagate them in the correct order. If a required message in the sequence fails to arrive for 10 seconds, the Resequence node skips the missing message and propagates the next message in the sequence, even though it is now out of order.

The following steps show how to write a message flow that can receive the XML document from WebSphere MQ, reorder the messages based on a sequence number in an XML message (in this example the path `$Root/XMLNSC/Doc/SeqNo` is used) and write it to a WebSphere MQ queue:

Procedure

1. Create a message flow called Resequence_Task2, containing an MQInput node, a Resequence node, and an MQOutput node. For more information about how to do this, see "Creating a message flow" on page 1431.
2. Connect the Out terminal of the MQInput node to the In terminal of the Resequence node.
3. Connect the Out, Missing, and Expire terminals of the Resequence node to the In terminal of the MQOutput node.



4. Set the following properties of the MQInput node:
   a. On the **Basic** tab, set the `Queue name` property to `RESEQUENCE_TASK2_IN1`
   b. On the **Input Message Parsing** tab, set the `Message domain` property to `XMLNSC`.
5. On the Resequence node, set the following properties on the **Basic** tab:

a. Set the Path to sequence number property to $Root/XMLNSC/Doc/SeqNo
b. Set the Missing message timeout property to 10
c. Set the End of sequence definition property to Automatic with a value of 60.

6. On the MQOutput node, set the Queue name property (on the **Basic** tab) to RESEQUENCE_TASK2_OUT1.
7. Save the message flow.

Results

Message processing in the message flow:

This section describes the way in which the Resequence node processes the messages that enter the message flow:

1. The following messages arrive on the WebSphere MQ queue RESEQUENCE_TASK2_IN1:

```
<Doc><SeqNo>0</SeqNo></Doc>,<Doc><SeqNo>1</SeqNo></Doc>,<Doc><SeqNo>2</SeqNo></Doc>,
<Doc><SeqNo>3</SeqNo></Doc>,<Doc><SeqNo>4</SeqNo></Doc>,<Doc><SeqNo>5</SeqNo></Doc>,
<Doc><SeqNo>6</SeqNo></Doc>,<Doc><SeqNo>7</SeqNo></Doc>,<Doc><SeqNo>8</SeqNo></Doc>,
```

2. The Resequence node first receives the message with sequence number 0. The Resequence node creates a new sequence group to manage the reordering process; the new sequence group is a default group because no sequence group has been defined in the message. The message (with sequence number 0) is the first one in the sequence, so it is propagated to the Out terminal.
3. The Resequence node then receives the rest of the messages up to and including sequence number 8, and propagates them in the order in which they arrived. Each message is stored before it is propagated, and a different transaction is used for propagating the messages downstream from the Resequence node.
4. Sixty seconds elapse and the sequence group is closed.
5. The next messages arrive on the WebSphere MQ queue RESEQUENCE_TASK2_IN1:

```
<Doc><SeqNo>0</SeqNo></Doc>,<Doc><SeqNo>3</SeqNo></Doc>,<Doc><SeqNo>2</SeqNo></Doc>,
<Doc><SeqNo>4</SeqNo></Doc>,<Doc><SeqNo>6</SeqNo></Doc>,<Doc><SeqNo>7</SeqNo></Doc>,
```

6. The Resequence node first receives the message containing sequence number 0. At this point, the Resequence node creates a new (default) sequence group and propagates the message with sequence number 0 to the Out terminal.
7. The next message contains sequence number 3, which is out of sequence. The Missing message timeout property is set on the Resequence node with a value of 10 seconds, and the timer starts.
8. Sequence number 2 arrives, which is still not the next required message but it is lower than the lowest message currently stored, so the missing message timer is reset.
9. The Resequence node then receives the rest of the messages, all of which have a higher sequence number than 2, so they are stored but not propagated. The missing message timer is not reset this time because each number is later in the sequence than number 2.
10. Sequence number 1 fails to arrive during the specified period, and after 10 seconds the timeout period expires.
11. The Resequence node propagates all the messages that are stored, starting with the lowest sequence number (in this case, 2) followed by all other

messages up to the next missing number in the sequence (in this case, messages with sequence numbers 3 and 4). Messages 2, 3, and 4 are propagated to the Expire terminal.

12. The Resequence node is moved to an unordered state for this sequence group, and will not propagate any messages in this group to the Out terminal. The Resequence node remains in the unordered state for this sequence group until the group expires and is closed.
13. When another 10 seconds has passed, the missing message timer expires again and messages 6 and 7 are propagated to the Expire terminal. At this point there are no more missing messages so the missing message timer is not restarted.
14. The group expiry timer is started and the group is closed after 60 seconds have passed. The group expiry timer is never started when a missing message timer is running.

Handling missing messages

You can configure the Resequence node to control how missing messages in a sequence are processed.

About this task

You can configure the Resequence node to time out if a message in the sequence fails to arrive in a specified period of time, and you can specify how subsequent messages are processed if a message is missing.

You can use the `Missing message timeout` property of the Resequence node to specify how long (in seconds) the node waits for the next message in the sequence before it moves on to the next message. Messages that arrive within the specified time limit are propagated in sequential order to the Out terminal. When the specified time limit has been exceeded, the messages are propagated in sequential order to the Expire terminal. Subsequent messages in the sequence group are also routed to the Expire terminal. If the missing message eventually arrives, it is propagated to the Missing terminal.

You can configure the Resequence node for any of the following scenarios:

- **The message sequence must always be maintained**

  If a message goes missing, you can route all subsequent messages to a holding queue after a specified timeout period. To configure the Resequence node in this way, wire the Out terminal to the main-line flow and wire the Expire and Missing terminals to separate branches for re-queueing.
- **Missing messages are allowed in the message sequence but all other messages must remain in sequence**

  If a message goes missing, you can pass over it and continue processing the rest of the sequence. If the missing message eventually arrives, you can either discard it or process it separately from the main-line processing. To configure the Resequence node in this way, wire the Out and Expire terminals to the main-line flow and leave the Missing terminal unwired (to discard the message) or wire it to a separate branch of the message flow.
- **Occasional out-of-sequence messages are allowed**

  You want the message flow to process the messages in sequential order, but you are prepared to tolerate occasional messages out of order. To configure the Resequence node in this way, wire the Out, Expire, and Missing terminals to the main-line message flow.

Configuring the storage of events for Resequence nodes

You can use a Resequence configurable service to control the storage of events for Resequence nodes.

About this task

By default, the storage queues used by all Resequence nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Collector node.

However, you can control the queues that are used by different Resequence nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Resequence configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the timeout and the start and end of the sequence:

Procedure

1. Create the storage queues to be used by the Resequence node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.

2. Use the **mqsicreateconfigurableservice** command to create a Resequence configurable service. You can create a configurable service to be used with either a specific sequence or with all sequences in an execution group.
   a. If you are creating a configurable service to be used with a specific sequence, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Resequence node. If you are creating a configurable service to be used with all sequences in the execution group, ensure that the configurable service has the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Missing message timeout**, **Start of sequence**, and **End of sequence** properties.

   For example, create a Resequence configurable service called `myResequenceService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, with a missing message timeout of 60 seconds, and which waits five seconds before determining the start and end numbers in a sequence:

   ```
   mqsicreateconfigurableservice MYBROKER -c Resequence -o myResequenceService
   -n queuePrefix,missingMessageTimeoutSeconds,startSequenceSeconds,endSequenceSeconds -v SET1,60,5,
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Resequence configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see "Configurable services properties" on page 3766
3. In the Resequence node:
   a. If the configurable service is to be used for a specific sequence, specify the name of the configurable service on the **Advanced** tab; for example, `myResequenceService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring timeout flows

Use the TimeoutControl and TimeoutNotification nodes in message flows to process timeout requests or to generate timeout notifications at specified intervals.

The following topics show how these nodes can be used in a message flow:

- "Sending timeout request messages" on page 2810
- "Sending a message after a timed interval" on page 2813
- "Sending a message multiple times after a specified start time" on page 2815
- "Automatically generating messages to drive a flow" on page 2817
- "Configuring the storage of events for timeout nodes" on page 760

Related concepts:

"Considering performance for timeout flows" on page 2822
When you design timeout flows, the decisions that you make can affect the performance of your brokers and applications.

Related reference:

"TimeoutControl node" on page 4932
Use the TimeoutControl node to process an input message that contains a timeout

request.

"TimeoutNotification node" on page 4936
Use the TimeoutNotification node to manage timeout-dependent message flows.

Sending timeout request messages

To set a controlled timeout, send a message with a set of elements with well known names to a TimeoutControl node. These elements control the properties of the timeout to be created or deleted.

Elements and format

The following example shows the elements and format of a timeout request message, showing the well known names and permissible values.

```
<TimeoutRequest>
  <Action>SET | CANCEL</Action>
  <Identifier>String (any alphanumeric string)</Identifier>
  <StartDate>String (TODAY | yyyy-mm-dd)</StartDate>
  <StartTime>String (NOW | hh:mm:ss)</StartTime>
  <Interval>Integer (seconds)</Interval>
  <Count>Integer (greater than 0 or -1)</Count>
  <IgnoreMissed>TRUE | FALSE</IgnoreMissed>
  <AllowOverwrite>TRUE | FALSE</AllowOverwrite>
</TimeoutRequest>
```

Message fields

The following table describes the fields in the message. The column headed M indicates whether the property is mandatory, and the column headed C indicates whether the property is configurable.

Property	M	C	Default	Description
Action	Yes	No	None	Set this element to either SET or CANCEL. An error is generated if you omit this element or set it to a different value. If you set it to CANCEL, the only other element that is required is the Identifier, which must match the Identifier of the TimeoutRequest that is to be canceled.
Identifier	Yes	No	None	Enter an alphanumeric string. An error is generated if you omit this element.
StartDate	No	No	TODAY	Set this element to TODAY or to a date specified in yyyy-mm-dd format. The default value is TODAY.
StartTime	No	No	NOW	Set this element to NOW or to a time in the future specified in hh:mm:ss format. The default value is NOW. StartTime is assumed to be the broker's local time. The start time can be calculated by adding an interval to the current time. If a delay occurs between the node that calculates the start time and the TimeoutControl node, the start time in the message will have passed by the time it reaches the TimeoutControl node. If the start time is more than approximately five minutes in the past, a warning is issued and the TimeoutControl node rejects the timeout request. If the start time is less than five minutes in the past, the node processes the request as if it were immediate. Therefore, ensure that the start time in the timeout request message is now or a time in the future.
Interval	No	Yes	0	Set this element to an integer that specifies the number of seconds between propagations of the message. The default value is 0.
Count	No	Yes	1	Set this element to an integer value that is either greater than 0 or is -1 (which specifies a timeout request that never expires). The default value is 1.

Property	M	C	Default	Description
IgnoreMissed	Yes	No	TRUE	Set this element to TRUE or FALSE to control whether timeouts that occur while either the broker or the timeout notification flow is stopped, are processed the next time that the broker or timeout notification flow is started. The default value is TRUE, which means that missed timeouts are ignored by the TimeoutNotification node when the broker or message flow is started. If this value is set to FALSE, the missed timeouts are all processed immediately by the TimeoutNotification node when the flow is started. You must set the `Request Persistence` property of the TimeoutControl node to Yes or Automatic (with the originating request message being persistent) for the stored timeouts to persist beyond the restart of the broker or the timeout notification flow.
AllowOverwrite	N	N	TRUE	Set this element to TRUE or FALSE, to specify whether subsequent timeout requests with a matching `Identifier` can overwrite this timeout request. The default value is TRUE.

How the TimeoutControl node uses these values

Set the `Request Location` on the TimeoutControl node to `InputRoot.XML.TimeoutRequest` to read these properties. If you want to obtain properties from a different part of your message, specify the appropriate correlation name for the parent element for the properties. The correlation name for the parent element can be in the local environment.

For details of how the TimeoutControl uses these values, see "TimeoutControl node" on page 4932

Use the TimeoutNotification node to manage timeout-dependent message flows.

Working with the predefined schema definition of an XML timeout request message:

A predefined schema definition of an XML timeout request message is provided in the WebSphere Message Broker Toolkit.

About this task

Take the following steps to review the definition or to define it in a message set.

1. Create or select a message set project that contains the message set.
2. Create a new message definition file (**File** > **New** > **Message Definition File From...**).
3. Select **IBM supplied message** and click **Next**.
4. Expand the tree for **Message Brokers IBM supplied Message Definitions**.
5. Select **Message Broker Timeout Request** and click **Finish**.

Example XML timeout request message:

The format used here is XML, but you can use any format that is supported by an installed parser.

```
<TimeoutRequest>
  <Action>SET</Action>
  <Identifier>TenTimes</Identifier>
  <StartDate>TODAY</StartDate>
  <StartTime>NOW</StartTime>
  <Interval>10</Interval>
  <Count>10</Count>
  <IgnoreMissed>TRUE</IgnoreMissed>
  <AllowOverwrite>TRUE</AllowOverwrite>
</TimeoutRequest>
```

For another example of a timeout request message, and for details of how to use the timeout nodes to add timeouts to message flows, see the timeout processing sample:

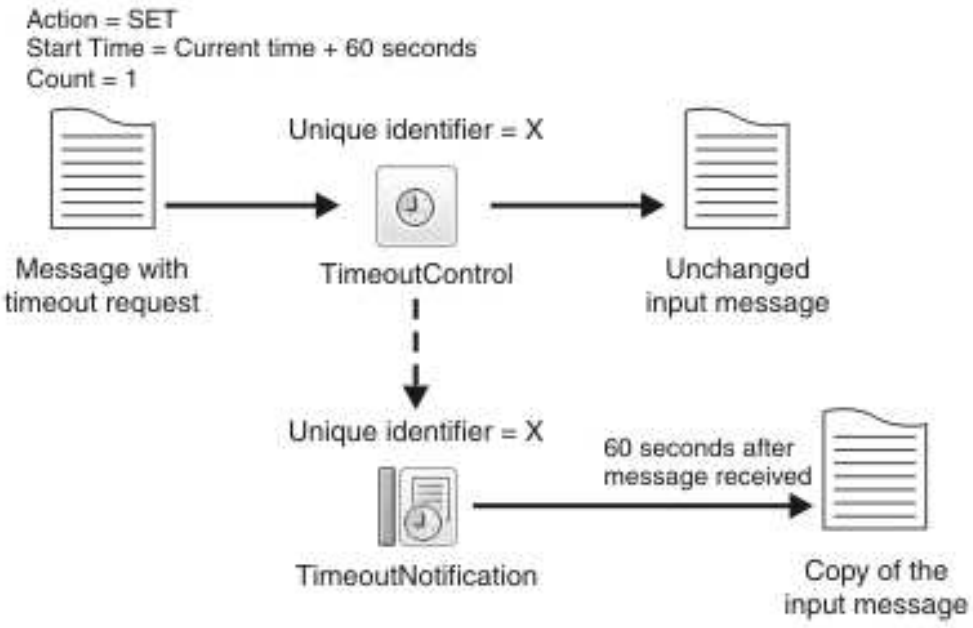
Sending a message after a timed interval

Use TimeoutControl and TimeoutNotification nodes to send a message into a message flow after a timed interval.

Aim

Use TimeoutControl and TimeoutNotification nodes to send a message into a message flow 60 seconds after the message is received.

Description of the flow



The diagram shows the path of a message that contains a timeout request through a TimeoutControl node. A TimeoutNotification node with an identifier matching the TimeoutControl node then processes the timeout request. The diagram also shows the message that the TimeoutNotification node produces after processing the timeout request.

The message comes into the TimeoutControl node with the following values set in the timeout request section of the message:

Action set to *SET*
Start Time set to *current time + 60*
Count set to *1*

The TimeoutControl node validates the timeout request; default values are assumed for properties that are not explicitly defined. The original message is then sent on to the next node in the message flow. If the request is valid, the TimeoutNotification node with the same `Unique identifier` as the TimeoutControl node propagates a copy of the message to the message flow 60 seconds after the message was received.

Timeout request messages are stored for processing on a queue used by the TimeoutNotification node. By default this queue is the SYSTEM.BROKER.TIMEOUT.QUEUE. However, you can use a Timer configurable service to specify an alternative timeout queue, which provides greater control over the storage of messages. For information about using an alternative timeout queue, see "Configuring the storage of events for timeout nodes" on page 760.

If a delay occurs between the node that calculates the start time and the TimeoutControl node, the start time in the message will have passed by the time it reaches the TimeoutControl node. If the start time is more than approximately five minutes in the past, a warning is issued and the TimeoutControl node rejects the timeout request. If the start time is less than five minutes in the past, the node processes the request as if it were immediate. Therefore, ensure that the start time in the timeout request message is a time in the future.

Look at the following sample for further details on constructing this type of message flow.

- Timeout Processing

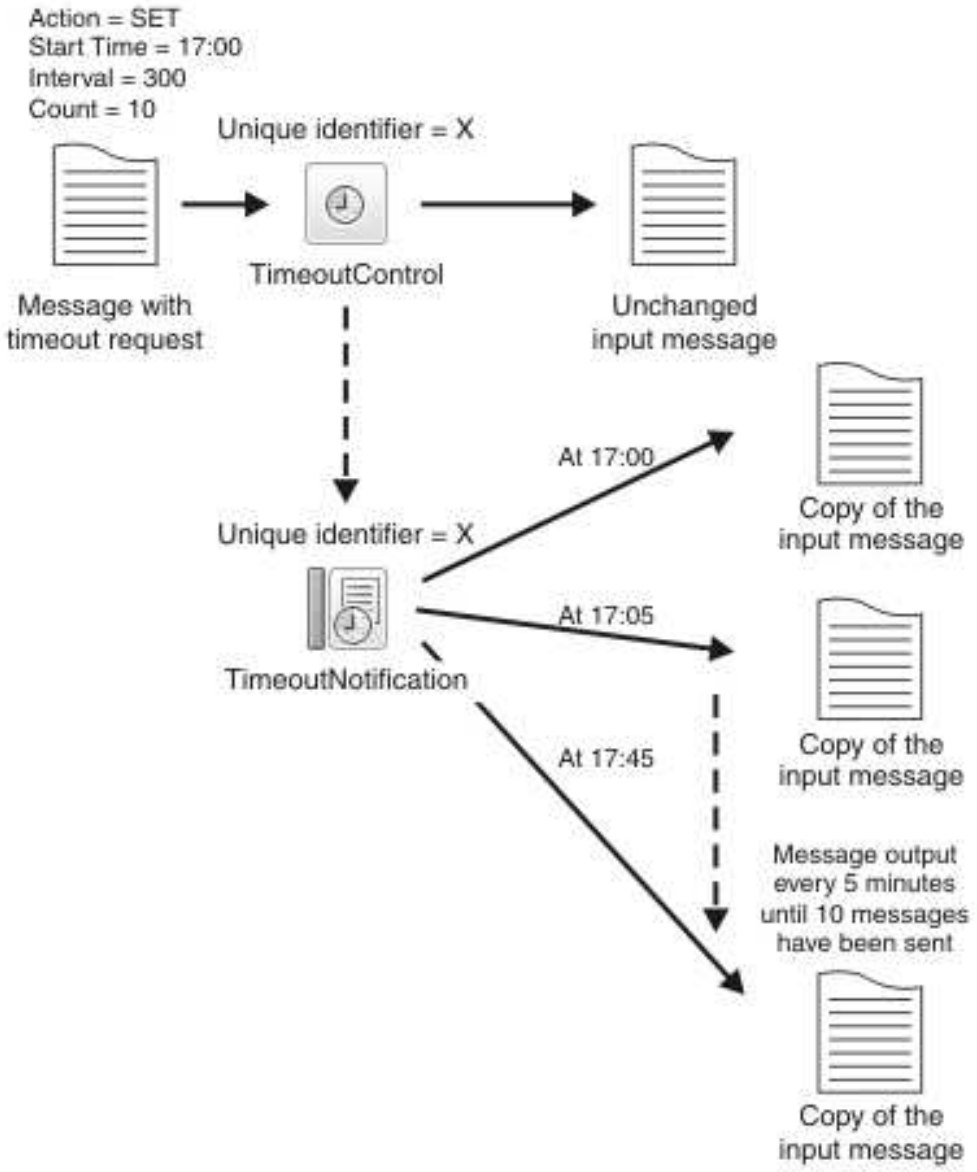
Sending a message multiple times after a specified start time

Use TimeoutControl and TimeoutNotification nodes to send a message into a message flow multiple times after a specified start time.

Aim

Use TimeoutControl and TimeoutNotification nodes to send a message into a message flow at 17:00 hours, then send the message again every 5 minutes until the message has been sent 10 times.

Description of the flow



The diagram shows the path of a message that contains a timeout request through a TimeoutControl node. A TimeoutNotification node with an identifier matching the TimeoutControl node then processes the timeout request. The diagram also shows the message that he TimeoutNotification node produces after processing the timeout request.

The message comes into the TimeoutControl node with the following values set in the timeout request section of the message:

Action set to *SET*
Start Time set to *17:00*
Interval set to *300*
Count set to *10*

The TimeoutControl node validates the timeout request; default values are assumed for properties that are not explicitly defined. The original message is then

sent on to the next node in the message flow. If the request is valid, the TimeoutNotification node with the same `Unique identifier` as the TimeoutControl node propagates a copy of the message to the message flow at 17:00. The message is sent again after an interval of 300 seconds, at 17:05. and every 300 seconds until the message has been sent 10 times, as the *Count* value in the timeout request specifies.

Look at the following sample for further details on constructing this type of message flow.

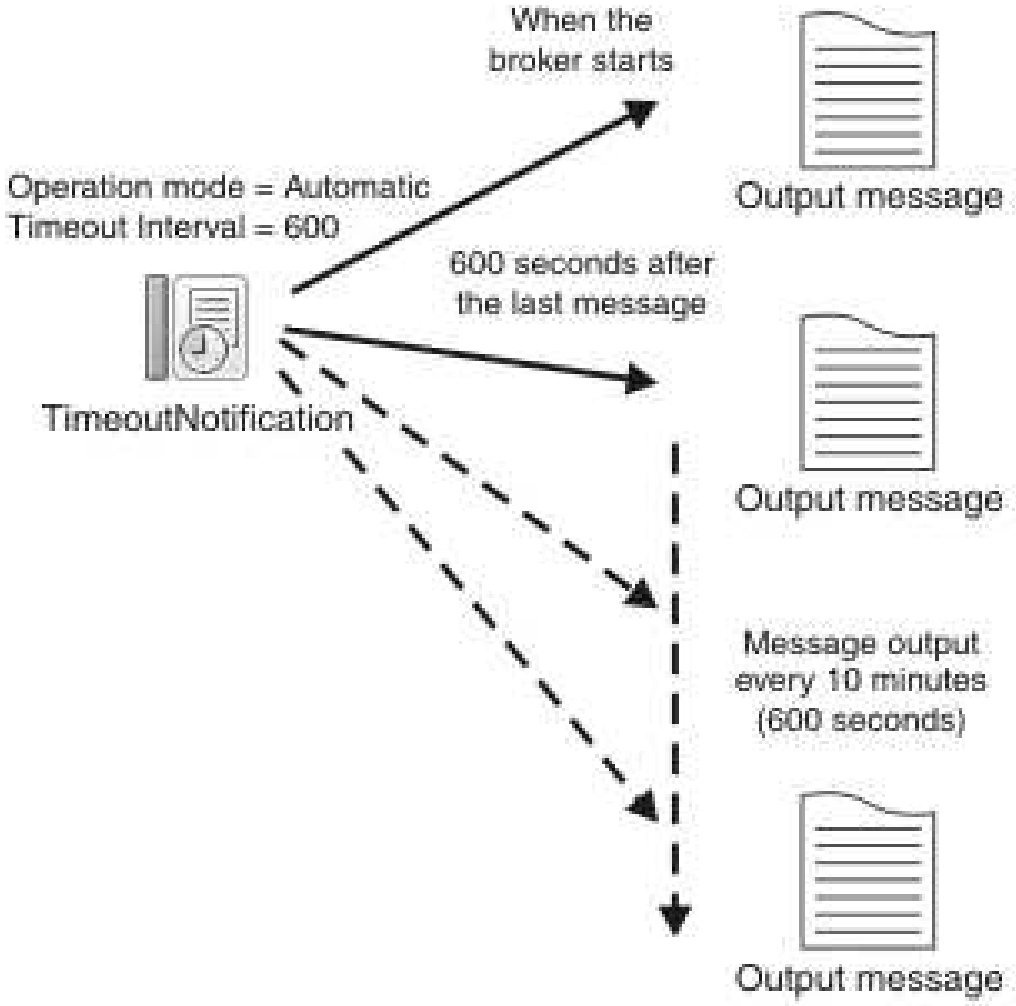
Automatically generating messages to drive a flow

Using the TimeoutNotification node to automatically send a message into a message flow.

Aim

Use the TimeoutNotification node to automatically send a message into a message flow every 10 minutes.

Description of the flow



The diagram shows a TimeoutNotification node automatically generating messages and propagating them every 10 minutes. To get the TimeoutNotification node to automatically generate messages, set the `Operation Mode` property of the node to automatic and specify a value for the `Timeout Interval` property. In this example the TimeoutNotification node has the following properties:

`Operation Mode` set to automatic
`Timeout Interval` set to 600

You can also use a Timer configurable service to control the timeout interval. A value set by the **`Timeout interval`** property of the Timer configurable service overrides the value specified on the TimeoutNotification node. For more information about the Timer configurable service, see "Configurable services properties" on page 3766.

When the broker has started, the TimeoutNotification node sends a message every 10 minutes (600 seconds). This message contains only a properties folder and a LocalEnvironment folder. A Compute node can then process this message to create a more meaningful message.

In the above example, the relevant property is IgnoreMissed, and for an automatic timeout this is implicitly set to TRUE. This means that if one of the period events is missed the event will not be resent, but instead the broker will trigger the event on the next scheduled timeout. If you want to be notified when events are missed, set a controlled timeout instead. For details of the properties you can set for a controlled timeout, see "Sending timeout request messages" on page 2810.

Look at the following sample for further details on constructing this type of message flow.

Configuring the storage of events for timeout nodes

You can use a Timer configurable service to control the storage of events for TimeoutNotification and TimeoutControl nodes.

About this task

By default, the storage queue used by all timeout nodes is the SYSTEM.BROKER.TIMEOUT.QUEUE.

However, you can control the queues that are used by different timeout nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Timer configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queue that is used to store event states:

Procedure

1. Create the storage queue to be used by the timeout nodes. The following queue is required:
   - SYSTEM.BROKER.TIMEOUT.*QueuePrefix*.QUEUE

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queue, WebSphere Message Broker creates the queue when the node is deployed; this queue is based on the default queue. If the queue cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Timer configurable service. You can create a configurable service to be used with either specific timeout requests or with all timeout requests in an execution group.
   a. If the configurable service is to be used with specific timeout requests, create the configurable service with the same name as the `Unique identifier` property on the TimeoutNotification and TimeoutControl nodes. If the configurable service is to be used with all timeout requests in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.

   For example, create a Timer configurable service that uses a queue prefixed with SYSTEM.BROKER.TIMEOUT.SET1:

   ```
   mqsicreateconfigurableservice MB7BROKER -c Timer -o myTimer
   -n queuePrefix -v SET1
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Timer configurable service. However, the storage queue is not deleted automatically when the configurable service is deleted, so you must delete it separately.For more information, see "Configurable services properties" on page 3766.
3. In the TimeoutNotification and TimeoutControl nodes:
   a. Ensure that the name of the Timer configurable service is the same as the name specified in the `Unique Identifier` property on the **Basic** tab; for example, `myTimer`. If there is no Timer configurable service with the same name as the `Unique Identifier`, and if there is a configurable service with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with

configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Considering performance for timeout flows

When you design timeout flows, the decisions that you make can affect the performance of your brokers and applications.

You can use the timeout nodes TimeoutControl and TimeoutNotification in your message flows to control the way in which your message flows operate:

- Set the Operation Mode property of the TimeoutNotification node to Automatic. This setting causes a flow to be invoked at the interval that you specify in the Timeout Value property. If the downstream processing is intensive, and the flow is still busy when the next timeout occurs, the flow is not started for that timeout instance. The flow is notified to start again only if it is free when a particular timeout occurs.

  The value of the Additional Instances property of the message flow is ignored downstream of a TimeoutNotification node, and you cannot use this property to change the behavior of the flow.
- Use two associated flows to perform user-defined timeout processing. Set a timeout with a TimeoutControl node, and notify the flow using a TimeoutNotification node (which behaves like an input node to start a new message flow thread). If the downstream processing from the TimeoutNotification node is significant, requests that are set up in the TimeoutControl node can build up. You can specify that the timeout messages are generated only when the flow that starts with the TimeoutNotification node becomes free again.

  You cannot increase the Additional Instances property of the message flow if it starts with a TimeoutNotification node, therefore you cannot apply more threads to increase the capacity of the flow.

Although you can use a TimeoutNotification node to cause nodes in a message flow to poll for the next item of work, this approach forces a delay between each transaction, and typically does not provide an efficient solution. If you want to periodically check a resource for the next piece of work, and process it immediately, consider one or more of the following alternative solutions:

- Use a built-in input node.
- Write your own input node by using the user-defined node API (in Java or C).
- Consider purchasing an IBM or vendor-provided adapter which polls the subsystem you want, and triggers the flow.

A message flow that uses these options can process more work overall than it can if you implement a timeout solution, and incurs lower CPU cost, although your initial development costs might be slightly higher.

Related concepts:

Handling errors in message flows

The broker provides basic error handling for all your message flows. If basic processing is not sufficient, and you want to take specific action in response to certain error conditions and situations, you can enhance your message flows to provide your own error handling.

About this task

For example, you might design a message flow that expects certain errors that you want to process in a particular way. Or perhaps your flow updates a database, and must roll back those updates if other processing does not complete successfully.

The options that you can use to do this are quite complex in some cases. The options that are provided for MQInput and TimeoutNotification nodes are extensive because these nodes deal with persistent messages and transactions. The MQInput node is also affected by configuration options for WebSphere MQ.

Because you can decide to handle different errors in different ways, there are no fixed procedures to describe. This section provides information about the principles of error handling, and the options that are available, and you must decide what combination of choices that you need in each situation based on the details that are provided in this section.

There are two general approaches to handling errors in a message flow:

- Failure checking

Wire the Failure terminal of a node to explicitly check for any errors that occur within that node. If errors occur, an exception list is propagated to the Failure terminal. The inflight message remains the same as it was before the node was invoked.

You can introduce more specialized error checking in nodes that can be customized by using ESQL. For example, you can create exit handlers within these nodes. For more information about using ESQL to create exit handlers, see "DECLARE HANDLER statement" on page 5124.

- Catching exceptions

  If you do not wire a Failure terminal, a failure in the node is converted into an exception which is thrown from the node. Any changes that were made to the inflight message before the exception was thrown are reversed. The exception might cause the current transaction to be rolled back which means that any updates to transactional resources are reversed.

  You can prevent the transaction from being rolled back, and control the extent to which message changes are reversed, by including a TryCatch node in your message flow. If an exception is thrown beyond the Try terminal of the TryCatch node, then an exception list is propagated to the node's Catch terminal. The inflight message reverts to the state it was in before it reached the TryCatch node.

  Other nodes apart from the TryCatch node have a Catch terminal. These nodes are typically at the start of a transaction, where an uncaught exception would cause a rollback. In these nodes, the Catch terminal behaves as though a TryCatch node was wired directly to the Out terminal. Use the Catch terminal to handle any exceptions that are thrown beyond the node in the message flow. Wire the Failure terminal to handle errors within the node itself.

You can choose one or more of these options in your message flows:

- Connect the Failure terminal of the node to a sequence of nodes that processes the node's internal exception (the fail flow).
- Connect the Catch terminal of the node to a sequence of nodes that processes exceptions that are generated beyond it (the catch flow).
- Insert one or more TryCatch nodes at specific points in the message flow to catch and process exceptions that are generated by the flow connected to the Try terminal.
- Include a Throw node, or code an ESQL THROW statement, to generate an exception.
- Ensure that all the messages received by an MQInput node are processed in a transaction, or are not processed in a transaction.
- Ensure that all the messages received by an MQInput node are persistent, or are not persistent.

If you include user-defined nodes in your message flow, you must see the information provided with the node to understand how you might handle errors with these nodes. The descriptions in this section cover only the built-in nodes.

When you design your error handling approach, consider the following factors:

- Most of the built-in nodes have Failure terminals. The exceptions are the AggregateControl, AggregateRequest, Input, Label, Output, Passthrough, Publication, Trace, and TryCatch nodes.

  When an exception is detected in a node, the message and the exception information are propagated to the node's Failure terminal. If the node does not have a Failure terminal, or it is not connected, the broker throws an exception

and returns control to the closest upstream node that can process it. This node might be a TryCatch node, an AggregateReply node, or the input node.

If an MQInput node detects an internal error, its behavior is slightly different; if the Failure terminal is not connected, it attempts to put the message to the input queue's backout requeue queue, or (if that is not defined) to the dead letter queue of the broker's queue manager.

For more information, see "Handling MQInput errors" on page 2829.

- Many built-in nodes have Catch terminals. These nodes are typically at the start of a transaction. For example:
  - Input nodes: FileInput, HTTPInput, JMSInput, MQInput, PeopleSoftInput, SAPInput, SCAInput, SiebelInput, SOAPInput, TCPIPClientInput, TCPIPServerInput, TwineballInput
  - Output and response nodes: SCAAsyncResponse, SOAPAsyncResponse
  - Routing nodes: AggregateReply, Collector, Resequence
  - Construction nodes: TryCatch
  - Timer nodes: TimeoutNotification

  A message is propagated to a Catch terminal only if it has first been propagated beyond the node (for example, to the nodes connected to the Out terminal).
- When a message is propagated to the Failure or Catch terminal, the node creates and populates a new exception list tree with an exception that represents the error that has occurred. The exception list is propagated as part of the message tree. When a message is propagated to the Failure terminal because of a problem that occurred in the Out or Catch flows (for example, repeated parsing errors that caused the backout threshold to be met), the original parsing errors are not in the exception list; the exception list contains the exception that indicates that the backout threshold has been met.
- The MQInput and TimeoutNotification nodes have additional processing for transactional messages (other input nodes do not handle transactional messages).

  For more information, see "Handling MQInput errors" on page 2829 and "Handling timeout notification errors" on page 2833.
- If you include a Trace node that specifies `$Root` or `$Body`, the complete message is parsed. This might generate parser errors that are not otherwise detected.

The general principles of error handling are:

- If you connect the Catch terminal of the input node, you are indicating that the flow handles all the exceptions that are generated anywhere in the out flow. The broker performs no rollback, and takes no action, unless there is an exception on the catch flow. If you want any rollback action after an exception has been raised and caught, you must provide this in the catch flow.
- If you do not connect the Catch terminal of the input node, you can connect the Failure terminal and provide a fail flow to handle exceptions generated by the node. The fail flow is started immediately when an exception occurs in the node.

  The fail flow is also started if an exception is generated beyond the MQInput node (in either out or catch flows), the message is transactional, and the reinstatement of the message on the input queue causes the backout count to reach the backout threshold.

  The HTTPInput node does not propagate the message to the Failure terminal if an exception is generated beyond the node and you have not connected the Catch terminal.

- If a node propagates a message to a catch flow, and another exception occurs that returns control to the same node again, the node handles the message as though the Catch terminal is not connected.
- If you do not connect either the Failure or Catch terminals of the input node, the broker provides default processing (which varies with the type of input node).
- If you need a more comprehensive error and recovery approach, include one or more TryCatch nodes to provide more localized areas of error handling.
- If you have a common procedure for handling particular errors, you might find it appropriate to create a subflow that includes the sequence of nodes required. Include this subflow wherever you need that action to be taken.

For more information, see "Connecting failure terminals" on page 2827, "Managing errors in the input node" on page 2828, and "Catching exceptions in a TryCatch node" on page 2835.

If your message flows include database updates, the way in which you configure the nodes that interact with those databases can also affect the way that errors are handled:

- You can specify whether updates are committed or rolled back. You can set the node property `Transaction` to specify whether database updates are committed or rolled back with the message flow (option Automatic), or are committed or rolled back when the node itself terminates (option Commit). You must ensure that the combination of these property settings and the message flow error processing give the correct result.
- You can specify how database errors are handled. You can set the properties `Treat warnings as errors` and `Throw exception on database error` to change the default behavior of database error handling.

For more information about coordinated database updates, see "Configuring transactionality for message flows" on page 1290.

Message flows for aggregation involve additional factors that are not discussed in this topic. For information about message flows for aggregation, see "Handling exceptions in aggregation flows" on page 2749.

The following sample demonstrates how to use an error handling routine to trap information about errors and to store that information in a database. The error handling routine is a subflow that you can add, unchanged, to your message flows. The sample also demonstrates how to configure message flows to control transactionality; in particular, the use of globally coordinated transactions to ensure overall data integrity.

- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Connecting failure terminals

When a node that has a failure terminal detects an internal error, it propagates the message to that terminal. If it does not have a failure terminal, or if you have not connected the failure terminal, the broker generates an exception.

About this task

The nodes sometimes generate errors that you can predict, and it is in these cases that you might want to consider connecting the failure terminal to a sequence of nodes that can take sensible actions in response to the expected errors.

Examples of expected errors are:

- Temporary errors when the input node retrieves the message.
- Validation errors detected by an MQInput, Compute, or Mapping node.
- Messages with an internal or format error that cannot be recognized or processed by the input node.
- Acceptable errors when a node accesses a database, and you choose not to configure the node to handle those errors.
- ESQL errors during message flow development (some ESQL errors cannot be detected by the editor, but are recognized only by the broker; these cause an exception if you have not connected the failure terminal. You can remove the fail flow when you have completely tested the runtime ESQL code).

You can also connect the failure terminal if you do not want WebSphere MQ to try a message again or put it to a backout or dead letter queue.

Managing errors in the input node

When you design your message flow, consider which terminals on the input node to connect.

About this task

- If the node detects an internal error before the message is propagated to the Out terminal, the node always propagates the message and an exception list to the Failure terminal if the node has a Failure terminal and if you have connected a fail flow. If the Failure terminal is not connected or an exception occurs downstream of the failure terminal, the transaction is rolled back.
- If you connect the Catch terminal (if the node has one), this indicates that you want to handle all exceptions that are generated in the out flow. If you do not connect the Catch terminal, or the node does not have a Catch terminal, or an exception occurs downstream of the Catch terminal the current transaction is rolled back.
- Any internal exceptions that occur in the node after the message has been propagated to the Out terminal cause a rollback of the transaction. This situation is rare but could happen for some input nodes.

Refer to the documentation for each input node to determine the effect of rolling back the transaction and also for the retry capabilities provided by some input nodes.

Handling MQInput errors

The MQInput node takes certain actions when handling errors with persistent and transactional messages. The node attempts retry processing when a transactional message is rolled back to the input queue. Non-transactional messages are not rolled back to the input queue when an exception occurs.

About this task

Errors encountered with non-transactional messages are handled as described in "Managing errors in the input node" on page 2828.

- The MQInput node detects an internal error in the following situations:
  - An exception occurs when the associated message parser is initialized. If the `Parse timing` property is set to `Immediate` or `Complete`, the parser parses the input message after initialization. This parsing can cause a parsing or validation error, which is treated as an internal error.
  - A warning is received on an MQGET call.
  - The backout threshold is reached when the message is rolled back to the input queue.
- If the MQInput node detects an internal error, one of the following actions occur:
  - If you have not connected the Failure terminal, the MQInput node attempts to put the message to the input queue's backout requeue queue, or (if that is not defined) to the dead letter queue of the broker's queue manager. If the put attempt fails, the message is rolled back to the input queue. The MQInput node writes the original error and the MQPUT error to the local error log. The MQInput node now invokes the retry logic, described in "Handling retry processing" on page 2830.
  - If you have connected the Failure terminal, you are responsible for handling the error in the flow connected to the Failure terminal. The broker creates a new exception list to represent the error and this is propagated to the Failure terminal as part of the message tree, but neither the MQInput node nor the broker provide any further failure processing.
- If the MQInput node has successfully propagated the message to the out terminal and an exception is thrown in the out flow, the message is returned to the MQInput node:
  - If you have not connected the Catch terminal, the message is rolled back to the input queue. The MQInput node writes the error to the local error log and invokes the retry logic, described in "Handling retry processing" on page 2830.

  - If you have connected the Catch terminal, you are responsible for handling the error in the flow connected to the Catch terminal. The broker creates a new exception list to represent the error and this list is propagated to the Catch terminal as part of the message tree, but neither the MQInput node nor the broker provide any further failure processing.
- If the MQInput node has already propagated the message to the Catch terminal and an exception is thrown in the flow connected to the Catch terminal, the message is returned to the MQInput node:
  - The MQInput node writes the error to the local error log.
  - The message is rolled back to the input queue.
- If the MQInput node has already propagated the message to the Failure terminal and an exception is thrown in the flow connected to the Failure terminal, the message is returned to the MQInput node and rolled back to the input queue. The MQInput node writes the error to the local error log and invokes the retry logic, described in "Handling retry processing." The message is not propagated to the Catch terminal, even if that is connected.

This action is summarized in the following table.

Error event	Failure terminal connected	Failure terminal not connected	Catch terminal connected	Catch terminal not connected
Node detects internal error	Flow connected to the Failure terminal handles the error	Message put to alternative queue; node retries if the put fails	Not applicable	Not applicable
Node propagates message to out terminal, exception occurs in out flow	Not applicable	Not applicable	Flow connected to the Catch terminal handles the error	Node retries
Node propagates message to Catch terminal, exception occurs in flow connected to the Catch terminal	Error logged, message rolled back	Error logged, message rolled back	Not applicable	Not applicable
Node propagates message to Failure terminal, exception occurs in flow connected to the Failure terminal	Not applicable	Not applicable	Node retries	Node retries

Handling retry processing:
About this task

The node attempts retry processing when a message is rolled back to the input queue. The node checks whether the message has been backed out before, and if it has, whether the backout count has reached (equalled) the backout threshold. The backout count for each message is maintained by WebSphere MQ in the MQMD.

You specify (or allow to default to zero(0)) the backout threshold attribute *BOTHRESH* when you create the queue. If you accept the default value of 0, the node increases this value to one (1). The node also sets the value to 1 if it cannot detect the current value. If the backout threshold is set to 1, the message is processed once but it is not retried through the Out terminal of the MQInput node. To retry the message at least once, set the backout threshold to 2.

1. If the node has propagated a message to the Out terminal many times following repeated failed attempts in the output flow, and the number of retries has reached the backout threshold limit, the node attempts to propagate the message through the Failure terminal if that is connected. If you have not connected the Failure terminal, the node attempts to put the message to another queue. When a message is propagated through the Failure terminal, the exception list does not contain the exceptions that occurred in the flows connected to the Out or Catch terminals; the exception list contains new exceptions that cover the reason that the message has gone through the Failure terminal (for example, the backout threshold was reached).

   If a failure occurs beyond the Failure terminal, further retries are made until the backout count field in the MQMD reaches twice the backout threshold set for the input queue. When this limit is reached, the node attempts to put the message to another queue.
2. If the backout threshold has not been reached, the node gets the message from the queue again. If this fails, this is handled as an internal error (described above). If it succeeds, the node propagates the message to the out flow.
3. If the backout threshold has been reached:
   - If you have connected the Failure terminal, the node propagates the message to that terminal. You must handle the error on the flow connected to the Failure terminal.
   - If you have not connected the Failure terminal, the node attempts to put the message on an available queue, in order of preference:
     a. The message is put on the input queue's backout requeue name (queue attribute *BOQNAME*), if one is defined.
     b. If the backout queue is not defined, or it cannot be identified by the node, the message is put on the dead letter queue (DLQ), if one is defined. (If the broker's queue manager has been defined by the **mqsicreatebroker** command, a DLQ with a default name of SYSTEM.DEAD.LETTER.QUEUE has been defined and is enabled for this queue manager.) The MQDLH **PutApplName** property is set to `WebSphereMQIntegrator` and appended with the broker major version number, for example: `WebSphereMQIntegrator9`
     c. If the message cannot be put on either of these queues because there is an MQPUT error (including queue does not exist), or because they cannot be identified by the node, it cannot be handled safely without risk of loss.

        The message cannot be discarded, therefore the message flow continues to attempt to backout the message. It records the error situation by writing errors to the local error log. A second indication of this error is the continual incrementing of the *BackoutCount* of the message in the input queue.

        If this situation has occurred because neither queue exists, you can define one of the backout queues mentioned above. If the condition preventing the message from being processed has cleared, you can temporarily increase the value of the *BOTHRESH* attribute. This forces the message through normal processing.

4. If twice the backout threshold has been reached or exceeded, the node attempts to put the message on an available queue, in order of preference, as defined in the previous step.

Handling transactions, event monitoring, and backout processing:
About this task

When the MQInput node performs retry processing, it can backout the transaction by putting the message to the backout requeue queue or the dead letter queue. The backout count is checked when the message is received from the input queue. If the backout threshold is exceeded, the message is backed out immediately with no further processing performed on the message. The backout operation occurs in a separate transaction from previous processing failures, and the message is not parsed or validated during the backout transaction. The backout transaction generates its own set of monitoring events. Therefore, information that is obtained through message parsing, such as the *exceptionList*, might not be available.

Handling message group errors:
About this task

WebSphere MQ supports message groups. You can specify that a message belongs to a group and its processing is then completed with reference to the other messages in the group (that is, either all messages are committed or all messages are rolled back). When you send grouped messages to a broker, this condition is upheld if you have configured the message flow correctly, and errors do not occur during group message processing.

To configure the message flow to handle grouped messages correctly, follow the actions described in the "MQInput node" on page 4594. However, correct processing of the message group cannot be guaranteed if an error occurs while one of the messages is being processed.

If you have configured the MQInput node as described, under normal circumstances all messages in the group are processed in a single unit of work which is committed when the last message in the group has been successfully processed. However, if an error occurs before the last message in the group is processed, the unit of work that includes the messages up to and including the message that generates the error is subject to the error handling defined by the rules documented here, which might result in the unit of work being backed out.

However, any of the remaining messages in the group might be successfully read and processed by the message flow, and therefore are handled and committed in a new unit of work. A commit is issued when the last message is encountered and processed. Therefore if an error occurs in a group, but not on the first or last message, it is possible that part of the group is backed out and another part committed.

If your message processing requirements demand that this situation is handled in a particular way, you must provide additional error handling to handle errors in message groups. For example, you could record the failure of the message group in a database, and include a check on the database when you retrieve each message, forcing a rollback if the current group has already encountered an error. This would ensure that the whole group of messages is backed out and not processed unless all are successful.

Handling timeout notification errors

The TimeoutNotification node takes various actions when it handles errors with transactional messages, depending on whether the Failure and Catch terminals are connected.

Errors that are encountered with non-transactional messages are handled as described in "Managing errors in the input node" on page 2828.

- If the TimeoutNotification node detects an internal error, one of the following actions occur:
  - If you have not connected the Failure terminal:
    1. The TimeoutNotification node writes the error to the local error log.
    2. The TimeoutNotification node repeatedly tries to process the request until the problem has been resolved.
  - If you have connected the Failure terminal, you are responsible for handling the error in the flow connected to the Failure terminal. The broker creates an exception list to represent the error, which is propagated to the Failure

terminal as part of the message tree. The TimeoutNotification node and the broker do not provide further failure processing. The message is written to the Failure terminal as part of the same transaction, and if the failure flow handles the error successfully the transaction is committed.

- If the TimeoutNotification node has successfully propagated the message to the Out terminal and an exception is thrown in the flow connected to the Out terminal, the message is returned to the TimeoutNotification node. The TimeoutNotification node writes the error to the local error log and does one of the following:
  - If you have not connected the Catch terminal, the TimeoutNotification node tries to process the message again until the problem is resolved.
  - If you have connected the Catch terminal, you are responsible for handling the error in the flow connected to the Catch terminal. The broker creates an exception list to represent the error, which is propagated to the Catch terminal as part of the message tree. The TimeoutNotification node and the broker do not provide further failure processing. The message is written to the Catch terminal as part of the same transaction, and if the flow connected to the Catch terminal handles the error successfully the transaction is committed.
- If the TimeoutNotification node has already propagated the message to the Catch terminal and an exception is thrown in the flow connected to the Catch terminal, the message is returned to the TimeoutNotification node. The TimeoutNotification node writes the error to the local error log and tries to process the message again.
- If the TimeoutNotification node has already propagated the message to the Failure terminal and an exception is thrown in the flow connected to the Failure terminal, the message is returned to the TimeoutNotification node. The TimeoutNotification node writes the error to the local error log, and tries to process the message again. The message is not propagated to the Catch terminal, even if that is connected.

This action is summarized in the following table.

Error event	Failure terminal connected	Failure terminal not connected	Catch terminal connected	Catch terminal not connected
The node detects an internal error.	The flow that is connected to the Failure terminal handles the error.	The error is logged and the node retries the operation.	Not applicable	Not applicable
The node propagates a message to the Out terminal and an exception occurs in the output flow.	Not applicable	Not applicable	The flow that is connected to the Catch terminal handles the error.	The error is logged and the node retries the operation.
The node propagates a message to the Catch terminal and an exception occurs in the flow that is connected to the Catch terminal.	The error is logged and the node retries the operation.	The error is logged and the node retries the operation.	Not applicable	Not applicable

Error event	Failure terminal connected	Failure terminal not connected	Catch terminal connected	Catch terminal not connected
The node propagates a message to the Failure terminal and an exception occurs in the flow that is connected to the Failure terminal.	Not applicable	Not applicable	The error is logged and the node retries the operation.	The error is logged and the node retries the operation.

Catching exceptions in a TryCatch node

You can design a message flow to catch exceptions before they are returned to the input node. You can include one or more TryCatch nodes in a flow to provide a single point of failure for a sequence of nodes. With this technique, you can provide specific error processing and recovery.

About this task

A TryCatch node does not process a message in any way, it represents only a decision point in a message flow. When the TryCatch node receives a message, it propagates it to the Try terminal. The broker passes control to the sequence of nodes that are connected to that terminal (the try flow).

If an exception is thrown in the try flow, the broker returns control to the TryCatch node. The node writes the current contents of the exception list tree to the local error log, then writes the information for the current exception to the exception list tree, overwriting the information that is stored there.

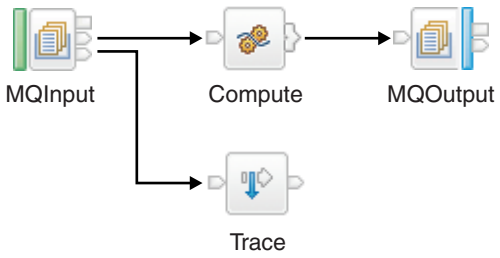
The node propagates the message to the sequence of nodes that are connected to the Catch terminal (the catch flow). The content of the message tree that is propagated is identical to the content that was propagated to the Try terminal, which is the content of the tree when the TryCatch node first received it. The node enhances the message tree with the new exception information that it wrote to the exception list tree. Any modifications or additions that the nodes in the try flow made to the message tree are not present in the message tree that is propagated to the catch flow.

However, if the try flow completes processing that involves updates to external databases, these updates are not lost. The updates persist while the message is processed by the catch flow, and the decision about whether the updates are committed or rolled back is made on the configuration of your message flow and the individual nodes that interact with the databases. If the updates are committed because of the configuration that you set, you must include logic in your catch flow that rolls back the changes that were made.

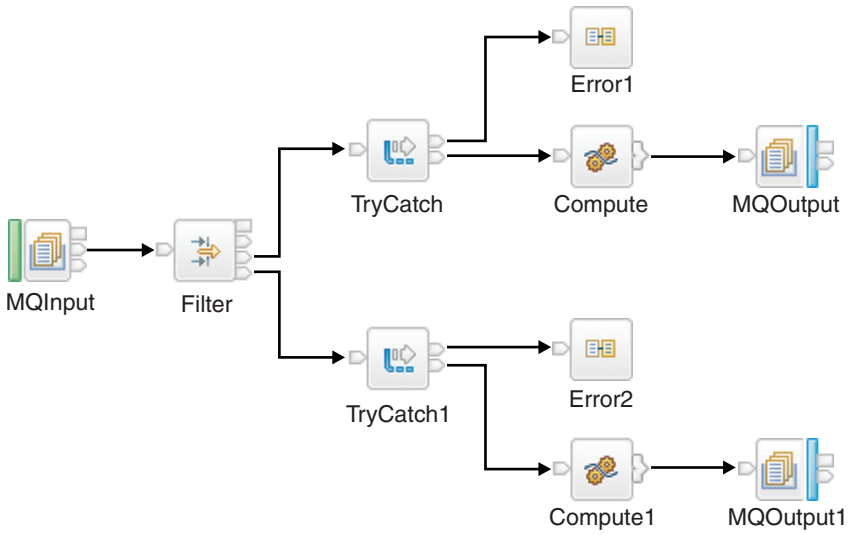
To review the options for configuration, see “Configuring transactionality for message flows” on page 1290.

If an exception is thrown in the catch flow of the TryCatch node (for example, if you include a Throw node, or code an ESQL THROW statement, or if the broker generates the exception), then the broker returns control to the next catch point in the message flow, such as another TryCatch node.

The following example shows how you can configure the flow to catch exceptions in the input node. The MQInput node's Catch terminal is connected to a Trace node to record the error.



In the following example, the message flow has two separate processing flows connected to the Filter node's True and False terminals. Here a TryCatch node is included on each of the two routes that the message can take. The Catch terminal of both TryCatch nodes is connected to a common error processing subflow.



If the input node in your message flow does not have a Catch terminal, and you want to process errors in the flow, you must include a TryCatch node.

Constructing message models

This topic area describes the concepts behind message modeling, and the tasks that are involved in working with message models.

About this task

If you are unfamiliar with message models, read the topics that describe the concepts, starting with “Message modeling” on page 1154. These topics explain when you might want to model messages, and describe the message modeling objects that you can use, such as message sets and message definition files.

The WebSphere Message Broker message model is based on XML Schema. For more information about XML Schema, see XML Schema Part 0: Primer.

The following tasks are provided for developing message models:

- “Working with a message set project”
- “Working with a message set” on page 2840
- “Working with a message definition file” on page 2863
- “Working with MRM message model objects” on page 2870
- “Creating a multipart message” on page 2919
- “Linking from one message definition file to another” on page 2921
- “Working with a message category file” on page 2923
- “Working with data structures” on page 2930
- “Generating documentation from message sets and message flows” on page 2962
- “Generating XML Schemas” on page 2963
- “Generating a Broker SCA definition from a message set” on page 2967
- “Generating a WSDL definition from a message set” on page 2968

Tip: The WebSphere Message Broker Toolkit provides a set of toolbar icons that invoke wizards that you can use to create many of the resources that are associated with message models; for example, a new message set. Hold the mouse pointer over a toolbar icon to see its function.

The WebSphere Message Broker Toolkit lets you open resource files with other editors. However, use only the WebSphere Message Broker Toolkit to edit resource files that are associated with message models because this editor correctly validates all changes that you make to these files.

Related concepts:

“Message modeling” on page 1154
Much of the business world relies on the exchange of information between applications. The information is contained in messages that have a defined structure that is known and agreed by the sender and the receiver.

“Why model messages?” on page 1158
WebSphere Message Broker supplies a range of parsers to parse and write message formats. Some message formats are self-defining and can be parsed without reference to a model. Most message formats, however, are not self-defining, and the parser must have access to a predefined model that describes the message, if it is to parse it correctly.

Working with a message set project

Creating and deleting a message set.

About this task

Before you begin to develop your message model, you must create a message set. A message set project is automatically created when you create a message set.

This topic area describes the tasks that are involved in working with a message set.

- "Creating a message set" on page 2842
- "Deleting a message set project"

Related concepts:

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

"Message set projects" on page 1161
A *message set project* is a specialized container in which you create and maintain all the resources associated with one message set.

Deleting a message set project

Delete a message set project and, optionally, the contents of the associated project directory.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

Tip: Close all open windows within the WebSphere Message Broker Toolkit that relate to the message set project or associated files that you want to delete. If you do not do this, errors might occur when you try to process objects that no longer exist your workspace.

About this task

This task topic describes how to delete a message set project and, optionally, the contents of the associated project directory.

To delete a message set project:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message set project that you want to delete, then click **Delete** on the pop-up menu. The Confirm Project Delete window opens.
3. Choose whether to delete or retain the contents of the project directory. By default, project directory contents are not deleted. To delete the contents of the project directory, click **Also delete contents**; all files and directories that are associated with the project are deleted.
4. Click **Yes** to delete the message set project. Alternatively, click **No** or press **Esc** to cancel the deletion.

Results

You can generate documentation from your message sets, message flows, message definition files, message maps, Java files, ESQL files, and deployable WSDL files.

Configuring message set preferences

This task topic explains how to make changes to preferences that relate to message set processing. These preferences are for message set editors, message set model validation, and importing XML Schema.

About this task

To configure message set preferences:

Procedure

1. Open the Preferences window by clicking **Window > Preferences**.
2. In the left hand pane, expand **Broker Development > Message Sets** by clicking **+**. This displays the following options:
   - Editors
   - Validation
   - XML Schema Importer

3. View or make any necessary changes to the preferences for message set processing. These preferences are shown in the right hand area of the window.
4. When you have finished, click **Apply**. Alternatively, click **Restore Defaults** to return to the default settings for the displayed fields.
5. Close the Preferences window by clicking **OK**.

Opening an existing message set

Open an existing message set in the Message Set editor so that you can view or edit its contents.

Before you begin

Before you start:

Create a message set by following the instructions in "Creating a message set" on page 2842.

Tip: Although you can open resource files with other editors you are advised to only use the WebSphere Message Broker Toolkit Message Set editor to work with message set files because this editor correctly validates changes made to the `messageSet.mset` files when they are saved. Other editors might not do this.

About this task

To open a message set so that you can view or edit its contents:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the `messageSet.mset` file of the message set that you are opening then click **Open** on the pop-up menu. This opens the Message Set editor for the selected file.

Results

You can now view or edit the file as required.

The Tagged/Delimited String Format (TDS) uses mnemonics for a number of properties for a message set, complex type, or both.

"Default TDS message set properties" on page 5394
The following tables define the defaults for the message set properties for the TDS Format for each of the industry standard messages that you can define.

"Documentation properties for all message set objects" on page 5413
Use the documentation property of an object to add information that describes the function of the object.

Creating a message set

Use the New Message Set wizard to create a message set.

About this task

The New Message Set wizard also creates a new message set project.

Note: You can also use a Quick Start wizard to create a message set, a message set project, and other resource files that you need to create a new application.

The New Message Set wizard allows you to select what kinds of message format you want to model in your message set. The message domain and the physical format created is inferred from the selection that you make. Note, however, that you can change the inferred domain using the message set editor.

The options are:

- XML documents (general)
- Web services (SOAP)
- Binary data (for example, C or COBOL structures)
- Text data (for example, CSV, SWIFT, or HL7)
- MIME documents other than Web services
- Data for WebSphere Adapters
- Database records

The default value is `XML documents (general)`.

Below the list of message formats there are check boxes corresponding to each of the message formats. The check box corresponding to the message format that you selected is not available, but you can select any of the other check boxes to add other message formats to your message set.

If you later select a different default message domain, the checked state for the domain that you originally selected as the default does not change, but the check box is enabled.

As you can now select more than one message domain you can, for example, use the default value of **XML documents (general)** together with **Binary data (for example, C or COBOL structures)** and **Text data (for example, CSV, SWIFT or HL7)**. This results in the selection of the XMLNSC and MRM domains (to handle non-XML documents) within the same message set if you require this functionality.

The mapping between the selection, the domain, and the wire format created is described in the following table:

Selection	Inferred message domain	Physical format created
XML documents (general)	XMLNSC	XML
Web services (SOAP)	SOAP and XMLNSC	XML
Binary data (for example, C or COBOL structures)	MRM	CWF
Text data (for example, CSV, SWIFT, or HL7)	MRM	TDS
MIME documents other than Web services	MIME	None
Data for WebSphere Adapters	DataObject	None
Data for CORBA	DataObject	None
Database records	DataObject	None

Depending on your selection, an appropriate IBM supplied message will be imported into the message set.

Note: The XML physical format is created only in case the user switches to MRM XML.

If you click **Finish** on the second page of the New Message Set wizard, the message set that is created has the following default property values:

Property	Default value
Message Domain	XML documents (general)
Physical Format	XML Wire Format (XML1)
Namespace support	Enabled

To create a new message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Set wizard. To do this, right-click anywhere in the Broker Development view, then click **New** > **Message Set**.
3. In the **Message set name** field, type the name for the message set that you are creating. The name that you type is also displayed in the **Message set project name** field.
4. Optional: You can choose a different message set project name; to do this, type this name into the **Message set project name** field.
5. Optional: You can specify a directory in which you want to store the project contents. If you do not specify a directory, the default workspace is used. To specify a directory, first clear the **Use default** check box, then either type into the **Directory** field the location of the directory, or click **Browse** to see a list of the folders that you can choose from for the location of the directory.
6. Optional: If you want to create a new message set whose definition is based on existing message set, click **Message Set** in the **Copy message set contents from another message set** pane and choose from the list of message set definitions that are shown; then click **Finish**. The new message set (and the message set project that contains it) is created immediately and the New Message Set wizard automatically closes.
7. Optional: If you want to create a message set whose definition is not based on an existing message set, click **Next**. You are presented with the next pane which allows you to choose the type of message data that you want to process.
   a. Expand the list shown under **Select the type of message data that you will be working with most often** and choose a value from the list shown. The value that you choose determines the default message domain of the message set. If you choose `XML Documents (general)`, the default message domain XMLNSC is used.
   b. Optional: You can now select additional types of message data. Under **Select any other types of message data that you will be working with** there are check boxes for each of the following message data types:
      - XML documents (general)
      - Web services SOAP
      - Binary data (for example, C or COBOL structures)
      - Text data (for example, CSV, SWIFT or HL7)

- MIME documents other than Web services
- Data for WebSphere Adapters

Note: These check boxes correspond to the list of data types from which you chose the data type that you will be working with most often, but the check box that corresponds to the data type that you chose from that list is not available.
By default, all these check boxes are cleared. You can select any, or all of these check boxes, to add the corresponding data types to your message set.

If you select the check box for text data, either for the type of message data that you will be working with most often or as another type of message data that you will be working with, you can additionally choose from the displayed list of text messaging standards. This list is the same as that given in the description of the `Messaging Standard` property in "TDS Format message set properties" on page 5381.

c. Click **Next**. A new panel is displayed that summarizes some information about the message set that you have created. Specifically, it lists:

   Supported message domains

   Physical formats to be created

   IBM supplied messages to be imported

8. Click **Finish** on this page to create the message set, and the message set project that contains it. The New Message Set wizard closes.

Results

After the New Message Set wizard finishes, the message set editor is opened.

What to do next

You can now create some message definitions in the new message set. You can either create new message definitions from scratch, or create them based on existing artifacts such as WSDL, XSD, DTD, C, COBOL files, or EIS metadata. Use the Message Definition File wizard and the Message Definition File From wizard to help you with this.

Related concepts:

Configuring logical properties: Message sets

Configure the logical properties of a message set using the Message Set editor.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

If the `messageSet.mset` file for the appropriate message set is not already open in the Message Set editor, you must first open it as described in "Opening an existing message set" on page 2841.

About this task

This task topic describes how to configure the logical properties of a message set using the Message Set editor.

To configure the logical properties of a message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Message Set editor, in the Properties Hierarchy, click **Message Set**. This displays the logical properties of the selected message set in the Details view.
3. Configure to your requirements the logical properties that are shown in the Details view.

   Note: Property fields that are disabled cannot be altered. For example, the **Message Set ID** field is disabled because the message set ID is generated automatically when the message set is created; the **Message Set ID** must not then be altered.
4. Save your changes by clicking **File> Save** or by pressing Ctrl+S. Alternatively click **File> Save All** or press Ctrl+Shift+S.

Results

Working with physical formats

If you are using the MRM domain to parse and write your messages, when you are developing your message model you might want to add one or more physical format layers to a message set, then configure the properties of these physical formats.

Before you begin

Before you start:

You must have completed the following tasks:
- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

About this task

This topic area covers the following tasks that relate to working with the physical properties of a message set:
- "Adding a Custom Wire Format (CWF)"
- "Configuring Custom Wire Format (CWF) properties: Message sets" on page 2849
- "Adding a TDS physical format" on page 2851
- "Configuring TDS properties: Message sets" on page 2852
- "Adding an XML wire format" on page 2853
- "Configuring XML Wire Format properties: Message sets" on page 2855
- "Renaming a physical format" on page 2856
- "Applying default physical format settings: Message sets" on page 2857
- "Removing a physical format" on page 2858
- "Observing 2007 U.S. changes to daylight saving time" on page 2859

Related concepts:

"Message sets overview" on page 1162
A message set is a container for grouping messages and associated message resources (elements, types, groups).

"Namespaces in the message model" on page 1201
Use namespaces to qualify message model object names.

"Physical formats in the MRM domain" on page 1211
Each message definition file within a message set describes both the *logical structure* of your messages, and the *physical formats* that describe the precise appearance of your message bit stream during transmission.

Adding a Custom Wire Format (CWF):

You can add a Custom Wire Format (CWF) physical format layer to a message set by using the Message Set editor.

Before you begin

Before you start:

You must have completed the following tasks:
- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

About this task

To add a CWF physical format layer to a message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Message Set editor, in the Properties Hierarchy, open the Add Custom Wire Format window by right-clicking **Custom Wire Formats**, then clicking **Add Custom Wire Format**.
3. On the Add Custom Wire Format window, specify the name that you want to use for the new CWF physical format. The default name is 'Binary1'.

   Tip: Physical format names must be unique across a message set. You are recommended to start the name of your new CWF physical format with 'CWF' or 'Binary', because this clearly identifies the type of the physical format that you are adding in relation to any of the other types.
4. Click **OK** to add the physical format layer to the message set. Alternatively, if you decide to cancel the process, click **Cancel** or press Esc on the keyboard.

   Tip: The new physical format layer is added with the relevant default property values. You can configure the message set properties according to your requirements, using the appropriate editor.
5. Save your changes either by clicking **File> Save** or by pressing Ctrl+S.

Related concepts:

"Message sets overview" on page 1162
A message set is a container for grouping messages and associated message resources (elements, types, groups).

"MRM Custom Wire Format" on page 1214
Custom Wire Format (CWF) is the physical representation of a message that is composed of a number of fixed-format data structures or elements, which are not separated by delimiters.

Related tasks:

Adding a TDS physical format:

Add a Tagged/Delimited String (TDS) physical format layer to a message set using the Message Set editor.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

About this task

This task topic describes how to add a Tagged/Delimited String (TDS) physical format layer to a message set using the Message Set editor.

To add a TDS physical format layer to a message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Message Set editor, in the Properties Hierarchy, open the Add Tagged/Delimited String Format window by right-clicking **Tagged/Delimited String Formats** then clicking **Add Tagged/Delimited String Format** on the pop-up menu.
3. In the Add Tagged/Delimited String Format window, specify the name that you want to use for the new TDS format. The default name is 'Text1'.

   Tip: Physical format names must be unique across a message set. You are recommended to start the name of your new TDS physical format with 'TDS' or 'Text', because this clearly identifies the type of the physical format that you are adding in relation to any of the other types.
4. Click **OK** to add the physical format to the message set. Alternatively, if you decide to cancel the process, click **Cancel** or press **Esc** on the keyboard.

   Tip: The new physical format layer is added with the relevant default property values. You can configure the message set properties according to your requirements, using the Message Set editor.
5. Save your changes either by clicking **File> Save** or by pressing Ctrl+S.

Related concepts:

Configuring XML Wire Format properties: Message sets:

Configure the XML Wire Format properties of a message set using the Message Set editor.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841
- "Adding an XML wire format" on page 2853

About this task

To configure the XML wire format properties of a message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Message Set editor, the **XML Wire Formats** node of the Properties Hierarchy shows the name of each of the XML physical formats that have been added to the message set. If the physical format names are not in view, expand **XML Wire Formats** by clicking **+**.
3. Click the chosen XML physical format so that the properties of this format appear in the Details view of the Message Set editor.
4. Configure the XML wire format properties shown in the Details view according to your requirements.
5. Save your changes either by clicking **File> Save** or by pressing Ctrl+S. Alternatively click **File> Save All** or press Ctrl+Shift+S.

Renaming a physical format:

Rename a physical format using the Message Set editor.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

This task assumes that you have added one or more physical formats to the message set that you are working with. For further information see "Adding a Custom Wire Format (CWF)" on page 2848 or "Adding an XML wire format" on page 2853 or "Adding a TDS physical format" on page 2851.

About this task

This task topic describes how to rename a physical format using the Message Set editor.

To rename a physical format previously added to the message model:

Procedure

1. Close all message definition (`.mxsd`) files that are currently open in the Message Definition editor, otherwise you will not be able to rename the physical format.
2. Switch to the Broker Application Development perspective.
3. In the Message Set editor, the Properties Hierarchy shows the name of each of the physical formats that have been added to the message set. If the physical format names are not in view, expand **XML Wire Formats**, **Custom Wire Formats**, or **Tagged/Delimited String Formats** by clicking **+**.
4. Right-click the physical format that you want to rename then click **Rename** on the pop-up menu to open the "Rename wire format" window.
5. In the "Rename wire format" window, type the new name for the physical format. The renaming operation modifies all of the message definition files in the message set and saves the amended message set file.
6. Click **Finish** to rename the physical format and save the message set file.

Applying default physical format settings: Message sets:

Apply the default settings to a physical format layer that has previously been added to a message set.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

The tasks in this topic area assume that you have added one or more physical formats to the relevant message set. For further information see "Adding a Custom

Wire Format (CWF)" on page 2848 or "Adding an XML wire format" on page 2853 or "Adding a TDS physical format" on page 2851.

About this task

To apply the default settings to a physical format that has previously been added to a message set:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Message Set editor, in the Properties Hierarchy, right-click the physical format to which you want to apply the default settings then click **Apply default physical format settings** on the pop-up menu.

Results

The default settings are applied to the physical format that you have selected. No warning appears beforehand.

Removing a physical format:

You can remove a physical format layer from your message set.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

The tasks in this topic area assume that you have added one or more physical formats to a message set. For further information see "Adding a Custom Wire

Format (CWF)" on page 2848 or "Adding an XML wire format" on page 2853 or "Adding a TDS physical format" on page 2851.

About this task

To remove a physical format layer from your message set:

Procedure

1. Close any message definition files that are currently open in the Message Definition editor, otherwise you will not be able to remove the physical format.
2. Switch to the Broker Application Development perspective.
3. In the Message Set editor, the Properties Hierarchy shows the name of each of the physical formats that have been added to the message set. If the physical format names are not in view, expand **XML Wire Formats**, **Custom Wire Formats**, or **Tagged/Delimited Wire Formats**, by clicking **+**.
4. Right-click the physical format that you want to remove, then click **Delete** on the pop-up menu.

   Tip: If you decide to proceed with deleting the physical format, all of the message definition files under the current message set are modified and the amended message set file is saved.
5. Click **Finish** to remove the physical format, or click **Cancel** to return to the Broker Application Development perspective without making any changes. Pressing Esc also returns you to the Broker Application Development perspective without making any changes.

Observing 2007 U.S. changes to daylight saving time

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842

- "Opening an existing message set" on page 2841

This task assumes that you have added and configured one or more physical formats to existing message sets. For further information see: "Working with physical formats" on page 2847.

About this task

This task describes how to ensure that the message sets observe daylight saving time (DST) in line with the 2007 U.S. changes.

If your message sets use a named time zone that is *not* changing DST in line with the 2007 U.S. changes, you do not need to do anything.

If you are using a GMT-04:00, GMT-05:00, GMT-06:00, GMT-07:00, or GMT-08:00 named time zone with DST, that must observe DST in line with the 2007 U.S. changes, do the following steps on every computer on which the broker is running:

1. Set the environment variable MQSI_USE_NEW_US_DST to an initial value: Y, for example.
2. Restart the broker to use the changed DST.

Related concepts:

Configuring documentation properties: Message sets

Document a message set in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a message set" on page 2842
- "Opening an existing message set" on page 2841

About this task

To configure the documentation for a message set:

Procedure

1. In the Message Set editor **Properties Hierarchy**, click **Message set**. The documentation text field appears in the Details view, with all the other logical properties of the message set.
2. Configure the documentation properties shown in the Details view to your requirements.

   You can use the `Documentation` property to set user-defined keywords and their value. These keywords are propagated to the broker when you deploy the message set in a BAR file. These keywords are used to give additional information about the message set when you display deployed message set properties in the WebSphere Message Broker Toolkit. See "Message set version and keywords" on page 1169 for more information.
3. Save your changes by clicking **File** > **Save**, or by pressing Ctrl+S. Alternatively, click **File** > **Save All**, or press Ctrl+Shift+S.

Results

Deleting a message set

If you want to delete a message set from your message model, you must delete the message set project that contains the message set.

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message set project folder that contains the message set that you want to delete and click **Delete** on the pop-up menu. This opens the Confirm Project Delete window, which asks whether you want to delete the message set project that you have specified.
3. Click **Also delete contents .....** to delete the contents of the message set project, or click **Do not delete contents** to cancel the deletion of the message set project. Pressing the Esc key on your keyboard also cancels the deletion of the message set project.

Results

Important: When you delete a message set project, the action cannot be undone after you have confirmed the deletion. All folders and associated files for the message set project are deleted.

Related concepts:

"Message sets overview" on page 1162
A message set is a container for grouping messages and associated message resources (elements, types, groups).

Use namespaces to qualify message model object names.

Applying a Quick Fix to a task list error

During the creation, migration and manipulation of message models, warnings or errors might occur; these are listed in the Problems view of the Broker Application Development perspective. Some of these warnings or errors can be cleared by applying a Quick Fix.

About this task

The types of warnings or errors that can be cleared using a Quick Fix are those where the construct has a broken link, where the construct has a facet that is not legal, or where the construct has been imported, and where a warning or error has occurred, but has been kept to ensure the integrity of structure that is being imported. This allows you to fix the problem in the most appropriate way.

To apply a Quick Fix:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Problems view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Problems view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Problems**.
3. In the Problems view, right-click the task list warning or error that you want to apply the Quick Fix to, then click **Quick Fix**. Note that **Quick Fix** might not be available for the problem that you are trying to fix.

4. Step through the windows that are displayed, making the selections that are required to ensure that the fix is applied in the appropriate way.

Results

When the Quick Fix has successfully been applied to the task list warning or error, it is removed from the Problems view.

Working with a message definition file

Create, open, and delete a message definition file.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

About this task

This topic area describes the tasks that are involved in working with a message definition file:

- "Opening an existing message definition file" on page 2864
- "Creating a message definition file" on page 2865
- "Deleting a message definition file" on page 2869

Related concepts:

"Message modeling concepts" on page 1155
Message modeling is a way of predefining the message formats that are used by your applications.

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

Add, configure, and delete objects.

Opening an existing message definition file

This task topic describes how to open an existing message definition file in the Message Definition editor; you can then view and edit the contents of the file.

About this task

To open an existing message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message definition file (file extension `*.mxsd`) that you want to open, and select **Open**. This opens the Message Definition editor for the message definition file that you have specified.

   Tip: The Eclipse framework lets you open resource files with other editors. However, you are advised to use only the WebSphere Message Broker Toolkit Message Definition editor to work with message definition files, because this editor correctly validates any changes that are made to the message definition files. Other editors might not do this.
3. View or edit the data in the file as required.

Creating a message definition file

Creating an empty message definition file to contain your message model objects.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

About this task

You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML Schema form.

You can create the message definition file in one of the following ways:

- Create the message definition file from scratch, see "Creating a message definition file from scratch" on page 2866.
- Base your message definition file on an existing resource (for example, an XML Schema file, an IBM supplied message, an XML DTD file, a C header file, a COBOL file, or a WSDL file), see "Creating a message definition file from an existing resource" on page 2867.
- Copy a message definition file from one message set to another.

  If you do copy a message definition file from one message set to another, you must check that the source and target message sets have identical physical formats, and that namespaces are enabled.

  If the source and target namespaces do not have identical formats, the physical format of the message definition file might be replaced by the default information applied to the target message set.

Create a new message definition file by using the New message definition file wizard.

Creating a message definition file from scratch:

Create an empty message definition file to contain message model objects.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

About this task

You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML Schema form.

To create an empty message definition file from scratch:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard.

   To do this, right-click the message set project in the Broker Development view that you are adding the message definition file to, and click **New> Message Definition File** on the pop-up menu. The **Message Definition File** panel of the wizard is displayed. The target message set list is filtered to only show artifacts in the active working set.
3. Click the message set, type a name into the File name field, and click **Next**.
4. Step through the remainder of the wizard, completing the details as required.

Results

The new empty message definition file, with the name that you have specified and a file extension of `*.mxsd`, opens in the Message Definition editor; you can use the editor to create your own message definitions. If you have chosen to use a target namespace, a directory structure that is based on the URI that you have supplied is created. The new message definition file is placed within this directory structure, which appears in the Broker Development view.

Creating a message definition file from an existing resource:

You must create a message definition file before you can create the message model objects. The message definition file contains the logical and physical model definitions of the objects in XML schema form.

Before you begin

You must have completed the following task:

- "Creating a message set" on page 2842

About this task

To create a new message definition file that is based on an existing resource:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the appropriate New Message Definition File From wizard.

   Right-click the message set project in the Broker Development view that you are adding the message definition file to, and click **New> Message Definition File From**. A submenu shows the list of resources from which you can choose.
3. Choose the resource on which to base your new message definition. Click one of the following resources:
   - **C Header File**
   - **COBOL File**
   - **CORBA IDL File**
   - **Database Definition File**
   - **IBM Supplied Message**
   - **SCA Import or Export**
   - **WSDL File**
   - **XML DTD File**
   - **XML Schema File**

   The first panel of the corresponding wizard is displayed.
4. Step through the remainder of the wizard supplying the details as required. For more information about using the New Message Definition File wizards, see "New message definition file wizards" on page 6360.

Results

The new message definition file, with the name that you have specified and a file extension of `.mxsd`, opens in the Message Definition editor. You can use the editor to create your own message definitions. If you have chosen to use a target namespace, a directory structure that is based on the URI that you have supplied is created. The new message definition file is placed within this directory structure, which is shown in the Broker Development view.

Deleting a message definition file

You can delete a message definition file from your message model.

Before you begin

Before you start:

Before you delete a message definition file, you can list resources that refer to that file and would therefore be affected by the deletion; for more information, see "Showing resource references" on page 1447.

About this task

To delete a message definition file from your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message definition file (file extension `*.mxsd`) that you want to delete, then click **Delete**. Alternatively, select the message definition file that you want to delete in the Broker Development view, then, from the menu bar, click **Edit** > **Delete**, or press the Delete key.
3. In the Confirm Resource Delete window, click **Yes** to delete the message definition file. Click **No**, or press the Esc key, to cancel the deletion of the message definition file.

Results

Important: All files and objects that are associated with the message definition file are deleted. This action cannot be undone.

Related concepts:

Working with MRM message model objects

Add, configure, and delete objects.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865

About this task

This topic area describes the tasks that are involved in working with message model objects:

- "Adding MRM message model objects"
- "Configuring MRM message model objects" on page 2896
- "Deleting objects" on page 2919

Related concepts:

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

"Message model objects" on page 1174
An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

Related tasks:

Adding MRM message model objects

Various tasks are involved in adding message model objects to a message definition file.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865

Before starting any of the tasks in this topic area, you must first open the message definition file to which you want to add message model objects in the Message Definition editor. See "Opening an existing message definition file" on page 2864 for further details.

About this task

This topic area describes the tasks that are involved in adding message model objects to a message definition file:

- "Adding a message" on page 2872
- "Adding a message from a global element" on page 2873
- "Adding a global element" on page 2876
- "Adding a local element" on page 2877
- "Adding an element reference" on page 2878
- "Adding a wildcard element" on page 2880
- "Adding a global attribute" on page 2881
- "Adding a local attribute" on page 2882
- "Adding an attribute reference" on page 2884
- "Adding a wildcard attribute" on page 2885
- "Adding a simple type" on page 2886
- "Adding a complex type" on page 2889
- "Adding a simple type to an element or attribute" on page 2904
- "Adding a complex type to an element" on page 2905
- "Adding a global group" on page 2890
- "Adding an attribute group" on page 2892
- "Adding a group reference" on page 2894

Related concepts:

"Message definition files" on page 1171

Access property information by property kind, or by object.

Adding a message:

Add a message to a message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a message to your message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Messages** then click **Add Message** on the pop-up menu. A simple message is immediately added to your message model and is assigned a default name.
4. Either type a new name for the message or press **Enter** to accept the default.

   Tip: When you add a message to your message model, an associated complex type and global element with the same name as the message are also created. The global element and the message cannot have different names and changing the name of one changes the names of both. The complex type can be renamed.

Results

You can now configure the properties of the message to your exact requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

"Message definition files" on page 1171
A *message definition file* contains the messages, elements, types, and groups which make up a message model within a message set.

Adding a message from a global element:

Add a message from a global element to a message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding a global element" on page 2876 (This must be a global element of complex type)

About this task

To add a message from a global element to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.

3. In the Outline view, right-click **Messages** then click **Add Message From Global Element** on the pop-up menu to open the Add Message From Global Element window. This window lists all the global elements of a complex type that are not already associated with a message.
4. In the **Select a global element of complex type that is not already used for a message** list, click the global element that you want to use to create your message.
5. Click **OK**. This immediately adds a message with the same name as the selected global element to your message model.

Results

You can now configure the properties of the message to your exact requirements. For further information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Adding a message from a global type:

Add a message from a global type to your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding a global element" on page 2876 (This must be a global element of complex type)

About this task

To add a message from a global type to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Messages** then click **Add Message From Global Type** on the pop-up menu to open the Add Message From Global Type window. This window lists all the global complex types that are not already associated with a message.
4. In the **Select a global complex type** list, click the global complex type that you want to use to create your message.
5. Click **OK**. This immediately adds a message with the same name as the selected global complex type to your message model.

Results

You can now configure the properties of the message to your exact requirements. For further information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Adding a global element:

Add a global element to a message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a global element to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Elements and Attributes** then click **Add Global Element** on the pop-up menu. This adds a global element of type string to your message model, and assigns a default name.
4. Either type a new name for the global element or press Enter to accept the default.

Results

You can now configure the global element to your requirements. For further information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Use the documentation property of an object to add information that describes the function of the object.

Adding a local element:

Add a local element to a message, type, group, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

This task assumes that you have previously added the relevant message, type, group, or complex element to your message model.

About this task

To add a local element to a message, type, group, or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding a local element then click **Add Local Element** on the pop-up menu. A local element of type string is added to the message model and is assigned a default name.
4. Either type a new name for the local element or press **Enter** to accept the default.

Results

You can now configure the local element to your exact requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Use the documentation property of an object to add information that describes the function of the object.

Adding an element reference:

Add an element reference to a message, type, group, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

This task assumes that you have previously added the relevant message, type, global group, or complex element to your message model.

About this task

To add an element reference to a message, type, global group, or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding the element reference, then click **Add Element Reference** on the pop-up menu. This adds a default element reference to the message model object that points to an existing global element. This existing global element might be in the current message definition file or in a message definition file defined under **Includes** or **Imports** for the current message definition file. For further information about Imports and Includes, see "Linking from one message definition file to another" on page 2921.

Results

You can now configure the element reference to your exact requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Adding a wildcard element:

Add a wildcard element to a message, type, group, or complex element in a message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add a wildcard element to a message, type, group or complex element. This task assumes that you have previously added the relevant message, type, group or complex element to your message model.

About this task

To add a wildcard element to a message, type, group or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the message model object (message, complex type, group or complex element) to which you are adding the wildcard element then click **Add Wildcard Element** on the pop-up menu. A wildcard element is added and appears in the Outline view.

Results

You can now configure the wildcard element to your exact requirements. For further information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Use the documentation property of an object to add information that describes the function of the object.

Adding a global attribute:

Add a global attribute to your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a global attribute to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.

3. In the Outline view, right-click **Elements and attributes** then click **Add Global Attribute** on the pop-up menu. A global attribute of type string is immediately added and is assigned a default name.
4. Either type a new name for the global attribute or press Enter to accept the default.

Results

You can now configure the global attribute to your requirements. For more information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Use the documentation property of an object to add information that describes the function of the object.

Adding a local attribute:

Add a local attribute to a message, complex type, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add a local attribute to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add a local attribute to a message, complex type or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, complex element, or attribute group) to which you are adding the local attribute then click **Add Local Attribute** on the pop-up menu. A local attribute of type string is immediately added to the message model object and is assigned a default name.
4. Either type a new name for the local attribute or press **Enter** to accept the default.

Results

You can now configure the local attribute to your requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Adding an attribute reference:

Add an attribute reference to a message, complex type, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add an attribute reference to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add an attribute reference to a message, complex type or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the message model object (message, complex type, complex element, or attribute group) to which you are adding the attribute reference then click **Add Attribute Reference** on the pop-up menu. This action adds a default attribute reference to the message model object that points to an existing global attribute.

Results

You can now configure the attribute reference to your exact requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Adding a wildcard attribute:

Add a wildcard attribute to a message, complex type, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add a wildcard attribute to a message, complex type, or complex element. This task assumes that you have previously added the relevant message, complex type, or complex element to your message model.

About this task

To add a wildcard attribute to a message, complex type or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, complex element, or attribute group) to which you are adding the wildcard attribute then click **Add Wildcard Attribute** on the pop-up menu. A wildcard attribute of type string is immediately added to the message model object and is assigned a default name.

4. Either type a new name for the wildcard attribute or press **Enter** to accept the default.

Results

You can now configure the wildcard attribute to your requirements. For further information about configuring message model objects see "Configuring MRM message model objects" on page 2896.

Related concepts:

Use the documentation property of an object to add information that describes the function of the object.

Adding a simple type:

Add a simple type to your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a simple type to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Types** then click either **Add Simple Type Restriction**, **Add Simple Type List**, or **Add Simple Type Union** on the pop-up menu.
   - For a restriction, a simple type of base type string is added, and assigned a default name.
   - For a list, a simple type of item type string is added, and assigned a default name.
   - For a union, a simple type with a single member type of string is added, and assigned a default name.
4. Either type a new name for the simple type or press **Enter** to accept the default.

Results

You can now configure the simple type to your exact requirements.

If the simple type is a restriction:

- You can change the base type using the editor Properties view.
- You can set the value constraints associated with the simple type. See "Setting value constraints" on page 2907.
- You can replace the base type with a new local simple type. In the Outline view right-click simple type and click one of:
  - **Add Simple Type Restriction**. This option replaces the base type with a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction'. The result is that the original simple type becomes a restriction of a restriction.
  - **Add Simple Type List**. This option replaces the base type with a new simple type list, with an item type of string. You can configure the list as described in 'If the simple type is a list'. The result is that the original simple type becomes a restriction of a list. It appears as a list in the editor, because a restriction of a list is itself a list, but you can also set certain value constraints.

If the simple type is a list:

- You can change the item type using the editor Properties view.
- You can replace the item type with a new local simple type. In the Outline view right-click the simple type and click one of:
  - **Add Simple Type Restriction**. This option replaces the item type with a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction'. The result is that the original simple type becomes a list of a restriction.
  - **Add Simple Type Union**. This option replaces the item type with a new simple type union, with a single member type of string. You can configure the union as described in 'If the simple type is a union'. The result is that the original simple type becomes a list of a union.

If the simple type is a union:

- If the member type of string is not required, in the Outline view right-click the string and click Delete.
- You can add further members to the union. In the Outline view right-click the simple type and click one of:
  - **Add Union Member Type**. This option adds a union member that is an existing simple type. Use the type selection dialog to select the simple type required.
  - **Add Local Member Type Restriction**. This option adds a union member that is a new simple type restriction, with a base type of string. You can configure the restriction as described in 'If the simple type is a restriction' referred to earlier.
  - **Add Local Member Type List**. This option adds a union member that is a new simple type list, with an item type of string. You can configure the list as described in 'If the simple type is a list' referred to earlier.
  - **Add Local Member Type Union**. This option adds a union member that is a new simple type union, with a single member type of string. You can configure the new union as described in 'If the simple type is a union'.
- New members are added to the end of the union. To change the order of a member, in the Outline view select the member and drag it to the required position in the union. All union members that are existing simple types must occur ahead of all members that are local restrictions, lists, and unions, so reordering is subject to this rule.

For further information about configuring message model objects see “Configuring MRM message model objects” on page 2896.

Adding a complex type:

Add a complex type to your message model.

Before you begin

Before you start:

You must already have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a complex type to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Types** then click **Add Complex Type** on the pop-up menu. A complex type is added and is assigned a default name.
4. Either type a new name for the complex type or press Enter to accept the default.

Results

You can now configure the complex type to your requirements. For further information on configuring message model objects see "Configuring MRM message model objects" on page 2896.

Adding a global group:

Add a global group to your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add a global group to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Groups** then click **Add Group** on the pop-up menu. A global group is added to your message model and is assigned a default name.
4. Either type a new name for the global group or press **Enter** to accept the default.

Results

You can now configure the global group to your requirements. For further information about configuring the properties of message model objects see "Configuring MRM message model objects" on page 2896.

Adding a local group:

Add a local group to a message, type, global group, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add a local group to a message, complex type, group, or complex element. This task assumes that you have previously added the relevant message, complex type, group, or complex element to your message model.

About this task

To add a local group to a message, complex type, group, or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.

3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you are adding the local group then click **Add Local Group** on the pop-up menu. A local group is immediately added to the message model with type composition set to *sequence* by default.

Results

You can now configure the local group to your requirements. For further information about configuring message model objects, see "Configuring MRM message model objects" on page 2896.

Related concepts:

Adding an attribute group:

Add an attribute group to your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To add an attribute group to your message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click **Groups** then click **Add Attribute Group** on the pop-up menu. A global attribute group is added to your message model and is assigned a default name.
4. Either type a new name for the attribute group or press **Enter** to accept the default.

Results

You can now configure the attribute group to your requirements. For further information about configuring the properties of message model objects see "Configuring MRM message model objects" on page 2896.

Adding a group reference:

You can add a group reference to a message, type, global group, or complex element.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

You can add a group reference to a message, complex type, group, or complex element. This task assumes that you have previously added the relevant message, complex type, group, or complex element to your message model.

About this task

To add a group reference to a message, complex type, group or complex element:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the object (message, complex type, group, or complex element) to which you want to add a group reference then click **Add Group Reference** on the pop-up menu. A group reference is immediately added to your message model.

Results

You can now configure the group reference to your requirements. For further information on configuring the properties of message model objects see "Configuring MRM message model objects" on page 2896.

Configuring MRM message model objects

Various tasks are involved in configuring MRM message model objects

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

Before starting any of the tasks in this topic area, you must first open the message definition file for which you want to configure message model objects in the Message Definition editor. See "Opening an existing message definition file" on page 2864 for further details.

About this task

This topic area describes the tasks that are involved in configuring message model objects:

- "Analyzing planned changes to message model objects" on page 2897
- "Renaming objects" on page 2898
- "Reordering objects" on page 2900
- "Copying objects" on page 2901
- "Pasting objects" on page 2901
- "Changing the type of an element or attribute" on page 2903

- "Setting value constraints" on page 2907
- "Configuring logical properties: Message model objects" on page 2909
- "Configuring documentation properties: Message model objects" on page 2910
- "Configuring physical properties" on page 2912
  - "Configuring Custom Wire Format (CWF) properties: Message model objects" on page 2913
  - "Configuring XML Wire Format properties: Message model objects" on page 2916
  - "Configuring TDS properties: Message model objects" on page 2914
  - "Applying default physical format settings: Message model objects" on page 2917
- "Deleting objects" on page 2919

Related concepts:

"Message model objects" on page 1174
An introduction to the objects that make up a message model. Message model objects are defined by XML Schema 1.0, except for Message which is a WebSphere Message Broker extension to XML Schema.

Analyzing planned changes to message model objects:

Use impact analysis to analyze the effect of renaming message model objects.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)
- "Enabling and disabling indexing" on page 1454

About this task

This information covers the following task:

- "Renaming message model objects"

Renaming message model objects:
About this task

You can analyze the effect of renaming the following objects:

- Complex and simple types
- Model Groups
- Elements
- Attributes

- Attribute Groups

Procedure

1. In the Broker Development view, right-click the object that you want to rename, then click **Impact Analysis** > **Rename**.
2. In the Impact Analysis - Rename Artifact window, type the new name of the object, then click **Analyze Impact**.

   The Rename Artifact dialog box shows the results of impact analysis, listing primary and secondary impacts.

   You can view the results of impact analysis in the Impact Analysis dialog box, or the Impact Analysis view of the WebSphere Message Broker Toolkit. For more information about how to view information about selected resources, mark changes as complete, copy results to an external application, and view previous results, see "Impact Analysis view" on page 6801.

:

Some artifacts are excluded from secondary analysis.

"Impact Analysis view" on page 6801
The Impact Analysis view shows information about selected resources, which changes have been marked as complete, and previous results. You can also use this view to copy results to the clipboard.

Renaming objects:

You can rename message model objects in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

Also read "Analyzing planned changes to message model objects" on page 2897 for information on the effects of the intended changes.

About this task

Objects in the WebSphere Message Broker Toolkit such as files, messages and elements can have different physical representations. Eclipse handles renaming differently depending on the object.

Tip: Not all objects can be renamed. For example, you cannot rename wildcards, local groups, or local types, because they do not have a name.

If an object can be renamed the usual way to do it is as follows:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Outline view, right-click the object that you want to rename then click **Rename** on the pop-up menu. Alternatively, right-click the object in the Message Definition editor **Overview** tab then click **Rename** on the pop-up menu. In both cases, depending on the object, either a renaming dialog opens or you will now be able to edit the name of the object directly.
3. Type the new name for the object.
4. If the renaming dialog is open, either press Enter or click **OK**.

Results

Rename a physical format using the Message Set editor.

Related reference:

"Message model object properties" on page 5416
Access property information by property kind, or by object.

Reordering objects:

Reorder message model objects within a message definition file.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To reorder objects within a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click the object that you want to move. For example, you could select a local element within a message in either the Outline view or Properties Hierarchy.
3. Use the mouse to drag the object to its new location.

   Tip: As you drag the object and the mouse cursor passes between objects, a black line appears, showing where the current focus is. If you try to drag the object to a location that it cannot be moved to (including objects that are highlighted as the cursor passes over them), the object remains in its original position when you release it.

Copying objects:

You can copy an object in a message definition file, such as a message for a local element object, or types for a complex type object.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To copy an object:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, right-click the message model object that you want to copy, then click **Copy**. Alternatively, right-click the object in the Message Definition editor **Overview** tab, then click **Copy**.

Results

The object is now copied.

Pasting objects:

Paste objects that you have previously copied within the same message definition file

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)
- "Copying objects" on page 2901

About this task

You can paste objects that you have previously copied within the same message definition file.

You can only copy and paste an object within the same message definition. You cannot copy an object and paste it into another message definition, either within the same message set or in a different message set.

To paste an object in the message definition from which you copied it:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, right-click the location where you are going to paste the object then click **Paste** on the pop-up menu. Alternatively, right-click the object in the Message Definition editor **Overview** tab then click **Paste** on the pop-up menu. The object appears in the new location with a default name which you can change if you want to.
4. Either type a new name for the object or press **Enter** to accept the default.

What to do next

Note: When you copy and paste objects within the message set, where physical properties exist for that object, these settings are not pasted, but are set to default values.

Tip: If you cannot select **Paste** from either menu, you might be trying to paste to a location that is not valid. For example, you cannot paste a complex type into a local element.

Related concepts:

Changing the type of an element or attribute:

You can change the type to a local element, global element, local attribute, or global attribute.

Before you begin

Before you start:

You must already completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

You can change the type of an element or attribute in your message model to another existing type, or you can create a new simple type or a new complex type.

To change the type of an element or attribute to an existing type:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, click the element for which you want to change the type.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy click **Logical Properties** > **Global Element** (or **Logical Properties** > **Local Element**, **Logical Properties** > **Global Attribute**, or **Logical Properties** > **Local Attribute**). If necessary, expand **Logical Properties** by clicking **+**.
6. In the Details view, in the **Type** property, click the new type that you require.

   Tip: If the type you require is not displayed, you can find it by clicking **(More...)** in the list. This displays the Type Selection window with additional options. If you know which type you require, specify the first letter in the text box at the top of the Type Selection window. Matching types are then displayed, making the selection process easier.
7. When you have selected the type that you require, click **OK**.

Results

The change to the type is applied wherever the element or attribute occurs.

The task above explains how to switch to an existing type. If you want to create a new simple type or a new complex type, select **(New Simple Type Restriction)**, **(New Simple Type List)**, **(New Simple Type Union)**, or **(New Complex Type)** in the **Type** list (see step 6 above). For information on how to create a new simple type or a new complex type see "Adding a simple type to an element or attribute" or "Adding a complex type to an element" on page 2905.

Related concepts:

Adding a simple type to an element or attribute:

You can add a simple type to a local element, global element, local attribute, or global attribute.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

This task assumes that you have previously added the relevant element or attribute to your message model.

About this task

To add a new simple type:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the element to which you want to add a new simple type.
4. In the Message Definition editor, click the **Properties** tab.

5. In the Properties Hierarchy, click **Logical Properties > Global Element** (or **Logical Properties > Local ElementLogical Properties > Global Attribute**, or **Logical Properties > Local Attribute**).
6. In the Details view, in the **Type** property, select **(New Simple Type Restriction)**, **(New Simple Type List)**, or **(New Simple Type Union)** to open the relevant New Simple Type window to create a simple type of the type that you specify.
7. In the New Simple Type window, in the **Base Type** list, click the type that you want to use.
8. Optional: If you want to add the new simple type as a global simple type, select the **Create as Global Simple Type** check box and specify the name for your new simple type in the **Name** field.
9. Click **OK**. A simple type is immediately added to your message model.

Results

Any changes that you make are reflected throughout where the element to which you have added a new simple type occurs.

Adding a complex type to an element:

You can add a complex type to a local element, global element, local attribute, or global attribute.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

This task assumes that you have previously added the relevant element or attribute to your message model.

About this task

When you add a complex type to an element or attribute, you can either create a new complex type or derive a new complex type from an existing base type.

To add a new complex type:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the element to which you want to add a new complex type.
4. In the Message Definition editor, click the **Properties** tab.
5. In the Properties Hierarchy, click **Logical Properties > Global Element** (or **Logical Properties > Local ElementLogical Properties > Global Attribute**, or **Logical Properties > Local Attribute**).
6. In the Details view, in the **Type** list, click **(New Complex Type)** to display the New Complex Type window.
7. If you want to create a new local complex type, click **Create a Local Complex Type**, in the **Composition** list, click the option that you require.
8. If you want to derive a new local complex type from an existing base type:
   a. Click **Derive a new Local Complex Type from existing base type**.
   b. In the **Base Type** list, click the base type that you want to use. Depending on the base type you select, the **Composition** and **Derived By** lists might become active.
   c. If the **Composition** and **Derived By** lists are active, click the options that you require in both lists.
9. If you want to add the new complex type as a global complex type, select the **Create as Global Complex Type** check box, and specify a name for your new complex type in the **Name** field.
10. Click **OK** to close the New Complex Type window and add the new complex type to your message model.

Results

Any changes that you make are reflected throughout where the element to which you are adding the complex type occurs.

Setting value constraints:

You can set the value constraints associated with a simple type.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding a simple type" on page 2886 or "Adding a simple type to an element or attribute" on page 2904 (You must have added one or more global or local simple types to your message model)

About this task

Value constraints are usually associated with a simple type; they refine a simple type by defining limits on the values which the simple type can represent. To set the value constraints associated with a simple type:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Outline view, click the simple type you are updating. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**.
3. Display the **Properties** tab of the Message Definition Editor by clicking **Properties** in the lower-left corner of the editor area. The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation
4. In the Properties Hierarchy under **Logical Properties** click **Value Constraints**. This displays the current value constraints settings for the selected simple type in the Details pane.

   Tip: If **Value Constraints** is not in view, expand **Logical Properties** by clicking **+**.
5. Set the value constraints for the selected simple type by making the appropriate changes to the information shown in the Details pane.

Results

Setting an enumeration:
About this task

An enumeration restricts which values can be set for the value constraint. For example, "ABC" and "123". Use this section to create a list of fixed values that the associated type must match.

To set an enumeration:

Procedure

1. Click **Add** to the right of the **Enumerations** field. This adds an enumeration that has a default enumeration (for example *enumeration1*).
2. Type the data that you want to set for this value constraint.
3. Press Enter on your keyboard.
4. Repeat the above steps for each enumeration that you are adding.

Setting a pattern:
About this task

Set a pattern to indicate that the value constraint defines a string used as a regular expression that must be matched by the data in the associated type. The regular expression syntax supported is XML Schema regular expressions.

See “Regular expression syntax” on page 6304 for a list of supported regular expression syntax elements.

To set a pattern:

Procedure

1. Select **Add** to the right of the **Patterns** field. This adds a pattern that has a default pattern (for example *pattern1*) and is in update mode.

2. Type the data that you want to set for this value constraint.
3. Press Enter on your keyboard.
4. Repeat the above steps for each pattern that you are adding.

Related concepts:

"Message model objects: simple type value constraints" on page 1188
Value constraints, also known as *facets* in XML Schema, refine a simple type by defining limits on the values that it can represent.

"Simple type logical value constraints" on page 5450
The properties, and their permissible values, vary according to the object type.

Configuring logical properties: Message model objects:

You can configure the logical properties of an object that has previously been added to the message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To configure the logical properties of an object that is part of the message model:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**. If the information listed above is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.

3. In the Outline view, select the message model object for which you want to configure the logical properties:
   a. Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** as appropriate by clicking **+**.
   b. Click the object that you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area. The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation

   The type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each of these nodes.

   If the items under **Logical Properties** are not in view, expand **Logical Properties** by clicking **+**.
5. Display the logical properties of the selected object in the Details view of the Message Definition editor, by clicking the appropriate item under **Logical Properties**.
6. Configure the logical properties of the selected item to your requirements by making the appropriate changes to the information shown in the Details view.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or by pressing Ctrl+S. Alternatively click **FileSave All** or press Ctrl+Shift+S.

Results

Configuring documentation properties: Message model objects:

You can configure the documentation properties of an object that has previously been added to the message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To configure the documentation properties of an object contained within a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**. If the information listed above is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the message model object for which you want to configure the documentation properties by taking the following steps:
   a. Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** as appropriate by clicking **+**.
   b. Click the object you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area. The Properties Hierarchy displays the following nodes:
   - Logical Properties
   - Physical Properties
   - Documentation

   The type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each of these nodes.

   Tip: If the items under **Documentation** are not in view, expand **Documentation** by clicking **+**.
5. Display the logical properties of the selected object in the Details view by clicking the appropriate item under **Documentation**.
6. Configure the documentation properties of the selected item to your requirements by typing text into the **Documentation** field. Right-clicking in the field allows you to select options for undoing changes you have made, cutting or copying text from the field, pasting text into the field, deleting highlighted text or selecting all text in the field.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** from the menu or pressing Ctrl+S. Alternatively, from the menu, click **File** > **Save All** or press Ctrl+Shift+S.

Configuring Custom Wire Format (CWF) properties: Message model objects:

You can configure the Custom Wire Format (CWF) properties of a message model object by using the Message Definition editor

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding a Custom Wire Format (CWF)" on page 2848
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To configure the *CWF* properties of a message model object:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the CWF properties by doing the following.
   a. Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b. Click the object you that want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area. In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the CWF physical format is called Binary1 but could have a user defined name instead.

5. Under **Physical Properties**, click the object type for the message model object that you have chosen to configure under the CWF physical format. The CWF properties of your selected message model object appear in the Details view.
6. Configure the CWF properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or pressing Ctrl+S. Alternatively click **FileSave All** or press Ctrl+Shift+S.

- "Opening an existing message definition file" on page 2864
- "Adding a TDS physical format" on page 2851
- "Adding MRM message model objects" on page 2870 (Adding one or more objects to your message model)

About this task

To configure the *TDS* properties of a message model object:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the TDS properties by taking the following steps:
   a. Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b. Click the object that you want to select within the expanded node.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area. In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

   Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the TDS physical format is called Text1 but could have a user defined name instead.
5. Select the **Properties** tab located in the lower-left corner of the Message Definition editor.
6. Under **Physical Properties**, under the TDS physical format, click the object type for the message model object that you have chosen to configure. The TDS physical format properties of your selected message model object appear in the Details view.
7. Configure the TDS physical format properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.
8. Save your changes by selecting **File** > **Save message_definition_file.mxsd** from the menu or press Ctrl+S. Alternatively, from the menu, select **File** > **Save All**, or press Ctrl+Shift+S.

Configuring XML Wire Format properties: Message model objects:

You can configure the XML Wire Format properties of a message model object.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding an XML wire format" on page 2853
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To configure the *XML Wire Format* properties of a message model object:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit and is displaying the following information:
   - The name of the message definition file
   - Messages
   - Types
   - Groups
   - Elements and Attributes

   If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**. If the above hierarchy is not displayed, ensure that the message definition file is open in the Message Definition Editor. Message definition files have an `.mxsd` file extension.
3. In the Outline view, select the object for which you want to configure the XML Wire Format properties by taking the following steps:
   a. Depending on the type of the object that you are selecting, expand **Messages**, **Types**, **Groups** or **Elements and Attributes** by clicking **+**.
   b. Click the object that you want to select within the expanded node.

4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area. In the Message Definition editor, in the Properties Hierarchy, the name of each of the physical formats that have been added to the message set appears under **Physical Properties**. The object type (for example, Local Element or Global Element) of the message model object that you selected in the Outline view is displayed under each physical format shown.

   Tip: If the physical formats are not in view in the Properties Hierarchy, expand **Physical Properties** by clicking **+**. By default the XML Wire Format is called XML1 but could have a user defined name instead.
5. Under **Physical Properties**, under the XML Wire Format, click the object type for the message model object that you have chosen to configure. The XML Wire Format properties of your selected message model object appear in the Details view of the Message Definition editor.
6. Configure the XML Wire Format properties of the selected object to your requirements by making the appropriate changes to the information shown in the Details view.

   Note: It is not possible to configure disabled fields.
7. Save your changes by clicking **File** > **Save message_definition_file.mxsd** or pressing Ctrl+S. Alternatively select **File** > **Save All** from the menu or press Ctrl+Shift+S.

Applying default physical format settings: Message model objects:

You can apply the default physical format settings to a message model object that is contained in a message definition file.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842

- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

This task assumes that you have added one or more physical formats to the relevant message set. For further information see "Adding a Custom Wire Format (CWF)" on page 2848 or "Adding an XML wire format" on page 2853 or "Adding a TDS physical format" on page 2851.

About this task

To apply the default physical format setting to a message model object previously added to a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Outline view, click the object to which you want to apply default physical format settings.
3. Click the **Properties** tab located in the lower-left corner of the Message Definition editor.
4. Check that the Message Definition editor Properties Hierarchy displays the following information:
   - Logical Properties
   - Physical Properties (For each of the physical formats that have been added to the message set, the name of the physical format appears under **Physical Properties**. Under each physical format the type of message model object that you selected is displayed as a child.)
   - Documentation

   Ensure that **Physical Properties** in the Properties Hierarchy is fully expanded by clicking **+**.
5. Right-click on the message model object type underneath the physical format to which you want to apply the default settings then click **Apply default physical format settings**. The default physical format settings for the message model object that you selected are applied without warning.
6. Save your changes by clicking **File** > **Save message_definition_file.mxsd** from the menu or pressing Ctrl+S. Alternatively, from the menu, click **File** > **Save All**, or press Ctrl+Shift+S.

Deleting objects

Delete an object from your message model.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864
- "Adding MRM message model objects" on page 2870 (You must have added one or more objects to your message model)

About this task

To *remove* objects contained within a message definition file:

Procedure

1. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
2. In the Outline view, right-click the object that you want to remove then click **Delete** on the pop-up menu. Alternatively right-click the object in the Message Definition editor **Overview** tab, and then click **Delete**.

   The type of object and the relationship that it has with other objects determines whether the object is now deleted without a confirmation window appearing, or whether a confirmation window opens with a list of all the objects that will be deleted along with the one that you have selected.
3. If a confirmation window opens, click **OK** to delete the objects.

   Tip: You can undo a deletion by selecting **Edit> Undo**, provided that you have not saved the changes that you have made.

Results

Creating a multipart message

A multipart message occurs when you embed a message in another message.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

To create a multipart (embedded) message:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, add one of the following objects to your message model:
   - A complex type (for further information on completing this task see "Adding a complex type" on page 2889)
   - A global group (for further information on completing this task see "Adding a global group" on page 2890)
   - A local group (for further information on completing this task see "Adding a local group" on page 2891)

   Tip: You can also use a local `ANONYMOUS` complex type when creating a multipart message. For further information see "Adding a complex type to an element" on page 2905.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy, under **Logical properties**, click one of the following items, depending on which of these you added in step 3:
   - **Complex Type**
   - **Global Group**
   - **Local Group**
6. In the Details view, make the following changes to the displayed logical properties:
   a. In the **Composition** drop-down list, click **message**.
   b. In the **Content validation** drop-down list, click **Open**, **Closed** or **Open Defined**, depending on your requirements. Note that if the embedded message is defined in a different message set, you must click **Open**. For further information about using these three options, see "MRM content validation" on page 5422.

Results

Note: There are a number of different ways for the parser to identify an embedded message within a message bit stream. For further information on identifying a message within another message refer to the following concept topics.

Linking from one message definition file to another

Add an 'include', or an 'import' to the file that you want to reference.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Creating a message definition file" on page 2865
- "Opening an existing message definition file" on page 2864

About this task

There are two ways to link one message definition file to another: either you can add an 'include', or you can add an 'import', for the file that you want to reference.

To check whether a message definition file currently includes or imports other files:

1. Open the message definition file in the Message Definition editor.
2. In the Outline view, in the displayed hierarchy, select the `.mxsd` file.
3. In the Properties Hierarchy, expand **Imports** or **Includes** as appropriate to display a list of the other files that the currently selected file includes or imports.

Include

About this task

Use the include option if you want to link to a message definition file with the same namespace, or if you want to link to a message definition file with no target namespace from a message definition file with a target namespace (chameleon

behavior). You must also add an include rather than an import if you want to link a message definition file with no target namespace to another message definition file that also has no target namespace.

Note: A message definition file can only reference objects in another message definition file if this other file has been included directly, so you might have a problem if you try to use the include option to include message definition files that are themselves included within other message definition files. For information about ways of resolving this situation, see "Resolving problems when developing message models" on page 3459.

This task assumes that you have opened an existing message definition file.

To add an include to a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window > Show View> Outline**.
3. In the Outline view, click the message definition (`.mxsd`) file name.
4. Display the **Properties** tab of the Message Definition Editor by clicking **Properties** in the lower-left corner of the editor area.
5. In the Properties Hierarchy, right-click **Includes** then click **Add Include** on the pop-up menu. The "Select Message Definition file to include" window opens.
6. In the Message Sets pane, select the message definition file that you want to include. If the message definition files within your project are not visible in this pane, expand the project hierarchy by clicking **+**.
7. Click **Finish**. The message definition file that you selected in step 4 is included within the message definition file that you opened before beginning this task.

Import

About this task

You use the import option if you want to link a message definition file to another message definition file in a different namespace. You cannot add an import from the same namespace. This restriction includes linking from a message definition file with no target namespace to another message definition file with no target namespace.

To add an import to a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Ensure that the Outline view is visible in the Broker Application Development perspective of the WebSphere Message Broker Toolkit. If the Outline view is not visible, from the WebSphere Message Broker Toolkit menu, click **Window** > **Show View** > **Outline**.
3. In the Outline view, click the message definition (`.mxsd`) file name.
4. Display the **Properties** tab of the Message Definition editor by clicking **Properties** in the lower-left corner of the editor area.

5. In the Properties Hierarchy, right-click **Imports** then click **Add Import**. The "Select Message Definition file to import" window opens.
6. In the Message Sets pane, select the message definition file that you want to import from the workspace. If the message definition files within your project are not visible in this pane, expand the project hierarchy by clicking **+**.
7. Click **Finish**. The message definition file that you selected in step 4 is imported into the schema of the message definition file that you opened before beginning this task.

Creating a message category file

Create a message category file to add categories that you can use to group different message sets.

Before you begin

Before you start:

Complete the following task:

- "Creating a message set" on page 2842

About this task

To create a message category file, complete the following steps.

Procedure

1. Right-click in the Broker Development view, then select **New** > **Message Category File** to open the New Message Category File wizard.

   Tip: To preselect the message set when the wizard opens, either right-click the message set to which you are adding the message category file, or select the message set, before you open the wizard.
2. In the first pane, select the `Category Kind` for the type of category that you are creating.
   - other. This value indicates that this message category represents a generic grouping of messages. The Category Usage field is disabled.
   - wsdl. This value indicates that this message category represents a WSDL operation. The specified category name is used as the WSDL operation name.
3. Optional: If you set `Category Kind` to wsdl, specify the WSDL operation type by selecting one of the following values for the `Category Usage` field, then click **Next**.
   - wsdl:request-response
   - wsdl:solicit-response
   - wsdl:one-way
   - wsdl:notification
4. Select a folder under the target message set for the new message category file to be saved. The message set folder view is filtered to show only resources in the active working set.
5. In the **File name** field, type a name for the new message category file, then click **Next**. The file is automatically given the file extension of `.category`.
6. Select all messages that you want to add to the new category. Use **Shift-click** to select a range of messages, and **Ctrl-click** to select or clear individual messages.

You cannot complete the creation of the category file without adding one or more messages, and setting the **Role Type** and **Role Usage** values of each message correctly.

7. Click **Finish**.

Results

The message category file is created in the message set folder that you selected. The new message category file opens in the Message Category editor, so that you can view and edit it as required.

Related concepts:

Opening an existing message category file

This describes how to open an existing message category file in the Message Category editor so that you can view or edit it.

Before you begin

Before you start:

To complete this task, you must have completed the following task:

- "Creating a message category file" on page 2924

About this task

To open an existing message category file:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message category file (with a file extension of `.category`) that you want to open, then click **Open** on the pop-up menu. This opens the message category file that you have selected in the Message Category editor.

3. View and edit the message category file as required.

Results

Tip: The Eclipse framework lets you open resource files with other editors. You are advised to only use the WebSphere Message Broker Toolkit Message Category editor to work with the message category files because this editor correctly validates changes made to the files. Other editors might not do this.

Related concepts:

"Message categories" on page 1200
Message category files have the suffix `.category`. These files are optional. You can have many message category files in a message set.

Adding a message to a message category

You can add a message to a message category file by using the Message Category editor.

Before you begin

Before you start:

You must have completed the following tasks:

- "Adding MRM message model objects" on page 2870 (to create at least one message)
- "Creating a message category file" on page 2924
- "Opening an existing message category file" on page 2925

About this task

To add a message to a message category file:

Procedure

1. Open the Message Category editor.
2. In the Properties Hierarchy, open the Add Messages window by right-clicking **Message Category**, then clicking **Add Messages**. The Add Messages window

lists all the messages that are available for adding to the message category file. All messages that are in the message set but have not already been added to the category are displayed.

3. Select the message or messages that you would like to add. Use **Shift-click** to select a range of messages and **Ctrl-click** to select or clear individual messages.
4. Click **OK**. The selected message or messages are added to the message category and now appear in the Properties Hierarchy.

   Tip: Until you save the message category file, you can undo all additions that you make. To undo a change, right-click **Message Category** in the Properties Hierarchy, then click **Undo**. If you have added multiple messages, this action removes all the messages that you have added. If you want to remove a single message, right-click this message, then click **Undo**. To redo an addition after undoing it, use the **Redo** option.
5. Save and validate the additions that you have made to the message category file by clicking **File** > **Save**, or by pressing Ctrl+S.

Results

When you have saved the message category file after adding a message, you can no longer undo the addition of this message by using the **Undo** option. To remove a message after saving your changes, delete the message from the message category file.

When you have added a message to a message category file, you can configure its properties, according to your requirements, in the Message Category editor Details view.

Related concepts:

Deleting a message from a message category

Delete a message from a message category file.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:

- "Creating a message category file" on page 2924
- "Opening an existing message category file" on page 2925
- "Adding a message to a message category" on page 2926

About this task

To delete a message from a message category file:

Procedure

In the Message Category editor, in the Properties Hierarchy, right-click the message that you want to delete, then click **Delete** on the pop-up menu.

Tip: The message is deleted from the message category file immediately, without a warning appearing first.

Results

Related concepts:

Viewing or configuring message category file properties

This topic describes how to view or configure the properties of a message category file and associated messages using the Message Category editor.

Before you begin

Before you start:

To complete this task, you must have completed the following tasks:

- "Creating a message category file" on page 2924
- "Opening an existing message category file" on page 2925
- "Adding a message to a message category" on page 2926 (You must have added one or more messages to your message category file)

About this task

To configure the properties of a message category file:

Procedure

1. Switch to the Message Category editor in the Broker Application Development perspective.
2. To view or configure the properties of a message category, click **Message Category** in the Properties Hierarchy. From the Details section of the Message Category editor you can now view the properties of the message category and make any changes to the properties that are necessary.
3. To view or configure the properties of a message in the message category file, click the name of the message in the Properties Hierarchy. From the Details section of the Message Category editor you can now view the properties of the message and make any changes to the properties that are necessary.
4. If you have changed any of the properties in the message category or messages, you can save those changes by selecting **File** > **Save** from the menu.

What to do next

Note: Note that some combinations of `Message Category Usage`, `Role Type` and `Role Usage` are not valid for WSDL and will result in task list errors being generated.

Deleting a message category file

You can delete a message category file from your message model.

Before you begin

Before you start:

To complete this task, you must have completed the following task:

- "Creating a message category file" on page 2924

About this task

To delete a message category file:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message category file (`*.category` file extension) that you want to delete, then click **Delete**. Alternatively select the message category file in the Broker Development view, then either click **Edit** > **Delete**, or press the Delete key.
3. On the Confirm Resource Delete window, click **Yes** to delete the message category file. Alternatively, to cancel the message category file deletion, either click **No** or press the Esc key.

Results

Tip: After you have deleted a message category file, the action cannot be undone.

Working with data structures

You can create a message definition file in a message set by importing from XML Schema, XML DTD, SCA import or export components, IBM supplied messages,

WSDL definitions, IDL files, C header files, and COBOL copybooks. This topic area describes how to import from these data structures using the command line or the WebSphere Message Broker Toolkit.

About this task

Before you attempt to create a message definition from a data structure, by using the WebSphere Message Broker Toolkit, you are advised to read "Importing file systems into the WebSphere Message Broker Toolkit."

The following tasks topics relate to importing by using the WebSphere Message Broker Toolkit:

- "Importing from C" on page 2934
- "Importing from COBOL copybooks" on page 2937
- "Importing from IBM supplied messages" on page 2942
- "Importing SCA import or SCA export components" on page 2943
- "Generating a Broker SCA definition from a message set" on page 2967
- "Exporting an SCA Import or Export from a Broker SCA definition" on page 2945
- "Importing from WSDL" on page 2946
- "Importing an IDL file" on page 2952
- "Importing from XML DTD" on page 2954
- "Importing from XML Schema" on page 2957

The following tasks relate to importing by using the command line:

- "Importing from the command line" on page 2936 for C header files, COBOL Copybooks, XML DTDs and XML Schemas.
- "Importing WSDL definitions from the command line" on page 2948

Related concepts:

"Ways to create message definitions" on page 1253
When you have created a message set, you must populate the message set with message definitions.

"Importing from other model representations to create message definitions" on page 1254
You can add message definitions to your message set by importing application message formats that already exist.

Related tasks:

"Working with a message set project" on page 2838
Creating and deleting a message set.

Importing file systems into the WebSphere Message Broker Toolkit

You can import file systems into the WebSphere Message Broker Toolkit by using the Import wizard, by dragging, or by copying.

About this task

Use one of the following options to import files for use by your selected message set project:

- "Using the Import wizard"
- "Dragging and dropping" on page 2933
- "Copying and pasting" on page 2933

You can then select the imported file in the New Message Definition File wizard to create a message definition that is based on the contents of this file.

Using the Import wizard:
About this task

Use the Import wizard to import all the files, or a selection of files, from the specified source.

To import files using the Import wizard:

Procedure

1. In the Broker Development view, click the project folder into which you are going to import the files.
2. Open the Import wizard by clicking **File** > **Import**.
3. On the Select page of the Import wizard, click either **File System** or **Archive file**, depending on the type of resource that you are importing.
4. Click **Next**.
5. On the File System page, in the **Directory** field, specify the import source. Either type the source name in the field, or click **Browse** and select the parent directory, or compressed file that contains the file or files that you want to import. Then click **OK** (directory) or **Open** (compressed file).

   Tip: Directories from which you recently imported files are shown in the list in the **Directory** field.
6. Using the left and right panes that are displayed under the **Directory** field, specify the folders or files, or both, that you want to import. Consider the following points when you are making your selections:
   - To import the entire contents of a folder, select the check box for this folder in the left pane. To view secondary folders within a folder, expand the folder by clicking the plus sign (+).
   - To import a specific file or files within a folder, use the right pane to select the individual files that you want to import. If you select a file or files in the right pane, the check box for the folder that contains these files is disabled in the left pane to indicate that only some of the files in the folder will be imported.
   - To restrict the type of files that you are importing, click **Filter Types**, then, on the Select Types window, select the check boxes for the file types that you want to include, and click **OK**. If you want to include files with extensions that are not shown in the list, type these extensions in the **Other Extensions** field.
   - To select all the folders and files that are shown on the File System page, click **Select All**.
   - To clear all the folders and files that are currently selected on the File System page, click **Deselect All**.

The **Select the destination for imported resources** field is already set to the name of the project folder that you selected in step 2.

7. Optional: To change the destination project or folder, click **Browse** to open the Folder Selection window. Select an alternative project folder by clicking the folder, then clicking **OK**.
8. Optional: To overwrite existing resources and not have a warning displayed, select the **Overwrite existing resources without warning** check box. This check box applies to both compressed files and file systems.
9. File system import only: Select one of the following options, depending on the folder structure that you want to create:
   - **Create complete folder structure**
   - **Create selected folders only**
10. Click **Finish**.

Results

The files that you selected are imported and are shown in the Broker Development view under the project folder that you selected.

Dragging and dropping:
About this task

You can use the drag-and-drop method to import files from your file system into the WebSphere Message Broker Toolkit. Drag the resources that you are importing to the exact location in the Broker Development view where you want the resources to be. Do not drag them onto a blank area in the Broker Development view.

To import files by dragging:

Procedure

1. In your file system, locate the file or folder that you want to import into the WebSphere Message Broker Toolkit.
2. Drag the file or folder to a specific location in the Broker Development view. When you are dragging resources into the Broker Development view, the project or folder into which you are trying to drop the resource is selected.
3. Ensure that the file or folder is copied into the WebSphere Message Broker Toolkit.

Results

Copying and pasting:
About this task

You can use the copy and paste function of your operating system as a method of importing a file system into the WebSphere Message Broker Toolkit.

To import files by copying and pasting:

Procedure

1. Locate the file or directory that you want to import into the WebSphere Message Broker Toolkit.

2. Using the copy and paste function in the operating system, copy the file or directory to your system clipboard.
3. Select the destination for the file or directory in the Broker Development view.
4. From the WebSphere Message Broker Toolkit menu, click **Edit** > **Paste**.

Results

The files or directories are copied into the WebSphere Message Broker Toolkit, and placed into the location that you selected.

Importing from C

Create a message definition file from a C header file for use in the MRM and IDOC domains.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

Be aware of the following points:

- The wizard can import C header files with `.h`, `.c` and `.css` extensions. If your source file has a different extension you must rename it before attempting to import it.
- If the message set to which you are adding the new message definition file *does not* have an Custom Wire Format (CWF) layer only the logical information appears in the model. You can add the physical layer to the message set before or after importing a C header file, but you should add the physical layer *before* importing it to ensure that it is populated with settings from the C header file.
- You can import a C header file from the command line using **`mqsicreatemsgdefs`**.

About this task

The following steps cover both creating a completely new message definition file and overwriting the contents of an existing file.

To create a message definition file from a C header file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard by clicking **File** > **New** > **Message Definition File** from the WebSphere Message Broker Toolkit menu. Alternatively, you can open the wizard by right-clicking a C header file previously imported into the WebSphere Message Broker Toolkit and clicking **New** > **Message Definition File** on the menu.
3. In the displayed list of options, click **C header file** then click **Next**.
4. Step through the remainder of the wizard completing the details as required.

Results

When you have completed importing the C header file using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.c.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors have appeared.

The C importer uses default values when mapping C data types to message model elements.

"New message definition file wizard: Create a new message definition file from a C header file" on page 6362
You can create a new message definition file from a C header file.

Importing from the command line:

This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Before you begin

Before you start:

Before you attempt this task, you should read the following information:

- "**mqsicreatemsgdefs** command" on page 3702

The command line importer allows you to create a new message set, into which the message definition files will be placed. When you create a new message set from the command line, only the logical information is created by default. However, the command line importer allows you to create a new message set based on an existing message set. The physical format information from the base message set is also created in the new message set. If you want physical format information to be created as well, you must do the following before you invoke the **mqsicreatemsgdefs** command:

1. Using the WebSphere Message Broker Toolkit, create a message set in your workspace that is to be used as a base message set.
2. To this base message set, add the physical formats that you want to be created in your new message set.

About this task

To import C, COBOL copybooks, XML DTD or XML Schema using the command line:

Procedure

1. Close the WebSphere Message Broker Toolkit. This must not be running when you use the command line importer.
2. Invoke the **mqsicreatemsgdefs** command from a command prompt specifying the message set project name, path name of the source files folder, and any other optional parameters that you require. If you want to add physical formats to the new message set that the **mqsicreatemsgdefs** command creates, specify the base message set that contains these physical formats as the `-base` parameter on the import command line.
3. When the command has completed, open `mqsicreatemsgdefs.report.txt`. This report is created when you invoke the **mqsicreatemsgdefs** command and by default is written to the directory from which you invoked the command. The report provides you with the following information:
   - Details of the parameters that were used when **mqsicreatemsgdefs** was invoked.
   - The message set level action.
   - The name of the file or files that have been imported.
   - Details of the import process (for example, any warnings that have been generated and message model objects that have been created).

- The number of files imported.

4. Start the WebSphere Message Broker Toolkit and switch to the Broker Application Development perspective. The message definition file that was created when you invoked **mqsicreatemsgdefs** is visible in the project that you specified.

Results

If an error occurs during the import of a C, COBOL copybook, XML DTD, or XML Schema file, carefully check any errors that the importer reports. By default, all errors are written to the screen and to the log file described above. To gather additional information about the import, specify the `-v` (Verbose) command line parameter. This parameter displays more detailed information as the import proceeds.

Importing from COBOL copybooks

This topic describes how to create a new message definition from a COBOL data structure using the New Message Definition File wizard in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

Be aware of the following points:

- The wizard can import COBOL files with `.cbl`, `.ccp`, `.cob` and `.cpy` extensions. If your source file has a different extension, you must rename it before attempting to import it.
- If the message set to which you are adding the new message definition file *does not* have a Custom Wire Format (CWF) layer, or a Tagged/Delimited String (TDS) format layer, only the logical information appears in the model.

  You can add the physical layer to the message set before or after importing a COBOL data structure but ensure that you add the physical layer *before* you import the data structure to ensure that it is populated with settings from the COBOL copybook.
- You can import a COBOL data structure from the command line using **`mqsicreatemsgdefs`**.
- The copybook must not contain field names that are COBOL reserved keywords.

About this task

The following steps cover creating a new message definition file and overwriting the contents of an existing file.

To create a message definition file from a COBOL data structure:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard by clicking **File** > **New** > **Message Definition File** from the WebSphere Message Broker Toolkit menu. Alternatively, you can open the wizard by right-clicking a C header file previously imported into the WebSphere Message Broker Toolkit and clicking **New** > **Message Definition File** on the menu.
3. Click **COBOL file**, then click **Next**.
4. Step through the remainder of the wizard supplying the details as required.

   For more information, see "New message definition file wizard: Create a new message definition file from a COBOL file" on page 6363.

Results

When you have completed importing the COBOL file using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.cobol.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors have appeared.

Creating a message definition from a database definition

You can create a new message definition from a database definition file (`.dbm`) by using the New Message Definition File wizard in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Adding database definitions to the WebSphere Message Broker Toolkit" on page 2278

About this task

The following steps cover both creating a completely new message definition and overwriting the contents of an existing definition.

To create a message definition from a database definition:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard by clicking **File> New> Message Definition File** from the WebSphere Message Broker Toolkit menu.

   Tip: You can create a message definition by right-clicking a `.dbm` file.
3. In the displayed list of options, click **Database Definition File** to select it, then click **Next**.
4. Step through the remainder of the wizard completing the details as required. The final page of the wizard reports any errors, for example:
   - Unknown user-defined data types.
   - The database name, schema name, or table name contain characters. The non-NCName characters are replaced by an underscore.

Results

When you have completed creating the database definitions using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.dbm.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors have appeared.

Importing from IBM supplied messages

You can create a new message definition file from an IBM supplied message.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a message set" on page 2842

About this task

The following steps describe how to create a new message definition file, and how to overwrite the contents of an existing file.

To create a message definition from an IBM supplied message:

Procedure

1. Switch to the Broker Application Development perspective.

2. Open the New Message Definition File wizard by clicking **File** > **New** > **Message Definition File From** on the WebSphere Message Broker Toolkit menu.
3. In the displayed list of options, select **IBM supplied message** and click **Next**.
4. Complete the fields of the panel that is displayed by the wizard. See "New message definition file wizard: IBM supplied message" on page 6366.

Results

When you have finished the import of the IBM supplied message:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project that contains the message definition that you have created. The report has a `.xsd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors are displayed.

You can import IBM supplied messages to create a new message definition file.

Importing SCA import or SCA export components

You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to import SCA import or SCA export components from WebSphere Integration Developer. You must import an SCA import or SCA export into the workspace to provide a broker SCA definition for use in configuring the SCA nodes.

Before you begin

Before you start:

There are two methods for importing from SCA import or export:

- Create a message set and use the New Message Definition File wizard. This method is described in this topic.
- Use the Start from SCA Import or Export Quick Start wizard. See "Creating an application based on SCA import or export files" on page 1422.

If you choose the first of these options, before you start you must have completed the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

About this task

Ensure that the SCA import or SCA export components that you import from WebSphere Integration Developer use SOAP 1.1 bindings; a validation error occurs if you attempt to import SCA Import or SCA Export components that have been generated with SOAP 1.2 bindings.

The following steps are required to create a new message definition file, or to overwrite the contents of an existing file.

To create a message definition from an SCA import or SCA export:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File From wizard by clicking **File** > **New** > **Message Definition File From ...** on the WebSphere Message Broker Toolkit menu.
3. In the displayed list of options, select **SCA Import or Export** and click **Next**. Alternatively, open the wizard by right-clicking a file with extension `.zip` that was previously imported into the WebSphere Message Broker Toolkit and clicking **New> Message Definition File From ...** on the menu.
4. Step through the remainder of the wizard supplying the details as required.

   You must choose whether the SCA import or SCA export that you want to import is in the current workspace in the WebSphere Message Broker Toolkit or is outside the workspace.

   Check boxes provide options to:

   - Copy the source file (or files) into the 'importFiles' directory of the message set project. By default, this check box is cleared.
   - Add appropriate supported domains if they do not exist. Selecting this check box adds the XMLNSC domain for all binding types; the SOAP domain is also added for Web service bindings.
   - Create an appropriate physical format if one does not exist. By default, this check box is selected.

   Note:

- The panels and options that are available in the wizard are dependent on the settings that you select.
- Some fields in the wizard might not be available perhaps because the field has a mandatory setting, or because the field has only one possible value, or because the field is not being used as a result of other settings that have been made.

Related tasks:

"Developing SCA applications for non-XML data" on page 2103
The SCA nodes allow non-XML data to be sent and received from WebSphere Process Server by using the WebSphere MQ binding. For example, create a message model from a COBOL copybook, and use that message model to parse messages received from WebSphere Process Server.

Related reference:

"New message definition file wizard: Create a new message definition file from an SCA Import or Export" on page 6369
You can create a new message definition file from an SCA import or export.

Exporting an SCA Import or Export from a Broker SCA definition

You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to export SCA import or SCA export components. You must export an SCA import or SCA export if the Broker SCA definition is to be used by WebSphere Integration Developer.

Before you begin

You must have completed the following task:

- "Generating a Broker SCA definition from a message set" on page 2967

About this task

The following steps are required to export an SCA Import or Export from a Broker SCA definition:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the folder that contains the SCA definition from which you want to export an SCA import or SCA export and select **Export** to start the Export wizard.
3. In the displayed list of options, select **Message Sets** > **SCA Import or Export from Broker SCA Definition** and click **Next**. This action starts the SCA Import or Export from Broker SCA Definition wizard.
4. Step through the remainder of the wizard and provide the details as required.

   Check boxes provide options to:

   - Overwrite existing files without warning. By default, this check box is cleared.
   - Apply working set filtering to artifact selections on this page. By default, this check box is selected.

   Note:

   - The panels and options that are available in the wizard are dependent on the settings that you select.

- Some fields in the wizard might not be available. This might be because the field has a mandatory setting, or because the field has only one possible value, or because the field is not being used as a result of other settings that have been made.

Results

The wizard creates a folder on the file system that contains the individual files from the broker SCA definition (.import or .export, .wsdl and .xsd files).

What to do next

In WebSphere Integration Developer, import the SCA import or export component and WSDL that have been exported from WebSphere Message Broker. Do not select the XSD files. See *Importing WSDL files* in the WebSphere Integration Developer Information Center.

Related tasks:

"Developing SCA applications for non-XML data" on page 2103
The SCA nodes allow non-XML data to be sent and received from WebSphere Process Server by using the WebSphere MQ binding. For example, create a message model from a COBOL copybook, and use that message model to parse messages received from WebSphere Process Server.

Related reference:

"Export SCA Import or Export from Broker SCA Definition wizard" on page 6380
The Export SCA Import or Export from Broker SCA Definition wizard exports an SCA import or export from a Broker SCA definition in a message set.

Importing from WSDL

You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from WSDL.

Before you begin

There are two methods for importing from WSDL:

- Create a message set and use the New Message Definition File wizard. This method is described here.
- Use the Start from WSDL and/or XSD files Quick Start wizard. See "Creating an application based on WSDL or XSD files" on page 1413.

If you choose the first of these options, before you start you must have completed the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

About this task

The following steps are required to create a completely new message definition file, or to overwrite the contents of an existing file.

To create a message definition from a WSDL file (or files):

Procedure

1. Switch to the Broker Application Development perspective.

2. Open the New Message Definition File From wizard by clicking **File** > **New** > **Message Definition File From** on the WebSphere Message Broker Toolkit menu.
3. In the displayed list of options, select**WSDL file** and click **Next**. Alternatively, open the wizard by right-clicking a `.wsdl` file that was previously imported into the WebSphere Message Broker Toolkit and clicking **New** > **Message Definition File From** on the menu.
4. Step through the remainder of the wizard completing the details as required.

   You must choose whether the WSDL file, or files, that you want to import are in the current workspace in the WebSphere Message Broker Toolkit or are outside the workspace.

   Check boxes provide options to:

   - Copy the source file (or files) into a directory of the message set project. By default, this check box is cleared.
   - Add the SOAP and XMLNSC domains to your message set so that you can use the SOAP nodes. By default, this check box is selected.

   Note:

   - The panels and options available in the wizard are dependant on the settings that you select.
   - Some fields in the wizard might not be available. This might be because the field has a mandatory setting, or because the field has only one possible value, or because the field is not being used as a result of other settings that have been made.

Results

When you have finished importing the WSDL file (or files) using the wizard:

- Check carefully for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project that contains the message definition that you have tried to create. The report has a `<wsdl-file-name>.wsdl.report.txt` file descriptor, where `<wsdl-file-name>` is the name of the WSDL definition that you are importing.
- Review the messages that are shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors have appeared.

Note: Any required SOAP Envelope and SOAP encoding message definitions are automatically added to your message set during the import. If required, you can also import these manually using the New Message Definition File wizard by selecting the new option **IBM supplied message**.

You can create a new message definition file from a WSDL file.

Importing WSDL definitions from the command line:

WSDL definitions can be imported using the (**mqsicreatemsgdefsfromwsdl**) command.

Before you begin

Before you start:

Before you attempt this task, read the following information:

- "**mqsicreatemsgdefsfromwsdl** command" on page 3712.

The WSDL command line importer allows you to create a new namespace enabled message set into which the message definition files will be placed. It also allows you to add message definition files to an existing message set that is namespace enabled.

If you are adding new message definition files to an existing message set, the message set must have an XML physical format layer. To improve Web services interoperability, avoid unnecessary customization of the XML physical format layer for messages that participate in Web services processes.

When you create a new message set from the command line, only the logical information is created by default. If you require physical formats in the message set you have two options:

- Create a new message set based on an existing message set. The physical format information from the base message set is also created in the new message set.
- Use the WebSphere Message Broker Toolkit to create or open the message set and directly add the physical formats to the message set prior to importing the WSDL definitions into it.

Before starting the import, the **mqsicreatemsgdefsfromwsdl** command copies the WSDL files that it needs into the workspace. These are the top level WSDL file and any further files that might be imported by it. The files are copied under the specified message set in a folder called importFiles and are not removed after the import finishes. This allows you to update them, or run validation on them, in the WebSphere Message Broker Toolkit at a later time.

About this task

To import WSDL definitions using the command line:

Procedure

1. Close the WebSphere Message Broker Toolkit. The WebSphere Message Broker Toolkit must not be running when you use the command line importer.
2. Invoke the **mqsicreatemsgdefsfromwsdl** command from a command prompt; you must specify the message set project name, the path name of the directory where the top level WSDL file is located, the name of that file, the location of the workspace, and any other optional parameters that you require. If you want to add physical formats to the new message set that the **mqsicreatemsgdefsfromwsdl** command creates, specify the base message set that contains these physical formats as the `-base` parameter on the import command line.
3. When the command has completed, check the log file. The name of the log file is the name that you specified in the command, and it has the file extension `*.wsdl.report.txt`. This report is created when you invoke the **mqsicreatemsgdefsfromwsdl** command and, by default, it is written to the directory from which you invoked the command. The report provides you with the following information:
   - Details of the parameters that were used when **mqsicreatemsgdefsfromwsdl** was invoked.
   - The name of the file that has been imported.
   - Details of the import process (for example, any warnings that have been generated and message model objects that have been created).
4. Start the WebSphere Message Broker Toolkit and switch to the Broker Application Development perspective. The message definition file that was created by the **mqsicreatemsgdefsfromwsdl** command is visible in the project that you specified.

Results

If an error occurs during the import of a WSDL definition, carefully check any errors that are reported. By default, all errors are written both to the screen and to the file described above. To gather additional information about the import, specify the `-v` (Verbose) command line parameter. This parameter displays more detailed information as the import proceeds.

Accepting self-signed certificates when importing WSDL:

You can import WSDLs that reference schemas on self-signed secure HTTPS servers, by adding security certificates to the Java Virtual Machine JVM.

About this task

The following procedure enables you to add certificates from the SSL server to each instance of your JVM.

If you are using Windows Vista or Windows 7, you must enter the commands from a console that has administration privileges.

Procedure

1. Obtain the certificate from the server (it is a `.cer` file) and copy it into your filesystem. somewhere.

   This example uses `D:\mb.cer`
2. Open a command prompt and navigate to your Java runtime environment (JRE) bin directory that is located in your WebSphere Message Broker install directory, for example, `C:\Program Files\IBM\WMBT700\jdk\jre\bin`.
3. Type in `keytool -printcert -file D:\mb.cer`
4. You obtain some output, and the important parameter to check is the `CN=value`.

   The value should be the same as the server name from which the WSDL is requesting files.
5. Input the certificate into a new keystore file.
   a. This procedure assumes that you can store your keystore file in `D:\mb.keystore`

Note, that the alias must be the same name as the server and the name can be anything you require.

For example, the name can be of the form `<userID>.<servername>.ibm.com` or `subdomain.messagebroker.com`

The example within this topic uses the form `<userID>.<servername>.ibm.com`

b. Type in:

```
keytool -import -alias <userID>.<servername>.ibm.com -file
 D:\mb.cer -keystore D:\mb.keystore
```

c. Import the certificate into a keystore file.

You are either asked for a password, or you need to create a password when the system requests one. This is the password used in Step 7, and the example within this topic uses the word `broker`.

d. Select `Yes` to trust the certificate.

6. Add the keystore as an argument when you start WebSphere Message Broker.

You must do this so that you can use the certificates you have just added to the keystore.

a. Go back three directories to: `C:\Program Files\IBM\WMBT700`.

7. Type in:

```
mb -vmargs -Djavax.net.ssl.trustStore=d:\\mb.keystore
 -Djavax.net.ssl.trustStorePassword=broker
```

8. Validate and import the WSDL

Results

You obtain a console output that is of the following format:

```
C:\Program
Files\IBM\WMBT700\jdk\jre\bin>keytool -printcert -file d:\
mb.cerOwner: EMAILADDRESS=jdoe@xx.ibm.com, CN=<userID>.

Importing an IDL file

You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a message definition from an IDL file.

Before you begin

Before you start:

Complete the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931
- Ensure that you have a valid IDL file. If you select an IDL file that is not valid, you see an error message and you cannot complete the wizard. When you import an IDL file, supported and unsupported operations are listed. You can import an IDL file that contains operations with types that are not supported by WebSphere Message Broker, but if you try to call an unsupported operation, you see an error message. The CORBA IDL file must contain at least one interface that has one operation. For more information about the IDL operations that are supported, see "CORBA support" on page 2149.
- For more information about how IDL types correspond to XML schema types, see "IDL data types" on page 2150.

About this task

The following steps describe how to use an IDL file to create a message definition file or overwrite the contents of an existing file.

Procedure

1. Right-click the message set, then click **New** > **Message Definition File From** > **CORBA IDL File** to open the New Message Definition File From wizard.
2. Complete the wizard by following the on-screen instructions.
   a. Select an IDL file either from the list of files in your workspace, or by using **Browse** to search outside your workspace. If you have imported an IDL file that contains includes, select the top-level IDL file.
   b. Ensure that the check box to add the DataObject domain to the message set is selected. By default, this check box is selected.
   c. Optional: You can provide a target namespace.
   d. By default, the message definition file name is the same as the name of the IDL file. You can change the name of the message definition file.
   e. If the IDL or message definition file exists, click **Next**. To rename or overwrite the existing files, select them.
3. Click **Finish**.
4. After you have imported the IDL file, check for errors.
   - Check for errors in the report that is created when the file is imported. You can find this report in the `log` directory of the project that contains the new message definition. The report is named `<idl-file-name>.idl.report.txt`, where `<idl-file-name>` is the name of the IDL file that you are importing.
   - Check for errors in the WebSphere Message Broker Toolkit task list.

Results

When you have finished importing the IDL file, the message definition opens. A read-only copy of the IDL file is stored in the `CORBA IDLs` folder.

For each IDL file, a single message definition is created. (If you have imported an IDL file that contains includes, all the elements and types in the IDL files are generated into a single message definition.) In the message definition, two messages are created for each operation in the IDL file (one message for the request, and one for the response), and a message is created for each user-defined exception. The request has a child element for each in and inout parameter; the response has a child element for each inout and out parameter, and a child element named "_return" for the return type of the operation.

The name of these elements is based on the interface name and operation name; for example, for the operation *sayHello* in the Interface *Hello*, the request element is called *Hello.sayHello*, and the response element is called *Hello.sayHelloResponse*. If the interface is contained in a module, the request and response element names are qualified with the names of the modules. For example, if the operation *sayHello* in the Interface *Hello* is contained in *ModuleB*, which in turn is contained in ModuleA, the response element would be called *ModuleA.ModuleB.Hello.sayHelloResponse*.

Another message definition is created with a message for each CORBA system exception.

What to do next

Next: Develop a message flow, as described in "Developing a message flow with a CORBARequest node" on page 2161.

You can create a new message definition file from a CORBA IDL file.

Importing from XML DTD

You can create a new message definition from an XML DTD by using the New Message Definition File wizard in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

Before you begin this task, you should be aware of the following points:

- If the message set to which you are adding the new message definition file *does not* have an XML wire format (XML) layer only the logical information appears

in the model. You can add the physical layer to the message set before or after importing from a XML DTD, but you should add the physical layer *before* importing it to ensure that it is populated with settings from the XML DTD.

- It is also possible to import an XML DTD from the command line using **mqsicreatemsgdefs**.
- The file extension must be `.dtd` in lowercase.

About this task

The following steps cover both creating a completely new message definition file and overwriting the contents of an existing file.

To create a message definition from an XML DTD:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard by clicking **File> New> Message Definition File** from the WebSphere Message Broker Toolkit menu.
3. In the displayed list of options, click **XML DTD file** to select it then click **Next**.
4. Step through the remainder of the wizard completing the details as required.

Results

When you have completed importing the XML DTD using the wizard:

- Carefully check for any errors in the report that is created when the file is imported. You can find this report in the `log` directory within the project containing the message definition that you have attempted to create. The report has a `.dtd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or errors have appeared.

The message definition file is created from the XML DTD and is opened in the Message Definition editor so that you can check the imported information and make any required changes. While you are checking the newly created message definition file, review any messages that appear in the WebSphere Message Broker Toolkit task list to see whether you need to make any corrections to resolve errors or warnings relating to the new file.

Related concepts:

"Ways to create message definitions" on page 1253
When you have created a message set, you must populate the message set with message definitions.

"Importing from other model representations to create message definitions" on page 1254
You can add message definitions to your message set by importing application message formats that already exist.

Related tasks:

Creating and deleting a message set.

"Importing from the command line" on page 2936
This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a

message set with message definitions.

"Adding an XML wire format" on page 2853
You can add an XML wire format physical format layer to a message set by using the Message Set editor.

Related reference:

"Import formats" on page 6346
Supported features of formats that have been imported from C, COBOL, SCA Export, SCA Import, WSDL, or XML Schema.

"New message definition file wizard: Create a new message definition file from an XML DTD file" on page 6371
You can create a new message definition file from an XML DTD file.

Importing from the command line:

This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Before you begin

Before you start:

Before you attempt this task, you should read the following information:

- "**mqsicreatemsgdefs** command" on page 3702

The command line importer allows you to create a new message set, into which the message definition files will be placed. When you create a new message set from the command line, only the logical information is created by default. However, the command line importer allows you to create a new message set based on an existing message set. The physical format information from the base message set is also created in the new message set. If you want physical format information to be created as well, you must do the following before you invoke the **mqsicreatemsgdefs** command:

1. Using the WebSphere Message Broker Toolkit, create a message set in your workspace that is to be used as a base message set.
2. To this base message set, add the physical formats that you want to be created in your new message set.

About this task

To import C, COBOL copybooks, XML DTD or XML Schema using the command line:

Procedure

1. Close the WebSphere Message Broker Toolkit. This must not be running when you use the command line importer.
2. Invoke the **mqsicreatemsgdefs** command from a command prompt specifying the message set project name, path name of the source files folder, and any other optional parameters that you require. If you want to add physical formats to the new message set that the **mqsicreatemsgdefs** command creates, specify the base message set that contains these physical formats as the `-base` parameter on the import command line.
3. When the command has completed, open `mqsicreatemsgdefs.report.txt`. This report is created when you invoke the **mqsicreatemsgdefs** command and by

default is written to the directory from which you invoked the command. The report provides you with the following information:

- Details of the parameters that were used when **mqsicreatemsgdefs** was invoked.
- The message set level action.
- The name of the file or files that have been imported.
- Details of the import process (for example, any warnings that have been generated and message model objects that have been created).
- The number of files imported.

4. Start the WebSphere Message Broker Toolkit and switch to the Broker Application Development perspective. The message definition file that was created when you invoked **mqsicreatemsgdefs** is visible in the project that you specified.

Results

If an error occurs during the import of a C, COBOL copybook, XML DTD, or XML Schema file, carefully check any errors that the importer reports. By default, all errors are written to the screen and to the log file described above. To gather additional information about the import, specify the **-v** (Verbose) command line parameter. This parameter displays more detailed information as the import proceeds.

Importing from XML Schema

You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to create a new message definition from an XML Schema

Before you begin

Before you start you must have completed the following tasks:

- "Creating a message set" on page 2842
- "Importing file systems into the WebSphere Message Broker Toolkit" on page 2931

Before you begin this task, you should be aware of the following points:

- If you are importing a collection of related XML Schema files, you are advised to use the **mqsicreatemsgdefs** command. This imports all the XML Schema files in a single operation, and automatically adjusts the import and include paths.
- If the message set to which you are adding the new message definition file *does* have an XML wire format layer, but *no* namespace support, the imported schema is modified to remove namespaces. For this reason, you should enable namespace support before importing a schema.
- If the message set to which you are adding the new message definition file *does not* have an XML wire format layer, but *does* have namespace support, only the logical information appears in the model. For this reason, you should add the physical layer to the message set before importing the schema. This ensures that the message set is populated with the settings and values from the schema. The XML Schema is not modified to remove namespaces.
- If the message set to which you are adding the new message definition file *does not* have an XML wire format layer, and *does not* have namespace support, only the logical information appears in the model and the imported schema is modified to remove namespaces.
- If you are working with a message set that does not have namespace support, you must specify the preferences that apply when you import a schema into the message set. These preferences allow you to specify how the importer treats certain individual schema constructs. You can either reject the schema if any occurrences of the construct are encountered or modify occurrences of the construct. If you choose modify, the importer modifies all occurrences of the construct.
- The extension to the XML Schema file must be `.xsd` in lowercase.

About this task

The following steps create a completely new message definition file or overwrite the contents of an existing file.

To create a message definition from an XML Schema file:

Procedure

1. Switch to the Broker Application Development perspective.
2. Open the New Message Definition File wizard by clicking **File> New> Message Definition File** on the WebSphere Message Broker Toolkit menu. Alternatively, you can open the wizard by right-clicking an `*.xsd` file that was previously imported into the WebSphere Message Broker Toolkit and clicking **New> Message Definition File** on the menu.
3. In the displayed list of options, click **XML Schema file** to select it, and then click **Next**.
4. Step through the remainder of the wizard, competing the details as required. The processing time for importing the XML Schema varies according to the size

and complexity of that schema. In a large and complex schema, it can take some time to import the file, generate the log file and display any task list warnings or errors.

Results

When you have finished importing the XML Schema using the wizard:

- Carefully check the log file for any warnings or errors in the report that is created when the file is imported. These warnings and error messages give information about whether the schema failed to import or needed to be modified to enable it to be successfully imported. You can find this report in the `log` directory structure within the project that contains the message definition that you have tried to create. The report has a `.xsd.report.txt` file extension, prefixed with the name that you specified for the new message definition file.
- Review the messages that are shown in the WebSphere Message Broker Toolkit task list to check whether any new warnings or error messages have appeared. Although you might have imported a perfectly valid schema, the task list will display warnings or error messages for any errors that exist in the message definition file. The following situations are examples where messages appear:
  - If the XML Schema that you are importing contains xsd:key, xsd:keyref and xsd:unique constructs, warning messages appear in the task list to tell you that these constructs are unsupported and will be ignored by the broker. If you prefer to delete these constructs, open the message definition file in the Message Definition editor, and delete the constructs as described in "Deleting objects" on page 2919. Deleting the constructs also removes the warning messages from the task list. If you decide not to delete the constructs, they remain in the message model but are not be deployed to the broker, or used for any other purpose. The warning messages remain in the task list, but you can use the message model normally.
  - If the XML Schema that you are importing contains xsd:redefine constructs, error messages appear in the task list to tell you that this construct is unsupported. If you right-click the error messages and select **Quick Fix**, you can choose to convert the xsd:redefine constructs into xsd:include constructs. This also removes the error messages.
  - If the XML Schema that you are importing contains xsd:attribute constructs that contain both a fixed value and a default value, error messages appear in the task list to tell you that this construct is unsupported. However, the schema is still imported and the fixed value is used, not the default value. The error messages can be ignored.
  - If you are importing a collection of related XML Schema files and the Message Definition Editor cannot resolve the links between two of the imported files, messages appear in the task list to say that referenced types or other objects cannot be found. If this occurs, refer to "Resolving problems when developing message models" on page 3459 for more information.

Specify the options for the **mqsicreatemsgdefs** command when you import an XML Schema file.

Importing from the command line:

This describes how to use the command line importer **mqsicreatemsgdefs** to import C, COBOL copybooks, XML DTD or XML Schema in order to populate a message set with message definitions.

Before you begin

Before you start:

Before you attempt this task, you should read the following information:

- "**mqsicreatemsgdefs** command" on page 3702

The command line importer allows you to create a new message set, into which the message definition files will be placed. When you create a new message set from the command line, only the logical information is created by default. However, the command line importer allows you to create a new message set based on an existing message set. The physical format information from the base message set is also created in the new message set. If you want physical format information to be created as well, you must do the following before you invoke the **mqsicreatemsgdefs** command:

1. Using the WebSphere Message Broker Toolkit, create a message set in your workspace that is to be used as a base message set.
2. To this base message set, add the physical formats that you want to be created in your new message set.

About this task

To import C, COBOL copybooks, XML DTD or XML Schema using the command line:

Procedure

1. Close the WebSphere Message Broker Toolkit. This must not be running when you use the command line importer.
2. Invoke the **mqsicreatemsgdefs** command from a command prompt specifying the message set project name, path name of the source files folder, and any other optional parameters that you require. If you want to add physical formats to the new message set that the **mqsicreatemsgdefs** command creates, specify the base message set that contains these physical formats as the `-base` parameter on the import command line.
3. When the command has completed, open `mqsicreatemsgdefs.report.txt`. This report is created when you invoke the **mqsicreatemsgdefs** command and by default is written to the directory from which you invoked the command. The report provides you with the following information:
   - Details of the parameters that were used when **mqsicreatemsgdefs** was invoked.
   - The message set level action.
   - The name of the file or files that have been imported.
   - Details of the import process (for example, any warnings that have been generated and message model objects that have been created).
   - The number of files imported.
4. Start the WebSphere Message Broker Toolkit and switch to the Broker Application Development perspective. The message definition file that was created when you invoked **mqsicreatemsgdefs** is visible in the project that you specified.

Results

If an error occurs during the import of a C, COBOL copybook, XML DTD, or XML Schema file, carefully check any errors that the importer reports. By default, all errors are written to the screen and to the log file described above. To gather additional information about the import, specify the `-v` (Verbose) command line parameter. This parameter displays more detailed information as the import proceeds.

Generating documentation from message sets and message flows

You can generate documentation from your message sets, message flows, message definition files, message maps, Java files, ESQL files, and deployable WSDL files.

About this task

To generate documentation that describes your message sets, message flows, message definition files, message maps, Java files, ESQL files, and deployable WSDL files, complete the following steps.

Bidirectional text is not fully supported in generated documentation. For example, if you enter text in the WebSphere Message Broker Toolkit that has a right-to-left orientation, the text is displayed in the generated documentation with a left-to-right orientation.

Procedure

1. Switch to the Broker Application Development perspective.

2. In the pop-up menu of the Broker Development view, right-click a message set project, a message set, a message flow, a message definition file, a Java file, an ESQL file, or a deployable WSDL file, and select the action **Generate Documentation**. The Documentation Generation wizard opens.
3. Provide the information that is requested to describe the documentation report that you want, and click **Next** to move to the next panel of the wizard.
4. Step through the wizard, clicking **Next** to move to a new panel, and clicking **Finish** when you have described all the information that you want your report to document.

Generating XML Schemas

You can generate either a single XML Schema from a message definition file, or multiple XML Schemas from a message set.

About this task

To generate a single XML Schema from a message definition file, see "Generating an XML Schema" on page 2965.

To generate multiple XML Schemas (one from each message definition file in a message set) see "Generating multiple XML Schemas."

Generating multiple XML Schemas

You can generate an XML Schema for each message definition file in a message set.

Before you begin

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Working with a message definition file" on page 2863
- "Working with MRM message model objects" on page 2870

Note: WebSphere Message Broker uses XML Schema 1.0 to describe the logical structure of messages.

Tip: You should replace any deprecated constructs before you generate XML Schema representations of your models.

About this task

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message set folder from which you want to generate XML Schemas, and click **Generate> XML Schemas**.
3. The Generate XML Schemas window is displayed, and you must put into the **Zip file name** field the name of the compressed file (`*.zip` file extension) that you want to contain the generated XML Schemas.
4. Select a destination folder for this compressed file. You can choose a location either inside or outside the workspace:
   - Click **Create in a workspace directory** and select the required destination folder from the expanded workspace directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Create New Folder**.

     c. Click OK
   - Click **Export to an external directory** and click **Browse** to expand the directory. Select a folder from the expanded directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.

     b. Click **Make New Folder** and type the name of the new folder into the directory tree.

     c. Click OK
5. Optional: Choose from the list given in the **XML Wire Format** field an XML wire format that you want to use to generate the XML Schemas.

   Tip: You must have previously added one or more XML Wire Format layers to the message set if you want to use an XML physical format when you generate XML Schemas. For further information see "Adding an XML wire format" on page 2853.
6. If you do not want strict generation of an XML Schema, clear the **Strict generation** check box at the bottom of the Generate XML Schemas page. By default, this check box is selected.

   Tip: For further information on strict and lax generation of an XML Schema, see "Generate XML schema" on page 1272.
7. Click **Finish**. The compressed file that contains your generated XML Schemas is created.

Related concepts:

Generating an XML Schema

You can generate an XML schema from a message definition file.

Before you begin

Before you start:

You must have completed the following tasks:

- "Creating a message set" on page 2842
- "Working with a message definition file" on page 2863
- "Working with MRM message model objects" on page 2870

Note: WebSphere Message Broker uses XML Schema 1.0 to describe the logical structure of messages.

Tip: You should replace any deprecated constructs before generating XML Schema representations of your models.

About this task

This task topic describes how to generate an XML Schema from a message definition file:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the message definition file (`*.msxd` file extension) from which you want to generate an XML Schema, then click **Generate** > **XML Schema** on the menu.
3. The Generate XML Schema window is displayed, and the message definition file that you selected is highlighted. The message definition file list is filtered to only show artifacts in the active working set. If this is not the message definition file from which you want to generate an XML Schema, select the correct message definition file.
4. Optional: From the drop down list at the bottom of the Generate XML Schema window, select the XML Wire Format that you want to use to generate the XML Schema.

Tip: You must have previously added one or more XML Wire Format layers to a message set if you want to use an XML physical format when you generate XML Schema. For further information see "Adding an XML wire format" on page 2853.

5. If you do not want strict generation of an XML Schema, clear the **Strict generation** check box at the bottom of the Generate XML Schema page. By default, this check box is selected.

   Tip: For further information on strict and lax generation of XML Schema, see "Generate XML schema" on page 1272.
6. Click **Next** to move to the next page of the wizard.
7. Select a destination folder for the XML Schema. You can choose a location either inside or outside the workspace:
   - Click **Create in a workspace directory** and select the required destination folder from the expanded workspace directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.
     b. Click **Create New Folder**.
     c. Click OK
   - Click **Export to an external directory** and click **Browse** to expand the directory. Select a folder from the expanded directory. The contents of the folder that you select are overwritten.

     If you want to create a new folder:

     a. Click the desired location.
     b. Click **Make New Folder** and type the name of the new folder into the directory tree.
     c. Click OK
8. Click **Finish**. Your XML Schema is generated.
9. Use the Broker Development view to locate the destination folder that you specified for the generated XML Schema. This folder contains a file with exactly the same name as your message definition file with the file extension `*.xsd`. This is the generated XML Schema. To view this file, right-click it, then click **Open** on the menu. This opens the schema editor.

   Tip: The **Design**, **Source** or **Graph** tabs located in lower-left corner of the schema editor provide you with different views of generated XML Schema.

Generating a Broker SCA definition from a message set

WebSphere Message Broker creates a Broker SCA definition from existing message definitions.

Before you begin

Before you start: You must have created a message set that contains message definitions. The wizard gives an error if the set of message definitions is empty.

About this task

To generate a Broker SCA definition:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the folder that contains the message set file from which you want to generate a Broker SCA definition, and select **Generate** > **Broker SCA definition**. This action starts the Generate Broker SCA Definition wizard.
3. Step through the wizard providing the details as required. Some of the panels and options are subject to settings that you make within the wizard and might not always be shown. Also, some fields in the wizard might be grayed out. This happens when a field has a mandatory setting, or when the field is not used because of settings that have already been made in other fields.

   By default, the wizard creates the Broker SCA definition in the message set project.

Results

On completion of the Generate Broker SCA Definition wizard, you have generated either a `.insca` or a `.outsca` Broker SCA definition that is stored in the SCA category under the message set project.

A `.insca` Broker SCA definition is a compressed file that contains an SCA import and all the XSDs and WSDLs that are referenced directly or indirectly by the SCA import and a `.outsca` Broker SCA definition is a compressed file that contains an SCA export and all the XSDs and WSDLs that are referenced directly or indirectly by the SCA export.

Specifically, the Broker SCA definition contains:

- A WSDL interface that contains one or more operations.
- XSDs that correspond to the messages that are used in the operations defined in the interface.

- If you have selected a Web services binding, the WSDL contains service and binding information that defines the endpoint.
- If you have not selected a Web services binding, the SCA Import or Export must contain binding information for another binding that is supported by WebSphere Message Broker.

Related tasks:

"Creating a message set" on page 2842
Use the New Message Set wizard to create a message set.

"Developing SCA applications for non-XML data" on page 2103
The SCA nodes allow non-XML data to be sent and received from WebSphere Process Server by using the WebSphere MQ binding. For example, create a message model from a COBOL copybook, and use that message model to parse messages received from WebSphere Process Server.

"Exporting an SCA Import or Export from a Broker SCA definition" on page 2945
You can use the New Message Definition File wizard in the WebSphere Message Broker Toolkit to export SCA import or SCA export components. You must export an SCA import or SCA export if the Broker SCA definition is to be used by WebSphere Integration Developer.

Related reference:

"Broker SCA definition generation" on page 6340
The Broker SCA Definition wizard creates a Broker SCA definition that includes objects that define the binding, interface, and message format information to permit interoperation between WebSphere Message Broker and WebSphere Process Server.

The Generate Broker SCA Definition wizard creates a Broker SCA definition from a message set.

Generating a WSDL definition from a message set

To ensure the highest interoperability of your Web services, use the document style of WSDL whenever possible. If rpc style WSDL is necessary, use literal encoding.

Before you begin

Before you start you must already have completed the following tasks:

- "Creating a message set" on page 2842

Replace any deprecated constructs before generating WSDL representations of your message models.

About this task

To generate a WSDL definition:

Procedure

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the folder that contains the message set file from which you want to generate a Web service definition, and select **Generate** > **WSDL Definition**. This starts the Generate WSDL wizard.
3. Step through the wizard completing the details as required. Some of the panels and options are subject to settings that you make within the wizard and might not always be shown. Also, some fields in the wizard might be greyed out. This

happens when a field has a mandatory setting, or when the field is not used because of settings that have already been made in other fields.

By default, the wizard creates the WSDL in the message set project. If you are going to use the WSDL to configure a SOAP node, create the WSDL in the message set, not the message set project.

Results

On completion of the Generate WSDL wizard, you have generated a WSDL definition. The file extension for WSDL files is .wsdl, and the file extension for any imported schema files in multi-file mode (where the WSDL definition is split over a number of files) is .xsd.

This following is an example of the WSDL that is generated for a JMS binding:

```
<wsdl:service name='HTTP'>
  <wsdl:port binding='tns:JMSSoapBinding' name='HTTP'>
    <wsdlsoap:address
       location='jms:/queue?destination=jms/MyQueue&amp;
                 connectionFactory=jms/MyCF&amp;
                 priority=5&amp;
                 targetService=GetQuote'/>
  </wsdl:port>
</wsdl:service>
```

Note: The various parts of the location string are broken over separate lines for clarity, but are generated as a continuous string without additional white space.

Developing user-defined extensions

A user-defined extension is a component that you design and implement to extend the function of WebSphere Message Broker.

You can create and implement the following types of user-defined extension:

- User-defined nodes
- User-defined parsers
- User-defined exits

The user-defined nodes, parsers, and exits that you create can be used with the nodes and parsers that are supplied with the product, and with nodes and parsers that are supplied by independent software vendors.

For information about each type of user-defined extension that you can create, see the relevant topics listed under the related links. These topics help you to understand how your user-defined extension interacts with other components of WebSphere Message Broker, such as message flows and their associated execution groups. A good understanding of the broker architecture helps you to plan and construct user-defined extensions more effectively.

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

"Why use a user-defined extension?" on page 2972
Use a user-defined node or parser when the built-in resources do not provide the required functions.

User-defined extensions overview

A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

You can create the following types of user-defined extension:

- Input nodes
- Message processing nodes
- Output nodes
- Parsers
- User exits

The user-defined nodes and parsers that you create can be used with the nodes and parsers supplied with the product, and with nodes and parsers that are supplied by other vendors. You can configure a user-defined node to use a user-defined parser.

You can write user-defined exits and parsers only in the C programming language. You can write user-defined nodes in the C or the Java programming languages, or you can use a subflow as a user-defined node. You must compile user-defined nodes and parsers that are written in C into a loadable implementation library (LIL), and user exits that are written in C into a loadable exit library (LEL): that is, a shared library on Linux and UNIX systems, or a dynamic link library (DLL) on Windows systems. You must package user-defined nodes that are written in Java as a JAR file. You must import any user-defined nodes that you create into the WebSphere Message Broker Toolkit before you can use them.

The samples on the start screen of the WebSphere Message Broker Toolkit has examples of user-defined nodes and parsers. Look at the following sample for an example of how a node is created and used.

- User-defined Extension

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To achieve platform independence, use the ANSI standard C or Java programming languages, and avoid platform-specific code in your user-defined extension.

The related links help you to understand how your user-defined extensions interact with other components of WebSphere Message Broker, such as message flows and execution groups. A good understanding of the broker architecture helps you to plan and construct user-defined extensions more effectively.

Java user-defined extensions API

Why use a user-defined extension?

Use a user-defined node or parser when the built-in resources do not provide the required functions.

Before you start to create your user-defined extension, be clear about its purpose. Most tasks can be performed by using the functions already provided with WebSphere Message Broker, but you might need a user-defined extension for your particular task.

To write user-defined extensions you need to be a skilled programmer, with some knowledge of WebSphere Message Broker and its architecture, therefore make sure that you have the skills and knowledge required. You also need the time to test and debug your user-defined node or parser, and a safe environment in which to do this.

Also note that the maintenance and servicing of your own user-defined extensions is your responsibility. You should ensure that there will be someone available who can perform future updates or fixes.

A user-defined extension might be appropriate in the following situations:

- When you cannot manipulate the supplied nodes or parsers to perform the function you require. For example, you might want to connect to another software component in your message flow outside of WebSphere MQ. If there is no supplied node for doing this, you must create your own.
- When you can improve performance, ease of use, or reliability by using your own user-defined extensions in place of the supplied nodes or parsers.
- If the available choices are not appropriate for your requirement. You can create user-defined extensions to handle internal, customer-specific, or generic commercial messages formats.

Consider the following design factors when you are planning or writing a user-defined node or parser. You should be familiar with the concepts covered in the following topics before designing a user-defined extension.

- "Errors and exception handling" on page 2973

- "Storage management in user-defined nodes" on page 2976

Errors and exception handling:

Correct handling of errors and exceptions is important for correct broker operation. You must consider how and when your user-defined extension must handle errors and exceptions.

The errors and exception handling here describes factors that you must consider when you develop user-defined extensions for WebSphere Message Broker in the C programming language. If you are developing user-defined extensions using the Java programming language, you can use standard Java error and exception handling methods. If, for example, WebSphere Message Broker throws an exception internally, a Java exception of class **`MbException`** is made available.

The broker generates C++ exceptions to handle error conditions. These exceptions are caught in the relevant software layers in the broker, and are handled accordingly. However, programs written in C cannot catch C++ exceptions, and all exceptions thrown, by default, bypass all C user-defined extension code and are caught in a higher layer of the broker.

Utility functions, by convention, typically use the return value to pass back requested data; for example, the address or handle of a broker object. The return value sometimes indicates that a failure has occurred. For example, if the address or handle of a broker object could not be retrieved, zero (CCI_NULL_ADDR) is returned. Additionally, the reason for an error condition is stored in the return code output parameter, which is, by convention, part of the function prototype of all utility functions. If the utility function completed successfully and `returnCode`

was not null, `returnCode` contains CCI_SUCCESS. Otherwise, it contains one of the return codes described here. You can test the value of `returnCode` to determine whether a utility function was successful.

If the call to a utility function causes the broker to generate an exception, the error is visible to the user-defined extension only if it specified a value for the `returnCode` parameter to that utility function. If a null value was specified for `returnCode`, and an exception occurs:

- The user-defined extension is not be aware of that exception
- The utility function does not return to the user-defined extension
- Execution control passes to higher layers in the broker stack to process the exception

Therefore, a user-defined extension cannot perform its own error recovery. If, however, the `returnCode` parameter is specified, and an exception occurs, a return code of CCI_EXCEPTION is returned. In this case, cciGetLastExceptionData or cciGetLastExceptionDataW (the difference being that cciGetLastExceptionDataW returns a CCI_EXCEPTION_WIDE_ST which can contain Unicode trace text) can be used to obtain diagnostic information on the type of exception that occurred. The data is returned in the CCI_EXCEPTION_ST or CCI_EXCEPTION_WIDE_ST structure.

If there are no resources to be released, do not set the returnCode argument in your user-defined extension. Not setting this argument allows exceptions to bypass your user-defined extensions. These exceptions can then be handled higher up the WebSphere Message Broker stack, by the broker.

Message inserts can be returned in the CCI_STRING_ST members of the CCI_EXCEPTION_ST structure. The CCI_STRING_ST allows the user-defined extension to provide a buffer to receive all required inserts. The broker copies the data into this buffer, and returns the number of bytes output and the actual length of the data. If the buffer is not large enough, no data is copied and the "dataLength" member can be used to increase the size of the buffer, if required.

The user-defined extension can set a non-null value for `returnCode` and provide its own error recovery, if required. The utility function calls return to the user-defined extension and pass their status through `returnCode`. All exceptions that occur in a utility function must be passed back to the broker for additional error recovery to be performed; that is, when CCI_EXCEPTION is returned in `returnCode`. You do this by calling cciRethrowLastException, after the user-defined extension has completed its own error processing. Calling cciRethrowLastException causes the C interface to re-throw the last exception so that it can be handled by other layers in the broker. In the same way as the C **`exit`** call, **`cciRethrowLastException`** does not return in this case.

If an exception occurs and is caught by a user-defined extension, the extension must not call utility functions except cciGetLastExceptionData, cciGetLastExceptionDataW, or cciRethrowLastException. An attempt to call other utility functions results in unpredictable behavior that can compromise the integrity of the broker.

If a user-defined extension encounters a serious error, cciThrowException or cciThrowExceptionW can be used to generate an exception that is processed by the broker in the correct manner. The generation of such an exception causes the

supplied information to be written to the system log (syslog or Eventviewer) if the exception is not handled. The information is also written to trace (if trace is active).

Types of exception and broker behavior: The broker generates a set of exceptions that can be passed to a user-defined extension. These exceptions can also be generated by a user-defined extension when an error condition is encountered. The exception classes are:

Fatal Fatal exceptions are generated when a condition occurs that prevents the broker process from continuing execution safely, or where it is broker policy to terminate the process. Examples of fatal exceptions are a failure to acquire a critical system resource, or an internally-caught severe software error. The broker process terminates following the throwing of a fatal exception.

Recoverable
These exceptions are generated for errors which, although not terminal in nature, mean that the processing of the current message flow has to be ended. Examples of recoverable exceptions are invalid data in the content of a message, or a failure to write a message to an output node. When a recoverable exception is thrown, the processing of the current message is canceled on that thread, but the thread recommences execution at its input node.

Configuration
Configuration exceptions are generated when a configuration request fails. This can be because of an error in the format of the configuration request, or an error in the data. When a configuration exception is thrown, the request is rejected and an error response message is returned.

Parser These exceptions are generated by message parsers for errors that prevent the parsing of the message content or creating a bit stream. A parser exception is treated as a recoverable exception by the broker.

Conversion
These exceptions are generated by the broker character conversion functions if invalid data is found when trying to convert to another data type. A conversion exception is treated as a recoverable exception by the broker.

User These exceptions are generated when a Throw node throws a user-defined exception.

Database
These exceptions are generated when a database management system reports an error during broker operation. A database exception is treated as a recoverable exception by the broker.

“cciLog” on page 6651
Use cciLog to write an error, warning, or informational event.

“cciRethrowLastException” on page 6659
This function re-throws the last exception that has been generated on the current thread. It is used to pass the exception back to the broker for further handling. The function, like a C **exit** call, does not return to the caller.

“cciThrowException” on page 6666
Use this function to throw an exception. The exception is thrown by the broker interface, and includes the specified arguments as exception data.

“cciGetLastExceptionDataW” on page 6649
Gets diagnostic information about the last exception generated. Information about the last exception generated on the current thread is returned in a CCI_EXCEPTION_WIDE_ST output structure. The user-defined extension uses this function to determine whether any recovery is required when a utility function returns an error code.

“cciLogW” on page 6653
cciLogW logs an error, warning, or informational event. The event is logged by the broker interface and uses the specified arguments as log data.

“cciThrowExceptionW” on page 6668
The cciThrowExceptionW exception is thrown by the broker interface and uses the specified arguments as exception data.

Storage management in user-defined nodes:

Consider issues that relate to storage management when you develop user-defined extensions in the C programming language.

If you are developing user-defined extensions using the Java programming language, you can use standard Java string handling methods.

All memory that is allocated by a user-defined extension must be released by the user-defined extension. The construction of a node at run time causes the cniCreateNodeContext function to be invoked, which allows the user-defined extension to allocate node instance specific data areas to store a context. The address of the context is returned to the broker, and is passed back from the broker when an internal method causes a user-defined extension function to be invoked; thus, the C user-defined extension can locate and use the correct context for the function processing.

The broker passes addresses of C++ objects to the user-defined extension, which are used as handles to be passed back on subsequent function calls. Your C

user-defined extension must not manipulate or use these pointers in any way, for example, by trying to release storage using the free function. Such actions cause unpredictable behavior in the broker.

The cniCreateNodeContext implementation function is invoked whenever the underlying node object has been constructed internally. It is called when a broker is defined with a message flow that uses a user-defined node. This activity is not necessarily the same as creating (or reusing) a thread to execute a message flow instance that contains the node. The cniCreateNodeContext function is called only once, during the configuration of the message flow, regardless of how many threads are executing the message flow.

Similar considerations apply to user-defined parsers, and the corresponding implementation function cpiCreateContext.

"User-defined parsers" on page 3010
A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

Related reference:

"cpiCreateContext" on page 6553
This function creates a user-defined extension context associated with a parser object. It is called by the broker when an instance of a parser object is constructed or allocated. This action occurs when a message flow causes the message data to be parsed; the broker constructs or allocates a parser object to acquire the appropriate section of the message data.

"cniCreateNodeContext" on page 6447
This function creates a context for an instance of a node object. It is called by the broker whenever an instance of a node object is constructed. Nodes are constructed when a message flow is deployed by the broker, or when the execution group is started.

String handling in user-defined nodes:

Consider issues that relate to string handling when you develop user-defined extensions in the C programming language.

If you are developing user-defined extensions using the Java programming language, you can use standard Java string handling methods.

To enable a broker to handle messages in all languages at the same time, text processing within the broker is done in UCS-2 Unicode. UCS-2 Unicode character strings are also used across the Java and C language user-defined extension APIs to pass and return character data. Attributes are received in XML configuration messages as character strings, regardless of data type. If the true data type of an attribute is not a string, the cniSetAttribute function must perform the necessary verification and conversion before storing the attribute value. Similarly, when an attribute value is retrieved using cniGetAttribute2, conversion must be performed to a UCS-2 Unicode character string before returning the result.

`CciChar` defines a 16-bit character with UCS-2 Unicode representation. A `CciChar*` is a string of such characters terminated with a `CciChar` of 0. By default, a `CciChar` is represented by type `wchar_t`. However, some platforms do not have a convenient way of representing UCS-2 constants in source code, typically because of 4-byte `wchar_t` or EBCDIC representation. For example, a source-code constant such as L"ABC" expands to 12 bytes on Solaris.

For this reason, WebSphere Message Broker provides the utility functions cciMbsToUcs and cciUcsToMbs. Use these functions, where appropriate, to ensure portability of your user-defined nodes.

"cciUcsToMbs" on page 6672
Use this function to convert Universal Character Set (UCS) data to multibyte string data. This function is, typically, used only for formatting diagnostic messages. Normal processing is best done in UCS-2, which can represent all characters from all languages.

Threading considerations for user-defined extensions:

Message processing nodes and parsers must work in a multi-instance, multithreaded environment. Many node objects or parser objects are available, each with several syntax elements, and many threads can be executing methods on these objects.

An instance of a message flow processing node is shared and used by all the threads that service the message flow in which the node is defined. Parsers are invoked on the same thread as the nodes, therefore, if the flow is using multiple threads, the parsers are as well.

A user-defined extension must use this model. If a user-defined node requires global data or resources, you must protect the global data or resources by using semaphores to serialize access across threads. However, such serialization can result in performance bottlenecks. Avoid using global data and resources to create a more scalable solution.

The functions implemented by user-defined extensions must be reentrant, and any functions that they invoke must also be reentrant. All user-defined extension utility functions are fully reentrant.

Although a user-defined extension can create additional threads if required, all C utility functions and Java methods must be invoked on the same thread that called the cniEvaluate function in C or the evaluate method in Java, as appropriate for the language in which the node is written. If the same thread is not used, your code might compromise the integrity of the broker and cause unpredictable behavior. Any additional threads must not call the user-defined extension API. The API must only be used from the main thread that is invoked by the Broker.

For information about the cniEvaluate function see "cniEvaluate" on page 6475.

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"User-defined extensions execution model"
The execution model is the system used to start message flows through a series of nodes.

"Developing user-defined extensions" on page 2970
A user-defined extension is a component that you design and implement to extend the function of WebSphere Message Broker.

User-defined extensions execution model:

The execution model is the system used to start message flows through a series of nodes.

When an execution group is initialized, the appropriate loadable implementation library (LIL) files and Plug-in Archive (PAR) files are made available to the runtime environment. The execution group runtime process starts, and creates a dedicated configuration thread. You are responsible for ensuring that a user-defined node is thread-safe. If a node updates a variable across multiple threads, appropriate locking must be in place. Do not compromise this threading model in your implementation of user-defined nodes. Consider the following points:

- An input message sent to a message flow is processed only by the thread that received it.
- A single instance of a user-defined extension might be invoked on several threads concurrently.
- The message flow execution environment is conceptually like procedural programming. Nodes that you insert into a message flow are like subroutines called using a function call interface. However, rather than a call-return interface, in which parameters are passed in the form of input message data, the execution model is referred to as a propagation-and-return model.

As an example, consider a message flow in which you use both user-defined nodes and parsers. You use a user-defined node to process messages, and a user-defined parser to parse messages; both the node and parser contain implementation functions. The broker calls the implementation functions, or callback functions, when certain events occur:

- When an input message is received by the message flow and is propagated to the user-defined node:
  - For C nodes, the broker calls the cniEvaluate function for the user-defined node. See "cniEvaluate" on page 6475.
  - For Java nodes, the broker calls the evaluate method that is implemented by the user-defined node.
- If the user-defined node wants to query the message to decide what to do with it, the node calls a C utility function or a Java method, as appropriate for the language in which the node is written.

The broker invokes the user-defined parser on one of its implementation functions, for example cpiParseFirstChild. This function instructs the parser to build the parse tree. The parser builds the tree by invoking utility functions that create elements in the parse tree, for example cpiCreateElement. The parser can be called many times by the broker.

Node and parser factory behavior:

The node factory and the parser factory assume roles in declaring a node to the broker or defining a parser.

Each loadable implementation library (LIL) has one node factory, or one parser factory, or has both. A node factory can identify many nodes, and a parser factory can identify many parsers.

When the broker loads the LIL, it calls the following functions:

- **`bipGetMessageflowNodeFactory`**

  After the operating system has loaded and initialized the LIL, the broker calls initialization function `bipGetMessageflowNodeFactory`. The `bipGetMessageflowNodeFactory` function calls the utility function `cniCreateNodeFactory`, which passes back a factory name (or group name) for all the nodes that your LIL supports.

- **`bipgetparserfactory`**

  After the operating system has loaded and initialized the LIL, the broker calls initialization function `bipgetparserfactory`. The `bipgetparserfactory` function defines the name of the factory that the user-defined parser supports, and the classes of objects, or shared object, that the factory supports. The initialization

function `bipgetparserfactory` calls the utility function `cpiCreateParserFactory`, which passes back a factory name (or group name) for all the parsers that your LIL supports.

Before the node factory is returned, the broker calls the following functions:

1. **cniCreateNodeFactory**

   This function creates a single instance of the node factory in the broker.

2. **cndDefineNodeClass**

   This function defines the name of a node class that a node factory supports, and identifies the nodes that the node factory can create.

Before the parser factory is returned, the broker calls the following functions:

1. **cpiCreateParserFactory**

   This function creates a single instance of the named parser factory in the message broker.

2. **cpiDefineParserClass**

   This function defines the name of a parser class that a parser factory supports, and identifies the parsers that the factory can create.

See the following topics for information on these functions:

Why use a user exit?

Use a user exit to intercept the progress of messages through message flows without having to redesign the message flow.

User exits provide a mechanism to apply actions (such as monitoring, message tracking, and auditing) operationally to deployed message flows at run time.

You can use user exits to call (by using callbacks) your custom C code, which is provided in a loadable exit library (LEL), at key points in message transactions in deployed message flows. These user exits can use utility functions from the user-defined extensions APIs to extract details of the broker, execution group, message flow, node, and message assembly. In addition, the user exits can use utility functions from the user-defined extensions APIs to modify parts of the message assembly.

To write user exits, you must be a skilled programmer with an understanding of WebSphere Message Broker and its architecture. Testing and debugging user exits can be time-consuming, and must be done in a safe environment. You must also maintain and service your own user exit.

Consider the following design factors when you plan and write a user exit:

- The effect on performance

User exit callbacks are run inline with the current message transaction; that is, progress of the transaction is blocked until the return from the callback is received. Updating the message in a user exit callback can affect performance, particularly if the input message would not otherwise be changed in the message flow.

- Message parse timing

  On-demand parsing, referred to as partial parsing, is used to parse a message bit stream only as far as is necessary to satisfy the current reference in the message assembly. A user exit can navigate the message at each of its callback points, which can mean that the parse timing of the message flow is changed when you enable the user exit.

- Error handling

  To ensure that the error handling that is provided by the designer of a message flow that is being intercepted by a user exit continues to operate as designed, you must program the user exit in the following way:

  – All internal errors must be handled within the user exit, and the normal return from the callback must enable the message flow transaction to complete as normal.

  – All exception condition that is encountered when the user exit calls utility functions in the user-defined extensions APIs must be returned to the flow for normal error processing. This behavior is achieved by calling cciRethrowLastException() to cut short the callback processing.

Exploiting user exits:

Your message flows can benefit from user exits.

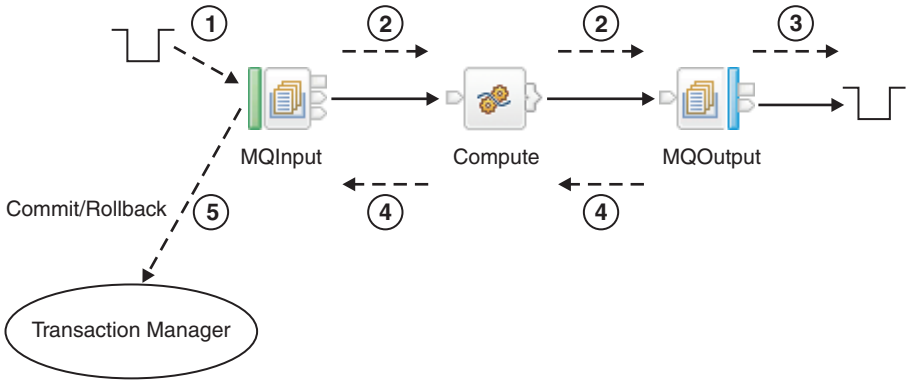
Before you begin

Before you start:

- Read "User exits" on page 3015.
- Read "Why use a user exit?" on page 2984

About this task

The following diagram illustrates how a user exit works. The numbered events are described after the diagram. The MQInput node is used as an example, but the function applies to all input nodes, including user-defined input nodes. Similarly, the Compute and MQOutput nodes could be replaced by any equivalent nodes.



1. (cciInputMessageCallback) The message is dequeued from the input source (read into the flow).

   Built-in nodes and user-defined nodes differ slightly in the way in which user exits are called. For built-in input nodes, the user exit is called as soon as possible after the data has been read from the external source. For user-defined input nodes, the user exit is called just before the node propagates the message.
2. (cciPropagatedMessageCallback) The message is propagated to the node for processing.
3. (cciOutputMessageCallback). A request message is sent to the output node's transport, and transport-specific destination information is written to WrittenDestination in the LocalEnvironment (for example, this information includes the queueName and msgId for an MQ message). The call is made when a node successfully puts a message to a transport, from either an output or a request node. The outputMessageEvent is called by built-in nodes only. The topic for each node that supports WrittenDestination information contains details about the data that it contains.
4. (cciNodeCompletionCallback) Node processing completes.
5. (cciTransactionEventCallback) The user exit is called after the transaction has completed, so that user exit processing is not part of that transaction. The user exit is invoked even if no transactional processing is completed by the flow.

   Where the message flow property `Commit Count` is greater than one, many-to-one ratios exist between events 1 and 5. This ratio also exists for some scenarios that are specific to the particular input node; for example, when an MQInput node is configured with the `Commit by Message Group` property selected.

You can write a user exit to track any number of these events. For each of these events, the following data is available to the user exit. All access is read-only, unless stated otherwise:

- The message is dequeued:
  - Bit stream
  - Input node

  - Environment tree (read and write)
- The message is propagated to the node:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Source node
  - Target node
- A message is sent to a transport:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Output or request node
- Node processing completes:
  - Message tree (body element read and write)
  - LocalEnvironment tree (read and write)
  - Exception list
  - Environment tree (read and write)
  - Node
  - Upstream node
  - Exception (if any)
- The end of the transaction:
  - Input node
  - Exception (if any)
  - Environment tree (read and write)

You can register multiple user exits, and, if they are registered, they are invoked in a defined order (see "**mqsichangeflowuserexits** command" on page 3751). Any changes that are made to the message assembly (the message and environment) by a user exit are visible to subsequent user exits.

When the user exit is invoked, it can query the following information:

- Message flow information:
  - Message flow name
  - Broker name
  - Broker's queue manager name
  - Execution group name
  - Message flow's commit count property
  - Message flow's commit interval property
  - Message flow's coordinated transaction property
- Node information:
  - Node name
  - Node type
  - Terminal name
  - Node properties

The user exit can also perform the following tasks:

- Navigate and read the message assembly (Message, LocalEnvironment, ExceptionList, Environment)
- Navigate and write the Message body, LocalEnvironment, and Environment tree

You can register the user exits on a dynamic basis, without needing to redeploy the configuration.

User-defined nodes:

User-defined nodes are the main mechanism for extending the functions of WebSphere Message Broker.

The most common uses for a user-defined node are:

- Calling an external system for which WebSphere Message Broker does not provide nodes
- Calling already defined program libraries that perform a transformation or calculation that is required in the design of a message flow
- Packaging a subflow

Before you consider constructing a user-defined node, make sure that no built-in node is available to perform the required actions. For example, you might have considered creating a user-defined node to perform the following tasks, but you can use a JavaCompute node instead:

- Allowing programming languages other than ESQL to be used for coding message flow functions
- Performance advantages in performing some actions in compiled code
- Complex functions that are not available in ESQL, such as the large number of classes provided in JS2E

The following topics describe the different types of user-defined node in more detail:

- "User-defined input nodes" on page 2990

User-defined input nodes:

A user-defined input node is an extension to the broker that provides a new input node in addition to the nodes supplied with the product.

You create user-defined input nodes by using the C or Java programming language, or from a subflow, to provide message input to a message flow from a message queue when you want your broker to accept messages from a transport protocol other than WebSphere MQ.

You can use a user-defined input node to receive data from an external data source and to allow that data to be processed in a broker. In this way, you can complement the primitive input node types provided by WebSphere Message Broker.

You cannot use a user-defined input node to provide the In terminal to a message subflow. If you want to provide the In terminal to a subflow, you must use the supplied Input node.

Before writing a user-defined node, make sure that you are familiar with the concepts that are introduced in "Why use a user-defined extension?" on page 2972 and "User-defined extensions in the runtime environment" on page 2980.

Use a user-defined node or parser when the built-in resources do not provide the

required functions.

"Using a subflow as a user-defined node" on page 3008
You can develop a user-defined node that packages a subflow from scratch, in the same way that you can create any other user-defined node that has its implementation based on Java, or base it on an existing subflow.

C user-defined input node life cycle:

A user-defined input node that is written in the C programming language progresses through several stages during its lifetime.

The stages of the life cycle are:
- Registration
- Instantiation
- Processing
- Destruction

Registration: During the registration phase, the broker discovers which resources are available and which LILs can provide them. In this instance, the resources available are nodes. The phase starts when an execution group starts. The LILs are loaded on the startup of an execution group, and the broker queries them to find out what resources they can provide.

A CciFactory structure is created during the registration phase, when the user-defined node calls **cniCreateNodeFactory**.

The following APIs are called by the broker during this stage:
- biGetMessageflowNodeFactory
- bipGetParserFactory

The following API is called by the user-defined node during this stage:
- cniCreateNodeFactory

Instantiation: An instance of a user-defined input node is created when the **mqsistart** command starts or restarts the execution group process, or when a message flow that is associated with the node is deployed.

The following APIs are called during this phase:
- **cniCreateNodeContext**. This API allocates memory for the instantiation of the user-defined node to hold the values for configured attributes. This API is called once for each message flow that is using the user-defined Input node.
- **cniCreateInputTerminal**. This API is invoked within the cniCreateNodeContext API, and is used to tell the broker what input terminals, if any, your user-defined input node has.

  Your user-defined input node only has input terminals if it is also acting as a message processing node. If this is the case, it is typically better to use a separate user-defined message processing node to perform the message processing, rather than combine both operations in one, more complex, node.
- **cniCreateOutputTerminal**. This API is invoked within the cniCreateNodeContext API, and is used to tell the broker what output terminals your user-defined input node has.
- **cniSetAttribute**. This API is called by the broker to establish the values for the configured attributes of the user-defined node.

During this phase, a CciTerminal structure is created when cniCreateTerminal is called.

Processing: The processing phase begins when the cniRun function is called by the broker. The broker uses the cniRun function to determine how to process a message, including determining the domain in which a message is defined, and invoking the relevant parser for that domain.

A thread is demanded from the message flow's thread pool, and is started in the run method of the input node. The thread connects to the broker's queue manager, and retains this connection for its lifetime. When a thread has been allocated, the node enters a message processing loop while it waits to receive a message. It remains in the loop until a message is received. If the message flow is configured to use multiple threads, thread dispatching is activated.

The message data can now be propagated downstream.

The following APIs are called by the broker during this phase:

- **cniRun**. This function is called by the broker to determine how to process the input message.
- **cniSetInputBuffer**. This function provides an input buffer, or tells the broker where the input buffer is, and associates it with a message object.

Destruction: A user-defined input node is destroyed when the message flow is redeployed, or when the **mqsistop** command is used to stop the execution group process. You can destroy the node by implementing the cniDeleteNodeContext function.

When a user-defined input node is destroyed in one of these ways, you should free any memory used by the node, and release any held resources, such as sockets.

The following APIs are called by the broker during this phase:

- cniDeleteNodeContext. This function is called by the broker to destroy the instance of the input node.

Java user-defined input node life cycle:

A user-defined input node that is written in the Java programming language progresses through several stages during its lifetime.

The stages of the life cycle are:
- Registration
- Instantiation
- Processing
- Destruction

Registration: During the registration phase a user-defined input node written in Java makes itself known to the broker. The node is registered with the broker through the static getNodeName method. Whenever a broker starts, it loads all the relevant Java classes. The static method getNodeName is called at this point, and the broker registers the input node with the node name specified in the getNodeName method. If you do not specify a node name, the broker automatically creates a name for the node based on the package in which it is contained.

Using a static method here means that the method can be called by the broker before the node itself is instantiated.

Instantiation: A Java user-defined input node is instantiated when a broker deploys a message flow containing the user-defined input node. When the node is instantiated, the broker calls the constructor of the input node's class.

When a node is instantiated, any terminals that you have specified are created. A message processing node can have any number of input and output terminals associated with it. You must include the createInputTerminal and createOutputTerminal methods in your node constructor to declare these terminals.

To handle exceptions that are passed back to your input node, use createOutputTerminal to create a catch terminal for your input node. When the input node catches an error, the catch terminal processes it in the same way as an MQInput node would. You can allow most exceptions, such as exceptions that are caused by deployment problems, to pass back to the broker, and the broker will warn the user of any possible configuration errors.

As a minimum, your constructor class needs only to create these output terminals on your input node. However, if you need to initialize attribute values, such as defining the parser that will initially parse a message passed from the input node, you should also include that code at this point in your input node.

Processing: Message processing for an input node begins when the broker calls the run method. The run method creates the input message, and should contain the processing function for the input node.

The run method is defined in MbInputNodeInterface, which is the interface used in a user-defined node that defines it as an input node. You must include a run method in your node. If you do not include a run method in your user-defined input node, the node source code will not compile.

When a message flow containing a user-defined input node is deployed successfully, the broker calls the node's run implementation method, and continues to call this method while it waits for messages to process.

When a message flow starts, a single thread is dispatched by the broker, and is called into the input node's run method. If the dispatchThread() method is called, further threads can also be created in the same run method. These new threads immediately call into the input node's run method, and can be treated the same as the original thread. The number of new threads that can be created is defined by the additionalInstances property. Make sure that threads are dispatched after a message has been created, and before it is propagated, to ensure that only one thread at a time is waiting for a new message.

The user-defined input node can choose a different threading model and is responsible for implementing the chosen model. If the input node supports the additionalInstances property, and dispatchThread() is called, the code must be fully re-entrant, and any functions that are invoked by the node should also be re-entrant. If the input node forces single threading, that is, it does not call dispatchThread(), the node documentation must state that setting the additionalInstances property has no effect on the input node.

For more information on the threading model for user-defined input nodes, see "Threading considerations for user-defined extensions" on page 2978.

Destruction: A Java user-defined input node is destroyed when the node is deleted or the broker is shut down. You do not need to include anything in your code that specifies the node should be physically deleted, because this can be handled by the garbage collector.

However, if you want notification that a node is about to be deleted, you can use the **onDelete** method. You might want to do this if there are resources that you want to delete, other than those that will be garbage collected. For example, if you have opened a socket, this will not be properly closed when the node is automatically deleted. You can include this instruction in your **onDelete** method to ensure that the socket is closed properly.

Java user-defined extensions API

Planning user-defined input nodes:

Before you develop a user-defined input node, plan and design its content and purpose.

Analysis: Before you develop a user-defined input node, ask yourself the following questions:

- Do you need to create a custom input node?

  You must include at least one input node in a message flow. Which one you choose depends on the source of the input messages:

  – If the messages arrive at the broker on a WebSphere MQ queue, use the MQInput node.
  – If SOAP messages are received over HTTP, use the SOAPInput node.
  – If other messages are received over HTTP, use the HTTPInput node.
  – If the messages are received from a JMS source, use the JMSInput node.
  – If the messages are received from an EIS, use the PeopleSoftInput, SAPInput, or SiebelInput node.
  – If the messages are retrieved from files, use the FileInput node.
  – If the message source is any other, you must use a user-defined input node.

  For information about using more than one input node in a message flow, see "Using more than one input node" on page 1473.
- To successfully input the data concerned, does the input node have to interface with vendor software? If so, does the API that enables access to this software break your threading model?
- Do you need a new user-defined parser to interpret the body (payload) of the message generated by this input node, or can it be parsed by a standard built-in parser?
- Do you need the user-defined input node to operate the message flow instance in which it resides under transactional control as a globally-coordinated transaction?
- Do you need the new user-defined input node to offer configuration options?
- Do you need messages propagated by this input node to be processed by the following primitives?

  – All primitive output nodes
  – ResetContentDescriptor nodes

Design considerations: Before developing and implementing your input node, decide on the following factors:

- Which message parser will initially parse the input message.
- Whether to override the default message parser attribute values for this input node.
- Which threading model is appropriate for the input node.
- What kind of message processing and transaction support will the node support.
- Which configuration attributes required by the input node should be externalized for alteration by the message flow designer.
- What optional node APIs will the user-defined node provide.
- How you will handle general development issues:

  – "Threading considerations for user-defined extensions" on page 2978
  – "Storage management in user-defined nodes" on page 2976

- "String handling in user-defined nodes" on page 2977
- "Errors and exception handling" on page 2973
- Expected message formats for primitive nodes that expect specific header folders.

When you design nodes to be used as extensions to WebSphere Event Broker, the following restrictions apply:

- User-defined input nodes can support only XML, BLOB, and the WebSphere MQ parsers, because the MRM parser is not shipped with WebSphere Event Broker and user-defined parsers are not supported.
- User-defined nodes must not allow users to evaluate user ESQL code, because the use of ESQL in WebSphere Event Broker is not supported. For example, nodes that expose the input to **`MbSQLStatement`** as a node attribute are effectively emulating a Compute node.

Related concepts:

"Parsers" on page 1072
A parser is a program that interprets the physical bit stream of an incoming message, and creates an internal logical representation of the message in a tree structure. The parser also regenerates a bit stream for an outgoing message from the internal message tree representation.

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

User-defined message processing nodes:

A user-defined message processing node is a node that you can create to complement the supplied built-in node types.

You might consider the use of a user-defined message processing node in the following situations:

- Your messages need transformations that the built-in nodes do not provide. For example, you might need a currency converter node.
- You want to reuse a subflow.
- You want to hide a message flow implementation by packaging it in a user-defined node.

Combine your user-defined nodes with the built-in nodes to create message flows that meet your exact business requirements.

C user-defined message processing nodes life cycle:

A user-defined message processing node for the C programming language goes through various stages.

This topic covers the objects that are created and destroyed, and the implementation functions and classes that are called in the following stages:

- Registration
- Instantiation
- Processing
- Destruction

The information in this topic applies to both output nodes and message processing nodes. Both of these node types can be considered together, because although a message processing node is typically used to process a message, and an output node is used to provide an output in the form of a bit stream, you can use either type of node to perform either of these functions.

Registration: A user-defined message processing node is registered with the broker when the LIL that contains the node has been loaded and initialized by the operating system.

The broker calls **bipGetMessageflowNodeFactory** to establish the function of the LIL, and how the LIL should be called.

The **bipGetMessageflowNodeFactory** function in turn calls the **cniCreateNodeFactory** function, which returns a factory or group name for all of the nodes that are supported by your LIL.

The LIL should then call the utility function **cniDefineNodeClass** to pass both the name of each node and a virtual function table of the function pointers of the implementation functions.

Instantiation: During the instantiation phase, an instance of a user-defined message processing node is created. The phase starts when the broker creates a message flow and calls the **cniCreateNodeContext** function for each instantiation of the user-defined node in that message flow. The **cniCreateNodeContext** function is that which is specified in the **iFpCreateNodeContext** field of the CNI_VFT struct passed to **cniDefineNodeClass** for that node type. This function should allocate the resources required for that node, including memory such that the instantiation of the user-defined node can hold the values for the configured attributes.

The broker will create a node instance and call **cniCreateNodeContext** on the following occasions:

- Message flow is created:
  - Broker is being started (user has run mqsistart). Any message flows previously deployed are re-created when the broker starts.
  - Execution group is being reloaded (user has run mqsireload). Any message flows that have been deployed previously are re-created when the execution group reloads.
  - A severe error has occurred within the execution group which results in the execution group being restarted.
- Message flow is redeployed. When a message flow is changed and redeployed, the broker processes redeploy by deleting all nodes in the flow and then re-creating them with the new configuration.

Note: A message flow is not created when starting an execution group. Stopping an execution group simply stops all flows and does not delete the flow or bring the process down. Restarting an execution group, starts the message flows but does not re-create the message flows.

Within **cniCreateContext**, the user-defined extension calls the two functions **cniCreateInputTerminal** and **cniCreateOutputTerminal** in order to establish what input and output terminals the message processing node has.

Processing: During the processing phase of the life cycle of a user-defined message processing node, the message is transformed in some way, when some processing operation takes place on the input message.

When the broker retrieves a message from the queue and that message arrives at the input terminal of your user-defined node, the broker calls the implementation function **cniEvaluate**. This function is used to decide what to do with the message.

You can use a range of node utility functions in your user-defined message processing node to perform a range of message processing functions, such as accessing the message data, accessing ESQL, transforming a message object, and

propagating a message. You should include the node utility functions you are going to use to process the message within the **cniEvaluate** function.

This interface does not automatically generate a properties subtree for a message. It is not a requirement for a message to have a properties subtree, although you might find it useful to create one to provide a consistent message tree structure regardless of input node. If you want a properties subtree to be created in a message, and you are also using a user-defined input node, you must do this yourself

Destruction: When a user-defined message processing node has processed a message, you should ensure that it is destroyed, to release any system resources that it used, and to release any data areas specific to the node instance, such as context, that were acquired when the message was constructed or processed.

An instance of a user-defined message processing node is destroyed when the broker calls the **cniDeleteNodeContext** function.

The broker calls **cniDeleteNodeContext** when the instance of the node is deleted. The following events can cause a node to be deleted:

- Controlled termination of the execution group process:
  - Broker is being stopped (user has run mqsistop)
  - Execution group is being reloaded (user has run mqsireload)
  - A severe error has occurred within the execution group, which results in the execution group being restarted.

  Note: This does NOT include stopping an execution group. Stopping an execution group simply stops all flows, and does not delete the flow or bring the process down.
- Message flow is deleted.
- Message flow is redeployed. When a message flow is changed and redeployed, the broker processes redeploy by deleting all nodes in the flow and then re-creating them with the new configuration.

Java user-defined message processing nodes life cycle:

During the lifecycle of the user-defined nodes that you create in Java, objects are created and destroyed, and different methods and classes called.

Every node goes through the following stages:

- Registration
- Instantiation
- Processing
- Destruction

The information here applies to both output nodes and message processing nodes. Both of these node types can be considered together, because although a message processing node is typically used to process a message, and an output node is used to provide an output, in the form of a bit stream, from a message, you can use both types of node to perform either of these functions.

Registration: The registration phase occurs when a user-defined message processing node that is written in Java contacts the broker, or registers with the broker.

Whenever a broker starts, it loads all relevant LIL files and Java classes. To ensure that a message processing node is registered with the broker, you must provide the broker with a class that implements the MbNodeInterface interface and is contained in the classpath used by the broker.

Instantiation: A Java user-defined message processing node is instantiated when a broker deploys a message flow that contains the user-defined message processing node. When the node is instantiated, the constructor of the message processing node class is called.

When a node is instantiated, all terminals that you have specified are created. A message processing node can have an unlimited number of input and output terminals associated with it. You must include the createInputTerminal and createOutputTerminal methods in your node constructor to declare these terminals.

Output terminals include out, failure, and catch terminals. Use the createOutputTerminal class within the node class constructor in order to create as many output terminals as you require.

As a minimum, you must create only these output terminals by using your constructor class. However, if you need to initialize attribute values, you must also include that code at this point in your message processing node.

If you want to handle exceptions that are passed back to your message processing node, it is good practice to do this by creating a failure terminal for your user-defined message processing node, by using the createOutputTerminal method. It is sensible to use the failure terminal for this process because that is the terminal to which errors are propagated.

Make sure that all exceptions that are caught by the message processing node are dealt with properly. If you do not include a failure terminal, the message processing node does not attempt to handle the exception. If your message flow does not contain a method of exception handling, all exceptions thrown are passed back to the input node, where the input node deals with the exceptions.

If you do catch exceptions, make sure that you rethrow all exceptions that the message processing node cannot deal with. This action causes the exception to be passed back to the input node for handling; for example, when you want to rollback a transaction.

Processing: During the processing phase of the life cycle of a user-defined message processing node, the message processing node takes the logical hierarchy of the message and processes it in some way.

Destruction: A Java user-defined message processing node is destroyed when the node is deleted, or the broker is shut down. You do not have to include anything in your code to specify that the node is physically deleted, because this process can be handled by the garbage collector.

However, if you want notification that a node is about to be deleted, you can use the onDelete method. You might want to receive notification if the node has resources that you want to delete, other than those that will be garbage collected. For example, if you have opened a socket, it is not properly closed when the node is automatically deleted. You can include this instruction in your onDelete method to ensure that the socket is closed properly.

Planning user-defined message processing nodes:

Plan how to write your message processing node or output node, and how to navigate the message within the node.

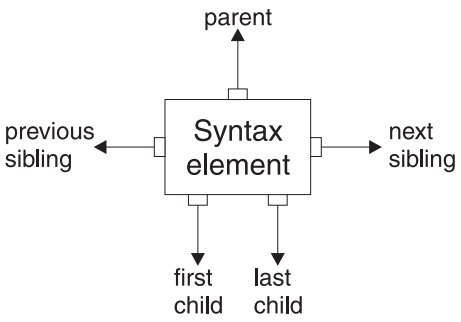
Design factors: Before developing and implementing your message processing node, consider the following points:

- Which parser will parse messages.
- Whether to override the default message parser attribute values for this message processing node.
- What is the appropriate threading model for the message processing node.
- How to implement the end of message processing and transaction support that the node must support.
- What configuration properties required by the message processing node must be externalized for alteration by the message flow designer.
- What optional node APIs will the user-defined node provide.
- General development issues:
  - "Threading considerations for user-defined extensions" on page 2978
  - "Storage management in user-defined nodes" on page 2976
  - "String handling in user-defined nodes" on page 2977
  - "Errors and exception handling" on page 2973
  - Expected message formats for built-in nodes that expect specific header folders, see "Element definitions for message parsers" on page 4237

Syntax element navigation: The broker provides functions that your node can call to traverse the tree representation of the message, as well as functions and methods that support navigation from the current element to other elements:

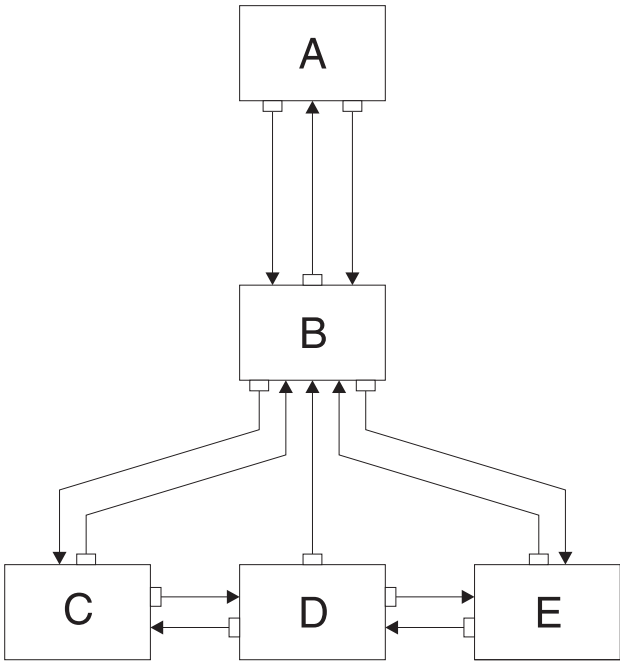
- Parent
- First child
- Last child
- Previous (or left) sibling
- Next (or right) sibling

These relationships are shown in the following diagram.



Other functions and methods support the manipulation of the elements themselves, with functions and methods to create elements, to set or query their values, to insert new elements into the tree, and to remove elements from the tree. See “C node utility functions” on page 6419 and “C parser utility functions” on page 6539, or the Javadoc information for more details.

The following diagram describes a simple syntax element tree that shows a full range of interconnections between the elements.

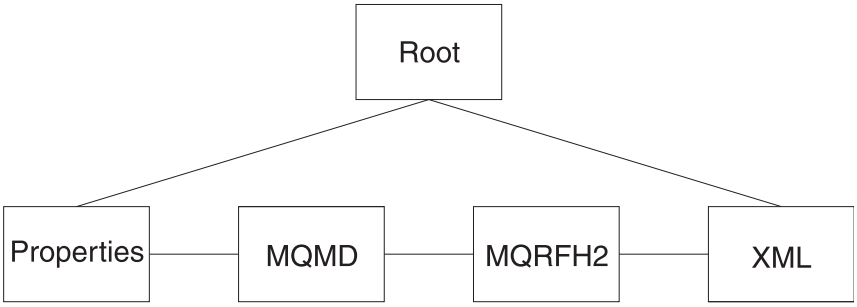


The element **A** is the root element of the tree. It has no parent because it is the root. It has a first child of element **B**. Because **A** has no other children, element **B** is also the last child of **A**.

Element **B** has three children: elements **C**, **D**, and **E**. Element **C** is the first child of **B**; element **E** is the last child of **B**.

Element **C** has two siblings: elements **D** and **E**. The next sibling of element **C** is element **D**. The next sibling of element **D** is element **E**. The previous sibling of element **E** is element **D**. The previous sibling of element **D** is element **C**.

The following diagram shows the first generation of syntax elements of a typical WebSphere MQ message received by a broker. (Not all messages have an MQRFH2 header.)



These elements at the first generation are often referred to as folders, in which syntax elements that represent message headers and message content data are stored. In this example, the first child of root is the Properties folder. The next sibling of Properties is the folder for the MQMD header. The next sibling is the folder for the MQRFH2 header. The last folder represents the message content, which (in this example) is an XML message.

The previous figure includes an MQMD and an MQRFH2 header. All messages that are received by a processing node that handles WebSphere MQ include an MQMD header; a number of other headers can also be included.

Navigating an XML message: Consider the following XML message:

```
<Business>
  <Product type='messaging'></Product>
  <Company>
    <Title>IBM</Title>
    <Location>Hursley</Location>
    <Department>WebSphere MQ</Department>
  </Company>
</Business>
```

In this example, the elements are of the following types:

Name element
Business, Product, Company, Title, Location, Department

Value element
IBM, Hursley, WebSphere MQ

Name-value element
type='messaging'

Use supplied node utility functions and methods (or the similar parser utility functions) to navigate through a message. Using the XML message shown, you must call cniRootElement first, with the message received by the node as input to this function. In Java, you must call getRootElement on the incoming MbMessage

object. This call returns an MbElement that represents the root of the element. Do not modify this root element in the user-defined node.

The figure of the first generation of the syntax elements of a typical message that is received by the broker, shows that the last child of the root element is the folder containing the XML parse tree. Navigate to this folder by calling cniLastChild (with the output of the previous call as input to this function) in a C node, or by calling the method getLastChild on the root element, in a Java node.

Only one element (`<Business>`) is at the top level of the message, therefore call cniFirstChild (in C) or getFirstChild (in Java) to move to this point in the tree. Use cniElementType or getType to get its type (which is `name`), followed by cniElementName or getName to return the name itself (`Business`).

The element `<Business>` has two children, `<Product>` and `<Company>`. Use cniFirstChild or getFirstChild followed by cniNextSibling or getNextSibling to navigate to each child in turn.

The element `<Product>` has an attribute (`type='messaging'`), which is a child element. Use cniFirstChild or getFirstChild to navigate to this element, and cniElementType or getType to return its type (which is `name-value`). Use cniElementName or getName to get the name. To get the value, call cniElementValueType to return the type, followed by the appropriate function in the cniElementValue group, in this example it is cniElementCharacterValue. In Java use the method getValue, which returns a Java object representing the element value.

The element `<Company>` has three children, each one having a child that is a value element (`IBM`, `Hursley`, and `WebSphere MQ`). Use the functions already described to navigate to them and access their values.

Other functions are available to copy the element tree (or part of it). The copy can then be modified by adding or removing elements, and changing their names and values, to create an output message. See “C node utility functions” on page 6419 and “C parser utility functions” on page 6539, or the Java user-defined node API, for more information.

Java user-defined extensions API

User-defined output nodes:

A user-defined output node is an extension to the broker that provides a new message flow output node in addition to the nodes supplied with the product.

If you want your message flow to send messages by using a protocol that is not supported by WebSphere Message Broker, you can create your own output node.

WebSphere Message Broker provides the following output nodes:

- MQOutput - delivers an output message from a message flow to a WebSphere MQ queue
- MQReply - sends a response to the originator of the input message.
- SCADAOutput - sends a message to a client connecting using the MQIsdp protocol
- Publication - filters output messages from a message flow and transmit them to subscribers who have registered an interest in a particular set of topics.
- JMSOutput - sends a message to a JMS destination
- EmailOutput - sends an email message to one or more recipients
- FileOutput - writes a message to a file

If the target application expects to receive message in any other way, you must use a user-defined output node.

User-defined output nodes can be considered together with user-defined message processing nodes. Conceptually, these two kinds of user-defined nodes are the same. Although a message processing node is typically used to process a message, and an output node is used to provide an output, in the form of a bit stream, from a message, you construct output nodes and message processing nodes in a similar way, and you can use either type of node to perform either function.

You can also create a user-defined output node from a subflow, see "Using a subflow as a user-defined node" on page 3008

For more information about user-defined output nodes, read the topics that cover user-defined message processing nodes, see "User-defined message processing nodes" on page 2996.

Java user-defined extensions API

Using a subflow as a user-defined node:

You can develop a user-defined node that packages a subflow from scratch, in the same way that you can create any other user-defined node that has its implementation based on Java, or base it on an existing subflow.

The project that contains user-defined nodes can be exported as a plug-in that is installed in the development environment of the user. The nodes that are packaged in the plug-in are displayed in the palette in the Message Flow editor, and can be used in a message flow in the same way as a built-in node.

Packaging a subflow as a user-defined node provides all the benefits of a subflow, such as reusability and maintainability, as well as the following benefits:

- The user-defined node can be distributed to other developers as a plug-in.

- The user-defined node hides the implementation details of the subflow from developers who reuse the subflow.
- The user-defined node prevents developers who reuse the subflow from modifying it.
- The subflow is displayed in the palette in the Message Flow editor.

Limitations

- All the flow resources (Maps, ESQL, XSL, or other external resources), except Java code and message sets, that are referenced in the subflow, must be located in the user-defined node project.
- A user-defined node can reference another user-defined node in the same or different user-defined node project, but it must not reference anything from a regular message flow project.
- The user-defined node project can have references to other projects, such as message set and Java projects.
- If the user-defined node references a message set, you must deploy the message set to the runtime separately. You can copy the message set to your workspace and deploy it through the broker archive (BAR) file.
- A subflow implementation of a user-defined node can contain other subflows, but all the subflows must be contained in the user-defined node project.
- Promoted properties from the nodes within the subflow are supported. Configurable promoted properties from nodes in the subflow are displayed as configurable node properties in the Broker Archive editor.
- User-defined properties (UDP) on the subflow are supported. If you create multiple instances of user-defined nodes in your flow, each type of user-defined property that you define must have the same value in each instance.
- You can use the same subflow more than once to construct a flow of your own.
- You can use the following node types that have named correlators to create a user-defined node, but you must not use more than one instance of the user-defined node within a flow, an execution group, or a broker. For example, you cannot use asynchronous request and asynchronous response nodes, aggregate nodes, TimeoutControl and TimeoutNotification pairs of nodes, or label nodes.

  If you do use one of these node types, the resultant message flow is invalid. If you deploy flows that contain asynchronous request, asynchronous response, or label nodes, you receive an error message. However, you do not receive an error message if you deploy flows that contain TimeoutControl, TimeoutNotification, or aggregate nodes.
- Resources in the plug-in space are visible to all projects in the workspace. Keep user-defined nodes and their associated flows, maps, ESQL, and other similar resources, in appropriately named broker schemas. Do not put such resources in a default schema, or schemas with special names, for example, `mqsi`.

Develop message flows that use a user-defined node.

User-defined parsers:

A user-defined parser is a program that interprets the bit stream of an incoming message and creates an internal representation of the message in a tree structure. A user-defined parser can also regenerate a bit stream for an outgoing message from the internal message tree representation

Create a user-defined parser when the WebSphere Message Broker parsers are not sufficient to parse user-defined messages.

Do not use user-defined parsers to provide connectivity or transformation functions. In most cases, the MRM or other IBM supplied parsers are capable of passing most standard type of format. You can also parse a message and construct a message tree in a user-defined node without the need to write a parser. For example, a user-defined node that reads emails from a POP3 server can parse the email and construct a message tree without the need to write a user-defined parser.

If the parser is going to be used only in a user-defined node, you do not need to use a user-defined parser. However, consider a user-defined parser if the parser will be called from other message flow nodes.

User-defined parser life cycle:

Various stages exist in the life of a user-defined message flow parser.

These stages are involved:
- Registration
- Instantiation
- Processing
- Destruction

This topic describes the interactions that take place between WebSphere Message Broker components when you run a user-defined parser. It explains each stage in terms of the events that start each stage, and the events that occur during and after each stage, and the APIs that are called. Understanding the concepts here help you to design and develop your parser more effectively.

Registration: The first phase in the user-defined parser's life cycle is the registration phase. The purpose of the registration phase is to register the user-defined parser with the broker. This phase starts when the execution group starts.

Instantiation: The parser is created during the instantiation phase of the parser life cycle. When an input message is received, or an output message is built in a Compute node, the relevant parser is identified, and parser requirements are taken from the message header, such as the MQMD. The broker starts and loads the Loadable Implementation Library (LIL) and the parser factory. Before the cpiCreateContext function is called, the broker creates a name element as the effective root element for the parser. However, this element is not named. The parser should name this element in the cpiSetElementName function. The execution group process creates an instance of the parser, and the broker makes a call to cpiCreateContext to allow the parser object to acquire the appropriate section of the message.

The broker then makes a call to cpiParseBuffer. cpiParseBuffer performs any necessary initialization, and returns the length of the message content that the parser is taking ownership of. The parser assesses how much of the message data to parse, and claims the appropriate number of bytes.

Whenever an instance of a user-defined parser object is created, the context creation implementation function cpiCreateContext is also invoked by the broker. This call allows the parser to allocate instance data associated with the parser. A cpiDeleteContext function to delete the context of the parser object is also required.

Processing: During the processing phase, the parser manipulates, alters, and references elements within the message object. The message flow processing phase begins when any message processing activity occurs, such as navigation, that requires access to an element within a message that does not exist in the broker's internal model representation of the message concerned.

During the message flow processing phase, the parser is invoked in response to attempts to navigate into the message tree. The parser examines the buffer that was allocated when cpiParseBuffer was called, and creates any necessary message elements.

The parser can then navigate through the message elements, using any or all of the following parser implementation functions:

- cpiParseFirstChild
- cpiParseLastChild
- cpiParsePreviousSibling
- cpiParseNextSibling

These functions are invoked when any form of navigation is made (such as a filter expression that specifies a message field) into the part of the syntax element tree that logically represents the data for a message format supported by a user-defined parser. This navigation occurs when an operation within the broker requires a syntax element tree to be built or extended.

Consider the following points when deciding how best to navigate the syntax element tree:

- A Syntax element has five pointers to its parents, siblings, and first and last children, so that a finite set of navigations is available.
- The same internal classes are used to perform all of these navigations.
- The parser does not control the navigation. The ESQL or a user-defined node makes the decision about the direction in which to navigate, and the order in which the navigational parser implementation functions are invoked. The user-defined parser has no control over the direction and order, and needs to respond correctly to the chosen navigation scheme; for example, parsing right to left, as well as left to right.
- When writing a user-defined parser, place the parser code in a parseNextItem function. This function should build the syntax element tree one element at a time, setting names, values and complete flags appropriately. How you implement this function depends on the nature of the bit stream to be parsed. The supplied sample parser demonstrates this behavior.

When the parser has finished parsing the relevant parts of the syntax element tree, it calls cpiWriteBuffer. This function appends its portion of the syntax element tree to the bit stream in the message buffer that is associated with the parser object, and creates the output message.

Destruction: The Destruction phase is the final phase in the user-defined parser life cycle. When the parser has written its portion of the syntax element tree to the bit stream and created the output message, the system resources that were created by the broker for the parser to use need to be released.

The destruction phase begins when the **mqsistop** command is used to stop the execution process.

Use the **mqsistop** command to stop the specified component.

Planning user-defined parsers:

Read about the concepts that you should consider before you develop a user-defined parser.

When you have considered the information provided here, and are ready to develop your own parser, use the instructions in "Implementing a user-defined parser" on page 3099 to construct your parser.

Analysis: Before you start to create your own parser, be clear about its purpose. You can perform most tasks using the functions that are provided with WebSphere Message Broker, so you might not need to create a user-defined parser for your particular task.

Before you construct and implement a user-defined parser, consider the following questions:

- Do you need to create a user-defined parser?

  If the available parsers in WebSphere Message Broker are not appropriate for your needs, define your own parser to parse internal, customer-specific, or generic commercial message formats.
- Does WebSphere Message Broker already provide a parser for the domain or message header?

  See "Parsers" on page 1072 for details of message domains for which the supplied parsers can accept input messages, and message headers with which the supplied parsers can work.
- Does the syntax of the in-house or commercial message dictate a format that can be parsed?
- To parse the message successfully, does the parser need to interact with vendor software? If so, does the API that enables access to this software break your threading model?
- Do you need to process multi-part, multi-format messages?

  WebSphere Message Broker does not support multi-part, multi-format messages. A multi-part MRM message must consist of messages that are all in the same format.
- What type of parsing strategy will provide best performance?

  WebSphere Message Broker supports partial parsing, which allows your parser to parse only relevant fields in a message. Using partial parsing can save system resources.

Partial and full parsing: WebSphere Message Broker supports *partial parsing*. If an individual message contains hundreds or even thousands of individual fields, the parsing operation requires considerable memory and processor resources to complete. An individual message flow might reference only a few of these fields, or none at all, so it is inefficient to parse every input message completely. For this reason, WebSphere Message Broker allows parsing of messages on an as-needed basis. (This ability does not prevent a parser from processing the entire message in one step, and some parsers are written to process the entire message in this way.)

Each syntax element in a logical message has two bits that indicate whether all the elements on either side of an element are complete, and whether its children are complete. Parsing is typically completed in a bottom-to-top, left-to-right manner. When a parser has parsed the siblings of a particular element that precede the given element and the first child, it sets the first completion bit to one. Similarly, when the pointer to the next sibling of an element is complete, as well as its last child pointer, the other completion bit is set to one.

In partial parsing, the broker waits until a part of the message is referenced, and invokes the parser to parse that part of the message. Message processing nodes refer to fields within a message using hierarchical names. The name begins at the root of the message and proceeds down the message tree until the particular element is located. If an element is encountered without its completion bits set, and further navigation from this element is required, the appropriate parser entry point is called to parse the necessary part of the message. The relevant part of the message is parsed, appropriate elements are added to the logical message tree, and the element in question is marked as complete.

If you do not need to parse the full bit stream, you can use partial parsing. During partial parsing, a parser is called recursively until the requested element is returned, or until the message tree has been marked as complete, and the requested element is known not to exist.

Whether you choose to perform a full or partial parse depends on how the message will be processed. If most field elements within the message are likely to be accessed during processing, performing a full parse of the message when an attempt is made to access it is typically more efficient, particularly for smaller messages.

However, if most field elements within the message are not likely to be accessed during processing, performing a partial parse of the message when an attempt is made to access a specific field is typically more efficient, particularly when the message size grows.

Related tasks:

Create a user-defined parser to interpret messages with a different format and structure.

Related reference:

"Parsing on demand" on page 4173
On-demand parsing, referred to as partial parsing, is used to parse an input message bit stream only as far as is necessary to satisfy the current reference. The parsers that can perform partial parsing of input messages are the JSON, MRM, XML, XMLNS, and XMLNSC parsers.

Specific types used by parsers:

Specific types are used when a parser needs additional information that is associated with some or all the elements in a tree in order to generate the bit stream.

For the XML parser, the specific type information is used to mark special elements such as components, processing instructions, and CDATA sections. The methods getSpecificType and setSpecificType are used by user-defined nodes to query this information and to generate message trees that use these special types.

Developers of user-defined parsers can generate their own specific type values to control special handling characteristics in their parser code using the existing C user-defined parser interface. The getSpecificType and setSpecificType methods enable Java user-defined nodes to fully use this parser capability.

"Getting and setting the specific type of an Mb element" on page 3073
Two methods are provided for handling the specific type of an Mb syntax element.

"Creating a user-defined extension in Java" on page 3054
You must complete a series of tasks to create user-defined nodes that use the Java language.

"Creating a user-defined extension in C" on page 3026
You must complete a series of tasks to create user-defined extensions that use the C language.

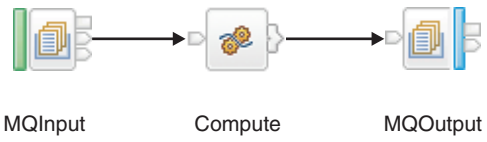
User exits:

A user exit is user-provided custom software, written in C, to track data passing through message flows.

User-provided functions can be invoked at specific points during the life cycle of a message while it passes through the message flow, and can invoke utility functions to query information about the point in the flow, and the contents of the message assembly. The utility function can also modify certain parts of the message assembly. For more information about using user exits, see "Why use a user exit?" on page 2984.

The user exits can be invoked when one or more of the following events occur:

- The end of a unit-of-work (UOW) or transaction (COMMIT or ROLLBACK).
- A message passes between two nodes.
- A message is successfully enqueued or sent to a transport in an output, reply, or request node.
- A message is dequeued or received in an input, response, or TimeoutNotification node.



In the basic message flow shown here, you can track messages at three levels:

- Transaction level
- Node level

- Input or output level

At the transaction level, you can track the following events:
- Messages being read into the flow
- Completion of the transaction

At the node level, you can track the following events:
- A message passing from one node to another
- Completion of processing for one node

At the message input or output level, you can track the following events:
- Messages being read into the flow
- Messages being written from the flow

Therefore, you can track five different types of event, which occur in the following sequence:

1. A message is dequeued from the input source (read into the flow).
2. A message is propagated to the node for processing.
3. A request message is sent to the output node's transport, and transport-specific destination information is written to "WrittenDestination" in the LocalEnvironment.
4. Node processing is completed.
5. The transaction ends.

Which language to use to implement a user-defined extension

You can use Java or C to implement a user-defined extension.

You can use C to implement all types of user-defined extension, but you can use Java to implement only user-defined nodes.

If you can, use Java for user-defined nodes, and use C for everything else.

You must compile user-defined nodes, parsers, and exits that are written in C into a loadable implementation library (LIL): that is, a shared library on Linux and UNIX systems, or a dynamic link library (DLL) on Windows systems. You must package user-defined nodes that are written in Java as a JAR file.

To achieve platform independence, use the ANSI standard C or Java programming languages, and avoid platform-specific code in your user-defined extension.

Related concepts:

Implementing the supplied user-defined extension samples

WebSphere Message Broker provides some sample code to help you understand how to write user-defined nodes and parsers.

About this task

You can see sample code for user-defined extensions in the following ways:

- By using the sample that is supplied in the WebSphere Message Broker Toolkit. To use the sample, see User-defined Extension.

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
- By using sample code that is installed with WebSphere Message Broker. To use the sample code, read the following information in this topic.

The sample code consists of a sample parser, and the following sample nodes:

Node	Description
Switch	A node, implemented in both C and Java versions, that propagates an input message to one of several output terminals depending on the message content.

Node	Description
Transform	A node, implemented in both C and Java versions, that performs a simple message transformation.

Each sample node consists of the source files and some files that you can use to test each node. For the sample parser there are only source files. See “Sample node files” on page 6412 and “Sample parser files” on page 6414 for details of the sample files and where to find them.

To implement the supplied samples from the sample code that is installed with WebSphere Message Broker:

1. Compile the samples. For information about how to compile a Java node, see “Compiling a Java user-defined node” on page 3074. For information about how to compile a C node or parser, see “Compiling a C user-defined extension” on page 3047.
2. Install the user-defined extension in a broker domain. For instructions on completing this step, see “Installing user-defined extension runtime files on a broker” on page 3125.
3. Copy and extract the `SampleNodesProject.zip` file by competing the following steps:
   a. From a computer that has WebSphere Message Broker installed, copy the `SampleNodesProject.zip` file to a computer with WebSphere Message Broker Toolkit installed. The `.zip` file is in the `sample` subdirectory. For example, on Windows, the `SampleNodesProject.zip` is in the *`install_dir`*`\sample\extensions\nodes\com.ibm.samples.nodes` directory, where *install_dir* is the home directory of your WebSphere Message Broker installation.
   b. On the computer that has WebSphere Message Broker Toolkit installed, extract the `SampleNodesProject.zip` file, and copy the extracted files to a directory from which the WebSphere Message Broker Toolkit can access them. For more information about where to copy the files, see “Installing a user-defined extension to current and past versions of WebSphere Message Broker” on page 3128.
4. Open the WebSphere Message Broker Toolkit and switch to the Broker Application Development perspective. The category called "Sample nodes" is now visible in the palette, and the sample nodes are shown below it. Documentation about the sample nodes is also visible in the help system under "Samples".
5. Include the sample nodes in a message flow (see “Adding a message flow node” on page 1494).
6. Deploy the message flow; see Chapter 11, “Packaging and deploying,” on page 3209.
7. For the Switch and Transform nodes, you can put a message to the input queue of the message flow and observe the results, as follows:
   a. Make sure that the message flow that contains the sample node is deployed successfully; see “Checking the results of deployment” on page 3243.
   b. Use the Enqueue message function to put the sample input messages (provided in `.xml` files) to the input queue named on the input node of the message flow; see “Debug: putting a test message on an input queue” on page 3162.

   You can also use a Trace node or the Flow debugger to see what is happening in your message flow.

Implementing user-defined extensions

Create the resources for your user-defined extension. You can write user-defined nodes in C or Java, or you can use a subflow to create a node. You can write user-defined parsers and exits only in C.

Before you begin

Before you start:

Read the following topics:

- "User-defined extensions overview" on page 2971
- "Which type of user-defined extension to use" on page 2988

About this task

To create a user-defined extension, follow the instructions in the appropriate topic:

- "Implementing a user-defined node" on page 3022
- "Implementing a user-defined parser" on page 3099
- "Implementing a user-defined exit" on page 3113

For user-defined nodes only, you must create a WebSphere Message Broker Toolkit Eclipse plug-in. For user-defined nodes created in Java and C, you must also create the run time `.lil` or `.jar` file. The WebSphere Message Broker Toolkit plug-in adds the user-defined node to the node palette in the Message Flow editor, so that you can include the new node in message flows. This additional task is described in "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079. This step is not required for user-defined parsers or exits.

The following table shows the tasks required for creating the different types of user-defined extension.

Action	Topics to view
To use one of the Java sample nodes	1. "Compiling a Java user-defined node" on page 3074 2. "Installing user-defined extension runtime files on a broker" on page 3125 3. Implementing a user-defined node

You can implement a user-defined node to extend the function of WebSphere Message Broker.

Before you begin

Before you start:

Read the following topics:

- "User-defined extensions overview" on page 2971
- "Why use a user-defined extension?" on page 2972
- "User-defined nodes" on page 2989
- "Which type of user-defined extension to use" on page 2988

About this task

Consider the following restrictions and factors when developing user-defined nodes:

- Interfacing a C user-defined node to Java and providing a JNI wrapper is not supported. This restriction exists because the broker internally initializes a JVM, which is unavailable through the user-defined extension interface. The JVM initializes with various parameters that are specific to the requirements of the broker. Because only one JVM exists in a process, whoever initializes it first specifies these parameters. If a user-defined node uses Java, and the broker is initialized first, these parameters might not be suitable for the user-defined node. If the user-defined node creates the JVM before the broker starts, the broker might not function correctly.
- User-defined input nodes can support only XML, BLOB, and the WebSphere MQ parsers.
- Avoid using functions that are specific to an operating system. If you code in this way, your user-defined extensions can work on various operating systems without requiring changes to the source code.

- Always put a user-defined node into a non-default schema because a user-defined node in a broker schema is known to other message flows by its schema qualified name. For example, if a user-defined node is named `ErrorHandler` and it is in broker schema `com.ibm.mb.toolkit`, it is referenced as `com.ibm.mb.toolkit.ErrorHandler`. If a second provider also has an error handler named `ErrorHandler` and it is in broker schema `com.xxx.product`, it is referenced as `com.xxx.product.ErrorHandler`. A user-defined node in a default schema is addressed by its name only. Therefore, if two different providers develop two unrelated error handlers and both are named `ErrorHandler` and both are placed in a default schema, when both user-defined nodes are in the plug-in space for a third user, the reference to `ErrorHandler` is ambiguous.
- If you want to use a subflow to create a user-defined node, read the limitations section in the following topic: "Using a subflow as a user-defined node" on page 3008.

To implement a user-defined node, complete the following tasks in the specified order:

Procedure

1. "Designing a user-defined node" on page 3024
2. "Creating a user-defined node" on page 3025
3. "Packaging and distributing user-defined extensions" on page 3117
4. "Testing a user-defined node" on page 3094

Designing a user-defined node:

Decide what type of node you need to implement the functions that are required by your application.

Before you begin

Before you start:

Read "Deciding which nodes to use" on page 1457 to understand the different types of node. You might need more than one node to implement all the functions that you require.

About this task

The functions that you require might not be satisfied by a template that already exists for several reasons:

- The functions that you require do not relate to interacting with external systems. Most of the node design pattern concentrates on communication with external systems, which is the most likely requirement for a user-defined node.
- The functions that are required are not well suited to the WebSphere Message Broker architecture, so you should implement them in an end application, or an application server.
- The functions require complex control and state information, which you should not implement as a plug-in.

Creating a user-defined node:

You can write user-defined nodes in C, Java, or from a subflow.

Before you begin

Before you start:

Read "Designing a user-defined node" on page 3024.

About this task

When you have created a user-defined node, you can test it, as described in "Testing a user-defined node" on page 3094. If you want to test or use user-defined nodes or parsers on multiple computers, follow the instructions given in "Packaging and distributing user-defined extensions" on page 3117.

Decide whether you want to create a user-defined node in C, Java, or from a subflow, then follow the instructions in the appropriate topic.

- "Creating a user-defined extension in C" on page 3026
- "Creating a user-defined extension in Java" on page 3054
- "Creating a user-defined node from a subflow" on page 3076
- "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079

The following table shows the tasks that are involved in creating the different types of user-defined node. For more information about using user-defined nodes, see the following sample: User-defined Extension.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Creating an input node in C:

Create a user-defined input node in C to receive messages into a message flow.

Before you begin

Before you start

Read the following topics:

- "Why use a user-defined extension?" on page 2972
- "User-defined input nodes" on page 2990

About this task

A loadable implementation library, or *LIL*, is the implementation module for a C node. A LIL is implemented as a shared or dynamic link library (DLL), but has the file extension `.lil` not `.dll`.

The implementation functions that you write for the node are listed in "C node implementation functions" on page 6417. You can call utility functions, implemented in the runtime broker, to help with the node operation; these functions are listed in "C node utility functions" on page 6419.

WebSphere Message Broker provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them.

To create an input node in C:

1. "Declaring and defining the node"
2. "Creating an instance of the node" on page 3029
3. "Setting attributes" on page 3030
4. "Implementing the node functionality" on page 3031
5. "Overriding the default message parser attributes (optional)" on page 3031
6. "Deleting an instance of the node" on page 3032

Declaring and defining the node:
About this task

To declare and define a user-defined node to the broker, include an initialization function, bipGetMessageflowNodeFactory, in your LIL. The following steps outline how the broker calls your initialization function, and how your initialization function declares and defines the user-defined node:

Procedure

1. The initialization function, bipGetMessageflowNodeFactory, is called by the broker after the operating system has loaded and initialized the LIL. The broker calls this function to understand what your LIL can do and how the broker can call the LIL. For example:

   ```
   CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
   bipGetMessageflowNodeFactory()
   ```

2. The bipGetMessageflowNodeFactory function must call the utility function cniCreateNodeFactory. This function passes back a unique factory name (or group name) for all the nodes that your LIL supports. Every factory name (or group name) that is passed back must be unique throughout all the LILs in a single runtime broker.
3. The LIL must call the utility function cniDefineNodeClass to pass the unique name of each node, and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single node called InputxNode:

   ```
   {
    CciFactory* factoryObject;
    int rc = 0;
    CciChar factoryName[] = L"MyNodeFactory";
    CCI_EXCEPTION_ST exception_st;

    /* Create the Node Factory for this node */
    factoryObject = cniCreateNodeFactory(0, factoryName);
    if (factoryObject == CCI_NULL_ADDR) {

     /* Any local error handling can go here */
    }
    else {
     /* Define the nodes supported by this factory */
     static CNI_VFT vftable = {CNI_VFT_DEFAULT};

    /* Setup function table with pointers to node implementation functions */
    vftable.iFpCreateNodeContext = _createNodeContext;
    vftable.iFpDeleteNodeContext = _deleteNodeContext;
    vftable.iFpGetAttributeName2 = _getAttributeName2;
    vftable.iFpSetAttribute      = _setAttribute;
    vftable.iFpGetAttribute2     = _getAttribute2;
    vftable.iFpRun               = _run;
   ```

```
 cniDefineNodeClass(0, factoryObject, L"InputxNode", &vftable);
 }

 /* Return address of this factory object to the broker */
 return(factoryObject);
}
```

A user-defined node identifies itself as providing the features of an input node by implementing the cniRun implementation function.

User-defined nodes have to implement either a cniRun or a cniEvaluate implementation function. If they do not, the broker does not load the user-defined node, and the cniDefineNodeClass utility function fails, returning CCI_MISSING_IMPL_FUNCTION.

For example:

```
int cniRun(
  CciContext* context,
  CciMessage* localEnvironment,
  CciMessage* exceptionList,
  CciMessage* message
){
  ...
  /* Get data from external source */
  return CCI_SUCCESS_CONTINUE;
}
```

Use the return value periodically to return control to the broker.

When a message flow that contains a user-defined input node is deployed successfully, the cniRun function of the node is called repeatedly to enable the node to retrieve messages and propagate them to the rest of the message flow. For the minimum code required to compile a C user-defined node, see the "C skeleton code" on page 6683.

Creating an instance of the node:
About this task

To instantiate your node:

Procedure

1. When the broker has received the table of function pointers, it calls the function cniCreateNodeContext for each instantiation of the user-defined node. For example, if three message flows are using your user-defined node, your cniCreateNodeContext function is called for each of them. This function must allocate memory for that instantiation of the user-defined node to hold the values for the configured attributes. For example:
   a. Call the cniCreateNodeContext function:

```
CciContext* _createNodeContext(
  CciFactory* factoryObject,
  CciChar*    nodeName,
  CciNode*    nodeObject
){
  static char* functionName = (char *)"_createNodeContext()";
  NODE_CONTEXT_ST* p;
  CciChar          buffer[256];
```

   b. Allocate a pointer to the local context and clear the context area:

```
  p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));

  if (p) {
     memset(p, 0, sizeof(NODE_CONTEXT_ST));
```

   c. Save the node object pointer in the context:

```
p->nodeObject = nodeObject;
```

d. Save the node name:

```
CciCharNCpy((CciChar*)&p->nodeName, nodeName, MAX_NODE_NAME_LEN);
```

e. Return the node context:

```
return (CciContext*) p;
```

2. An input node has a number of output terminals associated with it, but typically does not have any input terminals. Use the utility function cniCreateOutputTerminal to add output terminals to an input node when the node is instantiated. These functions must be invoked within the cniCreateNodeContext implementation function. For example, to define an input node with three output terminals:

```
{
   const CciChar* ucsOut = CciString("out", BIP_DEF_COMP_CCSID) ;
   insOutputTerminalListEntry(p, (CciChar*)ucsOut);
   free((void *)ucsOut) ;
 }
 {
   const CciChar* ucsFailure = CciString("failure", BIP_DEF_COMP_CCSID) ;
   insOutputTerminalListEntry(p, (CciChar*)ucsFailure);
   free((void *)ucsFailure) ;
 }
 {
   const CciChar* ucsCatch = CciString("catch", BIP_DEF_COMP_CCSID) ;
   insOutputTerminalListEntry(p, (CciChar*)ucsCatch);
   free((void *)ucsCatch) ;    }
```

For the minimum code required to compile a C user-defined node, see "C skeleton code" on page 6683.

Setting attributes:

About this task

Attributes are set whenever you start the broker, or when you redeploy the message flow with new values.

Following the creation of output terminals, the broker calls the cniSetAttribute function to pass the values for the configured attributes of the user-defined node. For example:

```
{
  const CciChar* ucsAttr = CciString("nodeTraceSetting", BIP_DEF_COMP_CCSID) ;
  insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_INTEGER);
  _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constZero);
  free((void *)ucsAttr) ;
}
{
  const CciChar* ucsAttr = CciString("nodeTraceOutfile", BIP_DEF_COMP_CCSID) ;
  insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_STRING);
  _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constSwitchTraceLocation);
  free((void *)ucsAttr) ;
}
```

The number of configuration attributes that a node can have is unlimited. However, a user-defined node must not implement an attribute that is already implemented as a base configuration attribute. The base attributes are:

- label
- userTraceLevel
- traceLevel
- userTraceFilter

- traceFilter

Implementing the node functionality:
About this task

When the broker knows that it has an input node, it calls the cniRun function of this node at regular intervals. The cniRun function must then decide what course of action it must take. If data is available for processing, the cniRun function can propagate the message. If no data is available for processing, the cniRun function must return with CCI_TIMEOUT so that the broker can continue configuration changes.

For example, to configure the node to call cniDispatchThread and process the message, or return with CCI_TIMEOUT:

```
If ( anything to do )
 CniDispatchThread;

   /* do the work */

 If ( work done O.K.)
  Return CCI_SUCCESS_CONTINUE;
 Else
  Return CCI_FAILURE_CONTINUE;
Else
  Return CCI_TIMEOUT;
```

Overriding the default message parser attributes (optional):
About this task

An input node implementation typically determines what message parser initially parses an input message. For example, the MQInput node dictates that an MQMD parser is required to parse the MQMD header. A user-defined input node can select an appropriate header or message parser, and the mode in which the parsing is controlled, by using or overriding the following attributes that are included as default:

rootParserClassName
Defines the name of the root parser that parses message formats that are supported by the user-defined input node. It defaults to `GenericRoot`, a supplied root parser that causes the broker to allocate and chain parsers together. It is unlikely that a node would need to modify this attribute value.

firstParserClassName
Defines the name of the first parser, in what might be a chain of parsers that are responsible for parsing the bit stream. It defaults to `XML`.

messageDomainProperty
An optional attribute that defines the name of the message parser that is required to parse the input message. The supported values are the same as the values that are supported by the MQInput node. (See "MQInput node" on page 4594 for more information.)

messageSetProperty
An optional attribute that defines the message set identifier, or the message set name, in the `Message Set` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageTypeProperty
An optional attribute that defines the identifier of the message in the `MessageType` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageFormatProperty
An optional attribute that defines the format of the message in the `MessageFormat` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

If you have written a user-defined input node that always begins with data of a known structure, you can ensure that a specific parser handles the start of the data. For example, the MQInput node reads data only from WebSphere MQ queues, therefore this data always has an MQMD at the beginning, and the MQInput node sets firstParserClassName to MQHMD. If your user-defined node always handles data that begins with a structure that can be parsed by a specific parser, for example "MYPARSER", set firstParserClassName to MYPARSER in the following way::

1. Declare the implementation functions:

```
CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix bipGetMessageflowNodeFactory()
{
  ....
  CciFactory*      factoryObject;
  ....
  factoryObject = cniCreateNodeFactory(0, (unsigned short *)constPluginNodeFactory);
  ...
  vftable.iFpCreateNodeContext = _createNodeContext;
  vftable.iFpSetAttribute      = _setAttribute;
  vftable.iFpGetAttribute      = _getAttribute;
  ...
  cniDefineNodeClass(&rc, factoryObject, (CciChar*)constSwitchNode, &vftable);
  ...
  return(factoryObject);
}
```

2. Set the attribute in the cniCreateNodeContext implementation function:

```
CciContext* _createNodeContext(
  CciFactory* factoryObject,
  CciChar*    nodeName,
  CciNode*    nodeObject
){
  NODE_CONTEXT_ST* p;
  ...

    /* Allocate a pointer to the local context */
    p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));
    /* Create attributes and set default values */
    {
      const CciChar* ucsAttrName  = CciString("firstParserClassName", BIP_DEF_COMP_CCSID);
      const CciChar* ucsAttrValue = CciString("MYPARSER", BIP_DEF_COMP_CCSID) ;
      insAttrTblEntry(p, (CciChar*)ucsAttrName, CNI_TYPE_INTEGER);
      /*see sample BipSampPluginNode.c for implementation of insAttrTblEntry*/

      _setAttribute(p, (CciChar*)ucsAttrName, (CciChar*)ucsAttrValue);
      free((void *)ucsAttrName) ;
      free((void *)ucsAttrValue) ;
    }
```

In the code example above, the insAttrTblEntry method is called. This method is declared in the SwitchNode and TransformNode sample user-defined nodes.

Deleting an instance of the node:

About this task

Nodes are destroyed when a message flow is redeployed, or when the execution group process is stopped (using the **mqsistop** command). When a node is destroyed, you must call the cniDeleteNodeContext function to free all used memory and release all held resources. For example:

```
void _deleteNodeContext(
  CciContext* context
){
  static char* functionName = (char *)"_deleteNodeContext()";

  return;
}
```

Extending the capability of a C input node:

When you have created a user-defined node, you can extend its capability.

Before you begin

Before you start

Read "Creating an input node in C" on page 3027.

About this task

After you have created a user-defined node, the following options are available:

1. "Receiving external data into a buffer"
2. "Controlling threading and transactions"
3. "Propagating the message" on page 3035

Receiving external data into a buffer:
About this task

An input node can receive data from any type of external source, such as a file system or FTP connection, provided that the output from the node is in the correct format. For connections to queues or databases, use the built-in nodes and the API calls supplied, principally because the built-in nodes are already set up for error handling. Do not use the MQGET or MQPUT calls for direct access to WebSphere MQ queues.

You must provide an input buffer (or bit stream) to contain input data, and associate it with a message object. In the C API, the buffer is attached to the CciMessage object that represents the input message by using the cniSetInputBuffer utility function. For example:

```
{
  static char* functionName = (char *)"_Input_run()";
  void*        buffer;
  CciTerminal* terminalObject;
  int          buflen = 4096;
  int          rc = CCI_SUCCESS;
  int          rcDispatch = CCI_SUCCESS;

  buffer = readFromDevice(&buflen);
  cniSetInputBuffer(&rc, message, buffer, buflen);
}
/*propagate etc*/
```

Controlling threading and transactions:
About this task

An input node must perform appropriate end-of-message processing when a message has been propagated through a message flow. Specifically, the input node needs to cause any transactions to be committed or rolled back, and return threads to the thread pool.

Each message flow thread is allocated from a pool of threads that is maintained for each message flow, and starts execution in the cniRun function. You determine the behavior of a thread using the cniDispatchThread utility function, together with the appropriate return value.

From the cniRun function, you can call the cniDispatchThread utility function to cause another thread to start executing the cniRun function. The most appropriate time to execute another thread is directly after you have established that data could be available for the function to process on the new thread.

The term *transaction* is used generically to describe either a globally coordinated transaction, or a broker-controlled transaction. Globally coordinated transactions are coordinated by either WebSphere MQ as an XA-compliant Transaction Manager, or Resource Recovery Service (RRS) on z/OS. WebSphere Message Broker controls transactions by committing (or rolling back) any database resources, and then committing any WebSphere MQ units of work. However, if a user-defined node is used, the broker cannot automatically commit any resource updates. The user-defined node uses return values to indicate whether a transaction has been successful, and to control whether transactions are committed or rolled-back. The broker infrastructure catches any unhandled exceptions, and rolls back the transaction.

The following table describes each of the supported return values, the effect that each one has on any transactions, and what the broker does with the current thread.

Return value	Affect on transaction	Broker action on the thread
CCI_SUCCESS_CONTINUE	Committed	Calls the same thread again in the cniRun function.
CCI_SUCCESS_RETURN	Committed	Returns the thread to the thread pool.
CCI_FAILURE_CONTINUE	Rolled back	Calls the same thread again in the cniRun function.
CCI_FAILURE_RETURN	Rolled back	Returns the thread to the thread pool.
CCI_TIMEOUT	Not applicable. The function periodically times out while it is waiting for an input message.	Calls the same thread again in the cniRun function.

The following code is an example of using the SUCCESS_RETURN return code with the cniDispatchThread function:

```
{
  ...
  cniDispatchThread(&rcDispatch, ((NODE_CONTEXT_ST *)context)->nodeObject);
  ...
  if (rcDispatch == CCI_NO_THREADS_AVAILABLE) return CCI_SUCCESS_CONTINUE;
  else return CCI_SUCCESS_RETURN;
}
```

Propagating the message:
About this task

Before you propagate a message, decide what message flow data you want to propagate, and which terminal is to receive the data.

The terminalObject is derived from a list that the user-defined node maintains.

For example, to propagate the message to the output terminal, use the cniPropagate function:

```
if (terminalObject) {
  if (cniIsTerminalAttached(&rc, terminalObject)) {
    if (rc == CCI_SUCCESS) {
      cniPropagate(&rc, terminalObject, localEnvironment, exceptionList, message);
    }
  }
```

In the above example, the cniIsTerminalAttached function is used to test whether the message can be propagated to the specified terminal. If you do not use the cniIsTerminalAttached function, and the terminal is not attached to another node by a connector, the message is not propagated and no warning message is returned. Use the cniIsTerminalAttached function to prevent this error occurring.

Creating a message processing or output node in C:

A message processing node is used to process a message in some way, and an output node is used to produce a message as a bit stream.

Before you begin

Before you start

Read the following topics:

- "Why use a user-defined extension?" on page 2972
- "User-defined message processing nodes" on page 2996
- "User-defined output nodes" on page 3006

About this task

When you code a message processing node or an output node, the nodes provide essentially the same services. You can perform message processing in an output node, and you can send a message to a bit stream by using a message processing node. For simplicity, this topic refers mainly to the node as a message processing node but it does also contain information about the functions of both types of node.

A loadable implementation library (LIL), is the implementation module for a C node. A LIL is implemented as a shared or dynamic link library (DLL), but has the file extension `.lil` not `.dll`.

For more information about the C node implementation functions that you write for the node, see "C node implementation functions" on page 6417. You can call C node utility functions, implemented in the runtime broker, to help with the node operation; see "C node utility functions" on page 6419.

WebSphere Message Broker provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them. In addition, you can view the following sample which demonstrates the use of user-defined nodes, including a message processing node written in C.

- User-defined Extension

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create either type of node complete the following tasks:

1. "Declaring and defining your node"
2. "Creating an instance of the node" on page 3039
3. "Setting attributes" on page 3041
4. "Implementing the node functionality" on page 3041
5. "Deleting an instance of the node" on page 3042

Declaring and defining your node:
About this task

To declare and define a user-defined node to the broker, include an initialization function, bipGetMessageflowNodeFactory, in your LIL. The following steps take place on the configuration thread and outline how the broker calls your initialization function and how your initialization function declares and defines the user-defined node:

Procedure

1. The broker calls the initialization function bipGetMessageflowNodeFactory after the operating system has loaded and initialized the LIL. The broker calls this function to understand what your LIL can do and how the broker can call the LIL. For example:

   ```
   CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
   bipGetMessageflowNodeFactory()
   ```

2. The bipGetMessageflowNodeFactory function must call the utility function cniCreateNodeFactory. This function passes back a factory name (or group name) for all the nodes that your LIL supports. The factory name (or group name) must be unique throughout all the LILs in a single runtime broker.

3. The LIL must call the utility function cniDefineNodeClass to pass the unique name of each node and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single node called MessageProcessingxNode:

   ```
   {
    CciFactory* factoryObject;
    int rc = 0;
    CciChar factoryName[] = L"MyNodeFactory";
    CCI_EXCEPTION_ST exception_st;

    /* Create the Node Factory for this node */
    factoryObject = cniCreateNodeFactory(0, factoryName);
    if (factoryObject == CCI_NULL_ADDR) {
     /* Any local error handling can go here */
    }
    else {
     /* Define the nodes supported by this factory */
    static CNI_VFT vftable = {CNI_VFT_DEFAULT};

    /* Setup function table with pointers to node implementation functions */
    vftable.iFpCreateNodeContext = _createNodeContext;
    vftable.iFpDeleteNodeContext = _deleteNodeContext;
    vftable.iFpGetAttributeName2 = _getAttributeName2;
    vftable.iFpSetAttribute      = _setAttribute;
    vftable.iFpGetAttribute2     = _getAttribute2;
    vftable.iFpEvaluate          = _evaluate;

    cniDefineNodeClass(0, factoryObject, L"MessageProcessingxNode", &vftable);

    }

    /* Return address of this factory object to the broker */
    return(factoryObject);
   }
   ```

   A user-defined node identifies itself as a message processing or output node by implementing the cniEvaluate function. User-defined nodes must implement either a cniEvaluate or a cniRun implementation function, otherwise the broker does not load the user-defined node, and the cniDefineNodeClass utility function fails, returning CCI_MISSING_IMPL_FUNCTION.

   When a message flow containing a user-defined message processing node is deployed successfully, the node's cniEvaluate function is called for each message propagated to the node.

   Message flow data is received at the input terminal of the node, that is, the message, Environment, LocalEnvironment, and ExceptionList.

   For example:

```
void cniEvaluate(
  CciContext* context,
  CciMessage* localEnvironment,
  CciMessage* exceptionList,
  CciMessage* message
){
  ...
}
```

For the minimum code required to compile a C user-defined node, see "C skeleton code" on page 6683.

Creating an instance of the node:
About this task

To instantiate your node:

Procedure

1. When the broker has received the table of function pointers, it calls the function cniCreateNodeContext for each instantiation of the user-defined node. For example, if three message flows are using your user-defined node, your cniCreateNodeContext function is called for each of them. This function allocates memory for that instantiation of the user-defined node to hold the values for the configured attributes. For example:
   a. The user function cniCreateNodeContext is called:
   ```
   CciContext* _Switch_createNodeContext(
     CciFactory* factoryObject,
     CciChar*    nodeName,
     CciNode*    nodeObject
   ){
     static char* functionName = (char *)"_Switch_createNodeContext()";
     NODE_CONTEXT_ST* p;
     CciChar          buffer[256];
   ```
   b. Allocate a pointer to the local context and clear the context area:
   ```
     p = (NODE_CONTEXT_ST *)malloc(sizeof(NODE_CONTEXT_ST));

     if (p) {
        memset(p, 0, sizeof(NODE_CONTEXT_ST));
   ```
   c. Save the node object pointer in the context:
   ```
      p->nodeObject = nodeObject;
   ```
   d. Save the node name:
   ```
    CciCharNCpy((CciChar*)&p->nodeName, nodeName, MAX_NODE_NAME_LEN);
   ```
   e. Return the node context:
   ```
   return (CciContext*) p;
   ```
2. The broker calls the appropriate utility functions to find out about the node's input terminals and output terminals. A node has a number of input terminals and output terminals associated with it. Within the user function cniCreateNodeContext, calls must be made to cniCreateInputTerminal and cniCreateOutputTerminal to define the user node's terminals. These functions must be started within the cniCreateNodeContext implementation function. For example, to define a node with one input terminal and two output terminals:
   ```
   {
     const CciChar* ucsIn = CciString("in", BIP_DEF_COMP_CCSID) ;
     insInputTerminalListEntry(p, (CciChar*)ucsIn);
     free((void *)ucsIn) ;
   }
   {
   ```

```
    const CciChar* ucsOut = CciString("out", BIP_DEF_COMP_CCSID) ;
    insOutputTerminalListEntry(p, (CciChar*)ucsOut);
    free((void *)ucsOut) ;
  }
  {
    const CciChar* ucsFailure = CciString("failure", BIP_DEF_COMP_CCSID) ;
    insOutputTerminalListEntry(p, (CciChar*)ucsFailure);
    free((void *)ucsFailure) ;
  }
```

The previous code starts the insInputTerminalListEntry and insOutputTerminalListEntry functions. You can find these functions in the sample code `Common.c`; see "Sample node files" on page 6412. These functions define the terminals to the broker and store handles to the terminals. Handles are stored in the structure referenced by the value returned in CciContext*. The node can then access the terminal handles from within the other implementation functions (for example CciEvaluate) because CciContext is passed to those implementation functions.

The following code shows the definition of insInputTerminalListEntry:

```
TERMINAL_LIST_ENTRY *insInputTerminalListEntry(
  NODE_CONTEXT_ST* context,
  CciChar*         terminalName
){
  static char* functionName = (char *)"insInputTerminalListEntry()";
  TERMINAL_LIST_ENTRY* entry;
  int                  rc;

  entry = (TERMINAL_LIST_ENTRY *)malloc(sizeof(TERMINAL_LIST_ENTRY));
  if (entry) {

    /* This entry is the current end of the list */
    entry->next = 0;

    /* Store the terminal name */
    CciCharCpy(entry->name, terminalName);

    /* Create terminal and save its handle */
    entry->handle = cniCreateInputTerminal(&rc, context->nodeObject, (CciChar*)terminalName);

    /* Link an existing previous element to this one */
    if (context->inputTerminalListPrevious) context->inputTerminalListPrevious->next = entry;
    else if ((context->inputTerminalListHead) == 0) context->inputTerminalListHead = entry;

    /* Save the pointer to the previous element */
    context->inputTerminalListPrevious = entry;
  }
  else {
    /* Error: Unable to allocate memory */
  }

  return(entry);
}
```

The following example shows the code for insOutputTerminalListEntry:

```
TERMINAL_LIST_ENTRY *insOutputTerminalListEntry(
  NODE_CONTEXT_ST* context,
  CciChar*         terminalName
){
  static char* functionName = (char *)"insOutputTerminalListEntry()";
  TERMINAL_LIST_ENTRY* entry;
  int                  rc;

  entry = (TERMINAL_LIST_ENTRY *)malloc(sizeof(TERMINAL_LIST_ENTRY));
  if (entry) {
```

```
    /* This entry is the current end of the list */
    entry->next = 0;

    /* Store the terminal name */
    CciCharCpy(entry->name, terminalName);

    /* Create terminal and save its handle */
    entry->handle = cniCreateOutputTerminal(&rc, context->nodeObject, (CciChar*)terminalName);

    /* Link an existing previous element to this one */
    if (context->outputTerminalListPrevious) context->outputTerminalListPrevious->next = entry;
    else if ((context->outputTerminalListHead) == 0) context->outputTerminalListHead = entry;

    /* Save the pointer to the previous element */
    context->outputTerminalListPrevious = entry;
  }
  else {
    /* Error: Unable to allocate memory */
  }

  return(entry);
}
```

For the minimum code required to compile a C user-defined node, see "C skeleton code" on page 6683.

Setting attributes:
About this task

Attributes are set whenever you start the broker, or when you redeploy a message flow with new values. Attributes are set by the broker calling user code on the configuration thread. Your code needs to store these attributes in its node context area, for later use when processing messages.

Following the creation of input and output terminals, the broker calls the cniSetAttribute function to pass the values for the configured attributes for this instantiation of the user-defined node. For example:

```
{
  const CciChar* ucsAttr = CciString("nodeTraceSetting", BIP_DEF_COMP_CCSID) ;
  insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_INTEGER);
  _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constZero);
  free((void *)ucsAttr) ;
}
{
  const CciChar* ucsAttr = CciString("nodeTraceOutfile", BIP_DEF_COMP_CCSID) ;
  insAttrTblEntry(p, (CciChar*)ucsAttr, CNI_TYPE_STRING);
  _setAttribute(p, (CciChar*)ucsAttr, (CciChar*)constSwitchTraceLocation);
  free((void *)ucsAttr) ;
}
```

The number of configuration attributes that a node can have is unlimited. However, a node must not implement an attribute that is already implemented as a base configuration attribute. The following list shows base attributes:

- label
- userTraceLevel
- traceLevel
- userTraceFilter
- traceFilter

Implementing the node functionality:

About this task

When the broker retrieves a message from the queue, and that message arrives at the input terminal of your user-defined message processing or output node, the broker calls the implementation function cniEvaluate. This function is called on the message processing thread and it must decide what to do with the message. This function might be called on multiple threads, especially if additional instances are used.

Deleting an instance of the node:
About this task

If a node is deleted, the broker calls the cniDeleteNodeContext function. This function is started on the same thread as cniCreateNodeContext. Use this function to release resources used by your user-defined node. For example:

```
void _deleteNodeContext(
  CciContext* context
){
  static char* functionName = (char *)"_deleteNodeContext()";
  free ((void*) context);
  return;
}
```

"Sample node files" on page 6412
Several sample node files are provided on all platforms.

Extending the capability of a C message processing or output node:

When you have created a user-defined message processing or output node in C, you can extend its capability.

Before you begin

Before you start

Read the topic "Creating a message processing or output node in C" on page 3036.

About this task

After you have created a user-defined node, the following options are available:

1. "Accessing message data"
2. "Transforming a message object" on page 3044
3. "Accessing ESQL" on page 3045
4. "Propagating a message" on page 3045
5. "Writing to an output device" on page 3046

Accessing message data:

About this task

In many cases, the user-defined node must access the contents of the message that is received on its input terminal. The message is represented as a tree of syntax elements. Groups of utility functions are provided for message management, message buffer access, syntax element navigation, and syntax element access. (See "C node utility functions" on page 6419 for details of the utility functions.)

The types of query that you are likely to want to perform include:

- Obtaining the root element of the required message object
- Accessing the bit stream representation of an element tree
- Navigating or querying the tree by asking for child or sibling elements by name
- Getting the type of the element
- Getting the value of the element

For example, to query the name and type of the first child of body:

```
void cniEvaluate( ...
){
  ...
/* Navigate to the target element */
  rootElement = cniRootElement(&rc, message);
  bodyElement = cniLastChild(&rc, rootElement);
  bodyFirstChild = cniFirstChild(&rc, bodyElement);

/* Query the name and value of the target element */
  cniElementName(&rc, bodyFirstChild, (CciChar*)&elementname, sizeof(elementName));
  bytes = cniElementCharacterValue(
  &rc, bodyfirstChild, (CciChar*)&eValue, sizeof(eValue));
  ...
}
```

To access the bit stream representation of an element tree you can use the cniElementAsBitstream function. Using this function, you can obtain the bit stream representation of any element in a message. See "cniElementAsBitstream" on page 6458 for details of how to use this function, and sample code.

Transforming a message object:
About this task

The received input message is read-only, therefore before a message can be transformed, you must write it to a new output message using the cniCreateMessage function. You can copy elements from the input message, or you can create new elements and attach them to the message. New elements are typically in a parser's domain.

For example:

1. To write the incoming message to a new message:

   ```
   {
     ...
     context = cniGetMessageContext(&rc, message));
     outMsg = cniCreateMessage(&rc, context));
     ...
   }
   ```

2. To make a copy of the new message:

   ```
   cniCopyElementTree(&rc, sourceElement, targetElement);
   ```

3. To modify the value of a target element:

```
cniSetElementIntegerValue(&rc, targetElement, L"newValue", 8);
```

4. After finalizing and propagating the message, you must delete the output message using the cniDeleteMessage function:

```
cniDeleteMessage(&rc, outMsg);
```

As part of the transformation, you might want to create a new message body. To create a new message body, use one of the following functions, which assign a parser to a message tree folder:

```
cniCreateElementAsFirstChildUsingParser
cniCreateElementAsLastChildUsingParser
cniCreateElementAfterUsingParser
cniCreateElementBeforeUsingParser
```

When creating a message body, do not use the following functions because they do not associate an owning parser with the folder:

```
cniCreateElementAsFirstChild
cniCreateElementAsLastChild
cniCreateElementAfter
cniCreateElementBefore
```

Accessing ESQL:
About this task

Nodes can invoke ESQL expressions using Compute node ESQL syntax. You can create and modify the components of the message using ESQL expressions, and you can refer to elements of both the input message and data from an external database using the cniSqlCreateStatement, cniSqlSelect, cniSqlDeleteStatement, and cniSqlExecute functions.

For example, to populate the Result element from the contents of a column in a database table:

```
{
  ...
  sqlExpr = cniSqlCreateStatement(&rc,
   (NODE_CONTEXT_ST *)context->nodeObject,
   L"DB", CCI_SQL_TRANSACTION_AUTO,
   L"SET OutputRoot.XMLNS.Result[] = (SELECT T.C1 AS Col1 FROM Database.TABLE AS T;");
  ...
  cniSqlSelect(&rc, sqlExpr, localEnvironment, exceptionList, message, outMsg);
  cniSqlDeleteStatement(&rc, sqlExpr);
  ...
}
```

For more information about ESQL, see “ESQL overview” on page 2371.

If your user-defined node primarily uses ESQL, consider using a “Compute node” on page 4340.

Propagating a message:
About this task

Before you propagate a message, decide what message flow data you want to propagate, and which terminal is to receive the data.

1. If the message has changed, finalize the message before you propagate it using the cniFinalize function. For example:

```
cniFinalize(&rc, outMsg, CCI_FINALIZE_NONE);
```

2. The terminalObject is derived from a list that the user-defined node maintains itself. To propagate the message to the output terminal, use the cniPropagate function:

```
if (terminalObject) {
  if (cniIsTerminalAttached(&rc, terminalObject)) {
    if (rc == CCI_SUCCESS) {
      cniPropagate(&rc, terminalObject, localEnvironment, exceptionList, outMsg);
    }
  }
```

   In the above example, the cniIsTerminalAttached function is used to test whether the message can be propagated to the specified terminal. If you do not use the cniIsTerminalAttached function and the terminal is not attached to another node by a connector, the message is not propagated and no warning message is returned. Use the cniIsTerminalAttached function to prevent this error occurring.

3. If you created a new output message using cniCreateMessage, after propagating the message, delete the output message using the cniDeleteMessage function:

```
cniDeleteMessage(&rc, outMsg);
```

Writing to an output device:
About this task

A transformed message must be serialized to a bit stream; a message can be serialized only once.

The bit stream can then be accessed and written to an output device. Write the message to a bit stream using the cniWriteBuffer function. For example:

```
{
  ...
  cniWriteBuffer(&rc, message);
  writeToDevice(cniBufferPointer(&rc, message), cniBufferSize(&rc, message));
  ...
}
```

In this example, the method writeToDevice is a user-written method which writes a bit stream to an output device.

Do not write a user-defined output node to write messages to WebSphere MQ queues; use the supplied MQOutput node in this scenario. The broker internally maintains a WebSphere MQ connection and open queue handles on a thread-by-thread basis, and these are cached to optimize performance. In addition, the broker handles recovery scenarios when certain WebSphere MQ events occur; this recovery would be adversely affected if WebSphere MQ MQI calls are used in a user-defined output node.

Compiling a C user-defined extension:

Compile user-defined extensions in C for all supported operating systems.

Before you begin

Before you start:

If you create your own user-defined nodes, parsers, and user exits in C, compile them on the operating system on which the target broker is running. Samples are provided for both nodes and parsers, and are described in "Sample node files" on page 6412 and "Sample parser files" on page 6414. Use the instructions here to compile the samples. If you want to create your own extensions, see the following topics:

- "Creating a user-defined extension in C" on page 3026
- "Implementing a user-defined parser" on page 3099
- "Implementing a user-defined exit" on page 3113

About this task

These instructions use the file names of the supplied samples. If you are compiling your own user-defined extensions, substitute your own file names.

When you compile a user-defined extension that is written in C, you need a compatible compiler. For details of supported compilers, see "Optional software support" on page 3603.

Header files:
About this task

The following header files define the C interfaces:

BipCni.h
: Message processing nodes

BipCpi.h
Message parsers

BipCci.h
Interfaces common to both nodes and parsers

BipCos.h
Platform-specific definitions

Compiling:
About this task

Compile the source for your user-defined extension on each of the supported operating systems to create the executable file that the broker calls to implement your user-defined extension. On Linux, UNIX, and z/OS systems, this file is a loadable implementation library (LIL) file; on Windows systems, it is a dynamic load library (DLL) file.

The libraries that you build to contain user-defined nodes or parsers must have the extension `.lil` on all operating systems so that the broker can load them. Libraries that contain user exits must have the extension `.lel` on all operating systems. The examples in this topic show libraries with the extension `.lil`

Refer to the documentation for the compiler that you are using for full details of available compile and link options that might be required for your programs.

Navigate to the directory where your user-defined extension source code is located, and follow the instructions for your operating system:
- AIX
- HP-Itanium
- Linux
- Solaris
- Windows
- z/OS

Compiling on AIX:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension for a 64-bit execution group; 32-bit execution groups are not supported.

```
xlc_r -q64 \
   -I. \
   -I/install_dir/include/plugin \
   -c SwitchNode.c \
   -o SwitchNode.o

xlc_r -q64 \
   -I. \
   -I/install_dir/include/plugin \

   -L install_dir/jre16/lib/IA64N\
   -L install_dir/jre16/lib/IA64N/server \
   -l imbdfplg

chmod a+r output_dir/SwitchNode.lil
```

Compiling on Linux:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

When you compile programs on Linux on POWER, replace the option `-fpic` with `-fPIC` if you want to use dynamic linking and avoid any limit on the size of the global offset table.

The following instructions are for compiling an extension for a 64-bit execution group on Linux on x86-64, Linux on POWER, and Linux on IBM z Systems. 32-bit execution groups are not supported on those platforms. To compile the extension for a 32-bit execution group on Linux on x86, replace `-m64` with `-m32` in the compile and link examples.

```
g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   TransformNode.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   SwitchNode.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   BipSampPluginUtil.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   Common.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
```

```
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   NodeFactory.c

g++ -m64 -O2 -o samples.lil \
   TransformNode.o \
   SwitchNode.o \
   BipSampPluginUtil.o \
   Common.o NodeFactory.o \
   -shared -lc -lnsl -ldl \
   -L/install_dir/lib -limbdfplg
```

These commands create the file `samples.lil` that provides TransformNode and SwitchNode objects.

Compiling on Solaris:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension for a 64-bit execution group on Solaris on SPARC; 32-bit execution groups are not supported. To compile the extension for a default 64-bit execution group on Solaris on x86-64, replace `-xarch=v9` with `-xarch=amd64` in the compile examples; 32-bit execution groups are not supported.

```
cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c SwitchNode.c \
   -o output_dir/SwitchNode.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c TransformNode.c \
   -o output_dir/TransformNode.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c BipSampPluginUtil.c \
   -o output_dir/BipSampPluginUtil.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c NodeFactory.c \
   -o output_dir/NodeFactory.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c Common.c \
   -o output_dir/Common.o

cc -xarch=v9  -xcode=pic32 -mt -G \
```

```
   -o output_dir/SwitchNode.lil \
      output_dir/SwitchNode.o \
      output_dir/BipSampPluginUtil.o \
      output_dir/NodeFactory.o \
      output_dir/Common.o \
   -L /install_dir/lib \
   -l imbdfplg

chmod a+r output_dir/SwitchNode.lil
```

Compiling on Windows:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Ensure that you include a space between `SwitchNode.c` and `BipSampPluginUtil.c`, and also between `-link` and `/DLL`.

Enter the command as a single line of input; in the following example the lines are split to improve readability.

```
cl /VERBOSE /LD /MD /Zi /EHsc /I.
   /Iinstall_dir\include\plugin
   SwitchNode.c BipSampPluginUtil.c Common.c
   NodeFactory.c TransformNode.c
   -link /DLL install_dir\lib\imbdfplg.lib
   /OUT:SwitchNode.lil
```

If you have correctly set the *LIB* environment variable, you do not have to specify the full paths to the LIB files.

Compiling on z/OS:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Force your link to use prelinker or linker by setting the `_CC_STEPS` variable to `-1`:

```
export _CC_STEPS=-1
```

Alternatively, add these two lines to your makefile to export it:

```
_CC_STEPS=-1
.EXPORT : _CC_STEPS
```

To create optimized builds, use **-2** in place of **-g** in the following commands:

```
cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./SwitchNode.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./SwitchNode.o ./SwitchNode.c

cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./TransformNode.lst\) \
 -I. -I${install_dir}/include \
```

```
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./SwitchNode.o ./TransformNode.c

cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./BipSampPluginUtil.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./BipSampPluginUtil.o ./BipSampPluginUtil.c

cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./Common.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./Common.o ./Common.c

cc -c \
  -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./NodeFactory.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./NodeFactory.o ./NodeFactory.c

cc \
 -Wl,DLL,LP64 -g -Wl,p,map -Wl,LIST=ALL,MAP,XREF,REUS=RENT \
 -Wl,xplink \
 -o ./SwitchNode.lil ./SwitchNode.o ./BipSampPluginUtil.o \
 ./Common.o ./NodeFactory.o \
 ${install_dir}/lib/libimbdfplg.x
```

Run the following command to set the file permissions of the user-defined extension to `group read` and to be executable:

```
chmod a+rx {output_dir}/SwitchNode.lil
```

Creating a user-defined extension in Java:

You must complete a series of tasks to create user-defined nodes that use the Java language.

About this task

Complete the appropriate tasks from the following list:

- "Creating an input node in Java" on page 3055
- "Creating a message processing or output node in Java" on page 3062
- "Compiling a Java user-defined node" on page 3074
- "Packaging a Java user-defined node" on page 3118

You can write only user-defined nodes in Java: you must write user-defined parsers in C.

What to do next

When you have completed this set of tasks, continue with the following tasks:

- "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079
- "Testing a user-defined node" on page 3094
- "Packaging and distributing user-defined extensions" on page 3117

Related concepts:

Java user-defined extensions API

Creating an input node in Java:

An input node is used to receive a message into a message flow, typically from a source that is not supported by the built-in input nodes.

Before you begin

Before you start

Read the following topics:

- "Why use a user-defined extension?" on page 2972
- "User-defined input nodes" on page 2990

About this task

To create an input node in the Java language:

1. "Creating a Java project" on page 3056
2. "Declaring the input node class" on page 3056
3. "Defining the node constructor" on page 3057
4. "Receiving external data into a buffer" on page 3057

5. "Propagating the message" on page 3058
6. "Controlling threading and transactionality" on page 3058
7. "Declaring the node name" on page 3059
8. "Declaring attributes" on page 3060
9. "Implementing the node functionality" on page 3060
10. "Overriding default message parser attributes (optional)" on page 3060
11. "Deleting an instance of the node" on page 3061

A Java user-defined node is distributed as a `.jar` file.

Creating a Java project:
About this task

Before you can create Java nodes in the WebSphere Message Broker Toolkit, you must create a Java project:

Procedure

1. Click **File** > **New** > **Project**, select **Java Project** then click **Next**.
2. Give the project a name, then click **Next**.
3. On the Java Settings pane, select the **Libraries** tab, and click **Add External JARs**.
4. Select *install_dir*`\classes\jplugin2.jar`, where *install_dir* is the home directory of your WebSphere Message Broker installation.
5. Follow the prompts on the other tabs to define any other build settings.
6. Click **Finish**.

What to do next

You can now develop the source for your Java node in this project.

Declaring the input node class:
About this task

Every class that implements MbInputNodeInterface and is contained in the broker LIL path is registered with the broker as an input node. When you implement MbInputNodeInterface, you must also implement a run method for this class. The run method represents the start of the message flow, contains the data that formulates the message, and propagates it down the flow. The broker calls the run method when threads become available in accordance with your specified threading model.

The class name must end with the word "Node". For example, if the name is BasicInput in the WebSphere Message Broker Toolkit, the class name must be BasicInputNode.

For example, to declare the input node class:

```
package com.ibm.jplugins;

import com.ibm.broker.plugin.*;

public class BasicInputNode extends MbInputNode implements MbInputNodeInterface
{
...
```

Follow these steps to complete this action in the WebSphere Message Broker Toolkit:

Procedure

1. Click **File** > **New** > **Class**.
2. Set the package and class name fields to appropriate values.
3. Delete the text in the **Superclass** text field and click the **Browse** button.
4. Select **MbInputNode**.
5. Click the **Add** button next to Interfaces text field, and select **MbInputNodeInterface**.
6. Click **Finish**.

Defining the node constructor:
About this task

When the node is instantiated, the constructor of the node class is called. This class is where you create the terminals of the node, and initialize the default values for the attributes.

An input node has a number of output terminals associated with it, but does not typically have any input terminals. Use the createOutputTerminal method to add output terminals to a node when the node is instantiated. For example, to create a node with three output terminals:

```
public BasicInputNode() throws MbException
{
 createOutputTerminal ("out");
 createOutputTerminal ("failure");
 createOutputTerminal ("catch");
 setAttribute ("firstParserClassName","myParser");
 attributeVariable  = "none";
}
```

Receiving external data into a buffer:
About this task

An input node can receive data from any type of external source, such as a file system, a queue, or a database, in the same way as all other Java programs, if the output from the node is in the correct format.

Provide an input buffer (or bit stream) to contain input data, and associate it with a message object. Create a message from a byte array by using the createMessage method of the **MbInputNode** class, and then generate a valid message assembly from this message. For example, to read the input data from a file:

Procedure

1. Create an input stream to read from the file:
   ```
   FileInputStream inputStream = new FileInputStream("myfile.msg");
   ```
2. Create a byte array the size of the input file:
   ```
   byte[] buffer = new byte[inputStream.available()];
   ```
3. Read from the file into the byte array:
   ```
   inputStream.read(buffer);
   ```
4. Close the input stream:
   ```
   inputStream.close();
   ```
5. Create a message to put on the queue:

```
MbMessage msg = createMessage(buffer);
```

6. Create a message assembly to hold this message:

```
msg.finalizeMessage(MbMessage.FINALIZE_VALIDATE);
MbMessageAssembly newAssembly =
     new MbMessageAssembly(assembly, msg);
```

Propagating the message:
About this task

After creating a message assembly, you can propagate it to one of the output terminals that are defined on the node.

For example, to propagate the message assembly to the terminal named **out**:

```
MbOutputTerminal out = getOutputTerminal("out");
out.propagate(newAssembly);
```

To delete the message:

```
msg.clearMessage();
```

To clear the memory that is allocated for the message tree, call the clearMessage() function within the finally block of `try/catch`.

Controlling threading and transactionality:
About this task

The broker infrastructure handles transaction issues such as controlling the commit of a WebSphere MQ or database unit of work when message processing has completed. However, resources modified from within a user-defined node are not necessarily under the transactional control of the broker.

Each message flow thread is allocated from a pool of threads maintained for each message flow, and starts in the run method.

The user-defined node uses return values to indicate whether a transaction is successful, to control whether transactions are committed or rolled back, and to control when the thread is returned to the pool. The broker infrastructure catches all unhandled exceptions, and rolls back the transaction.

You determine the behavior of transactions and threads by using the appropriate return value:

MbInputNode.SUCCESS_CONTINUE
The transaction is committed and the broker calls the run method again by using the same thread.

MbInputNode.SUCCESS_RETURN
The transaction is committed and the thread is returned to the thread pool, assuming that it is not the only thread for this message flow.

MbInputNode.FAILURE_CONTINUE
The transaction is rolled back and the broker calls the run method again by using the same thread.

MbInputNode.FAILURE_RETURN
The transaction is rolled back and the thread is returned to the thread pool, assuming that it is not the only thread for this message flow.

MbInputNode.TIMEOUT
The run method must not block indefinitely while waiting for input data to arrive. While the flow is blocked by user code, you cannot shut down or reconfigure the broker. The run method must yield control to the broker periodically by returning from the run method. If input data is not received after a certain period (for example, 5 seconds), the method must return with the TIMEOUT return code. Assuming that the broker does not need to reconfigure or shut down, the run method of the input node gets called again immediately.

To create multithreaded message flows, you call the dispatchThread method after a message is created, but before the message is propagated to an output terminal. This action ensures that only one thread is waiting for data while other threads are processing the message. New threads are obtained from the thread pool up to the maximum limit specified by the `Additional Instances` property of the message flow. For example:

```
public int run( MbMessageAssembly assembly ) throws MbException
{
  byte[] data = getDataWithTimeout();  // user supplied method
                                       // returns null if timeout
  if( data == null )
    return TIMEOUT;

  MbMessage msg = createMessage( data );
  msg.finalizeMessage( MbMessage.FINALIZE_VALIDATE );
  MbMessageAssembly newAssembly =
       new MbMessageAssembly( assembly, msg );

  dispatchThread();

  getOutputTerminal( "out" ).propagate( newAssembly );

  return SUCCESS_RETURN;
}
```

Declaring the node name:
About this task

You must declare the name of the node for use and identification by the WebSphere Message Broker Toolkit. All node names must end with the characters "Node". Declare the name by using the following method:

```
public static String getNodeName()
{
   return "BasicInputNode";
}
```

If this method is not declared, the Java API framework creates a default node name by using the following rules:

- The class name is appended to the package name.
- The periods are removed, and the first letter of each part of the package and class name is capitalized.

For example, by default, the following class is assigned the node name "ComIbmPluginsamplesBasicInputNode":

```
package com.ibm.pluginsamples;
public class BasicInputNode extends MbInputNode implements MbInputNodeInterface
{
   ...
```

Declaring attributes:
About this task

Declare node attributes by using the same method that you use for Java bean properties. You are responsible for writing get and set methods for the attributes; the API framework infers the attribute names by using the Java bean introspection rules. For example, if you declare the following two methods:

```
private String attributeVariable;

public String getFirstAttribute()
{
  return attributeVariable;
}

public void setFirstAttribute(String value)
{
  attributeVariable = value;
}
```

The broker infers that this node has an attribute called firstAttribute. This name is derived from the names of the get or set methods, not from the variable names of any internal class members. Attributes can be exposed only as strings, so convert numeric types to and from strings in the get or set methods. For example, the following method defines an attribute called timeInSeconds:

```
int seconds;

public String getTimeInSeconds()
{
  return Integer.toString(seconds);
}

public void setTimeInSeconds(String value)
{
  seconds = Integer.parseInt(value);
}
```

Implementing the node functionality:
About this task

As already described, the run method is called by the broker to create the input message. This method must provide all the processing function for the input node.

Overriding default message parser attributes (optional):
About this task

An input node implementation normally determines which message parser initially parses an input message. For example, the built-in MQInput node dictates that an MQMD parser is required to parse the MQMD header. A user-defined input node can select an appropriate header or message parser, and the mode in which the parsing is controlled, by using the following default attributes that are included, which you can override:

rootParserClassName
Defines the name of the root parser that parses message formats supported by the user-defined input node. It defaults to `GenericRoot`, a supplied root parser that causes the broker to allocate and chain parsers together. It is unlikely that a node would have to modify this attribute value.

firstParserClassName
Defines the name of the first parser, in what might be a chain of parsers that are responsible for parsing the bit stream. It defaults to `XML`.

messageDomainProperty
An optional attribute that defines the name of the message parser required to parse the input message. The supported values are the same as the values that are supported by the MQInput node.

messageSetProperty
An optional attribute that defines the message set identifier, or the message set name, in the `Message Set` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageTypeProperty
An optional attribute that defines the identifier of the message in the `MessageType` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

messageFormatProperty
An optional attribute that defines the format of the message in the `Message Format` field, only if the MRM parser was specified by the `messageDomainProperty` attribute.

Deleting an instance of the node:
About this task

An instance of the node is deleted when either:

- You shut down the broker.
- You remove the node or the message flow that contains the node, and redeploy the configuration.

When the node is deleted, it can perform cleanup operations, such as closing sockets, if it implements the optional onDelete method. This method, if present, is called by the broker just before the node is deleted.

Implement the onDelete method as follows:

```
public void onDelete()
{
  // perform node cleanup if necessary
}
```

Java user-defined extensions API

Creating a message processing or output node in Java:

A message processing node is used to process a message, and an output node is used to output a message as a bit stream.

Before you begin

Before you start

Read the following topics:

- "Why use a user-defined extension?" on page 2972
- "User-defined message processing nodes" on page 2996
- "User-defined output nodes" on page 3006
- "Restrictions when creating Java nodes" on page 3055

About this task

WebSphere Message Broker provides the source for two sample user-defined nodes called SwitchNode and TransformNode. You can use these nodes in their current state, or you can modify them.

When you code a message processing node or an output node, the two types provide essentially the same functions. You can perform message processing within an output node, and likewise you can propagate an output message to a bit stream from a message processing node. For simplicity, this topic refers mainly to the node as a message processing node, but it does discuss the functionality of both types of node.

Complete the following steps:

1. "Creating a new Java project" on page 3063
2. "Declaring the message processing node class" on page 3063
3. "Defining the node constructor" on page 3064

4. “Accessing message data” on page 3064
5. “Transforming a message object” on page 3064
6. “Propagating the message” on page 3066
7. “Declaring the node name” on page 3066
8. “Declaring attributes” on page 3067
9. “Implementing the node functionality” on page 3067
10. “Deleting an instance of the node” on page 3068

A Java user-defined node is distributed as a `.jar` file.

Creating a new Java project:
About this task

Before you can create Java nodes in the WebSphere Message Broker Toolkit, you must create a new Java project:

1. Click **File** > **New** > **Project**. Select **Java** and click **Next**.
2. In the **Project name** field, enter a project a name, then click **Next**.
3. On the Java Settings pane, select the **Libraries** tab, and click **Add External JARs**.
4. Select install_dir\classes\jplugin2.jar.
5. Follow the prompts on the other tabs to define any other build settings.
6. Click **Finish**.

You can now develop the source for your Java node within this project.

Declaring the message processing node class:
About this task

Any class that implements MbNodeInterface, and is contained in the broker's LIL path, is registered with the broker as a message processing node. When you implement MbNodeInterface, you must also implement an evaluate method for this class. The evaluate method is called by the broker for each message that passes through the flow.

The class name must end with the word "Node". For example, if you have assigned the name as Basic in the WebSphere Message Broker Toolkit, the class name must be BasicNode.

For example, to declare the message processing node class:

```
package com.ibm.jplugins;

import com.ibm.broker.plugin.*;

public class BasicNode extends MbNode implements MbNodeInterface
```

Declare the class in the WebSphere Message Broker Toolkit:

1. Click **File** > **New** > **Class**.
2. Set the package and class name fields to appropriate values.
3. Delete the text in the Superclass text field and click **Browse**.
4. Select **MbNode** and click **OK**.
5. Click the **Add** button next to Interfaces text field, and select **MbNodeInterface**.
6. Click **Finish**.

Defining the node constructor:
About this task

When the node is instantiated, the constructor of the user's node class is called. Create the terminals of the node, and initialize any default values for attributes in this constructor.

A message processing node has a number of input terminals and output terminals that are associated with it. Use the methods createInputTerminal and createOutputTerminal to add terminals to a node when the node is instantiated.

For example, to create a node with one input terminal and two output terminals:

```
public MyNode() throws MbException
{
  // create terminals here
  createInputTerminal ("in");
  createOutputTerminal ("out");
  createOutputTerminal ("failure");
}
```

Accessing message data:
About this task

In many cases, the user-defined node needs to access the contents of the message received on its input terminal. The message is represented as a tree of syntax elements. Use the supplied utility function to evaluate methods for message management, message buffer access, syntax element navigation, and syntax element access.

The MbElement class provides the interface to the syntax elements.

For example:

Procedure

1. To navigate to the relevant syntax element in the XML message:

```
MbElement rootElement = assembly.getMessage().getRootElement();
MbElement switchElement =
rootElement.getLastChild().getFirstChild().getFirstChild();
```

2. To select the terminal indicated by the value of this element:

```
String terminalName;
String elementValue = (String)switchElement.getValue();
if(elementValue.equals("add"))
  terminalName = "add";
else if(elementValue.equals("change"))
  terminalName = "change";
else if(elementValue.equals("delete"))
  terminalName = "delete";
else if(elementValue.equals("hold"))
  terminalName = "hold";
else
  terminalName = "failure";

MbOutputTerminal out = getOutputTerminal(terminalName);
```

Results

Transforming a message object:

About this task

The received input message is read-only, so before you can transform a message, you must write it to a new output message. You can copy elements from the input message, or you can create new elements in the output message.

The MbMessage class provides the copy constructors, and the methods to get the root element of the message. The MbElement class provides the interface to the syntax elements.

For example, if you have an incoming message assembly with embedded messages, you could have the following code in the evaluate method of your user-defined node:

1. To create a new copy of the message assembly and its embedded messages:

```
MbMessage newMsg = new MbMessage(assembly.getMessage());
MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);
```

2. To navigate to the relevant syntax element in the XML message:

```
MbElement rootElement = newAssembly.getMessage().getRootElement();
MbElement switchElement =
rootElement.getFirstElementByPath("/XML/data/action");
```

3. To change the value of an existing element:

```
String elementValue = (String)switchElement.getValue();
  if(elementValue.equals("add"))
    switchElement.setValue("change");
  else if(elementValue.equals("change"))
    switchElement.setValue("delete");
  else if(elementValue.equals("delete"))
    switchElement.setValue("hold");
  else
    switchElement.setValue("failure");
```

4. To add a new tag as a child of the switch tag:

```
MbElement tag = switchElement.createElementAsLastChild(MbElement.TYPE_NAME,
                                                        "PreviousValue",
                                                        elementValue);
```

5. To add an attribute to this new tag:

```
tag.createElementAsFirstChild(MbElement.TYPE_NAME_VALUE,
                               "NewValue",
                               switchElement.getValue());

MbOutputTerminal out = getOutputTerminal("out");
```

As part of the transformation, you might need to create a new message body. To create a new message body, use one of the following methods, which specifically assigns a parser to a message tree folder:

```
createElementAfter(String)
createElementAsFirstChild(String)
createElementAsLastChild(String)
createElementBefore(String)
createElementAsLastChildFromBitstream(byte[], String, String, String, String, int, int, int)
```

Do not use the following methods, which do not associate an owning parser with the folder:

```
createElementAfter(int)
createElementAfter(int, String, Object)
createElementAsFirstChild(int)
createElementAsFirstChild(int, String, Object)
```

```
createElementAsLastChild(int)
createElementAsLastChild(int, String, Object)
createElementBefore(int)
createElementBefore(int, String, Object)
```

Propagating the message:
About this task

Before you propagate a message, decide what message flow data you want to propagate, and whether to propagate to a node terminal, or to a Label node.

For example:

1. To propagate the message to the output terminal "out":
   ```
   MbOutputTerminal out = getOutputTerminal("out");
          out.propagate(newAssembly);
   ```
2. To propagate the message to a Label node:
   ```
   MbRoute label1 = getRoute ("label1");
   Label1.propagate(newAssembly);
   ```

Call the clearMessage() function within the finally block of try/catch to clear the memory that is allocated for the message tree.

To propagate the same MbMessage object multiple times, call the finalizeMessage() method on the MBMessage object, so that any changes made to the message are reflected in the bit stream that is generated downstream of the Java node; for example:

```
MbMessage newMsg = new MbMessage(assembly.getMessage());
MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(newAssembly;
...
newMsg.finalizeMessage(MbMessage.FINALIZE_NONE);
out.propagate(newAssembly);
```

Declaring the node name:
About this task

The name of the node must be the same as the one that is used in the WebSphere Message Broker Toolkit. All node names must end with "Node". Declare the name using the following method:

```
public static String getNodeName()
{
   return "BasicNode";
}
```

If this method is not declared, the Java API framework creates a default node name using the following rules:

- The class name is appended to the package name.
- The dots are removed, and the first letter of each part of the package and class name are capitalized.

For example, by default, the following class is assigned the node name "ComIbmPluginsamplesBasicNode":

```
package com.ibm.pluginsamples;
public class BasicNode extends MbNode implements MbNodeInterface
{
   ...
```

Declaring attributes:
About this task

Declare node attributes in the same way as Java Bean properties. You must write getter and setter methods for the attributes. The API framework infers the attribute names using the Java Bean introspection rules. For example, if you declare the following two methods:

```
private String attributeVariable;

public String getFirstAttribute()
{
  return attributeVariable;
}

public void setFirstAttribute(String value)
{
  attributeVariable = value;
}
```

the broker infers that this node has an attribute called firstAttribute. This name is derived from the names of the get or set methods, not from any internal class member variable names. Attributes can only be exposed as strings, therefore, you must convert any numeric types to and from strings in the get or set methods. For example, the following method defines an attribute called timeInSeconds:

```
int seconds;

public String getTimeInSeconds()
{
  return Integer.toString(seconds);
}

public void setTimeInSeconds(String value)
{
  seconds = Integer.parseInt(value);
}
```

Implementing the node functionality:
About this task

The evaluate method, defined in MbNodeInterface, is called by the broker to process the message. All the processing function for the node is included in this method.

The evaluate method has two parameters that are passed in by the broker:

1. The MbMessageAssembly, which contains the following objects that are accessed using the appropriate methods:
   - The incoming message
   - The LocalEnvironment
   - The global Environment
   - The ExceptionList
2. The input terminal on which the message has arrived.

For example, the following code extract shows how you might write the evaluate method:

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    // add message processing code here

    getOutputTerminal("out").propagate(assembly);
  }
```

The message flow data, which consists of the message, Environment, LocalEnvironment, and ExceptionList, is received at the input terminal of the node.

Deleting an instance of the node:
About this task

An instance of the node is deleted when either:

- You shut down the broker.
- You remove the node or the message flow that contains the node, and redeploy the configuration.

If you want the node to perform any cleanup operations, for example closing sockets, include an implementation of the onDelete method:

```
public void onDelete()
{
  // perform node cleanup if necessary
}
```

This method is called by the broker immediately before it deletes the node.

Related information:

Java user-defined extensions API

Extending the capability of a Java message processing or output node:

Within a message processing or output node, you can add extended functions to your Java node.

Before you begin

Before you start

Read "Creating a message processing or output node in Java" on page 3062.

About this task

You can add one or more of the following functions:

- "Accessing ESQL"
- "Interacting with databases" on page 3070
- "Handling exceptions" on page 3070
- "Writing to an output device" on page 3072

Accessing ESQL:
About this task

Nodes can invoke ESQL expressions using Compute node ESQL syntax. You can create and modify the components of the message using ESQL expressions, and you can refer to elements of both the input message and data from an external database.

The following procedure demonstrates how to use ESQL to control transactions from the evaluate method in your user-defined node:

1. Set the name of the ODBC data source to use. For example:

   ```
   String dataSourceName = "myDataSource";
   ```

2. Set the ESQL statement to run:

   ```
   String statement =
      "SET OutputRoot.XMLNS.data =
             (SELECT Field2 FROM Database.Table1 WHERE Field1 = 1);";
   ```

   Or, if you want to run a statement that returns no result:

```
String statement = "PASSTHRU(
                         'INSERT INTO Database.Table1 VALUES(
                              InputRoot.XMLNS.DataField1,
                              InputRoot.XMLNS.DataField2)');";
```

3. Select the transaction you want from the following types:

   MbSQLStatement.SQL_TRANSACTION_COMMIT
   Immediately commit the transaction after the ESQL statement has completed.

   MbSQLStatement.SQL_TRANSACTION_AUTO
   Commit the transaction when the message flow has completed. (Rollbacks are performed if necessary.)

   For example:

   ```
   int transactionType = MbSQLStatement.SQL_TRANSACTION_AUTO;
   ```

4. Get the ESQL statement. For example:

   ```
   MbSQLStatement sql =
          createSQLStatement(dataSourceName, statement, transactionType);
   ```

   You can use the method createSQLStatement(data source, statement to default the transaction type to MbSQLStatement.SQL_TRANSACTION_AUTO).

5. Create the new message assembly to be propagated:

   ```
   MbMessageAssembly newAssembly =
          new MbMessageAssembly(assembly, assembly.getMessage());
   ```

6. Run the ESQL statement:

   ```
   sql.select(assembly, newAssembly);
   ```

   Or, if you want to run an ESQL statement that returns no result:

   ```
   sql.execute(assembly);
   ```

Interacting with databases:
About this task

You can interact with databases from the Java code in your message processing node. The support that is provided is identical to the support for Java code that you write for the JavaCompute node; for details of the available options, and the advantages and restrictions that apply, see "Interacting with databases by using the JavaCompute node" on page 2661.

Handling exceptions:
About this task

Use the MbException class to catch and access exceptions. The MbException class returns an array of exception objects that represent the children of an exception in the broker exception list. Each element returned specifies its exception type. An empty array is returned if an exception has no children. The following code sample shows an example of how you might use the MbException class in the evaluate method of your user-defined node.

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    try
      {

        // plug-in functionality

      }
    catch(MbException ex)
```

```
    {
      traverse(ex, 0);

      throw ex; // if re-throwing, it must be the original exception that was caught
    }
  }

  void traverse(MbException ex, int level)
  {
    if(ex != null)
      {
        // Do whatever action here
        System.out.println("Level: " + level);
        System.out.println(ex.toString());
        System.out.println("traceText:  " + ex.getTraceText());

        // traverse the hierarchy
        MbException e[] = ex.getNestedExceptions();
        int size = e.length;
        for(int i = 0; i < size; i++)
          {
            traverse(e[i], level + 1);
          }
      }
  }
```

You can develop a user-defined message-processing or output node in such a way that it can access all current exceptions. For example, to catch database exceptions you can use the MbSQLStatement class. This class sets the value of the 'throwExceptionOnDatabaseError' attribute, which determines broker behavior when it encounters a database error. When it is set to true, if an exception is thrown it can be caught and handled by the evaluate method in your user-defined extension.

The following code sample shows an example of how to use the MbSQLStatement class.

```
public void evaluate(MbMessageAssembly assembly, MbInputTerminal inTerm) throws MbException
  {
    MbMessage newMsg = new MbMessage(assembly.getMessage());
    MbMessageAssembly newAssembly = new MbMessageAssembly(assembly, newMsg);

    String table =
       assembly.getMessage().getRootElement().getLastChild().getFirstChild().getName();

    MbSQLStatement state = createSQLStatement( "dbName",
       "SET OutputRoot.XMLNS.integer[] = PASSTHRU('SELECT * FROM " + table + "');" );

    state.setThrowExceptionOnDatabaseError(false);
    state.setTreatWarningsAsErrors(true);

    state.select( assembly, newAssembly );

    int sqlCode = state.getSQLCode();
    if(sqlCode != 0)
      {
        // Do error handling here

        System.out.println("sqlCode = " + sqlCode);
        System.out.println("sqlNativeError = " + state.getSQLNativeError());
        System.out.println("sqlState = " + state.getSQLState());
        System.out.println("sqlErrorText = " + state.getSQLErrorText());
      }

    getOutputTerminal("out").propagate(newAssembly);
  }
```

Writing to an output device:
About this task

To write to an output device, the logical (hierarchical) message must be converted back into a bit stream in your evaluate method. Use the getBuffer method in **MbMessage** to perform this task:

```
public void evaluate( MbMessageAssembly assembly, MbInputTerminal in)
                                                        throws MbException
{
  MbMessage msg = assembly.getMessage();
  byte[] bitstream = msg.getBuffer();

  // write the bitstream out somewhere
  writeBitstream( bitstream );   // user method

 }
```

Typically, for an output node the message is not propagated to any output terminal, therefore you can just return at this point.

You must use the supplied MQOutput node when writing to WebSphere MQ queues, because the broker internally maintains a WebSphere MQ connection and the open queue handles on a thread-by-thread basis. These handles are cached to optimize performance. In addition, the broker handles exception scenarios when certain WebSphere MQ events occur, and this recovery is adversely affected if WebSphere MQ MQI calls are used in a user-defined output node.

Getting and setting the specific type of an Mb element:

Two methods are provided for handling the specific type of an Mb syntax element.

About this task

The following methods are available:
- getSpecificType
- setSpecificType

Use these methods to access or set the specific type of an XML element. For example, to update the current value:

Procedure

1. Call getSpecificType on the syntax element.

   The getSpecificType method does not take any parameters, but returns the specific type of the element as an int value.
2. Call setSpecificType on the syntax element.

   The setSpecificType method takes one parameter of the type int, which is the specific type that you want the Mb element to be. This method has no return value.

Results

Specific type values for the XML and MRM parsers are listed in "XML, MRM, and XMLNSC parser constants" on page 6691.

Related concepts:

"Specific types used by parsers" on page 3015
Specific types are used when a parser needs additional information that is associated with some or all the elements in a tree in order to generate the bit stream.

Compiling a Java user-defined node:

When you have created the code for your Java user-defined node, you must compile it for your operating system.

Before you begin

Before you start

You must have a user-defined node written in Java. This node can be one of the provided sample nodes that are described in "Sample node files" on page 6412, or a node that you have created yourself by using the instructions in either "Creating a message processing or output node in Java" on page 3062 or "Creating an input node in Java" on page 3055.

About this task

You can compile a Java user-defined node either from the command line, or from within the project in the WebSphere Message Broker Toolkit. Both options are described later in this section.

When you compile a Java user-defined node from the command line, you must have a compatible IBM Software Developer Kit for Java on the current operating system. For details of supported Java versions, see "Additional software requirements" on page 3598.

Compiling a Java user-defined node from the WebSphere Message Broker Toolkit:
About this task

Use the following procedure to compile your Java user-defined node from the WebSphere Message Broker Toolkit:

Procedure

1. In the Package Explorer, select the `/src` directory inside your node project, and click **File** > **Export**.
2. From the list displayed, select **JAR file**. Click **Next**. The resources that are available for you to export as a JAR file are listed.
3. Verify that **Export generated class files and resources** is selected.
4. Specify a name and location for your JAR file. Place the file inside the root directory of your node project, and give the file the same name as the name of the project (with a `.jar` extension). You can use the default values for the rest of the options. Click **Finish**.

Results

The `.jar` file that you have created is displayed in your node project, and is ready for you to install on one or more brokers (see "Installing user-defined extension runtime files on a broker" on page 3125), or to package for distribution (see "Packaging and distributing a user-defined node project" on page 3121).

Compiling a Java user-defined node from the command line:
About this task

Use the following procedure to compile your Java user-defined node from the command line:

Procedure

1. Add the location of `jplugin2.jar` to the CLASSPATH for your current platform:

   Windows *install_dir*`\classes\jplugin2.jar`

   Linux *install_dir*`/classes/jplugin2.jar`

   UNIX *install_dir*`/classes/jplugin2.jar`

   z/OS *install_dir*`/classes/jplugin2.jar`
2. Put your Java user-defined node class into the following directory:

   Windows *install_dir*`\sample\extensions\nodes`

   Linux *install_dir*`/sample/extensions/nodes`

   UNIX *install_dir*`/sample/extensions/nodes`

   z/OS *install_dir*`/sample/extensions/nodes`
3. Change to the directory that now contains your user-defined node class.
4. Compile the `.java` file by using the **`javac`** command; for example:

   `javac` *`nodename`*`.java`
5. Package the resulting `.class` file into a `.par` file. See "Packaging a Java user-defined node" on page 3118.

Results

The `.par` file that you have created is ready for you to install on one or more brokers (see "Installing user-defined extension runtime files on a broker" on page 3125), or to package for distribution (see "Packaging and distributing a user-defined node project" on page 3121).

Creating a user-defined node from a subflow:

Create user-defined nodes either from scratch, or by using an existing subflow.

About this task

Complete the appropriate tasks from the following list:

- "Creating a user-defined node from a subflow from scratch"
- "Creating a user-defined node from an existing subflow" on page 3078
- "Choosing the location of a user-defined node in the palette" on page 3092

Related concepts:

"User-defined nodes" on page 2989
User-defined nodes are the main mechanism for extending the functions of WebSphere Message Broker.

"Using a subflow as a user-defined node" on page 3008
You can develop a user-defined node that packages a subflow from scratch, in the same way that you can create any other user-defined node that has its implementation based on Java, or base it on an existing subflow.

Related tasks:

"Testing a subflow user-defined node project" on page 3097
Test how the user-defined node is displayed, and how it behaves in your environment.

"Packaging and distributing a user-defined node project" on page 3121
Export the user-defined node project to make it available for other users.

Creating a user-defined node from a subflow from scratch:

Create a user-defined node that packages a subflow by creating a user-defined node project, then creating the user-defined node.

About this task

After you have created a user-defined node, you can edit its properties in the Palette editor.

You can define as many user-defined nodes as you want in the same user-defined node project.

To create any type of user-defined node, use the following steps:

Procedure

1. Create a user-defined node project:
   a. To open the New User-defined Node Project wizard, click **File** > **New** > **New User-defined Node Project**, then click **Next**.
   b. Either choose an existing category, or create a category by clicking **Create a new category**. Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project. You can have only one category in each user-defined node project.
   c. Enter the details for the remainder of the fields as required, then click **Finish**.

   A user-defined node project is created.
2. Create a user-defined node:
   a. To open the New User-defined Node wizard, click **File** > **New** > **User-defined Node**.
   b. Select the user-defined node project that you created previously.
   c. Select the schema location that you want to host the user-defined node. Use a fully qualified schema. Do not use a default or `mqsi` schema.
   d. Enter the details for the remainder of the fields as required.
   e. Select **Implemented as a subflow**. The Message Flow editor opens.
   f. Click **Finish**.
3. Decide on the location of your user-defined node in the palette. See "Choosing the location of a user-defined node in the palette" on page 3092.

What to do next

You can now define the reusable logic and the terminals and properties of the user-defined node.

Creating a user-defined node from an existing subflow:

Create a user-defined node by converting the project for an existing subflow into a user-defined node project, and then creating the user-defined node.

About this task

To create a user-defined node from an existing subflow, use the following steps:

Procedure

1. To convert existing subflows into user-defined nodes, you must convert the project for the subflow into a user-defined node project:
   a. Right-click the existing project, click **Convert to User-defined Node Project**. The Convert to User-defined Node Project wizard is displayed.
   b. Choose a category from the following options. Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project.
      - To use an existing category, select a category from the list provided.
      - To create a new category, select **Create a new category**, enter a name for the category for the nodes that you want to create in the new project.
   c. Enter the details for the remainder of the fields as required.
   d. Click **Finish**.
2. Select the subflow that you want to convert to a user-defined node:
   a. Right-click the subflow to display the menu.
   b. Click **Convert to User-defined Node**. The Convert to User-defined Node wizard opens.
   c. Enter the details for the remainder of the fields as required.
   d. Click **Finish**.
3. Decide on the location of your user-defined node in the palette. See "Choosing the location of a user-defined node in the palette" on page 3092.

Creating a user-defined node project:

When you create user-defined nodes, you must first create a user-defined node project to contain the nodes and their supporting files.

About this task

To create a new project for your user-defined node, complete the following steps:

Procedure

1. Click **File** > **New** > **User-defined Node Project**. Click **Next** to start the User-defined Node Project wizard. The New User-defined Node Project window opens.
2. Either select an existing category, or select **Create a new category** and specify the name of a new category for the nodes that you are creating. Your user-defined nodes are displayed in the palette in the Message Flow editor under the category you specify for the project.
3. Specify a name for your project.
4. Specify a name for your plug-in identifier. To be consistent with the supplied nodes, and to avoid conflict with the names of node projects that are supplied by other independent software vendors, use your Internet domain name for your organization as part of the name and plug-in identifier. For example, the name and plug-in identifier must be of the form `com.xyz.nodegroup`, where *com.xyz* is the company Internet domain name.

   You can save any number of nodes in a single project.
5. Accept all default values and click **Finish**.
6. If warnings are displayed in the Problems view, that are associated with the newly created project, perform the following steps:
   a. Click **Window** > **Preferences**.
   b. Expand **Plug-In Development** and click **Target Platform**.
   c. Click **Add required Plug-ins** to select all loaded plug-ins and click **OK**.
   d. Select your user-defined node project in the Package Explorer view, and click **Project** > **Clean**. A dialog box opens in which you can select either of the following options:
      - **Clean all projects**.
      - **Clean projects selected below**. If you choose this option, select the projects that you want to clean.

Results

A project folder that contains all the supporting files that are required for your user-defined node is displayed in the Package Explorer view. The project is stored in the default workspace directory.

What to do next

Creating the user-defined node plug-in files:

Create the files that contain the message processing logic, for user-defined nodes created in Java and C only.

Before you begin

Before you start:

Complete the task following task: “Creating a user-defined node project” on page 3080.

About this task

Procedure

1. Launch the wizard by clicking **File** > **New** > **User-defined Node**. The **New User-defined Node** window opens.
2. Select the parent folder for the node from the list of names that are displayed. This folder is the project that you created to contain this node.
3. Specify a schema for this node. You must not use the default schema or any other common schema, such as `mqsi`.
4. Specify a name for the node. The name must be the name of the node, excluding the `Node` at the end. For example, if you have created a node called `BasicNode`, the node name must be `Basic`.
5. Click **Finish**. A `.msgnode` file for the new node is created and is added to the project in the Broker Development view. The `.msgnode` file is opened in the Message Node editor.

What to do next

Next:

When you have completed this task, define the node properties, see "Defining the node properties."

Related concepts:

When you create user-defined nodes, you must first create a user-defined node project to contain the nodes and their supporting files.

"Defining the node properties"
Define the properties for a user-defined node created in Java or C only, and add input and output terminals so that you can connect it to other nodes in a message flow.

Related reference:

"User-defined extensions" on page 6411
Reference material that supports the creation and management of your user-defined extensions.

Defining the node properties:

Define the properties for a user-defined node created in Java or C only, and add input and output terminals so that you can connect it to other nodes in a message flow.

Before you begin

Before you start:

Complete the following tasks:
1. "Creating a user-defined node project" on page 3080
2. "Creating the user-defined node plug-in files" on page 3082

About this task

When you complete the task described in "Creating the user-defined node plug-in files" on page 3082, a `.msgnode` file is created for the new node, and is opened in the Message Node editor of the Broker Application Development perspective. You can now add terminals and properties to the node.

Adding terminals to the node:
Procedure

1. If the Terminals page is not already displayed, click the **Terminals** tab at the bottom of the Message Node editor.
2. Click **Add** to the right of the **In Terminals** or **Out Terminals** fields to add an input or output terminal.

   You must define at least one input terminal, but output terminals are optional.
3. To rename a terminal, click the terminal name so that it is highlighted and shows a flashing cursor after the name, and enter a new name.
4. If your node supports dynamic input or output terminals, select the appropriate check box.

   Dynamic terminals are terminals that you can add to certain nodes after you have added them to a message flow in the Message Flow editor. For more information, see "Message flow node terminals" on page 1034.

Defining properties for the node:
Procedure

1. Click the **Properties** tab at the bottom of the Message Node editor.

   On the Properties page, you can set the properties for the node, for example, a database name, a host server name, or a password. The properties that you set here must match the properties that you specified in the user-defined node itself by using the get and set methods.
2. If the node is an input node, click the node name in the hierarchy to highlight it, and select **Input node**. Select **Use broker default values** if you want the node to initialize with the default values for the broker.
3. By default, all properties are grouped under the Basic group. You can add new groups in which to place properties. When your custom node is selected in the WebSphere Message Broker Toolkit, each group of properties is rendered as a separate tab in the Properties view. To create additional groups of properties, click **Add Property Group**  .
4. To add a simple property, click the name of a property group in the hierarchy to highlight it, and click **Add Simple Property** 

The new property is added to the hierarchy as a child of the property group. Its name is highlighted so that you can change it. A number of fields are displayed in the Details section, where you can configure the property.

a. Select the correct attribute type: one of the built-in types, or a type to match the list of values that the property can have.
b. Enter any default values, which are shown in the Properties view when the node is included in a message flow.
c. Optional: If you want to use a custom property compiler, in the **Custom Compiler Class** field specify the class you want to use for your custom compiler. The class must implement the IPropertyCompiler interface. For more information, see "Adding a property editor or compiler" on page 3091.
d. Optional: If you want to use a custom property editor, in the **Custom Editor Class** field specify the class you want to use for your custom editor. The class must implement the IPropertyEditor interface. For more information, see "Adding a property editor or compiler" on page 3091.
e. Specify the system property for each attribute that you define:

   Hidden
   The property is not displayed in the Properties view or the Promote Property dialog box.

   Read only
   The property is displayed, but cannot be changed.

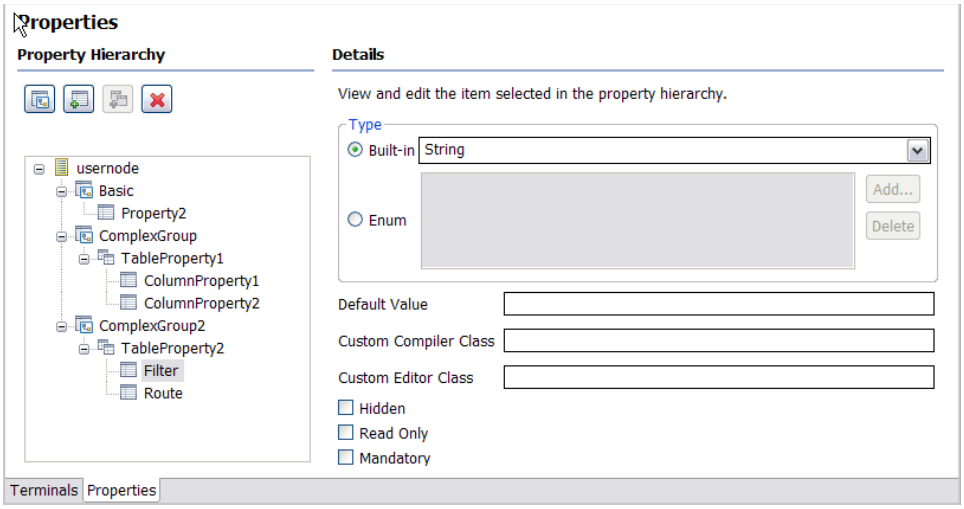
   Mandatory
   A value is required. The field cannot be left blank. Boolean and enum properties are always mandatory.

   Configurable
   The property can be configured at deployment time

5. To add a table property, select the name of a property group in the Properties view and click **Add Table Property**  .

   In addition to simple properties, a node can also have complex properties. A table property represents a repeating property of a complex type. The new property is added to the hierarchy as a child of the property group. A number of fields are displayed in the Details section where you can configure the table property.
6. To add a column to an existing table, select the name of the table property in the hierarchy, and click **Add Simple Property**  .

   For example, the following figure shows the Property Hierarchy of the usernode, where Filter and Route columns have been added.



A number of fields are displayed in the Details section where you can configure the properties of the column. Define table columns, where each column is assigned to a type.

a. Select the correct attribute type in the **Type** field: one of the built-in types, or enumeration.

b. Enter the default value, in the **Default Value** field. This value is shown in the Properties view when the node is included in a message flow.

c. Specify a qualified class name in the **Custom Compiler Class** field for a property compiler. To create a custom compiler, use the IPropertyCompiler interface. For more information about custom property editors and property compilers, see "Adding a property editor or compiler" on page 3091.

d. Specify a qualified class name in the **Custom Editor Class** field to generate a custom property editor. The property editor specified in this field implements the IColumnPropertyEditor interface responsible for cell editing behavior. Leaving the **Custom Editor Class** field blank means that a property editor matching-column type is used. Specify your own IColumnPropertyEditor only if you need custom cell editing behavior.

e. Specify the following attributes for each column that you define:

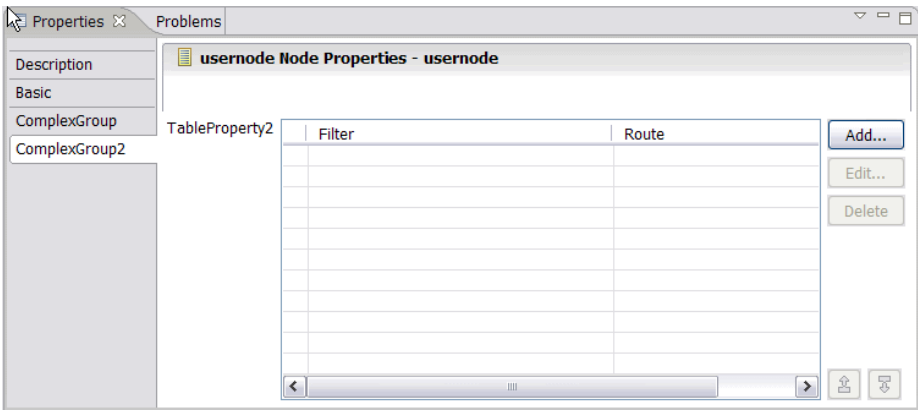
Hidden
Use a hidden column when you want to store, for each row, metadata that is not being displayed.

Read only
The column is displayed, but cannot be changed.

Mandatory
A value is required. The field cannot be left blank. Boolean and enum properties are always mandatory.

Leave the **Custom Editor Class** field of the Details section of a table property blank, unless you want to overwrite the behavior of the entire table. For example, if the table becomes disabled in response to a change in another property editor.

The following figure shows how the Table properties are rendered as a table in the Properties view, where you can add, edit, and delete values, and change the order of the values in the table.



7. Optional: Drag the properties in the properties hierarchy to change the order in which they are listed on the properties page.
8. Close the *nodename*.msgnode file.
9. Optional: You can customize the text that is displayed in the node properties view for each property. To set the text, open the *nodename*.properties file and edit the line:

   ```
   Property.propertyName = your descriptive text
   ```

What to do next

Next:

The following tasks are optional:

- "Adding help to the node" on page 3088
- "Creating node icons" on page 3090
- "Adding a property editor or compiler" on page 3091

You can now test your node, see "Testing a user-defined node" on page 3094.

Related concepts:

Related information:

Property editor API

Adding help to the node:

Add help information by adding an HTML file to the node that you have created.

Before you begin

Before you start:

Complete the following tasks:

1. "Creating a user-defined node project" on page 3080
2. "Creating the user-defined node plug-in files" on page 3082
3. "Defining the node properties" on page 3083

About this task

Add help information for the node that you have created to explain why and when to use the node, and how it must be configured:

- Topic information that is displayed in the information center
- Context-sensitive help that is displayed when you press F1
- Hover help that is displayed when you hold the mouse pointer over the node

All three forms of help are optional; you can create any one or more of the three resources described in the following section.

Procedure

1. Create a `help.html` file in the project to contain the online help that explains what the node does and how you can use it. If you have several files, create a separate doc subdirectory in the plug-in project, and store the online help files in that directory.

   You can make the online help for the node look like it is integrated with the product-supplied information center, under the leaf node called "User-defined nodes", which you can find at **Reference** > **Message flow development** > **User-defined extensions** > **User-defined nodes**. To make the online help for your node show at that point, complete the following steps:

a. Modify the `plugin.xml` file to include the following extension point to the information center:

```
<extension point="org.eclipse.help.toc">
<toc file="toc.xml"/>
</extension>
```

b. Create a `toc.xml` file in your user-defined node project, and modify the `link_to` attribute to link to the "UDNodes" anchor that is already defined in the information center contents views:

```
<toc label="My Plugin Node" topic="my_node.htm"
 link_to="../com.ibm.etools.mft.doc/toc.xml#UDNodes">
<topic label="Mytopic 1" href="topic1.htm">
</toc>
```

Your help topic is now displayed in the contents view under **Reference** > **Message flow development** > **User-defined extensions** > **User-defined nodes**.

The sample nodes that are provided with the product demonstrate this option.

For further explanation of extension points and how to use them, see the PDE guide at Eclipse documentation.

2. Add context sensitive (F1) help to the node. Context-sensitive help is displayed when you click a node in the Broker Application Development perspective and press F1.

   When a node is created, a `HelpContexts.xml` file is created. This file assigns a context identifier based on the name of the node. Modify the `HelpContexts.xml` file for your node by changing the text in the description field. The name of the `HelpContexts.xml` file must be unique within the project, but can contain multiple context entries; for example, if you have several nodes within a single project, each node can have its context-sensitive help in the file.

   Context-sensitive help is limited in length. A useful way of providing more help to the user is to link from the F1 help to an HTML file that contains further information; for example, to the online help for the node, described previously. Use the following code for the link:

   ```
   <topic href"../plug-in directory/html file" label="Link title">
   ```

3. Add hover help (known as ToolTip help on Windows) to the node. When you create a user-defined node, a `palette.properties` file is created. Modify this file to contain the hover help for your node, which shows the node name when the palette is not wide enough to display it all.

What to do next

You can add another optional feature, a node icon or a property editor or compiler, or you can test your node, see “Creating node icons” on page 3090, “Adding a property editor or compiler” on page 3091, and “Testing a user-defined node” on page 3094.

Creating node icons:

Create the icons that are displayed in the WebSphere Message Broker Toolkit when your user-defined node is present.

Before you begin

Before you start:

You must complete the following tasks:

1. "Creating a user-defined node project" on page 3080
2. "Creating the user-defined node plug-in files" on page 3082
3. "Defining the node properties" on page 3083

About this task

You can choose the icon when you create your user-defined node, or you can use the Palette editor to change the icon, see "Choosing the location of a user-defined node in the palette" on page 3092.

What to do next

You can add help, a property editor or compiler, or you can test your node, see "Adding help to the node" on page 3088 or "Adding a property editor or compiler" on page 3091, and "Testing a user-defined node" on page 3094.

Related concepts:

"User-defined input nodes" on page 2990

Reference material that supports the creation and management of your user-defined extensions.

Adding a property editor or compiler:

Create a property editor by using the IPropertyEditor interface to control how the properties of your user-defined node created in Java or C only, are displayed in the WebSphere Message Broker Toolkit. Create a custom compiler by using the IPropertyCompiler interface; for example, to encrypt a value before sending it to the server.

Before you begin

Before you start:

You must complete the following tasks:

1. "Creating a user-defined node project" on page 3080
2. "Creating the user-defined node plug-in files" on page 3082
3. "Defining the node properties" on page 3083

About this task

The IPropertyEditor interface is used as the basis for all the node property editors in the WebSphere Message Broker Toolkit. You can customize the property editor to contain different kinds of controls, such as text fields and lists. See the IPropertyEditor and IPropertyCompiler interfaces in the Property editor API.

Creating a Java class:
About this task

To create a Java class for your property editor or compiler, complete the following steps.

Procedure

1. Switch to the Java perspective.
2. Right-click your user-defined node project and click **New** > **Class**. If **Class** is not shown, click **Other**, select **Class** and click **Next**.
3. Type a name for your class in the **Name** field.
4. Complete the following steps, according to whether you are creating a property editor or a property compiler:
   - If you are creating a property editor:
   a. Delete any text in the **Superclass** text field, and click **Browse**.
   b. In the **Choose a type** field, type `AbstractPropertyEditor` and click **OK**. AbstractPropertyEditor implements the IPropertyEditor interface.

- If you are creating a property compiler:

a. Click **Add** next to the **Interfaces** field.

b. In the **Choose interfaces** field, type `IPropertyCompiler` and click **OK**.

5. Click **Finish**.

Testing your property editor or compiler:
About this task

To test your property editor, see "Testing a user-defined node" on page 3094.

To test your property compiler, deploy to a broker the flow that contains your user-defined node.

A custom property editor can use Rational Application Developer or Eclipse APIs. When you migrate to a new version of WebSphere Message Broker, your custom property editor might not work if the Rational Application Developer or Eclipse APIs change. Update your property editor code to comply with the changed API.

Property editor API

Choosing the location of a user-defined node in the palette:

Use the Palette editor to edit palette-specific information for user-defined nodes, add and delete separators, and rearrange user-defined nodes in the palette.

About this task

- If you change the details for a user-defined node in the Palette editor, save the changes before you add or remove another user-defined node or the changed details will be lost.
- Do not confuse the Palette editor and Customize functions:

  Palette editor
  The Palette editor is started from the Navigator when you select a user-defined node project or the user-defined node virtual folder. The

Palette editor is used to set the category, node names, and icons that you want to export so that the user can see the modified node.

Customize action
The Customize action is started from the palette in the Message Flow editor when you select a node. The Customize action is used to change the way that the nodes are displayed in the workspace of the current user.

Procedure

1. To open the Palette editor use one of the following options:
   - In the Broker Development view, under the user-defined node project, select **User Defined Nodes**, click **Edit and Arrange Palette**.
   - In the Broker Development view, in the user-defined node project, right-click **palette.xmi**. Click **Open With** and select **Palette Editor**.
2. To edit palette-specific information:
   a. In the left side of the Palette editor under the Category folder, click the user-defined node that you want to edit. The details about the user-defined node are displayed in the right side of the Palette editor.
   b. You can change the details in the **Display Name**, **Tooltip on palette**, and **Node Icons** fields, but you cannot change the **Node Implementation** section.
   c. You can change the category by selecting the Category folder on the left side of the Palette editor, and on the right side either choose an existing category, or rename your own category.
3. To group the user-defined nodes you can add or delete a separator:
   - To add a separator in a user-defined node:
     a. In the left side of the Palette editor, right-click the node.
     b. Select **Add Separator Below**. A separator is added below the node in the left side of the Palette editor.
   - To delete a separator:
     a. In the left side of the Palette editor, right-click **Separator**.
     b. Click **Delete Separator**.
4. To rearrange your user-defined nodes, in the left side of the Palette editor either drag the node to its new position, or right-click the node and select **Move Up** or **Move Down**.

Create a user-defined node that packages a subflow by creating a user-defined node project, then creating the user-defined node.

"Creating a user-defined node from an existing subflow" on page 3078
Create a user-defined node by converting the project for an existing subflow into a user-defined node project, and then creating the user-defined node.

"Using the node palette" on page 1489
The node palette contains all the built-in nodes, which are organized into categories.

Testing a user-defined node:

When you have created and installed the required resources, you can test your user-defined node.

Before you begin

Before you start

Complete the following tasks:

- "Creating a user-defined extension in C" on page 3026 or "Creating a user-defined extension in Java" on page 3054
- "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079
- "Installing user-defined extension runtime files on a broker" on page 3125

This topic is for user-defined nodes created in Java and C only.

For user-defined nodes created from a subflow, see "Testing a subflow user-defined node project" on page 3097.

Procedure

Use the following steps to test your user-defined node:

1. To test these projects and resources you must launch a second WebSphere Message Broker Toolkit by using the following steps:
   a. Right-click the user-defined node project. The menu opens.
   b. Click **Run in New Workbench**.
      - If the project contains errors, you receive an error message that gives you the option to continue, or to cancel the action.
      - If the project is error-free, the Workspace Launcher window opens.
        1) You can choose to use a new or an existing workspace. To choose an existing workspace, click **Browse**. The second workspace opens.
        2) You can now test by using the user-defined nodes in all error-free user-defined node projects in your first workbench.
2. Open the Message Flow editor in the second instance of the WebSphere Message Broker Toolkit. Your new nodes are displayed in the node palette.
3. Create a message flow that includes your node. See "Adding a message flow node" on page 1494.
4. Deploy the message flow to a broker. See "Deploying resources" on page 3234.

5. Send a test message through the flow and look for the results that you expect (for example, a message put to a target queue). You might have to write an application to send the test message to the message flow.
6. Use the diagnostic tools that are provided to determine whether your node works, or if not, what went wrong:
   a. For a description of some common problems and their solutions. See "Resolving problems with user-defined extensions" on page 3511.
   b. Check the Administration log. See "Administration Log view" on page 6840.
   c. Write entries to the Administration log from your node. See "Using error logging from a user-defined extension" on page 3137.
   d. Switch on user trace at debug level. See "Using trace" on page 3533.

      The following debug messages are generated by a user trace to help you to understand the execution of your user-defined nodes and parsers:

      - BIP2233 and BIP2234: A pair of messages traced before and after a user-defined extension implementation function is started. These messages report the input parameters and the returned value.

        In these messages, an "implementation function" can be interpreted as either a C implementation function or a Java implementation method.
      - BIP3904: A message traced before starting the Java evaluate() method of a user-defined node.
      - BIP3905: A message traced before starting the C cniEvaluate() implementation function (iFpEvaluate member of CNI_VFT) of a user-defined node.
      - BIP4142: A debug message that is traced when starting a user-defined node utility function, where the utility function alters the state of a syntax element. All utility functions that start with cniSetElement*, where * represents all nodes with that stem, are included.
      - BIP4144 and BIP4145: A pair of messages traced by certain implementation functions that, when started by a user-defined extension, can modify the internal state of an object in the broker. Possible broker objects include syntax element, node, and parser.

        In these messages, an "implementation function" can be interpreted as either a C implementation function or a Java implementation method.
      - BIP4146: A debug message that is traced when starting a user-defined parser utility function, where the utility function alters the state of a syntax element. All utility functions that start with `cpiSetElement*`, where * represents all nodes with that stem, are included.
      - BIP4147: An error message that is traced when a user-defined extension passes an invalid input object to a user-defined extension utility API function.
      - BIP4148: An error message that is traced when a user-defined extension damages an object in a broker.
      - BIP4149: An error message that is traced when a user-defined extension passes an invalid input data pointer to a user-defined extension utility API function.
      - BIP4150: An error message that is traced when a user-defined extension passes invalid input data to a user-defined extension utility API function.
      - BIP4151: A debug message that is traced when cniGetAttribute2 or cniGetAttributeName2 sets the return code to an unexpected value. Expected values are CCI_SUCCESS, CCI_ATTRIBUTE_UNKNOWN, and CCI_BUFFER_TOO_SMALL. Any other value is an unexpected value.

- BIP4152: A debug message that is traced in the following situations:
  1) cniGetAttribute2 or cniGetAttributeName2 sets the return code to CCI_BUFFER_TOO_SMALL.
  2) cniGetAttribute2 or cniGetAttributeName2 is called again with the correct size buffer, however the return code is set to CCI_BUFFER_TOO_SMALL.

e. Add a Trace node to your message flow, and check the output that is generated.

f. Use the flow debugger to debug the flow that contains your node. See Chapter 10, "Testing and debugging message flow applications," on page 3143.

What to do next

When your node behavior is complete and correct, add the new node into your normal palette of nodes in the Message Flow editor, see "Packaging and distributing a user-defined node project" on page 3121. Until you complete this task, the new nodes are available only in your test WebSphere Message Broker Toolkit session on your local system.

Testing a subflow user-defined node project:

Test how the user-defined node is displayed, and how it behaves in your environment.

About this task

You can test how the user-defined node is displayed, and how it behaves in your environment by simulating the node. The user-defined node is displayed in the palette in the Message Flow editor, and any change to the plug-in during the simulation is effective immediately; you are not required to restart the simulation.

- To start the simulation of a user-defined node:
  1. Right-click the user-defined node project, click **Start Simulation**. This action adds all the user-defined nodes that are in the project to the palette in the Message Flow editor under the category that you defined for the project.
  2. You can drag these nodes from the palette onto the Message Flow editor canvas in the same way as the built-in nodes.
- To stop the simulation of a user-defined node:
  1. Right-click the user-defined node project, click **Stop Simulation**.
  2. If any message flows are using the user-defined node, an error is generated because the node is no longer available, and the following message is displayed:

     ```
     User-defined nodes that are contributed by the user-defined node
     project Varname will be removed from the Message Flow editor palette.
     If a copy of these nodes is not available from the plug-in space,
     any message flows that use these nodes might get unresolved node
     errors.
     ```
- If you are using custom editors, compilers, or Java code, these resources cannot be tested in simulation mode. To test and debug these projects and resources you must launch a second WebSphere Message Broker Toolkit by using the following steps:
  1. Right-click the user-defined node project. The menu opens.
  2. Click **Run in New Workbench**.

- If the project contains errors, you receive an error message that gives you the option to continue, or to cancel the action.
- If the project is error-free, the Workspace Launcher window opens.
  a. You can choose to use a new or an existing workspace. To choose an existing workspace, click **Browse**. The second workspace opens.
  b. You can now test and debug by using the user-defined nodes in all error-free user-defined node projects in your first workbench.

- In previous versions of the WebSphere Message Broker Toolkit, you were able to use launch configurations to test custom editors, compilers, or Java code. However, launch configurations are not supported with user-defined nodes that are created from a subflow. To test custom editors, compilers, and Java code with user-defined nodes that are created from a subflow, right-click the user-defined node project and click **Run in New Workbench**.

Create user-defined nodes either from scratch, or by using an existing subflow.

Debugging the message flow in simulation mode:

Compile, deploy, test, and debug the message flow that includes your user-defined node.

About this task

You can compile, deploy, test, and debug the message flow that includes your user-defined node in the same way that you test any regular subflow. However, you must set a breakpoint so that the debugger stops at that point, see "Working with breakpoints in the flow debugger" on page 3166.

You can debug the message flow only if the following constraints are met:

- The user-defined node project must be in the workspace.
- The user-defined node project must be in the simulation mode.
- The subflow cannot be debugged after it has been exported as a plug-in, unless the source code is in your workspace.

Implementing a user-defined parser

Create a user-defined parser to interpret messages with a different format and structure.

Before you begin

Before you start

Read the following topics:

- "Why use a user-defined extension?" on page 2972
- "User-defined parsers" on page 3010

About this task

A loadable implementation library, or a *LIL*, is the implementation module for a C parser (or node). A LIL is a Linux or UNIX shared object or Windows dynamic link library (DLL), that does not have the file extension `.dll` but `.lil`.

The implementation functions that you must write are listed in “C parser implementation functions” on page 6538. The utility functions that are provided by WebSphere Message Broker to help you are listed in “C parser utility functions” on page 6539.

WebSphere Message Broker provides the source for a sample user-defined parser called BipSampPluginParser.c. This example is a simple pseudo-XML parser that you can use in its current state, or you can modify.

The task of writing a parser varies considerably according to the complexity of the bit stream to be parsed. Only the basic steps are described here:

1. “Declaring and defining the parser”
2. “Creating an instance of the parser” on page 3101
3. “Deleting an instance of the parser” on page 3102

Declaring and defining the parser:
About this task

To declare and define a user-defined parser to the broker, you must include an initialization function, bipGetParserFactory, in your LIL. The following steps outline how the broker calls your initialization function and how your initialization function declares and defines the user-defined parser:

The following procedure shows you how to declare and define your parser to the broker:

Procedure

1. The initialization function, bipGetParserFactory, is called by the broker after the LIL has been loaded and initialized by the operating system. The broker calls this function to understand what your LIL is able to do, and how it must be called. For example:

   ```
   CciFactory LilFactoryExportPrefix * LilFactoryExportSuffix
   bipGetParserFactory()
   ```

2. The bipGetParserFactory function calls the utility function cpiCreateParserFactory. This function passes back a unique factory name (or group name) for all the parsers that your LIL supports. Every factory name (or group name) passed back must be unique throughout all the LILs in the broker.
3. The LIL calls the utility function cpiDefineParserClass to pass the unique name of each parser, and a virtual function table of the addresses of the implementation functions.

   For example, the following code declares and defines a single parser called InputxParser:

   ```
   {
    CciFactory* factoryObject;
    int rc = 0;
    CciChar factoryName[] = L"MyParserFactory";
    CCI_EXCEPTION_ST exception_st;

    /* Create the Parser Factory for this parser */
    factoryObject = cpiCreateParserFactory(0, factoryName);
    if (factoryObject == CCI_NULL_ADDR) {

     /* Any local error handling can go here */
    }
    else {
     /* Define the parsers supported by this factory */
   ```

```
 static CNI_VFT vftable = {CNI_VFT_DEFAULT};

/* Setup function table with pointers to parser implementation functions */
vftable.iFpCreateContext            = cpiCreateContext;
vftable.iFpParseBufferEncoded       = cpiParseBufferEncoded;
vftable.iFpParseFirstChild          = cpiParseFirstChild;
vftable.iFpParseLastChild           = cpiParseLastChild;
vftable.iFpParsePreviousSibling     = cpiParsePreviousSibling;
vftable.iFpParseNextSibling         = cpiParseNextSibling;
vftable.iFpWriteBufferEncoded       = cpiWriteBufferEncoded;
vftable.iFpDeleteContext            = cpiDeleteContext;
vftable.iFpSetElementValue          = cpiSetElementValue;
vftable.iFpElementValue             = cpiElementValue;
vftable.iFpNextParserClassName      = cpiNextParserClassName;
vftable.iFpSetNextParserClassName   = cpiSetNextParserClassName;
vftable.iFpNextParserEncoding       = cpiNextParserEncoding;
vftable.iFpNextParserCodedCharSetId = cpiNextParserCodedCharSetId;

cpiDefineParserClass(0, factoryObject, L"InputxParser", &vftable);
}

/* Return address of this factory object to the broker */
return(factoryObject);
}
```

The initialization function must create a parser factory by starting cpiCreateParserFactory. The parser classes supported by the factory are defined by calling cpiDefineParserClass. The address of the factory object (returned by cpiCreateParserFactory) must be returned to the broker as the return value from the initialization function.

For example:

a. Create the parser factory using the cpiCreateParserFactory function:

```
factoryObject = cpiCreateParserFactory(&rc, constParserFactory);
```

b. Define the classes of message supported by the factory using the cpiDefineParserClass function:

```
if (factoryObject) {
   cpiDefineParserClass(&rc, factoryObject, constPXML, &vftable);
  }
else {
    /* Error: Unable to create parser factory */
  }
```

c. Return the address of this factory object to the broker:

```
  return(factoryObject);
}
```

Creating an instance of the parser:
About this task

When the broker has received the table of function pointers, it calls the function cpiCreateContext for each instantiation of the user-defined parser. If you have three message flows that use your user-defined parser, your cpiCreateContext function is called for each of them. This function allocates memory for that instantiation of the user-defined parser to hold the values for the configured attributes. For example:

Procedure

1. Call the cpiCreateContext function:

```
CciContext* _createContext(
  CciFactory* factoryObject,
  CciChar*    parserName,
  CciNode*    parserObject
```

```
){
  static char* functionName = (char *)"_createContext()";
  PARSER_CONTEXT_ST* p;
  CciChar          buffer[256];
```

2. Allocate a pointer to the local context and clear the context area:

```
p = (PARSER_CONTEXT_ST *)malloc(sizeof(PARSER_CONTEXT_ST));

if (p) {
   memset(p, 0, sizeof(PARSER_CONTEXT_ST));
```

3. Save the parser object pointer in the context:

```
p->parserObject = parserObject;
```

4. Save the parser name:

```
CciCharNCpy((CciChar*)&p->parserName, parserName, MAX_NODE_NAME_LEN);
```

5. Return the parser context:

```
return (CciContext*) p;
```

Deleting an instance of the parser:
About this task

Parsers are destroyed when a message flow is deleted or redeployed, or when the execution group process is stopped (using the **mqsistop** command). When a parser is destroyed, it must free any used memory and release any held resources using the cpiDeleteContext function. For example:

```
void cpiDeleteContext(
  CciParser*  parser,
  CciContext* context
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;

  return;
}
```

Compile user-defined extensions in C for all supported operating systems.

Related reference:

"C language user-defined parser API" on page 6538
The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

Extending the capability of a C user-defined parser:

When you have created a C parser, you can extend its capability.

Before you begin

Before you start

Ensure that you have read and understood the following topic:

- "Implementing a user-defined parser" on page 3099

About this task

You can extend the capability of a C parser in the following ways:

- "Implementing the parser functionality"
- "Implementing input functions"
- "Implementing parse functions" on page 3104
- "Implementing output functions" on page 3105
- "Implementing a message header parser" on page 3105

Implementing the parser functionality:
About this task

A parser needs to implement the following types of implementation function:

1. Input functions
2. Parse functions
3. Output functions

Implementing input functions:
About this task

Your parser must implement one, and only one, of the following input functions:

- "cpiParseBuffer" on page 6580
- "cpiParseBufferEncoded" on page 6582
- "cpiParseBufferFormatted" on page 6583

The broker invokes the *input* function when your user-defined parser is required to parse an input message. The parser must tell the broker how much of the input bitstream buffer that it claims to own. In the case of a fixed-size header, the parser claims the size of the header. If the parser is intended to handle the whole message, it claims the remainder of the buffer.

For example:

1. The broker invokes the cpiParseBufferEncoded input function:

```
int cpiParseBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
```

```
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;
```

2. Get a pointer to the message buffer and set the offset using the cpiBufferPointer utility function:

```
pc->iBuffer = (void *)cpiBufferPointer(&rc, parser);
pc->iIndex = 0;
```

3. Save the format of the buffer:

```
pc->iEncoding = encoding;
pc->iCcsid = ccsid;
```

4. Save the size of the buffer using the cpiBufferSize utility function:

```
pc->iSize = cpiBufferSize(&rc, parser);
```

5. Prime the first byte in the stream using the cpiBufferByte utility function:

```
pc->iCurrentCharacter = cpiBufferByte(&rc, parser, pc->iIndex);
```

6. Set the current element to the root element using the cpiRootElement utility function:

```
pc->iCurrentElement = cpiRootElement(&rc, parser);
```

7. Reset the flag to ensure parsing is reset correctly:

```
pc->iInTag = 0;
```

8. Claim ownership of the remainder of the buffer:

```
  return(pc->iSize);
}
```

Implementing parse functions:
About this task

General parse functions (for example, **cpiParseFirstChild**) are those invoked by the broker when the syntax element tree needs to be created in order to evaluate an ESQL or Java expression. For example, a Filter node uses an ESQL field reference in an ESQL expression. This field reference must be resolved in order to evaluate the expression. Your parser's general parse function is called, perhaps repeatedly, until the requested element is either created, or is known by the parser not to exist.

For example:

```
void cpiParseFirstChild(
  CciParser*  parser,
  CciContext* context,
  CciElement* element
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc;

  if ((!cpiElementCompleteNext(&rc, element)) &&
      (cpiElementType(&rc, element) == CCI_ELEMENT_TYPE_NAME)) {

    while ((!cpiElementCompleteNext(&rc, element))     &&
           (!cpiFirstChild(&rc, element)) &&
           (pc->iCurrentElement))
    {
      pc->iCurrentElement = parseNextItem(parser, context, pc->iCurrentElement);
    }
  }
  return;
}
```

Implementing output functions:
About this task

Your parser must implement one, and only one, of the following output functions:

- "cpiWriteBuffer" on page 6610
- "cpiWriteBufferEncoded" on page 6612
- "cpiWriteBufferFormatted" on page 6613

The broker invokes the *output* function when your user-defined parser is required to serialize a syntax element tree to an output bit stream. For example, a Compute node might have created a tree in the domain of your user-defined parser. When a node, such as an MQOutput node, needs to serialize this tree, the parser is responsible for appending the output bitstream buffer with data that represents the tree that has been built.

For example:

```
int cpiWriteBufferEncoded(
  CciParser*  parser,
  CciContext* context,
  int         encoding,
  int         ccsid
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                initialSize = 0;
  int                rc = 0;
  const void* a;
  CciByte b;

  initialSize = cpiBufferSize(&rc, parser);
  a = cpiBufferPointer(&rc, parser);
  b = cpiBufferByte(&rc, parser, 0);

  cpiAppendToBuffer(&rc, parser, (char *)"Some test data", 14);

  return cpiBufferSize(0, parser) - initialSize;
}
```

Implementing a message header parser:
About this task

Typically, the incoming message data is of a single message format, therefore one parser is responsible for parsing the entire contents of the message. The class name of the parser that is needed is defined in the `Format` field in the MQMD or the MQRFH2 header of the input message.

However, the message might consist of multiple formats, for example where there is a header in one format followed by data in another format. In this case, the first parser has to identify the class name of the parser that is responsible for the next format in the chain, and so on. In a user-defined parser, the implementation function cpiNextParserClassName is invoked by the broker when it navigates down a chain of parser classes for a message that is composed of multiple message formats.

If your user-defined parser supports parsing a message format that is part of a multiple message format, the user-defined parser *must* implement the cpiNextParserClassName function.

For example:

1. Call the **cpiNextParserClassName** function:

```
void cpiNextParserClassName(
  CciParser*  parser,
  CciContext* context,
  CciChar*    buffer,
  int         size
){
  PARSER_CONTEXT_ST* pc = (PARSER_CONTEXT_ST *)context ;
  int                rc = 0;
```

2. Copy the name of the next parser class to the broker:

```
  CciCharNCpy(buffer, pc->iNextParserClassName, size);

  return;
}
```

Related reference:

"C language user-defined parser API" on page 6538
The C language user-defined parser API consists of two complementary sets of functions that you can use to define the function of your parser.

Compiling a C user-defined extension:

Compile user-defined extensions in C for all supported operating systems.

Before you begin

Before you start:

If you create your own user-defined nodes, parsers, and user exits in C, compile them on the operating system on which the target broker is running. Samples are

provided for both nodes and parsers, and are described in “Sample node files” on page 6412 and “Sample parser files” on page 6414. Use the instructions here to compile the samples. If you want to create your own extensions, see the following topics:

- “Creating a user-defined extension in C” on page 3026
- “Implementing a user-defined parser” on page 3099
- “Implementing a user-defined exit” on page 3113

About this task

These instructions use the file names of the supplied samples. If you are compiling your own user-defined extensions, substitute your own file names.

When you compile a user-defined extension that is written in C, you need a compatible compiler. For details of supported compilers, see “Optional software support” on page 3603.

Header files:
About this task

The following header files define the C interfaces:

BipCni.h
Message processing nodes

BipCpi.h
Message parsers

BipCci.h
Interfaces common to both nodes and parsers

BipCos.h
Platform-specific definitions

Compiling:
About this task

Compile the source for your user-defined extension on each of the supported operating systems to create the executable file that the broker calls to implement your user-defined extension. On Linux, UNIX, and z/OS systems, this file is a loadable implementation library (LIL) file; on Windows systems, it is a dynamic load library (DLL) file.

The libraries that you build to contain user-defined nodes or parsers must have the extension `.lil` on all operating systems so that the broker can load them. Libraries that contain user exits must have the extension `.lel` on all operating systems. The examples in this topic show libraries with the extension `.lil`

Refer to the documentation for the compiler that you are using for full details of available compile and link options that might be required for your programs.

Navigate to the directory where your user-defined extension source code is located, and follow the instructions for your operating system:

- AIX
- HP-Itanium
- Linux
- Solaris

- Windows
- z/OS

Compiling on AIX:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension for a 64-bit execution group; 32-bit execution groups are not supported.

   -l imbdfplg

chmod a+r output_dir/SwitchNode.lil
```

Compiling on Linux:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

When you compile programs on Linux on POWER, replace the option `-fpic` with `-fPIC` if you want to use dynamic linking and avoid any limit on the size of the global offset table.

The following instructions are for compiling an extension for a 64-bit execution group on Linux on x86-64, Linux on POWER, and Linux on IBM z Systems. 32-bit

execution groups are not supported on those platforms. To compile the extension for a 32-bit execution group on Linux on x86, replace `-m64` with `-m32` in the compile and link examples.

```
g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   TransformNode.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   SwitchNode.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   BipSampPluginUtil.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   Common.c

g++ -c -O2 -m64 -Wall -Wno-format-y2k -fpic \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -D_LINUX -D_THREADS -D_POSIX_PTHREAD_SEMANTICS -D_REENTRANT \
   NodeFactory.c

g++ -m64 -O2 -o samples.lil \
   TransformNode.o \
   SwitchNode.o \
   BipSampPluginUtil.o \
   Common.o NodeFactory.o \
   -shared -lc -lnsl -ldl \
   -L/install_dir/lib -limbdfplg
```

These commands create the file `samples.lil` that provides TransformNode and SwitchNode objects.

Compiling on Solaris:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

The following instructions are for compiling an extension for a 64-bit execution group on Solaris on SPARC; 32-bit execution groups are not supported. To compile the extension for a default 64-bit execution group on Solaris on x86-64, replace `-xarch=v9` with `-xarch=amd64` in the compile examples; 32-bit execution groups are not supported.

```
cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
```

```
   -I/install_dir/include/plugin \
   -c SwitchNode.c \
   -o output_dir/SwitchNode.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c TransformNode.c \
   -o output_dir/TransformNode.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c BipSampPluginUtil.c \
   -o output_dir/BipSampPluginUtil.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c NodeFactory.c \
   -o output_dir/NodeFactory.o

cc -xarch=v9 -mt \
   -I. \
   -I/install_dir/include \
   -I/install_dir/include/plugin \
   -c Common.c \
   -o output_dir/Common.o

cc -xarch=v9  -xcode=pic32 -mt -G \
   -o output_dir/SwitchNode.lil \
      output_dir/SwitchNode.o \
      output_dir/BipSampPluginUtil.o \
      output_dir/NodeFactory.o \
      output_dir/Common.o \
   -L /install_dir/lib \
   -l imbdfplg

chmod a+r output_dir/SwitchNode.lil
```

Compiling on Windows:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Ensure that you include a space between `SwitchNode.c` and `BipSampPluginUtil.c`, and also between `-link` and `/DLL`.

Enter the command as a single line of input; in the following example the lines are split to improve readability.

```
cl /VERBOSE /LD /MD /Zi /EHsc /I.
   /Iinstall_dir\include\plugin
   SwitchNode.c BipSampPluginUtil.c Common.c
   NodeFactory.c TransformNode.c
   -link /DLL install_dir\lib\imbdfplg.lib
   /OUT:SwitchNode.lil
```

If you have correctly set the *LIB* environment variable, you do not have to specify the full paths to the LIB files.

Compiling on z/OS:
About this task

When you compile a user-defined extension that is written in C, use a supported compiler.

Force your link to use prelinker or linker by setting the _CC_STEPS variable to -1:

```
export _CC_STEPS=-1
```

Alternatively, add these two lines to your makefile to export it:

```
_CC_STEPS=-1
.EXPORT : _CC_STEPS
```

To create optimized builds, use **-2** in place of **-g** in the following commands:

```
cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./SwitchNode.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./SwitchNode.o ./SwitchNode.c
```

```
cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./TransformNode.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./SwitchNode.o ./TransformNode.c
```

```
cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./BipSampPluginUtil.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./BipSampPluginUtil.o ./BipSampPluginUtil.c
```

```
cc -c \
 -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./Common.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./Common.o ./Common.c
```

```
cc -c \
  -Wc,LP64 -g -W0,langlvl\(extended\),EXPORTALL,float\ieee\) \
 -Wc,xplink \
 -W0,LIST\(./NodeFactory.lst\) \
 -I. -I${install_dir}/include \
 -I${install_dir}/include/plugin \
 -I${install_dir}/sample/include \
 -I${install_dir}/sample/plugin \
 -o ./NodeFactory.o ./NodeFactory.c
```

```
cc \
 -Wl,DLL,LP64 -g -Wl,p,map -Wl,LIST=ALL,MAP,XREF,REUS=RENT \
 -Wl,xplink \
 -o ./SwitchNode.lil ./SwitchNode.o ./BipSampPluginUtil.o \
 ./Common.o ./NodeFactory.o \
 ${install_dir}/lib/libimbdfplg.x
```

Run the following command to set the file permissions of the user-defined extension to `group read` and to be executable:

```
chmod a+rx {output_dir}/SwitchNode.lil
```

Implementing a user-defined exit

You can develop and deploy a user-defined exit.

Before you begin

Before you start:

- Read "User exits" on page 3015.

About this task

The following topics describe the steps required to develop and deploy a user-defined exit.

Procedure

1. "Developing a user exit"
2. "Deploying a user exit" on page 3116

Related concepts:

"User-defined extensions overview" on page 2971
A user-defined extension is an optional component that you design and create to extend the functionality of WebSphere Message Broker.

"User exits" on page 3015
A user exit is user-provided custom software, written in C, to track data passing through message flows.

"Why use a user-defined extension?" on page 2972
Use a user-defined node or parser when the built-in resources do not provide the required functions.

Related tasks:

"Developing a user exit"
Develop a user exit by declaring it, implementing its behavior, then compiling it.

"Deploying a user exit" on page 3116
Deploy your user exit to the broker.

Related reference:

"User-defined extensions" on page 6411
Reference material that supports the creation and management of your user-defined extensions.

Developing a user exit:

Develop a user exit by declaring it, implementing its behavior, then compiling it.

About this task

To develop a user exit, follow these steps.

Procedure

1. Declare the user exit.

   Declare a user exit by using the bipInitializeUserExits function to specify the following properties:

   a. Name (used to register and control the active state of the exit)
   b. User context storage
   c. A function to be invoked (for one or more Event Types)
2. Implement the user exit behavior.

When the user exit is declared, a set of functions is registered, and these functions are invoked when specific events occur. The behavior of the user exit is provided by implementing these functions. The following table lists the events and their associated functions:

Event	Function
A message is dequeued from the input source	cciInputMessageCallback
A message is propagated to the node for processing	cciPropagatedMessageCallback
A request message is sent to the output node's transport, and transport-specific destination information is written to "WrittenDestination" in the LocalEnvironment	cciOutputMessageCallback
The node completes processing	cciNodeCompletionCallback
The transaction ends	cciTransactionEventCallback

3. Your user exit code must implement the cleanup function.

   The user exit library must implement the bipTerminateUserExits function. This function is invoked as the ExecutionGroup's process is ending, and your user exit must clear up any resources allocated during the bipInitializeUserExits function.

4. Compile.

   Use your existing process for your environment to compile your user exit. The supported C compilers are shown in “Optional software support” on page 3603. See “Compiling a C user-defined extension” on page 3047 for more details.

5. Link the compiled code to a library with the extension `.lel` that exports the bipInitializeUserExits and bipTerminateUserExits functions.

Use the **mqsireportflowuserexits** command to report the list of active and inactive user exits for the specified broker, execution group, or message flow.

“**mqsichangeflowuserexits** command” on page 3751
Use the **mqsichangeflowuserexits** command to set the list of active or inactive user exits. A list of active and a list of inactive user exits is maintained for each execution group and message flow. The effective state of user exits for a given flow is decided when the flow starts.

Deploying a user exit:

Deploy your user exit to the broker.

Before you begin

Before you start:

- Write and compile the user exit code. See "Developing a user exit" on page 3114.
- Ensure that the exit:
  1. Is in a library that has the extension `.lel`
  2. Exports the functions bipInitializeUserExits and bipTerminateUserExits

About this task

You can set the state of the user exit dynamically to active, or inactive, on a per-message flow basis without restarting the broker.

To deploy the user exit:

Procedure

1. Install the user exit code on a broker.

   The library containing the user exit code must be installed on a file system that can be accessed by the broker. For example, the file must have read and execute authority for the user ID under which the broker runs. The broker looks in the following places for libraries that contain user exits:

   - The broker property `UserExitPath` defines a list of directories separated by colons (semicolons on Windows). Use the `-x` flag on the **mqsicreatebroker** or **mqsichangebroker** command to set this property for execution groups for each broker.
   - Alternatively, you can append the directory containing the directory that holds the extension files to the environment variable MQSI_USER_EXIT_PATH associated with the environment in which the broker is running.

   If both are set, the environment variable takes precedence. All the directories in the environment variable are searched in the order in which they appear in the variable, then all the directories in the broker property are searched in the order in which they appear in the property.
2. Load the user exit library into the broker's processes.

   When the user exit library has been installed on the broker, you must load it in one of the following ways:

   - Stop and restart the broker.
   - Run the **mqsireload** command to restart the execution group processes.
3. Activate the user exit.

   User exits can be active or inactive, and are inactive by default. You can change the state of a user exit dynamically by using the **mqsichangeflowuserexits** command on a per-flow basis, without having to restart the broker. You can also change the default state for a set of user exits to active on a per-broker basis by using the **mqsichangebroker** command; in this case, you do have to restart the broker.

   To set the default user exit state for a broker:

   a. Stop the broker.

b. Set the `activeUserExits` property of the broker by using the **mqsichangebroker** command.

c. Start the broker and check the system log to ensure that all execution groups start without error. If any invalid user exit names are specified (that is, the user exit is not provided by any library loaded by the execution group), a BIP2314 message is written to the system log and all flows in the execution groups fail to start unless you take one of the following actions:

   - Provide a library in the user exit path that implements the exit; then run the **mqsireload** command, or restart the broker, to load an exit from the library.
   - Run the **mqsichangeflowuserexits** command to remove the exit from both the active and inactive lists.

You can also override the default user exit state for a broker. You can use the **mqsichangeflowuserexits** command to activate, or deactivate, user exits on a per-execution group or per-message flow basis, with the order of precedence being message flow then execution group. When multiple exits are active for a flow, the broker starts them in the order that is defined by the **mqsichangeflowuserexits** command.

Packaging and distributing user-defined extensions

When you have created and tested a user-defined extension, you can package and distribute it.

Before you begin

Before you start:

Complete the following tasks:

- "Implementing user-defined extensions" on page 3019
- "Testing a user-defined node" on page 3094

About this task

When you have created and tested your user-defined extension, you can distribute these resources to other computers.

For user-defined extensions created in Java or C:

1. Package and install the user-defined extensions. To package and install the resources that make up the workbench representation of your user-defined node, see "Packaging and distributing a user-defined node project" on page 3121.
2. Copy the files generated by the compilation step to all the computers on which you have created brokers that might need these resources. See "Installing user-defined extension runtime files on a broker" on page 3125. For a more automated approach, see "Installing a user-defined extension to current and past versions of WebSphere Message Broker" on page 3128.

For user-defined nodes created from subflows:

- Package and install the user-defined nodes implemented as a subflow, see "Packaging and distributing a user-defined node project" on page 3121.

Related concepts:

Packaging a Java user-defined node:

How to package a Java user-defined node.

Before you begin

Before you start

You must have a user-defined node written in Java. This node can be one of the provided sample nodes that are described in "Sample node files" on page 6412, or a node that you have created yourself by using the instructions in either "Creating a message processing or output node in Java" on page 3062 or "Creating an input node in Java" on page 3055.

About this task

You can package a user-defined node in two ways:

- **PAR**

  A Plug-in Archive (PAR) is the deployment unit for Java user-defined nodes. The PAR contains the user-defined node classes and, if required as dependencies, can contain JAR files. A PAR file is a compressed file with a `.par` file extension. The directory structure in the `.par` file has the following format:

  – `/classes`

    The user-defined node classes are stored in this location.

  – `/lib`

    JAR files that are required by the user-defined node are stored in this location. This directory is optional because it might not be necessary to include JAR files.

  The following procedure describes how to package an example user-defined node, *parexamplenode*. In this example, the PAR is to be contained in *par.example.parexamplenode.class* with a JAR file dependency *dependency.jar*.

  1. Create the directory structure; for example:
     – `/classes/par/example/parexamplenode.class`
     – `/lib/dep.jar`
  2. Issue a file compression command to create the PAR; for example:

     ```
     jar cvf parexample.par classes lib
     ```

  The PAR must be placed in the LIL path that is specified in "Installing user-defined extension runtime files on a broker" on page 3125.

- **JAR**

  User-defined nodes can be packaged by using a simple JAR. For example, if your node is defined in `example/jarexamplenode.class`, create the JAR by using the `jar cvf jarexample.jar example` command.

  The preferred way to package a Java user-defined node is to use a PAR file, because all dependencies can be packaged with the node, and each node is loaded in a separate class loader. For information about loading classes, see "User-defined node class loading" on page 3120.

  The JAR must be placed in the LIL path that is specified in "Installing user-defined extension runtime files on a broker" on page 3125.

Deployment dependencies:
About this task

If a user-defined node requires an external package, the package can be deployed in one of following ways:

- The external packages can be added to the `/lib` directory in the deployed PAR.
- For external packages that are shared between several node types, the packages can be added to one of the following locations:
  – One of the `shared-classes` directories. For more details of these directories, see "Java shared classloader" on page 2637.
  – The `CLASSPATH` environment variable, where all user-defined nodes that are in the broker installation can access the packages

Related concepts:

"User-defined node class loading" on page 3120
Details the Java classes packaging options and loading order precedence for

user-defined nodes.

Related tasks:

"Compiling a Java user-defined node" on page 3074
When you have created the code for your Java user-defined node, you must compile it for your operating system.

"Java shared classloader" on page 2637
Loads all the JAR files located within the shared-classes directories. The precedence order of loading is dictated by the directories the JAR files are located in.

User-defined node class loading:

Details the Java classes packaging options and loading order precedence for user-defined nodes.

Java user-defined node classes can be packaged and loaded in two ways:

- Plug-in Archive (PAR) file; a broker defined format - Each PAR file is given it's own class loader which isolates any classes it loads from any other part of the WebSphere Message Broker, including nodes in other PAR files.
- Standard Java archive (JAR) file - All JAR files containing plug-in nodes are loaded into the same classloader and can access classes in JAR files containing other user-defined nodes.

For both packaging mechanisms, if the classloader cannot find a required class within the package it defers to the shared class loader to find the required class. The shared classloader looks in a set of directories on the broker machine and loads any JAR files found. It can be used to install any required JAR files that do not need to be repeatedly deployed, such as client libraries that the Java compute nodes need to use. For more details, see "Java shared classloader" on page 2637.

If the required class cannot be found in any of the deployed JAR files, or in the JAR files installed in the shared classes directories, a classloader containing all of the broker supplied classes is checked (for example: this classloader contains the `jplugin2.jar`), followed by the classpath, and then finally the Java virtual machine (JVM) system classloader.

Two key points must be considered when deciding which of the above mechanisms are used to load a class:

- Isolation between different applications (for example: adding classes to the classpath makes them available to every part of WebSphere Message Broker and can cause conflicts).
- Delegation from one classloader to another can only occur in one direction. If a class is resolved in the shared classloader, then it cannot directly create classes in the PAR classloader.

User-defined nodes class loading search paths:
User-defined nodes package in a PAR file

The broker uses the following search path to find user-defined node classes:

1. `/classes` to locate classes in the deployed PAR file.
2. `/lib` to locate any JAR files in the deployed PAR file.
3. *`workpath`*`/config/`*`<my_broker_name>`*`/`*`<my_eg_label>`*`/shared-classes` to locate any JAR files in the execution group `shared-classes` directory.

4. *workpath*/shared-classes/ to locate any JAR files in the top level shared-classes directory.
5. CLASSPATH environment variable.

User-defined nodes package in a JAR file

The broker uses the following search path to find user-defined node classes:

1. The deployed JAR file.
2. *workpath*/config/<*my_broker_name*>/<*my_eg_label*>/shared-classes to locate any JAR files in the execution group shared-classes directory.
3. *workpath*/shared-classes/ to locate any JAR files in the top level shared-classes directory.

Related tasks:

Create user-defined nodes either from scratch, or by using an existing subflow.

"Testing a subflow user-defined node project" on page 3097
Test how the user-defined node is displayed, and how it behaves in your environment.

"Message sets packaged with a user-defined node" on page 1497
Adding message sets to an update site.

Packaging as plug-in JAR files:

Export the user-defined node project as plug-in JAR files to make it available for other users.

About this task

If you use this option, the user-defined node user must copy the user-defined node plug-ins into the plug-ins folder in the WebSphere Message Broker Toolkit. However, the user-defined node user can write a script to automate the copying process, so that the user-defined nodes are deployed automatically.

To package your user-defined node projects so that they are available in the environment of the user, complete the following tasks:

Procedure

1. Right-click the project that you want to package, select **Package**. The Package and Distribute User-Defined Nodes wizard opens.
2. Select **Plug-in jars**. Click **Next**.
3. Select the plug-ins and fragments that you want to use. Projects upon which the subflow user-defined node depends, such as message set projects, are automatically included and are not shown in the list.
4. Navigate through the wizard, completing the fields as required. Click **Finish**.

Related concepts:

"User-defined nodes" on page 2989
User-defined nodes are the main mechanism for extending the functions of WebSphere Message Broker.

Related tasks:

"Packaging as an update site"
Create an installation site for Web page distribution of the user-defined node projects that includes or references other projects or plug-ins. You can either create a new update site, or use an existing one.

"Packaging and distributing a user-defined node project" on page 3121
Export the user-defined node project to make it available for other users.

Adding message sets to an update site.

"Installing a user-defined node" on page 1496
Develop message flows that use a user-defined node.

Packaging as an update site:

Create an installation site for Web page distribution of the user-defined node projects that includes or references other projects or plug-ins. You can either create a new update site, or use an existing one.

About this task

To package your user-defined node projects so that they are available in the environment of the user, complete the following tasks:

Procedure

1. Right-click the project that you want to package, select **Package**. The Package and Distribute User-Defined Nodes wizard opens.
2. Select **Installation package**. You can either create a new installation site or use an existing installation site in the workspace.
   - To create a new installation site:
     a. Select **Create a new package**, and in the **Create a new package** field, enter a name for the package. If a project with that name exists in the workspace, you are asked if you want to delete the project so that you can continue with packaging.
     b. Click **Next**.
     c. Optional: Select any projects and plug-ins that you want to include in your package:
        1) The top section shows the user-defined node projects that are available in your workspace. Select the projects that you want to include in your package.
        2) The bottom section shows all the Eclipse plug-ins that the selected user-defined node projects require. WebSphere Message Broker Toolkit built-in plug-ins that have a plug-in identifier that starts with `com.ibm.etools.mft` are not shown. The Eclipse plug-ins that are required are a combination of the following plug-ins:
           – All Eclipse plug-ins that are listed as the dependency plug-ins in the plug-in manifest for the user-defined node project
           – All Eclipse plug-ins that contributed user-defined nodes that are being used by one of your selected user-defined node projects
        3) Click **Next**.
     d. Optional: Further customize your user-defined node package by adding in any detailed information that you want to include. Click **Next**.
     e. Click **Finish**. When you click **Finish**, the selected user-defined node project and its dependent user-defined node projects in the workspace are packaged into an Eclipse feature, and an Eclipse Update Site is built. The Eclipse feature and Eclipse update site project use the name that you have given to the package appended with `.feature` or `.site`. Any space in the package name is replaced by a dot (.).
     f. The Distribution window opens. To save the instructions to the clipboard, click **Save the instruction above to clip board**.
     g. To select a destination for your user-defined node package, in the "Web distribution" section, click **Copy project *Your project name*.** . The "Copy package" window opens. Select the location, click **OK**.
   - To use an existing installation site you must have already created an installation site.
     a. Select **Update user-defined nodes in an existing package**, select an installation site from the list. Click **Finish**. When you click **Finish**, the selected user-defined node project and its dependent user-defined node projects in the workspace are packaged into an Eclipse feature, and an Eclipse Update Site is built. The Eclipse feature and Eclipse update site

project use the name that you have given to the package appended with `.feature` or `.site`. Any space in the package name is replaced by a dot (.).

b. The Distribution window opens. To save the instructions to the clipboard, click **Save the instruction above to clip board**.

c. To select a destination for your user-defined node package, in the "Web distribution" section, click **Copy project *Your project name.*** . The "Copy package" window opens. Select the location, click **OK**.

Installing user-defined extension runtime files on a broker:

Install the compiled runtime files for your user-defined extension on the broker on which you want to test its function.

Before you begin

Before you start

- Create and compile your user-defined extension using the procedure described in "Compiling a Java user-defined node" on page 3074 or "Compiling a C user-defined extension" on page 3047.
  - The files that have been created for extension created in C depend on the underlying broker operating system:

    Windows A dynamic link library (DLL), named with a file type of `.lil`.

    Linux A shared object, again with a file type of `.lil`.

    UNIX A shared object, again with a file type of `.lil`.

z/OS A shared object, with a file type of `.lil`.

– For Java nodes, a Java Archive file (JAR), with a file type of `.jar` (on all operating systems).

- If you have created a user-defined node, you must also complete the task "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079.

About this task

This task instructs you to stop and restart brokers. This action is required in all but the two circumstances described in step 4 later in this section, although if you do stop and restart the broker, you can ensure that anyone with an interest in a particular execution group is made aware that recent changes have been made.

This task is applicable to user-defined nodes written in Java or C only.

To install runtime files on the broker:

Procedure

1. Stop the broker on which you want to install your compiled or packaged user-defined extension file (files with extension `.lil`, `.jar`, `.par`, `.pdb`, or `.lel`)
2. Create a directory if you do not already have one for this purpose. Add the directory to the LILPATH by using the **mqsichangebroker** command.

   CAUTION:
   Do not put the `.lil`, `.jar`, `.par`, `.pdb`, or `.lel` files in the WebSphere Message Broker installation directory, because they might be overwritten by the broker.
3. Put your user-defined file in the directory, and make sure that the broker has access to it. For example, on Linux or UNIX, use the **chmod 755*** command on the file.
4. Stop and restart the broker to implement the change and to ensure that the existence of the new file is detected. A broker restart is not necessary in the following circumstances:
   - If you have created an execution group in the WebSphere Message Broker Toolkit, and nothing is yet deployed to it, you can add the `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` file to your selected directory.
   - If something has already been deployed to the execution group that you want to use, add the `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` file to your selected directory, and issue the **mqsireload** command to restart the group. You cannot overwrite an existing file on the Windows system when the broker is running, because of the file lock that is put in place by the operating system.

   Use these two approaches with care, because any execution group that is connected to the same broker also detects the new `.lil`, `.pdb`, `.jar`, `.par`, or `.lel` files when that execution group restarts, or when something is first deployed to that execution group.
5. Repeat the previous steps for every broker that needs the user-defined extension file and user-defined node plug-in file. If all of your brokers are on the same operating system type, you can build the user-defined extension file once and distribute it to each of your systems.

   If you have a cluster, for example, that includes one AIX, one Solaris, and one Windows broker, you must build the user-defined extension files separately on each operating system type.

Windows On Windows, the `.pdb` file provides symbolic information that is used when stack diagnostic information is displayed in the event of access violations or other software malfunctions.

6. For C user-defined extensions, store the `.pdb` file in the same directory as the `.lil` file to which it corresponds.
7. Use either the **mqsichangebroker** command or the **mqsicreatebroker** command, as appropriate, to specify to the broker the directory that contains the user-defined extension file.

   When you have installed a user-defined extension, it is referred to by its schema and name, just like a message flow.

Results

The broker loads the user-defined extension files during initialization. After loading the files, the broker calls the registration functions in the user-defined extension and records what nodes or parsers the user-defined extension supports.

A C user-defined extension implements a node or parser factory that can support multiple nodes or parser types. For more information, see "Node and parser factory behavior" on page 2982. Java users are not required to write a node factory.

Installing a user-defined extension to current and past versions of WebSphere Message Broker:

Install user-defined extensions that you have developed yourself, or have acquired from an independent software vendor, with the minimum of user intervention.

Before you begin

Before you start

Complete the following tasks:

1. "Compiling a Java user-defined node" on page 3074, "Compiling a C user-defined extension" on page 3047, or "Creating a user-defined node from a subflow" on page 3076
2. "Creating the user interface representation of a user-defined node in the WebSphere Message Broker Toolkit" on page 3079
3. "Testing a user-defined node" on page 3094
4. "Packaging and distributing a user-defined node project" on page 3121

About this task

You must install user-defined extensions on all appropriate WebSphere Message Broker computers, and, if the extension is a user-defined node, on the WebSphere Message Broker Toolkit computers (user-defined parsers have no WebSphere Message Broker Toolkit component). Components can be installed separately, or as part of one process. The components can be on different systems, therefore check that the installations are completed on all affected systems.

If an extension writes messages to user trace, you must update the environment variable MQSI_CONSOLE_NLSPATH (Windows systems), or NLSPATH (all other systems), so that the **mqsiformatlog** command can find the message catalog.

The WebSphere Message Broker Toolkit installation:
Before you begin

Before installing a user-defined node, check the version of the WebSphere Message Broker Toolkit to which you are installing, because a specific version of the WebSphere Message Broker Toolkit might be a prerequisite of the user-defined extension, or it might require specific files to run.

To determine the version, see "Detecting installed versions of WebSphere Message Broker" on page 3132.

Procedure

1. Copy your files to a directory that the WebSphere Message Broker Toolkit can access, so that you can view your user-defined node in the WebSphere Message Broker Toolkit session. Choose one of the following options:
   - Add your new plug-in JAR file directly into the `dropins` directory where the WebSphere Message Broker Toolkit is installed. For example, on Windows 32-bit, add the file to `C:\Program Files\IBM\WMBT700\dropins`.

     If you choose this option, you might find it difficult to manage your plug-ins files safely if you later remove or replace them. Also, your system administrator might want to control security and access on computers that

are used by more than one user, and might not set permissions for users to write to the primary installation directories.

- Create Eclipse link files to the directories in which you maintain your plug-in files.

  For details about how to create link files, see the developerWorks article about using Eclipse features (the section entitled "Using link files to manage an Eclipse install").

  a. Linux On Linux: Delete any existing `.eclipse` directory in your home directory, and restart the WebSphere Message Broker Toolkit. For example, remove the following directory, where *userid* is your user identification: `/home/userid/.eclipse`

  b. Create a directory called `eclipse` in a suitable location in your file system; the directory structure that contains the `eclipse` directory is not significant.

  c. Within the `eclipse` directory, create directories named `features` and `plugins`.

  d. Windows On Windows: Under `C:\Program Files\IBM\WMBT700` create a new links folder, and create a file called *name*`.link`, where *name* is a name that you have chosen. Type the following text `path=C:/path/to/your/dir/` into the *name*`.link` file, where *path/to/your/dir/* is the path to your directory.

     Example: If you put your plug-ins into `C:\Temp\MyPlugins\eclipse\plugins\`, the content of the link file is `path=C:/Temp/MyPlugins`.

2. Restart your WebSphere Message Broker Toolkit session for the changes to take effect.

Broker installations:
About this task

You might be required to detect the versions of WebSphere Message Broker that are installed, to ensure that the correct LIL file is loaded by the correct level of the broker. See “Detecting installed versions of WebSphere Message Broker” on page 3132.

To add `.jar` or `.lil` files to broker installations on WebSphere Message Broker Version 6.0 and later, see “Installing user-defined extension runtime files on a broker” on page 3125.

Installing a user-defined extension for single broker:
About this task

Version 7.0 and Version 8.0

- To make an extension accessible from only one broker on the system, modify the *UserLilPath* setting for the broker by specifying the `-l` parameter on the **mqsicreatebroker** or **mqsichangebroker** command.

Version 6.1 and earlier

- To make a 32-bit extension accessible from only one broker on the system, modify the *UserLilPath* setting for the broker by specifying the `-l` parameter on the **mqsicreatebroker** or **mqsichangebroker** command.
- To make a 64-bit extension accessible from only one broker on the system, modify the *UserLilPath64* setting for the broker by specifying the `-r` parameter on the **mqsicreatebroker** or **mqsichangebroker** command.

For more information, see "**mqsicreatebroker** command" on page 3831 and "**mqsichangebroker** command" on page 3723.

Installing a user-defined extension for multiple brokers:
About this task

Version 7.0 and Version 8.0

- To affect all brokers on a system, you modify the system LILPATH. Append the directory containing the directory that holds the extension files to the environment variable MQSI_LILPATH. MQSI_LILPATH64 is not valid at this version.

Version 6.1 and earlier

- To affect all brokers on a system, you modify the system LILPATH. Append the directory containing the directory that holds the extension files to the environment variable MQSI_LILPATH (for 32-bit extensions) or MQSI_LILPATH64 (for 64-bit extensions).

Make this change by creating a custom environment script in the working directory:

- Linux UNIX On Linux and UNIX systems: `/var/mqsi/common/profiles`
- Windows On Windows: `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\profiles` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:
  - On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\common\profiles`
  - On Windows 7, Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\common\profiles`

  The actual value might be different on your computer.

You can give the environment script any name, but the file extension must be `.cmd` on Windows and `.sh` on all other platforms. The script can perform all the operations of a shell script, but you must limit the scope to only appending the following variables:

MQSI_LILPATH
Defines the directories to search for plug-ins

CLASSPATH
Defines the locations that Java searches for additional classes

MQSI_CONSOLE_NLSPATH
On Windows: Defines the location of message catalogs (DLL files)

NLSPATH
On Linux and UNIX: Defines the location of message catalogs (CAT files)

PATH
Defines the location of executable files. On Windows: This variable also defines the location of dependent libraries.

LIBPATH / SHLIB_PATH / LD_LIBRARY_PATH
On UNIX and Linux: Defines the location of dependent libraries.

Example scripts:

About this task

Windows On Windows: This example shows the environment profile for MyExtension, which is installed in `C:\Program Files\MyExtensions` on Windows 32-bit, or in `C:\Program Files(x86)\MyExtensions` on Windows 64-bit.

The script is called `MyExtension.cmd` and is stored in the working directory. The default location is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\profiles` where the default setting for the environment variable`%ALLUSERSPROFILE%` depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\`.
- On Windows Vista and Windows Server 2008: `C:\ProgramData\`.

The actual value might be different on your computer.

The Windows script contains the following content:

```
REM Added by MyExtension install, do not modify
set MQSI_LILPATH=%MQSI_LILPATH%;"C:\Program Files\MyExtension\bin"
```

Linux UNIX On Linux and UNIX: This example shows the environment profile for MyExtension, which is installed in `/opt/MyExtension`. The script is called `MyExtension.sh` and is stored in the working directory `/var/mqsi/common/profiles/`.

The Linux script contains the following content:

```
#!/bin/ksh
# Added by MyExtension install, do not modify
export MQSI_LILPATH=/opt/MyExtension/lil${MQSI_LILPATH:+":"${MQSI_LILPATH}}
```

You can test the following variables in the profile script, for example if you want to ensure that a user-defined extension runs only on a specific version of the broker:

MQSI_FILEPATH
The full path to the installed file for WebSphere Message Broker

MQSI_WORKPATH
The full path to the configuration data for WebSphere Message Broker

MQSI_VERSION
WebSphere Message Broker version, in the form `version.release.modification.fix`

MQSI_VERSION_V
The value of WebSphere Message Broker major version

MQSI_VERSION_R
The value of WebSphere Message Broker release

MQSI_VERSION_M
The value of WebSphere Message Broker modification number

MQSI_VERSION_F
The value of WebSphere Message Broker fix level

Detecting installed versions of WebSphere Message Broker:

A user-defined extension can detect which version of WebSphere Message Broker is installed.

About this task

Use the conditions described here to test for particular version or versions. If expected conditions are not met, a component might not have installed correctly, or might have become corrupted. Check the status of the installed component and the local logs to identify and resolve any errors.

Detecting installed versions on Windows:
About this task

Use the following instructions in your installer scripts on Windows to test for the following versions. To detect each version, look for the registry key given for each version. In the examples shown, x can be any integer.

WebSphere Message Broker Version 6.0 toolkit

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\
WMBT60\DisplayVersion = 6.x.x.x
```

WebSphere Message Broker (and later) toolkit

Check for the presence of the files `\IBM\Installation Manager\installed.xml` and `\IBM\Installation Manager\installRegistry.xml` in the working directory.

The default working directory is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI`
- On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI`

The actual value might be different on your computer; use `%ALLUSERSPROFILE%` to ensure that you access the correct location.

WebSphere Message Broker Version 6.0 (and later) runtime components

Open the file `install.properties` in the working directory.

The default working directory is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI`
- On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI`

The actual value might be different on your computer; use `%ALLUSERSPROFILE%` to ensure that you access the correct location.

Each line in the file is of the following format:

```
PATH_TO_INSTALLATION = VERSION_OF_INSTALLATION
```

For example, if you have installed Version 7.0 GA level in the default installation location, the line contains the following text:

```
C\:\\ Program\ Files\\IBM\\MQSI=7.0.0.0
```

The backslash character \ is interpreted as an escape character. It is inserted before each non-alphabetic and non-numeric character in the string to preserve the character. A colon, a space, and several backslash characters are escaped in this example.

Parse each line of the file to detect all the installed versions and the directory paths for the runtime components, and ignore all duplicates and non-existent directories.

Detecting installed versions on Linux and UNIX systems:

About this task

Linux and UNIX systems do not have a common packaging method: you must check which files are present in the file system. Look for the following files for each version of WebSphere Message Broker that you want to detect.

WebSphere Message Broker Version 6.0 toolkit

To detect Version 6 and later toolkits, look for the existence of /etc/IBM/WebSphereMessageBrokersToolkit/products/com.ibm.wbmt.

To determine the version, use the following code example. Shell-script notation is used in this code: '-e' means if file exists.

```
if [ -e /etc/IBM/WebSphereMessageBrokersToolkit/products/com.ibm.webt  ]
  # Event Broker installed
      if [ -e `grep location /etc/IBM/WebSphereMessageBrokersToolkit/products/
    com.ibm.webt | sed 's/location=//'`/webt_prod/version.txt` ]
        # it is FP1 or greater
        get version from version.txt
      else
        #version is 6.0
      fi
    fi
  if [ -e /etc/IBM/WebSphereMessageBrokersToolkit/products/com.ibm.wmbt ]
    # Message Broker installed
    if [ -e `grep location /etc/IBM/WebSphereMessageBrokersToolkit/products/
    com.ibm.wmbt | sed 's/location=//'`/wmbt_prod/version.txt` ]
      #It is FP1 or greater
      get version from version.txt
    else
      #version is 6.0
    fi
  fi
```

WebSphere Message Broker (and later) toolkit

Check for the presence of the files /var/ibm/InstallationManager/installed.xml and /var/ibm/InstallationManager/installRegistry.xml.

WebSphere Message Broker Version 6.0 (and later) runtime components

To detect Version 6.0 and later runtime components, look for the file /var/mqsi/install.properties. Each line in this file contains an installation path and V.R.M.F version information.

Install user-defined extensions that you have developed yourself, or have acquired from an independent software vendor, with the minimum of user intervention.

Updating a user-defined extension:

On all systems, you can change a user-defined extension file.

About this task

You must stop and restart the broker for your changes to show, However, you are not required to stop and restart the broker in the following two scenarios:

- If you have created an execution group in the WebSphere Message Broker Toolkit, but have not yet deployed to it, you can add the `.lil`, `.pdb`, and `.jar` files to your chosen directory.
- If an object has already been deployed to the execution group that you want to use, add the `.lil`, `.pdb`, and `.jar` files to your chosen directory and use the **mqsireload** command to restart the group. You cannot overwrite an existing file on the Windows system when the broker is running because a file lock is put in place by the operating system.

These two scenarios must be used with caution, because any execution group that is connected to the same broker also detects the new `.lil`, `.pdb`, and `.jar` files when that execution group is restarted, or when an object is first deployed to it. If you restart the broker, you must ensure that anyone with an interest in a particular execution group is made aware that recent changes have been made to the broker.

These two scenarios assume that you have used either the **mqsichangebroker** command or the **mqsicreatebroker** command to notify the broker of the directory in which the user-defined extension files have been placed.

Procedure

To change a user-defined extension file:

1. Stop the broker by using the **mqsistop** command.
2. Update or overwrite the `.lil` or `.jar` file.
3. Restart the broker by using the **mqsistart** command.

Using error logging from a user-defined extension:

Program user-defined extensions to write entries in the local error log.

About this task

In most circumstances, user-defined extensions should use exceptions to report errors. However, you can provide information about significant events, error or otherwise, for problem determination and operational purposes. The details that you supply are included in predefined message text that is extracted from a message source or catalog.

- In C code, use the utility function CciLog or CciLogW to report events. Two of the arguments that you pass to this function, `messageSource` and `messageNumber`, define the event source (catalog) and the integer representation of a message within that source, respectively.

  You can also write trace information, using CciUserTrace, CciUserTraceW, CciUserDebugTrace, and CciUserDebugTraceW when tracing and debugging is active.
- In Java code, use the class `MbService`, which provides static methods to log information to the event log. To log messages to the event log, package your messages into a standard Java resource bundle. You can use one of the three logging methods, passing in the resource bundle name and the message key. The message is fully resolved, and is then inserted as a single insert into the appropriate broker message as shown:
  - logInformation(...) - BIP4360 Java user-defined node information: *user message*
  - logWarning(...) - BIP4361 Java user-defined node warning: *user message*
  - logError(...) - BIP4362 Java user-defined node error: *user message*

You can write messages that are defined in the product message catalog (`BIPmsgs`), to which you can add your own text as an argument. If you prefer, you can create your own message catalog, so that you can create more complex messages, or share a message catalog with other applications. If you want to create your own message catalog, see "Creating message catalogs" on page 3138.

- Windows On Windows systems, messages are written to the Windows event log.
- Linux UNIX z/OS On Linux, UNIX, and z/OS systems, messages are written to the SYSLOG facility.

The description here covers exceptions that are raised during normal message flow processing. You must also provide for exceptions that are raised when you deploy and configure a message flow. Messages that result from these configuration exceptions are reported back to the WebSphere Message Broker Toolkit for display to the WebSphere Message Broker Toolkit user. Create an appropriately-named Java properties file to contain your messages, then copy the file to each computer on which you are running the WebSphere Message Broker Toolkit, so that your messages can be displayed.

Related tasks:

"Creating message catalogs"
Create your own message catalogs to write tailored entries to the local error log.

Creating message catalogs:

Create your own message catalogs to write tailored entries to the local error log.

About this task

In some error and other situations, you might choose to write information to the error log so that you can track what is happening in a message flow. You can use the Throw and Trace built-in nodes to generate entries in the log, or you can create your own nodes and user exits, and write entries in the log from your user-defined extensions.

You can write either or both of the following sets of messages:

- A fixed set of messages that are provided in the product message catalog. This set provides a range of numbers for Throw nodes (BIP3001 to BIP3001), and a second range for Trace nodes (BIP3051 to BIP3001). A third range (BIP2951 to BIP2999) is provided for the ESQL statements LOG and THROW.

  When you use these messages, you can also provide additional text that is displayed in the message text.
- Your own messages, created in your own message catalog. You can use this additional catalog to define specialized message content, and you can include variables or inserts that are determined by the code that generates the message. You can also share your own message catalog with other applications that are not associated with WebSphere Message Broker.

When you throw an exception from ESQL by using a THROW statement, the ESQL code adds an extra leading insert that contains the name of the current component. The rest of the inserts that are provided by the ESQL script follow this leading insert. Therefore, you must consider this insert when you are writing your own message catalog.

The instructions in this topic describe how to create message catalogs for C programs. If you want to create a Java resource bundle, refer to the documentation for the Java 2 Platform, Standard Edition.

Read the section appropriate to your broker operating system:

- "Building and installing a Windows message source"
- "Creating an XPG/4 catalog for Linux, UNIX, and z/OS" on page 3140

Building and installing a Windows message source:
About this task

On Windows, you must create your additional message catalog as a DLL file. The DLL file contains definitions of your event messages, which the event viewer can display in a readable format, based on the event message written by your application. When you compile a message catalog, a header file is created that defines symbolic values for each event message number you have created. You must include the header file in your application.

To create an event source for the Windows Event Log Service:

Procedure

1. Create a message compiler input (`.mc`) file with the source for your event messages. Refer to the Microsoft Developer Network Web site, and search on `.mc file` for details on the format of this input file.
2. Compile the message file to create a resource compiler input file:

   ```
   mc -v -w -s -h c:\mymessages -r c:\mymessages mymsg.mc
   ```

   where `c:\mymessages` is the location of the output files and *mymsg.mc* is the name of the input file.

   The message compiler produces an output header (`.h`) file that contains symbolic `#defines` that map to each message number that is coded in the input `.mc` file. Include this header file when you compile a user-defined extension source file that uses a utility function (for example, CciLog) to write an event message that you have defined. The `messageNumber` argument to utility function must use the appropriate value that is hash-defined in the output header file.
3. Compile the output file (`.rc`) from the message compiler to create a resource file (`.res`):

   ```
   RC /v output_file.rc
   ```
4. Create a resource DLL file from the `.res` file:

   ```
   LINK /DLL /NOENTRY resource_file.res
   ```
5. Append the location of the resource DLL file to the MQSI_CONSOLE_NLSPATH environment variable, for example:

   ```
   set MQSI_CONSOLE_NLSPATH=%MQSI_CONSOLE_NSPATH%;c:\messages
   ```

   You can do this by creating a custom environment script in your working directory. The default location is `%ALLUSERSPROFILE%\Application Data\IBM\MQSI\common\profiles` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:

   - On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\common\profiles`
   - On Windows Vista and Windows Server 2008: `C:\ProgramData\IBM\MQSI\common\profiles`

The actual value might be different on your computer.

6. Install the event source into the Windows Event Log Service:
   a. Start the Windows Registry Editor:
      ```
      regedit
      ```
   b. Create a new registry subkey for your user-defined extension under the existing structure:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Application
```

Right-click **Application** and select **New** > **Key**. The new key is created immediately under the Application key (not under the WebSphere Message Broker key). You must give the key the name that you specify for the `messageSource` on a utility function in your user-defined extension (for example, CciLog) or as the property of the built-in node that you have included in your message flow.

Create the following values for this entry:

`EventMessageFile`
Set the value of this string to contain the fully qualified path for the DLL file that you have created to contain your messages. This entry represents the message catalog.

`TypesSupported`
Set the DWORD value to "7".

Creating an XPG/4 catalog for Linux, UNIX, and z/OS:
About this task

On Linux, UNIX, and z/OS systems, messages are written to the SYSLOG facility. If you want to use your own message catalog, you must create an XPG/4 message catalog.

The process for creating a message catalog (a `.cat` file) depends on the operating system on which you are creating it. The commands that you use are typically **`gencat`** (create or modify a message catalog) and **`dspcat`** (to display all or part of a message catalog). The **`gencat`** command merges text files that contain your message text, to create or modify a formatted catalog. The text files typically have a file extension of `.msg`.

You must append the location of the message catalog to the NLSPATH environment variable. You can use %L and %N to represent the locale and the catalog name, for example:

```
export NLSPATH=${NLSPATH}:${MY_INST_PATH}/messages/%L/%N:${MY_INST_PATH}/messages/En_US/%N
```

In this example, the English version is hardcoded later in the search path, ensuring that messages are displayed even in locales for which no `.cat` file exists.

The messages that you define in the `.msg` files can include variables that are substituted at run time. Such variables must be of the format *{number}*, where *{number}* is the message insert number, surrounded by braces. The first message insert is numbered 0. For example:

```
1234 "MSG1234E: \
Syntax Error. \n
The value '{0}' is not valid for property '{1}'.\n
Correct it and then reissue the command.\n"
```

If you create a message catalog on one operating system, you cannot port it to another operating system because the catalogs are binary-encoded. However, you can use the same `.msg` files as input to the **gencat** command on another system.

See the relevant information in the documentation for your operating system. For example:

- AIX For AIX, see the *Commands Reference* in the information center.
- z/OS For z/OS, see the *UNIX System Services Command Reference* in the z/OS V1R8.0 LibraryCenter.

You must also check the information about additional supported locales, if you want to use messages in locales other than US English.

Chapter 10. Testing and debugging message flow applications

Use the flow debugger to track messages through your message flows and check for errors, or use the Test Client to test your message flows in a safe environment before they are used on a production system.

Before you begin

Before you start:

To use the flow debugger effectively, you must have a basic understanding of message flows and their representation in the WebSphere Message Broker Toolkit. See "Message flows overview" on page 1022.

About this task

The Test Client and the flow debugger are provided as part of the WebSphere Message Broker Toolkit.

- "Testing message flows by using the Test Client" on page 3144

  Use the Test Client to monitor the output nodes in the message flow, and provide information about the path that a test message takes through a message flow.
- "Flow debugger overview" on page 3158

  Learn about the function provided by the flow debugger, and why you might want to use it.
- "Debugging a message flow" on page 3157

  Start the flow debugger and set options to test and debug the message flow.
- "Debugging by using trace" on page 3194

  Use trace in various ways to debug messages flows.

Related concepts:

"Flow debugger overview" on page 3158
Use the flow debugger in the WebSphere Message Broker Toolkit to track messages through your message flows.

"Message flows overview" on page 1022
A message flow is a sequence of processing steps that run in the broker when an input message is received.

"Debug perspective" on page 6789

The Debug perspective uses various debugger icons and symbols.

Testing message flows by using the Test Client

You can test message flows in a safe environment before they are used on a production system by using the Test Client.

You can use the Test Client to send test messages to message flows that use WebSphere MQ, JMS, SOAP, or HTTP input nodes. The Test Client monitors the output nodes in the message flow, and can provide information about the path that a test message takes through a message flow. The Test Client can also provide information about errors that are generated by the message flow.

You can complete the following tasks by using the Test Client:

- "Testing a message flow" on page 3146
- "Configuring the test settings" on page 3148
- "Creating and editing a test message" on page 3152
- "Using the Test Client in trace and debug mode" on page 3155

Related concepts:

"Test Client overview"
Use the Test Client to test message flows in a safe environment before they are used in a production system.

Related reference:

"Test Client" on page 6708
Use the Test Client to test message flow applications.

"Enqueue" on page 6712
Enqueue is the term that is used to describe the process of putting a message on to a WebSphere MQ queue.

"Dequeue" on page 6712
Dequeue is the term that is used to describe the process of removing a message from a WebSphere MQ queue.

Test Client overview

Use the Test Client to test message flows in a safe environment before they are used in a production system.

You can use the Test Client to send test messages to message flows that use any of the following input nodes:

- WebSphere MQ
- JMS
- HTTP
- SOAP
- SCA

Configuring the input message

You can use the Test Client to change the content of test messages that are sent to a message flow, to help you determine if the message flow is working as expected.

WebSphere MQ queues
If your message flow uses WebSphere MQ queues, the Test Client clears the queues before your test messages are sent to the message flow.

XML messages
If the input node in the message flow that you select expects an XML

message from an associated message set, the message structure is provided, and it can be edited to produce the appropriate test message. Alternatively, you can create a new test message, or import an existing message from your file system.

WebSphere MQ and JMS messages
If the message format is WebSphere MQ or JMS, you can also configure an appropriate header for the test message.

Monitoring a flow with the Test Client

The Test Client monitors output nodes in the message flow so that you can see which nodes output messages are received on. When an error message is produced as the message passes along the flow, or when a message is received on an output node, a test event is recorded in the Test Client.

You can view the content of the output message, and view error messages. The details of the test configuration and the test events can be saved as a `.mbtest` file. You can use this file to repeat the test or to review the results later.

Deploying message flows when you use the Test Client

If you change your message flow, you can use the same test configuration to test the changes. The default behavior of the Test Client is to deploy the message flow that you want to test automatically to an execution group, whenever a change is made to the message flow. You can therefore change a message flow, and quickly test the result using the Test Client, without the need to manually deploy your message flows.

The first time that you send a test message to an input node, you configure the execution group to deploy the message flow by using the Deployment location wizard. You can configure the deployment options to override the default behavior of the Test Client to deploy the message flow manually, or to deploy the message flow every time that you pass a test message to the message flow.

Stopping the Test Client

The default behavior of the Test Client is to stop the test when the first output message is received. You can configure the Test Client to wait for multiple output messages to be received. In this case, you stop the test manually. Stopping the test disconnects the monitors that are running, but does not stop the message flow.

Synchronous tests
A synchronous test, such as when the message flow is invoked from an HTTPInput node, is stopped automatically when a reply message is received.

Asynchronous tests
You can stop an asynchronous test, such as when the message flow is invoked from an MQInput node, manually depending on the monitor setting in the configuration panel.

All test events are stopped when the Test Client is closed, and all test monitors removed.

Using The flow debugger with the Test Client

You can run the Test Client using the trace and debug mode to view more information about the path that the message takes through the message flow. A test event is produced when the message passes from one node to the next node in the message flow. The structure of the message is recorded as it leaves each node in the message flow. The flow debugger is launched in the trace and debug mode so that the test message stops at breakpoints that are configured in the message flow.

Testing a message flow

You can test your message flows using the Test Client.

Before you begin

Before you start:

You must have a broker running. If you do not have an existing broker, create one using the Default Configuration wizard; see "Creating a default configuration" on page 564.

About this task

To test a message flow, complete the following tasks:

Procedure

1. "Opening the Test Client editor" on page 3147
2. "Configuring the test settings" on page 3148
3. "Creating and editing a test message" on page 3152
4. "Selecting the deployment location for the message flow" on page 3154.

Results

The test message is put to the selected input node. The Test Client monitors the output nodes in the message flow and events are generated as the message passes through the message flow. You might need to stop the test manually, depending on the nodes in the message flow and the settings that you have configured in the Test Client.

What to do next

Next:

To test the message flow again, right-click **Invoke Message Flow** in the **Message Flow Test Events** pane and click **Invoke** to start a new test; or click **Duplicate** or **Re-run** to re-run the test using the same message.

Related concepts:

"Test Client overview" on page 3144

You can run the Test Client in trace and debug mode to trace the path of a test message through a message flow.

Related reference:

"Test Client **Events** tab" on page 6709
You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

Opening the Test Client editor

You can open the Test Client editor by using a menu, by right-clicking a message flow, or by right-clicking an input node.

Before you begin

Before you start:

Before you open your message flow in the Test Client, ensure that the flow contains no errors. Errors are shown in the Problems view; for more details, see "Problems view" on page 6787.

About this task

To begin testing your message flow with the Test Client editor, complete the following steps.

Procedure

Open the Test Client editor by using one of the following methods:

- In the Broker Development pane, right-click the message flow that you want to test and click **Test Message Flow**.
- Open the message flow that you want to test, right-click the input node, and click **Test**.

- Open the message flow that you want to test and click **Flow** > **Test**. (This menu option is disabled if there are no input nodes that can be tested.)

Results

The Test Client editor is opened with settings from the message flow.

What to do next

Next:

You can now configure the Test Client settings. For more details, see "Configuring the test settings."

Testing a message flow that has WebSphere MQ nodes:

You can configure settings in the Test Client for testing message flows that have WebSphere MQ nodes.

Before you begin

Before you start:

Open the Test Client by following the instructions in "Opening the Test Client editor" on page 3147.

About this task

To test a message flow that uses WebSphere MQ nodes, complete the following steps.

Procedure

1. Right-click a message flow and click **Test Message Flow**. The Test Client opens with the settings from the selected message flow.
2. Click the **Configuration** tab to display the Test Client configuration settings.
3. Click **MQ Settings** and select the appropriate options for your test.
4. Click **MQ Message Header "Default Header"** to view the settings for the message header that is used for the test message. You can edit the options for the default header, or you can create a new header to edit by completing the following steps.
   a. Click **MQ Message Headers**.
   b. Click **Add** and enter a unique name for the header.
   c. Optional: Select **Include RFH V2 Header** to define an MQRFH2 header; for further information, see "Test Client Configuration tab" on page 6713.
   d. Edit the header settings.
   e. Click the **Events** tab, and select the appropriate header for your message from the **Header** list.
5. You can use the Test Client to create WebSphere MQ queues that are used in nodes in your message flow. To configure the Test Client to create the queues, complete the following steps.
   a. Click **Window** > **Preferences**.

b. Expand **Broker Development** and click **Message Broker Test Client**.
c. Ensure that **Create queues of input and output nodes of message flows when host name is localhost** is selected and click **OK**.

6. Optional: Save the Test Client configuration in a `.mbtest` file by completing the following steps.
   a. Click **File** > **Save**. The Save Execution Trace wizard opens.
   b. Enter a name for the file, and select a project in which to save the file.
   c. Click **Finish** to save the file.
7. Create a test message to test your message flow by following the instructions in "Creating and editing a test message" on page 3152.

Related concepts:

Configure your test environment in the **Configuration** tab in the Test Client.

Testing a message flow that uses JMS nodes:

You can configure settings in the Test Client for testing message flows that uses JMS nodes.

Before you begin

Before you start:

Open the Test Client by following the instructions in "Opening the Test Client editor" on page 3147.

About this task

To test a message flow that uses JMS nodes, complete the following steps.

Procedure

1. Right-click a message flow and click **Test Message Flow**. The Test Client opens with the settings from the selected message flow.
2. Click the **Configuration** tab to display the Test Client configuration settings.
3. Click **JMS Settings** and select the appropriate options for your test. You can add references to the client JAR files used to create the JMS connection.

   To add a reference to these JAR files into your test configurations, complete the following steps.
   a. Click **Configure preference settings**. The Test Client preferences are displayed.
   b. Click **Add** and locate the JAR files in your file system.
   c. Click **OK** to add the reference to the JAR files.

d. Ensure that **Use preference settings** is selected on the **Configuration** tab.

4. To create a JMS header, click **JMS Message Headers**, then complete the following steps.
   a. Click **Add** and enter a unique name for the header.
   b. Edit the header settings.
   c. Click the **Events** tab and select the appropriate header for your message from the **Header** list.
5. Optional: Save the Test Client configuration in a `.mbtest` file by completing the following steps.
   a. Click **File** > **Save**. The Save Execution Trace wizard opens.
   b. Enter a name for the file, and select a project in which to save the file.
   c. Click **Finish** to save the file.
6. Create a test message to test your message flow by following the instructions in "Creating and editing a test message" on page 3152.

Related concepts:

Testing a message flow that has SCAInput nodes:

You can configure settings in the Test Client for testing message flows that have SCAInput nodes that use the MQ Binding type.

Before you begin

Before you start:

Open the Test Client by following the instructions in "Opening the Test Client editor" on page 3147.

About this task

To test a message flow that uses SCAInput nodes:

Procedure

1. Right-click a message flow and click **Test Message Flow**. The Test Client opens with the settings from the selected message flow. If the Binding type is Web services, skip to step 7 on page 3152, otherwise continue with step2 on page 3152

2. Click the **Configuration** tab to display the Test Client configuration settings.
3. Click **MQ Settings** and select the appropriate options for your test.
4. Click **MQ Message Header "Default Header"** to view the settings for the message header that is used for the test message. You can edit the options for the default header, or you can create a new header to edit by completing the following steps.
   a. Click **MQ Message Headers**.
   b. Click **Add** and enter a unique name for the header.
   c. Edit the header settings. If you expect a response, specify the **Reply to queue name** and **Reply to queue manager name**.
   d. Click the **Events** tab and select the appropriate header for your message from the **Header** list.
5. You can use the Test Client to create WebSphere MQ queues that are used in nodes in your message flow. To configure the Test Client to create the queues, complete the following steps.
   a. Click **Window** > **Preferences**.
   b. Expand **Broker Development** and click **Message Broker Test Client**.
   c. Ensure that **Create queues of input and output nodes of message flows when host name is localhost** is selected and click **OK**.
6. Optional: Save the Test Client configuration in a `.mbtest` file by completing the following steps.
   a. Click **File** > **Save**. The Save Execution Trace wizard opens.
   b. Enter a name for the file, and select a project in which to save the file.
   c. Click **Finish** to save the file.
7. Create a test message to test your message flow by following the instructions in "Creating and editing a test message."

Configure your test environment in the **Configuration** tab in the Test Client.

Creating and editing a test message

To use the Test Client, you must create or edit a test message to send to your message flow.

Before you begin

Before you start:

Complete these tasks before you edit your test message:

1. "Opening the Test Client editor" on page 3147
2. "Configuring the test settings" on page 3148

About this task

A number of editors are available in the Test Client for creating a test message. The most appropriate editor to use depends upon the type of test message you want to send to your message flow.

- If the input node that you want to send the message to for the test expects an XML message, and the message flow is associated with a message definition, the **Edit as XML structure** editor is available.
- If you want to send an XML message, but do not have a message definition defined, or you want to create a test message that is not in XML format, you can use the **Edit as text** editor.
- If you want to use an existing test message from a workspace resource or file system file, you can use the **Import from external file** editor.
- Alternatively you can import an existing test message into the **Edit as text** editor, or take the generated source from the **Edit as XML structure** editor and paste it into the **Edit as text** editor.

The Test Client provides limited support for the generation of XSD and WSDL test messages. If the Test Client cannot generate the test message automatically, you can create the test message by using either the Edit as text or Import from external file method described in this topic.

Select from the following options to create and edit a test message:

Procedure

- Edit as XML structure:
  1. In the Events tab of the Test Client, select **Edit as XML structure** from the **Body** list.
  2. Edit the entries in the **Value** column for each field to change the content of the test message.
  3. Right-click the fields in the **Edit as XML structure** editor to see additional options for defining the content of the test message. These options include adding message parts and elements, for example if your message has repeating fields.
  4. You can save your file with the updated test message by clicking **File** > **Save**.
  5. To view and copy the generated test message, click **Show Generated Source**.
- Edit as text:
  1. In the Events tab of the Test Client, select **Edit as text** from the **Body** list.
  2. Enter the text content for your test message. You can copy content into the editor from another source by right-clicking in the editor and selecting **Paste**, or import content from an existing test message by clicking **Import Source**.
  3. You can save your file with the updated test message by clicking **File** > **Save**.
- Import from external file:
  1. In the Events tab of the Test Client:
     - If the input node expects an XML message, select **Import from external file** from the **Body** list.
     - If the input node does not expect an XML message, select **Import from external file (Binary and Text)** from the **Body** list.
  2. Select from the following options to locate the file containing your test message:
     - Workspace resource

a. Click **Workspace**. You can then locate your existing test message from your workspace.
b. Click **OK** to use the selected resource.
c. Click **Edit** to open the default editor associated with the resource.

– File system file
a. Click **File system**. You can then locate your existing test message from your file system.
b. Click **Open** to use the selected file.

3. You can save your file with the updated test message file details by clicking **File** > **Save**.

What to do next

Next:

Ensure that you have selected the correct input node to send the test message to in your message flow. Click **Send Message** to send your test message to the selected input node. If this is the first time you have sent a message using this Test Client file, the Deployment Location wizard opens. See "Selecting the deployment location for the message flow."

You can use the **Events** tab in the Test Client to edit the properties and content of your test messages. You also view test events in the **Events** tab when you run the test.

Selecting the deployment location for the message flow

You can specify the execution group to which to deploy a message flow by using the Deployment Location wizard within the Test Client.

Before you begin

Before you start:

Before you can test your message flow, you must have configured a broker. The broker must be running. If you do not have an existing broker, you can create one using the Deployment Location wizard within the Test Client by selecting **New local broker**. Alternatively select **Add remote broker** to import a connection to a remote broker.

About this task

When you first send a test message to a message flow using the Test Client, the **Deployment Location** wizard is opened. You can use the wizard to select an execution group to which to deploy the message flow.

Procedure

1. In the Test Client, click **Send Message**, to open the **Deployment Location** wizard.
2. If your broker is not connected, click **Connect**.
3. From the list in the wizard, select the execution group to which to deploy your message flow. You can also create a new execution group from the **Deployment Location** wizard by selecting a broker, and clicking **New Exec Group**.
4. Select **Trace and debug** to display information about each node that the message passes through in the message flow and to run the flow debugger. You can select an option for the trace to **Stop at the beginning of the flow during debugging**. For more information see Using the Test Client in trace and debug mode.
5. Click **Next**.
6. Modify the test settings as required.
7. Click **Finish** to save the settings and deploy the message flow.

What to do next

Next:

You can change the deployment location settings from the **Configuration** tab.

1. Click **Configuration** in the Test Client.
2. Click **Deployment** to display the deployment settings.
3. Click **Change** to open the **Deployment Location** wizard.

Using the Test Client in trace and debug mode

You can run the Test Client in trace and debug mode to trace the path of a test message through a message flow.

Before you begin

Before you start:

Before you can test your message flow, you must have configured a broker. The broker must be running. You must also have created an execution group to which to deploy your message flows.

About this task

You can use the trace and debug mode to complete the following actions:

- Stop the test message at breakpoints in the message flow by using the flow debugger.
- Trace the message nodes and terminals that the test message passes through.
- See the test message change as it passes through the message flow.
- View a message node, where an exception occurs, and the associated exception message and trace details.

Note: If the message flow does not contain an MQOutput, HTTPReply, JMSOutput, or SOAPReply node, the Test Client stops the test after the test message is sent to the broker. Therefore, you might not see trace events when the flow is run.

All output from the trace and debug mode is written to the "Message flow test events" section on the **Message flow Test Events** tab.

To use the Test Client in trace and debug mode, complete the following steps:

Procedure

1. Configure the flow debug port for the execution group in the WebSphere Message Broker Toolkit:
   a. In the Brokers view, right-click the execution group with which you want to work.
   b. Click **Launch Debugger**.
   c. To set the Flow Debug Port, click **Configure**, and enter a number for the port.
   d. Click **OK**.

   The debugger is now enabled on the selected execution group. Click **Terminate Debugger** to stop the debugger.
2. In the Test Client, click **Send Message** to open the Deployment Location wizard.
3. If your broker is not connected, click **Connect**. From the list in the wizard, select the execution group to which you want to deploy your message flow.
4. Click **Trace and debug**.
5. Optional: If you want the test message to stop at a breakpoint after the input node, click **Stop at the beginning of the flow during debug**.
6. Click **Next** and modify the test settings as required.
7. Click **Finish** to save the settings and deploy the message flow.

What to do next

Next:

You can modify the deployment location settings from run mode to trace and debug mode by using the Deployment Location wizard:

1. Click **Configuration** in the Test Client.
2. Click **Deployment** to display the deployment settings.
3. Click **Change** to open the Deployment Location wizard.

Debugging a message flow

Use the tasks described in this section of the documentation to manage and work with the flow debugger.

Before you begin

Before you start

If you are new to debugging, see: "Flow debugger overview" on page 3158.

Deploy your message flow to an execution group in a broker and make sure that the broker is running. See: "Deploying resources" on page 3234.

About this task

To debug a message flow, perform the following tasks. You might want to vary the tasks you perfom and repeat certain tasks, depending on your particular debugging requirements.

Procedure

1. Start the flow debugger.

   Set the required preferences, then start debugging by attaching the flow debugger to an execution group. You can then send test messages along the flow. See: "Starting the flow debugger" on page 3160.
2. Work with breakpoints.

   Add and manipulate breakpoints in your message flow. See: "Working with breakpoints in the flow debugger" on page 3166.
3. Follow the progress of a test message.

   Use breakpoints to pause the progress of a test message so that you can observe its behavior. See: "Stepping through message flow instances in the debugger" on page 3172.
4. View message data.

View (and change) data in messages, ESQL code, Java code or mappings as debugging progresses. See: “Debugging data” on page 3180.

5. Manage message flows.

   During a debugging session, there are various administrative tasks you might need to do. When you have finished debugging, detach the debugger from the execution group. See: “Managing flows and flow instances during debugging” on page 3187.

Related concepts:

Flow debugger overview

Use the flow debugger in the WebSphere Message Broker Toolkit to track messages through your message flows.

Use the Debug perspective in the WebSphere Message Broker Toolkit to use the flow debugger. For an introduction to the Debug perspective and the views it presents, see “Debug perspective” on page 6789.

You can set breakpoints in a message flow, then step through the flow. While you are stepping through, you can examine and change the message variables and the variables used by ESQL code, Java code, and mappings. You can debug a wide variety of error conditions in flows, including the following:

- Nodes that are wired incorrectly (for example, outputs that are connected to the wrong inputs)
- Incorrect conditional branching in transition conditions
- Unintended infinite loops in flow

From a single WebSphere Message Broker Toolkit, you can attach the debugger to one or more execution groups, and debug multiple flows in different execution groups (and therefore multiple messages) at the same time. However, an execution group can be debugged by only one user at a time. Therefore, if you attach your debugger to an execution group, another user cannot attach a debugger to that same execution group until you have ended your debugging session.

When you debug message flows, use a broker that is not being used in a production environment. Debugging might degrade the performance of all

message flows in the same execution group and those in other execution groups that share the same broker because they might be affected by potential resource contention.

Debugging code and mappings in message flow nodes

You can use the flow debugger to examine the behavior of code and mappings in message flow nodes.

After you have deployed a message flow, you can set a breakpoint just before one of the nodes listed in this section so that, when the flow pauses at the breakpoint, you can step through the code or mappings line by line. This allows you to examine the logic, and check the actions taken and their results. You can set additional breakpoints and you can also examine and change variables.

The following nodes can contain ESQL code modules:
- Compute node
- Filter node
- Database node

The following nodes can contain Java code modules:
- User-defined nodes
- JavaCompute node

The following nodes can contain mappings:
- Mapping node
- DataInsert node
- DataUpdate node
- DataDelete node
- Extract node
- Warehouse node

Restrictions

The following restrictions apply when you debug a message flow:

- You must use the same version of the broker and the WebSphere Message Broker Toolkit; for example, you cannot use the WebSphere Message Broker Toolkit Version 6.1 to debug a message flow that you have deployed to a broker at an earlier version.
- You should not debug message flows over the Internet, because there might be security issues.

Attaching the flow debugger to an execution group for debugging

Before you can debug your message flow, you must attach the flow debugger to the execution group where your flow is deployed, then start a debugging session.

Before you begin

Before you start:

- If authorisation permissions are required, see: "Authorizing users for broker administration" on page 371
- Create a message flow. See: Chapter 9, "Developing message flow applications," on page 1019
- Deploy your message flow to a broker execution group. See: "Deploying resources" on page 3234
- Start the broker. See: "Starting and stopping a broker" on page 921

About this task

From a single WebSphere Message Broker Toolkit, you can attach the flow debugger to multiple execution groups that are running on the same or on different host computers, and debug their flows (and therefore multiple messages) simultaneously.

An execution group can be debugged by only one user at a time. If you attach your debugger to an execution group, another user cannot attach a debugger to that same execution group until you have ended your debugging session.

To attach the debugger to an execution group:

Procedure

1. Set a Flow Debug port number. To configure the broker JVM with a debug port number, use one of the following methods:
   - In the Brokers view in the WebSphere Message Broker Toolkit, right-click the execution group with which you want to work, and click **Launch Debugger**. Click **Configure**, and enter a port number. Click **OK** to enable debugging on the selected port, and attach the debugger to the selected execution group.
   - In the WebSphere Message Broker Explorer, right-click the execution group with which you want to work, and click **Properties**. Enter a port number in the Flow Debug Port field on the Extended page, and click **OK** to modify the Flow Debug port number. You must right-click the execution group and click **Flow Debug Port** > **Enable**. to enable debugging on the selected port.
   - Set the Java debug port by running the **mqsichangeproperties** command (all on one line) in the Command Console:

     ```
     mqsichangeproperties broker_name -e execution_group_name
     -o ComIbmJVMManager -n jvmDebugPort -v port_number
     ```

     For example:

     ```
     mqsichangeproperties TEST -e default
     -o ComIbmJVMManager -n jvmDebugPort -v 3920
     ```

     When this command has completed, restart the broker. See: “Starting and stopping a broker” on page 921.

   The Java JIT (just-in-time) compiler is disabled if the jvmDebugPort parameter is set to an integer greater than zero. If you are not debugging a message flow, reset the jvmDebugPort parameter to zero to maximize performance.
2. If you used the **mqsichangeproperties** command or the WebSphere Message Broker Explorer to configure the Flow Debug Port, you must use the Brokers view in the WebSphere Message Broker Toolkit to attach the flow debugger to the execution group. Right-click the execution group with which you want to work, and click **Launch Debugger**, and click **OK** to attach the debugger to the selected execution group.
3. Open the message flow that you want to debug in the Message Flow editor by double-clicking its name in the Broker Development view.
4. Add a breakpoint to a connection that leads out of the input node to ensure that the message flow does not run to completion before you can begin to debug it.

   The breakpoint appears as  . For information about adding a breakpoint, see “Working with breakpoints in the flow debugger” on page 3166.
5. Switch to the Debug perspective.
6. Right-click the Message Broker Launch Configuration in the Debug view, and click **Edit Source Lookup**. You can use Edit Source Lookup Path to tell the debugger where to look for your source files for message flows, and related resources such as ESQL, message maps and Java during debugging.

7. Click **Add**, and select the type of source to add to the lookup path. The lookup path can be an Eclipse project name, an external folder, or a compressed (`.zip`) file. You can specify multiple locations, but the debugger always looks first in the message flow project that you specify in the Edit Source Lookup Path dialog.
8. Select the resources to include in the lookup path, and click **OK**.
9. Click **Add** to include more resources in the lookup path, click **Up**, or **Down** to modify the order of the resources.
10. Click **OK** to exit the Edit Source Lookup Path dialog, and save your changes.
11. When the next message comes into your flow and arrives at breakpoint you added after the input node, the flow pauses, the breakpoint icon is highlighted:  , and you can start debugging.
12. In the Debug view, double-click the message flow that you want to debug. The message flow opens in the Message Flow editor. You can now add more breakpoints, start stepping over the flow, and so on.

What to do next

Next:

Continue with one of the following tasks:

- Optional: "Debug: putting a test message on an input queue" and "Debug: getting a test message from an output queue" on page 3164. These tasks involve putting messages to, and taking messages from, WebSphere MQ queues and are therefore useful only if your message flow includes MQInput and MQOutput nodes.
- "Working with breakpoints in the flow debugger" on page 3166.

Debug: putting a test message on an input queue

You can put a message on an input queue to test a message flow that you are debugging.

Before you begin

Before you start

Complete the steps described in "Attaching the flow debugger to an execution group for debugging" on page 3160.

About this task

If your message flow includes MQInput and MQOutput nodes, you can test the flow by putting a message on the input queue of your first MQInput node.

You can use the command line interfaces or WebSphere MQ Explorer to put a message to a queue.

You can also use the Test Client as a repeatable alternative. To use the Test Client, complete the steps described in the following sections:

- "Using enqueue in the Test Client"
- "Adding data to your message"
- "Optional: Using a file of sample data" on page 3164

If the message is processed by the message flow and is put on an output queue, you can retrieve it from that queue. See: "Debug: getting a test message from an output queue" on page 3164.

Using enqueue in the Test Client:
About this task

To configure an enqueue event in the Test Client so that you can use it to send a test message:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click **File** > **New** > **Other**. The **New** dialog opens.
3. Select **Message Broker Test Client** in the Message Brokers category and click **Next**. The wizard opens and displays its first panel.
4. Select the project in which you want to create the Test Client file.
5. Enter a name for the Test Client file and click **Finish**. The Test Client editor opens.
6. On the toolbar at the upper right of the Test Client editor, under Message Flow Test Events, click the **Put a message onto a queue** icon  .
7. Under Detailed Properties, enter the names of the queue manager and the queue for the input node for this flow. Queue manager names are case-sensitive; check that you enter the name correctly.

   If you are putting a message onto an input queue that is on a remote computer, ensure that the queue manager of the associated broker has a server-connection channel called SYSTEM.BKR.CONFIG.
8. If you are putting a message onto a remote queue, enter values to identify the host and port of the computer that is hosting the queue.
9. Click **File** > **Save** to save the file.

Adding data to your message:

About this task

If you want to add just a small amount of test data in your test message, type the data into the **Source** section of the **Message** pane:

Procedure

1. Open your Test Client file.
2. Type your test data directly into the **Source** section of the Message pane.
3. Put the test message by clicking **Send Message**.

Optional: Using a file of sample data:
About this task

If you want your test message to contain a larger quantity of sample data (for example some structured XML), you can import a file containing that data into the Test Client:

Procedure

1. In the **Events** tab of your Test Client file, click **Import Source**.
2. Select the file you want to use as the content for the test message, and click **Open**. The contents of the selected file is added to the **Source** pane.
3. Click **File** > **Save** when you have finished.
4. Put the test message by clicking the **Send Message** button.

Debug: getting a test message from an output queue

You can get a message from an output queue to test a message flow that you are debugging.

Before you begin

Before you start

Completed the following tasks:

- Chapter 9, “Developing message flow applications,” on page 1019
- Chapter 11, “Packaging and deploying,” on page 3209
- “Attaching the flow debugger to an execution group for debugging” on page 3160
- “Debug: putting a test message on an input queue” on page 3162

About this task

If your message flow includes MQInput and MQOutput nodes, you can test the flow by putting a message on the input queue of your first MQInput node and retrieving it from an MQOutput node.

You can use the command line interfaces or WebSphere MQ Explorer to get a message from an output queue.

You can also use the Test Client as a repeatable alternative. To use the Test Client, complete the following steps:

Procedure

1. Switch to the Broker Application Development perspective.
2. Click **File** > **New** > **Other**. The **New** dialog opens.
3. Select **Message Broker Test Client** in the Message Brokers category and click **Next**. The wizard opens and displays its first panel.
4. Select the project in which you want to create the Test Client file.
5. Enter a name for the Test Client file and click **Finish**. The Test Client editor opens.
6. On the toolbar at the upper right of the Test Client editor, under **Message Flow Test Events**, click the **Get a message from a Queue** icon  .
7. Under **Detailed Properties**, enter the name of the queue manager and output node queue.
8. Click **Get Message** to read a message from the queue.

Results

When a message is available on an output queue, you can see it in the Test Client editor.

Adding breakpoints in the flow debugger

Add breakpoints to connections in your message flow to control where flow processing will pause.

Before you begin

Before you start:

Attach the flow debugger to the execution group where your flow is deployed. See: "Attaching the flow debugger to an execution group for debugging" on page 3160.

About this task

You can add breakpoints to the connections of a message flow that is open in the Message Flow editor. Each breakpoint that you add to a flow is also automatically added to all other instances of the flow and you do not need to restart any of the instances.

Every breakpoint is automatically enabled when you add it to a connection and the connection is flagged with the enabled breakpoint symbol  .

Manually set a breakpoint after the collector node or any other multithreaded node. When you use the Debug perspective on the node, you see that the thread has been ended.

To add breakpoints to the connections of a message flow:

Procedure

1. Switch to the Debug perspective.
2. Add breakpoints to the appropriate connections. Use any of the following methods:

Option	Method
Add breakpoints individually to selected connections.	1. In the Message Flow editor, right-click the connection where you want to set the breakpoint. 2. Click **Add Breakpoint**.
Add breakpoints simultaneously to all connections *entering* a selected node.	1. In the Message Flow editor, right-click the node before which you want to set breakpoints. 2. Click **Add Breakpoints Before Node**.
Add breakpoints simultaneously to all connections *leaving* a selected node.	1. In the Message Flow editor, right-click the node after which you want to set breakpoints. 2. Click **Add Breakpoints After Node**.

What to do next

Next:

After you have set one or more breakpoints in the message flow, step through the flow, pausing at each active breakpoint. See: “Stepping through message flow instances in the debugger” on page 3172.

You can also examine message data, code, and mappings at appropriate points. See: “Debugging data” on page 3180.

Related concepts:

“Flow debugger overview” on page 3158
Use the flow debugger in the WebSphere Message Broker Toolkit to track messages through your message flows.

Related tasks:

"Restricting breakpoints in the flow debugger to specific flow instances"
Breakpoints can be applied to particular flow instances, instead of all instances, which is the default behavior.

You can view (and change) data in messages, ESQL code, Java code or mappings as debugging progresses.

Related reference:

"Flow debugger shortcuts" on page 6719

"Flow debugger icons and symbols" on page 6720
The Debug perspective uses various debugger icons and symbols.

Restricting breakpoints in the flow debugger to specific flow instances

Breakpoints can be applied to particular flow instances, instead of all instances, which is the default behavior.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

When you add a breakpoint to a message flow in the Message Flow editor, the breakpoint automatically applies to all instances of the flow. However, you can restrict a breakpoint to one or more instances of a flow. This enables you to work more easily with just those instances that you are currently interested in, rather than with all instances.

To restrict a breakpoint to one or more flow instances:

Procedure

1. Switch to the Debug perspective.
2. In the Breakpoints view, right-click the breakpoint that you want to restrict, then click **Properties** to open the Flow Breakpoints Properties window.
3. In the **Restrict to Selected Flow Instance(s)** list box, select those instances to which you want to restrict the breakpoint.
   - You must have at least one instance active; if not, the **Restrict to Selected Flow Instance(s)** list box is empty.
   - If any instance is currently paused at the breakpoint, all check boxes in the **Restrict to Selected Flow Instance(s)** list box are disabled and you cannot select them.

4. Click **OK**.

What to do next

Next:

Now you can add additional breakpoints (if needed), step through the flow instance, and work with data:

- "Adding breakpoints in the flow debugger" on page 3166

Enabling and disabling breakpoints in the flow debugger

You can disable breakpoints that are currently enabled, and vice versa.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

Message flow processing pauses only at breakpoints that are enabled. By controlling which breakpoints are enabled and which are disabled, you can, for example, allow processing to continue to the part of a flow that you are interested in without having to continually add and remove breakpoints.

The following symbols identify breakpoints:

 Enabled breakpoint

 Disabled breakpoint

If you disable all the breakpoints in a message flow, you cannot perform any other debugging tasks until you add a new breakpoint, or enable an existing breakpoint.

To change the state of breakpoints:

Procedure

1. Switch to the Debug perspective.
2. In the Breakpoints view, select one or more breakpoints that you want to enable or disable.
3. Right-click the selected breakpoints and click **Enable** or **Disable**.
4. Optional: to change the state of a single breakpoint, right-click the breakpoint and click **Properties**. Select or clear the **Enabled** check box as required, then click **OK**.

Results

The state of breakpoints is changed in all instances of the message flow where they are set.

What to do next

Removing breakpoints in the flow debugger

Remove breakpoints that are no longer required from connections in your message flow.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

The following symbols identify breakpoints:

 Enabled breakpoint

 Disabled breakpoint

If you remove a breakpoint from a message flow, it is automatically removed from all instances of the message flow where it is set.

If you remove all the breakpoints that you have added to your message flow, you cannot perform any other debugging tasks until you add a new breakpoint.

To remove breakpoints:

Procedure

1. Switch to the Debug perspective.
2. Remove the breakpoints. Use one of the following methods, depending on how many breakpoints you want to remove:

Option	Method
Remove individual breakpoints.	1. In the Message Flow editor, right-click the breakpoint that you want to remove, then click **Remove Breakpoint**.
Remove several breakpoints simultaneously.	1. Click the **Flow Breakpoints** tab to show the Breakpoints view. 2. Select one or more breakpoints that you want to remove. 3. Click the **Remove Selected Breakpoints** icon  on the toolbar, or right-click the selected breakpoints, then click  Remove.
Remove all breakpoints simultaneously.	1. Click the **Breakpoints** tab to show the Breakpoints view. 2. Click the **Remove All Breakpoints** icon  on the toolbar, or right-click any breakpoint, then click  Remove All.

The Debug perspective uses various debugger icons and symbols.

Debug: resuming message flow processing

Each time message flow processing pauses at an active breakpoint, you can investigate the state of the flow, then resume processing.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

When message flow processing has paused at a breakpoint, you can resume processing:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, take one of the following steps:
   - On the toolbar click **Resume Flow Execution**  .
   - Right-click the flow stack frame, then click **Resume**  .

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have completed debugging this message flow, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 3170

- "Debug: ending a session" on page 3191

Related concepts:

Debug: running to completion

When message flow processing pauses at an active breakpoint, you can let it continue to the end of the flow, ignoring other breakpoints.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

When message flow processing has paused at a breakpoint, you can restart processing so that the message flow runs to completion.

If you want the flow to continue processing, but you want to pause at the next enabled breakpoint instead of running to completion, see: "Debug: resuming message flow processing" on page 3173.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:
   - either, click **Run to completion** on the toolbar.
   - or, right-click the flow stack frame, then click **Run to completion** .

Results

The flow instance ignores all breakpoints and processing continues to the end. The flow instance is automatically removed from the Debug view.

What to do next

Next:

If you have finished debugging, you can remove the breakpoints, or end the debugging session:

Debug: stepping over nodes

When message flow processing pauses at an active breakpoint, you can step over the node and continue processing until the next active breakpoint, ignoring breakpoints that might have been set in code within the node.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

To step over the next node and continue message flow processing:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:
   - either, click **Step Over Node**  on the toolbar.
   - or, right-click the flow stack frame, then click **Step Over Node**  .

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint

at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have finished debugging, you can remove the breakpoints, or end the debugging session:

Debug: stepping into subflows

When message flow processing pauses at a breakpoint, you can step into the subflow that follows.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

To step into a subflow:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:
   - either, click **Step Into Subflow** on the toolbar.
   - or, right-click the flow stack frame, then click **Step Into Subflow** .

Results

The subflow opens in the Message Flow editor and displaces the parent message flow. Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have finished debugging, you can remove the breakpoints, or end the debugging session:

Debug: stepping out of subflows

When message flow processing has paused at a breakpoint in a subflow, you can step out of the subflow.

Before you begin

Before you start

Complet the following tasks:

- "Adding breakpoints in the flow debugger" on page 3166
- "Debug: stepping into subflows" on page 3176

About this task

To step out of a subflow:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:

- either, click **Step Out of Subflow** on the toolbar.
- or, right-click the flow stack frame, then click **Step Out of Subflow**.

Results

The debugger continues processing until it reaches the connection from the output terminal of the subflow, where it pauses. The parent flow opens in the Message Flow editor, displacing the subflow.

What to do next

Next:

If you have finished debugging, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 3170
- "Debug: ending a session" on page 3191

Debug: stepping through source code

When message flow processing has paused at a breakpoint on entry to a node that contains ESQL code, Java code, or mappings, you can step through the code.

Before you begin

Before you start:

Add one or more breakpoints to your message flow. See "Adding breakpoints in the flow debugger" on page 3166.

About this task

The nodes that can contain ESQL code, Java code, or mappings are listed in: "Flow debugger overview" on page 3158. Add breakpoints as appropriate:

- ESQL code: add a breakpoint in the ESQL code.
- Java code: add a breakpoint in the Java code.

- Mappings: add a breakpoint to a map using the Map Script panel. Note that mapping routines are implemented in ESQL; you might choose to step through the ESQL code rather than the mappings.

To step through your source code:

Procedure

1. Switch to the Debug perspective.
2. Step into the source code. In the Debug view:
   - either, click **Step into Source Code** on the toolbar.
   - or, right-click the flow stack frame, then click **Step Into** .
3. When message flow processing has paused at a breakpoint within ESQL code, Java code, or mappings, you can step through the source code, line by line. Repeat this step as often as necessary. In the Debug view:
   - either, click **Step Over** on the toolbar.
   - or, right-click the flow stack frame, then click **Step Over** .

   A single line of source code runs and the flow pauses at the next line of code. What you can do depends on what type of code is contained within the node. See:
   - "Debugging ESQL" on page 3182
   - "Debugging Java" on page 3183
   - "Debugging mappings" on page 3185

   If the debugger is paused before the last line of code when you step over, the last line of code runs and message flow processing continues until the next breakpoint in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.
4. If you have finished looking at the code or mappings before the last breakpoint, you can continue processing the message flow. In the Debug view:
   - either, click **Step Return** on the toolbar.
   - or, right-click the flow stack frame, then click **Step Return** .

   The source code runs to completion from the current breakpoint and message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have completed debugging this message flow, you can remove the breakpoints or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 3170

Debugging data

You can view (and change) data in messages, ESQL code, Java code or mappings as debugging progresses.

About this task

When you have added one or more breakpoints to a deployed message flow, the debugger stops the message flow processing at each breakpoint. Depending on the context of the breakpoint, you can do one of the following tasks:

- "Debugging messages" on page 3181
- "Debugging ESQL" on page 3182
- "Debugging Java" on page 3183
- "Debugging mappings" on page 3185

Results

When you have finished debugging a message flow, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 3170
- "Debug: ending a session" on page 3191

Debugging messages

When message flow processing has paused at a breakpoint in your message flow, you can examine and modify the message content.

Before you begin

Before you start

Add one or more breakpoints to your message flow. See: "Adding breakpoints in the flow debugger" on page 3166.

About this task

To examine and modify message data:

Procedure

1. Switch to the Debug perspective.
2. View the messages in the Variables view.

   The Breakpoints view and the Variables view share the same pane. Click the tab at the bottom to select the view that you want.
3. To alter a message, right-click it and select an option from the menu. You cannot alter the content of exceptions within a message.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have finished debugging this message flow, you can remove the breakpoints, or end the debugging session:

Debugging ESQL

When message flow processing has paused at a breakpoint that you have set in source code within a node that contains ESQL code, you can examine and modify the ESQL variables in the Flow Debugger.

Before you begin

Before you start

Complete the following tasks:

- "Adding breakpoints in the flow debugger" on page 3166
- "Debug: stepping through source code" on page 3178

About this task

You can browse ESQL variables in the Variables view in the Debug Perspective, and change their associated data values. You can also set breakpoints on lines in the ESQL code. See the following sections for further details:

- "Using breakpoints on ESQL code lines"
- "Working with ESQL variables"

Using breakpoints on ESQL code lines:
Procedure

1. Switch to the Debug perspective.
2. Open the ESQL editor.
3. Right-click a line where you want to set a breakpoint.

   You cannot set a breakpoint on a comment line or a blank line.
4. Select from the menu to create, delete, or restrict the breakpoint, in a similar way to normal debugger breakpoints, as described in "Working with breakpoints in the flow debugger" on page 3166.

Working with ESQL variables:
Procedure

1. Switch to the Debug perspective.
2. Open the Variables view. Variables are shown in a tree, using the symbol  .
3. To work with a variable, right-click it and select an option from the pop-up menu.

   You cannot update message trees, or REFERENCE variables.

   For example, if you have declared the following ESQL variables, you can change their values in the debugger:

   ```
   DECLARE myInt INT 0;
   DECLARE myFloat FLOAT 0.0e-1;
   DECLARE myDecimal DECIMAL 0.1;
   DECLARE myInterval INTERVAL DAY TO MONTH;
   ```

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have finished debugging this message flow, you can remove the breakpoints, or end the debugging session:

- "Removing breakpoints in the flow debugger" on page 3170

Debugging Java

When message flow processing has paused at a breakpoint that you have set in source code within a node that contains Java code, you can examine and modify the Java variables in the Flow Debugger.

About this task

If you notice that performance has degraded after following these steps, see "Resolving problems with performance" on page 3504.

Procedure

1. To open the Command Console, click **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console**.
2. Start the broker by running the **mqsistart** command in the Command Console.
3. Set the Java debug port by running the **mqsichangeproperties** command (all on one line) in the Command Console:

   ```
   mqsichangeproperties broker_name -e execution_group_name
   -o ComIbmJVMManager -n jvmDebugPort -v port_number
   ```

For example:

```
mqsichangeproperties TEST -e default
-o ComIbmJVMManager -n jvmDebugPort -v 3920
```

4. Stop and restart the broker by running the **mqsistop** and **mqsistart** commands.
5. Open the message flow that you want to debug in the Message Flow editor by double-clicking its name in the Broker Development view.
6. Add a breakpoint where the Java method is called, by following the instructions in "Adding breakpoints in the flow debugger" on page 3166.
7. To step directly into the Java code during the debugging process, add a breakpoint in the Java code.
8. Deploy the broker archive (BAR) file that includes the JAR file that contains the Java code, by following the instructions in "Deploying a broker archive file" on page 3235.
9. Click **Run** > **Debug** to open the Debug wizard.
10. Right-click **Message Broker Debug** in the list of elements on the left and click **New**.
11. Set the **Java Debug Port** with the same value that you specified for the **-v** parameter on the **mqsichangeproperties** command, and click **Apply** to save your changes.
12. Click the **Source** tab, specify the source file location, and click **Apply** to save your changes.
13. Click **Debug** to start the debug process.

Working with Java variables:
About this task

When message flow processing has paused at a breakpoint in the source code within a node that contains Java code (a user-defined node or a JavaCompute node), you can browse Java variables in the Variables view on the Debug perspective, and change their associated data values.

Procedure

1. Switch to the Debug perspective.
2. Click the **Variables** tab to open the Variables view if it is not already open.

   Variables are shown in a tree, using the symbol  .
3. To work with a variable, right-click it and select an option from the menu.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

When you have completed debugging the message flow, you can remove the breakpoints or end the debugging session:

Debugging mappings

When message flow processing has paused at a breakpoint that you have set in source code within a node that contains mappings, you can view the mapping routines and modify user-defined variables in the Flow Debugger.

Before you begin

Before you start

To complete this task, you must have completed the following tasks:

- "Adding breakpoints in the flow debugger" on page 3166
- "Debug: stepping through source code" on page 3178

About this task

Mapping routines are implemented in ESQL. If you step into the code, you can either step through the ESQL code, or step through the mappings.

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, take one of the following steps:
   - Click **Step into Source Code**  on the toolbar.

- Right-click the flow stack frame, then click **Step into**  .

The Message Mapping editor opens with the mapping routine highlighted in both the Mapping editor and the Outline view.

3. To use breakpoints on mapping lines:
   a. In the Message Mapping Editor, select the line for the mapping command that you want to use, right-click the space beside it and select from the menu to add or disable a breakpoint. (Alternatively, double-click the same space to add or remove a breakpoint.)
   b. Select from the menu to create, delete, or restrict the breakpoint, in a similar way to normal debugger breakpoints, as described in: "Working with breakpoints in the flow debugger" on page 3166.

   You cannot set a breakpoint on a comment line or a blank line.
4. Check the mapping routines by stepping through the mappings.

   In the Debug view, the stack frame shows the list of mapping commands and the current command. The Variables view shows your user-defined mapping variables and the current message. You can change the values of user-defined variables.

Results

Message flow processing continues until the next breakpoint that is set in the logical processing of the current message. If there is no further enabled breakpoint at which the flow instance can pause, processing runs to completion and the flow instance is removed from the Debug view.

What to do next

Next:

If you have finished debugging, you can remove the breakpoints, or end the debugging session:

Debug: querying a broker to find deployed flows

You can find the message flow that you want to work with in the Flow Debugger by refreshing the list of available flows.

About this task

During an active debugging session, you can query an execution group on a broker to find out what flows are currently deployed to it. The displayed list of message flows that are available in that execution group is updated. The updated list might include message flows that were not previously deployed, or that were not accessible because the flow was already being accessed by another developer.

To query an execution group for deployed flows:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, select the execution group that you want to query, then:
   - either, click **Refresh Selected Flow Engine to Get More Flow Types**  on the toolbar.
   - or, right-click the execution group, then click **Refresh**  .

Results

The Debug view is refreshed with the names of the flows that are currently deployed to the execution group and are available.

What to do next

Next:

You can continue your debugging session and debug one of the listed message flows, or end your debugging session:

- "Working with breakpoints in the flow debugger" on page 3166
- "Debug: ending a session" on page 3191

Debug: stopping a message flow instance

While debugging, a message flow cannot be redeployed until it has been stopped.

About this task

While you are debugging, you might need to stop a message flow instance. For example, you might want to correct an error in your flow or source code. To do this, you must stop the flow and then redeploy it. See "Debug: redeploying a message flow" on page 3189.

To stop message flow processing, run it to completion:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view:
   - either, click **Run to completion** on the toolbar.
   - or, right-click the flow stack frame, then click **Run to completion**  .

Results

The flow instance ignores all breakpoints and processing continues to the end. The flow instance is automatically removed from the Debug view.

What to do next

Next:

After stopping a flow instance, you can start to debug another message flow, or end your debugging session:

- "Attaching the flow debugger to an execution group for debugging" on page 3160
- "Debug: ending a session" on page 3191

Debug: redeploying a message flow

If you want to change your message flow while you are debugging it, you must redeploy it to the execution group, then reattach the flow debugger.

Before you begin

Before you start

Stop the message flow before you redeploy it. See: "Debug: stopping a message flow instance" on page 3188

About this task

During your debugging session, you might find a problem in a message flow that you want to correct or see a behavior that you want to change. You can alter the flow to resolve the situation and redeploy the flow to the broker:

Procedure

1. Switch to the Debug perspective.
2. Detach the debugger from the execution group by clicking **Detach from the Selected Flow Engines**  on the toolbar.
3. Switch to the Broker Application Development perspective.
4. Edit the flow in the Message Flow editor and save your changes.
5. Double-click the broker archive (BAR) file that contains your flow. Remove the flow, then add your edited version and save your changes.

   See “Adding files to a broker archive” on page 3223.
6. Deploy your BAR file.

   Drag your BAR file from the Broker Development view to the execution group in the Brokers view. Check the Administration log to make sure that the deployment was successful.

   See: “Deploying a broker archive file” on page 3235.
7. Switch to the Debug perspective.
8. Reattach the debugger to the execution group.

   Click the down-arrow on the **Debug** icon  on the toolbar, and select **Debug** to invoke the **Debug (Create, manage, and run configurations)** wizard, and attach the flow engine again, following the instructions in “Attaching the flow debugger to an execution group for debugging” on page 3160.

Results

The modified message flow is now deployed to the broker, and the debugging session is ready for you to debug the new flow logic.

What to do next

Next: Continue to use these tasks to debug your message flow:

- “Working with breakpoints in the flow debugger” on page 3166

Debug: ending a session

Finish debugging by detaching the flow debugger from the execution group to which your message flows are deployed.

About this task

When you have finished debugging a flow, detach the flow debugger from the execution group. Other developers are then able to attach the debugger to the execution group. Detaching the flow debugger also restores the performance of your workbench environment, which might have been reduced by having the debugger attached.

To detach the flow debugger from an execution group:

Procedure

1. Switch to the Debug perspective.
2. In the Debug view, select the name of the execution group from which you want to detach the flow debugger, then take one of the following steps:
   - On the toolbar, click **Detach from the Selected Flow Engines**  .
   - Right-click the execution group, then click  **Detach**).

Results

All existing flow instances are automatically run to completion and the flow debugger is detached from the execution group. Your debugging session is now finished. You can start a new debugging session at any time.

Related concepts:

"Flow debugger overview" on page 3158

Debugging message flows that contain WebSphere Adapters nodes

You can use various methods to monitor message flows that include WebSphere Adapters nodes.

About this task

Before you use any of the methods listed in this section, ensure that the appropriate JAR files and shared libraries are available to the WebSphere Adapters nodes. For more information, see "Preparing the environment for WebSphere Adapters nodes" on page 717.

Also, check for the latest information about WebSphere Adapters; see WebSphere Adapters technotes.

- **User and service trace:** You can use user and service trace to trace a message flow that contains WebSphere Adapters nodes. For more information, see "Using trace" on page 3533.
- **Flow debugger:** Use the flow debugger in the normal way to debug a message flow that contains WebSphere Adapters nodes. For more information, see "Debugging a message flow" on page 3157.
- **Adapter event table:** The WebSphere Adapters nodes use an event table to communicate the outcome of operations asynchronously to a calling application. For more information, see "Creating a custom event project in PeopleTools" on page 2083.

Handling exceptions that are raised by a WebSphere Adapters request node

The WebSphere Adapters request nodes raise exceptions that indicate the following Enterprise Information System (EIS) failures.

Message number	Exception type	Explanation
BIP3511	`RecordNotFound`	The requested record could not be found in the EIS.
BIP3512	`DuplicateRecord`	An attempt was made to create a record that already exists in the EIS.
BIP3513	`MultipleMatchingRecords`	A retrieve request matched more than one record. To retrieve multiple records, perform a `retrieveall` operation.
BIP3515	`MatchesExceededLimit`	A `retrieveall` exception returned more entries than the maximum allowed number.
BIP3516	`MissingData`	The message tree that was sent to the adapter request node does not have all the required fields set.

If an exception occurs that does not fit into the categories in the table, the node raises a general BIP3450 message that describes the problem.

You can use these exceptions to perform special processing when you do not want the exceptions to be treated as errors. For example:

- If a `create` operation fails because the record already exists, you could modify the request to an `update`.

- If a `retrieve` operation fails because the request matches more than one record, you could try a `retrieveall` operation instead.
- If a `retrieve` operation fails because the record could not be found, an empty record could be returned.

To handle these exceptions, you can connect a message routing node, Compute node, or JavaCompute node to the Failure terminal of the WebSphere Adapters request node, and route the exception to other processing nodes based on the exception message number.

XSD Schema Validation problem

When you configure an SAP adapter in the WebSphere Message Broker Toolkit, you might see the following warning, referring to an unresolvable IBM XML schema:

```
CTDX1101W : XSD: The location '' has not been resolved
example1.xsd /EAI_ESB_LIB line 2
example2.xsd /EAI_ESB_LIB line 2
XSD Schema Validation Problem
```

This warning is caused by the following namespace reference in an `<xsd:import>` element:

```
<xsd:import namespace="http://www.ibm.com/xmlns/prod/websphere/j2ca/sap/metadata"/>
```

No types or elements from this namespace are referenced in the logical structure of the XSD. An XML schema that references this namespace is in the referenced connector project, and is pointed to from the XML catalog. The XML catalog entry is populated when the SAP connector project is brought into the workspace.

This warning is benign and can be safely ignored, because it does not affect the structural content of your schema definition.

Tuning the SAP adapter for scalability and performance

You can monitor the performance of a message flow that contains SAP nodes by using user trace, and accounting and statistics data, then use that information to tune your flow by configuring an appropriate number of listeners and additional instances for the message flow. For more information, see “Tuning the SAP adapter for scalability and performance” on page 3278.

Related concepts:

Use the **mqsiformatlog** command to process the XML log created by **mqsireadlog**. The command retrieves and formats any messages that the XML log contains into a form suitable for the locale of the user who runs the command.

WebSphere Adapters technotes

Debugging by using trace

You can use trace in several ways to analyze message flow behavior.

About this task

Enabling user trace shows the history of processing that is carried out in a particular message flow, but it shows only those parts of the messages that were accessed. You can use Trace nodes to write out your own debugging information at specific points in the message flow, including the full message tree at that point, provided that you have coded the flow to include it.

You can use both of these methods to review behavior only after a message has been processed.

Procedure

- "Debugging with user trace" on page 3195
- "Debugging by adding Trace nodes to a message flow" on page 3205

Related concepts:

"Trace" on page 6871
If you cannot get enough information about a particular problem from the entries that are available in the various logs, the next troubleshooting method to consider is using trace. Trace provides more details about what is happening while code runs. The information produced from trace is sent to a specified trace record, so that you or IBM support personnel can analyze it to discover the cause of your problem.

Debugging with user trace

Message flow nodes write messages to user trace when they are processing work. You can use these messages offline to review the activity in a message flow and show information such as which nodes were invoked, what code they ran, and through which terminals the messages was sent.

Before you begin

Before you start:

Before you start to trace a broker, or any of its execution groups or messages flows, the broker must be running, and you must have deployed the message flows by using the WebSphere Message Broker Toolkit.

About this task

If part of the message is parsed by the nodes, user trace shows the fields that are being navigated.

If an error occurs while a message is being processed, the exception is written to user trace. If the error is not caught in the message flow, it is also be written to the system log. Each entry in user trace is prefixed by "BIP". You can search for BIP messages in the information center. For information about the location of user trace log files on different operating systems, see "User trace" on page 6873.

When you start user tracing, you cause additional processing for every activity in the component that you are tracing. Large quantities of data are generated by the components. Expect to see some effect on performance while trace is active. You can limit this additional processing by being selective about what you trace, and by restricting the time during which trace is active.

Procedure

- Trace is inactive by default. Turn it on by following the instructions in "Starting user trace" on page 3197.
- If you need to check what tracing options are currently active for your brokers, use the **mqsireporttrace** command, as described in "Checking user trace options" on page 3199.
- To change user trace options, use the **mqsichangetrace** command, as described in "Changing user trace options" on page 3201.
- To retrieve user trace, use the **mqsireadlog** command, as described in "Retrieving user trace" on page 3204.
- To format the information that is generated by the **mqsireadlog** command, use the **mqsiformatlog** command, as described in "Formatting trace" on page 3543.
- For information about how to interpret the contents of user trace, see "Interpreting trace" on page 3546.
- To stop user trace, use the **mqsichangetrace** command, as described in "Stopping user trace" on page 3202.
- To clear old information from trace files, use the **mqsichangetrace** command, as described in "Clearing old information from trace files" on page 3548.
- Alternatively, you can include a Trace node in your message flows when you design them. Use a Trace node when you want to specify an alternative location for the trace contents. For more details, see "Debugging by adding Trace nodes to a message flow" on page 3205.

Starting user trace

Use user trace for debugging your applications; you can trace brokers, execution groups, and deployed message flows. Start user trace facilities using the **mqsichangetrace** command or the WebSphere Message Broker Explorer.

Before you begin

Before you start:

Before you start to trace a broker, or one of its execution groups or message flows, the broker must be running, and you must have deployed the message flows by using the WebSphere Message Broker Explorer. Follow the instructions in the Chapter 11, "Packaging and deploying," on page 3209 topic.

About this task

To start a user trace:

Procedure

1. Start WebSphere Message Broker user trace facilities by using the **mqsichangetrace** command, or, for execution groups and assigned message flows, from the WebSphere Message Broker Explorer. You can select only one broker on each invocation of the command, but you can activate concurrent traces for more than one broker, by invoking the command more than once.
2. Specify an individual execution group or message flow within the specified broker to limit the scope of a trace. The events that are recorded when you select the message flow option include:
   - Sending a message from one Message Processing node to the next
   - Evaluating expressions in a Compute or Filter node
3. Start your trace. You can start trace at two levels:

   normal This tracks events that affect objects that you create and delete, such as nodes.

   debug This tracks the beginning and end of a process, as well as monitoring objects that are affected by that process.

Example: starting user trace for the default execution group:
About this task

To start normal level user tracing for the default execution group on a broker that you have created with the name MB7BROKER, on distributed systems, enter the command

```
mqsichangetrace MB7BROKER -u -e default -l normal
```

where:

-u specifies user trace
-e specifies the execution group (in this case, the default execution group)
-l specifies the level of trace (in this case, normal)

z/OS On z/OS, enter the command

```
F MQP1BRK,ct u=yes, e='default', l=normal
```

Example: starting user trace on all the message flows in the default execution group from the WebSphere Message Broker Explorer:
About this task

To start normal level user tracing on all the message flows in the default execution group from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the execution group with which you want to work.
2. Click **User Trace All Flows** > **Normal**

Example: starting user trace for a message flow from the WebSphere Message Broker Explorer:
About this task

To start normal level user tracing for one of your message flows from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the message flow with which you want to work.
2. Click **User Trace** > **Normal**

Results

An alert saying `Message Flow is tracing at level 'normal'` is displayed in the Alert Viewer.

Advice for dealing with some common problems that can arise when you work with user-defined extensions

Related reference:

“User trace” on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

“**mqsichangetrace** command” on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Checking user trace options

Use the **mqsireporttrace** command or the WebSphere Message Broker Explorer to check what tracing options are currently active for your brokers, execution groups and message flows.

About this task

If you use the **mqsireporttrace** command, you must specify the component for which the check is required, for example, the execution group or message flow. The command responds with the current trace status for the component that you have specified.

Example: checking user trace options for a message flow using the WebSphere Message Broker Explorer:
About this task

Follow these steps to check the user trace options for one of your message flows from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the message flow with which you want to work.
2. Click **User** to view user trace settings for your message flow.
3. Click **Trace nodes** to see if trace nodes are disabled or enabled for your message flow.
4. Click **Service** to view service trace settings for your message flow.

Example: checking user trace options for a broker:
About this task

To check what options are currently set for the broker `MB7BROKER` and its execution group `test`, on distributed systems, enter the command

```
mqsireporttrace MB7BROKER -u -e test
```

where:

-u specifies user trace
-e specifies the execution group (in this case, test)

z/OS On z/OS, enter the command

```
F MQP1BRK,reporttrace u=yes, e='test'
```

Results

If you have started tracing by following the example in "Starting user trace" on page 3197, the response to the **mqsireporttrace** command is:

```
BIP8098I: Trace level: normal, mode: safe, size: 1024 KB
BIP8071I: Successful command completion
```

"Changing user trace options" on page 3201
Use the **mqsichangetrace** command to change the trace options that you have set. You can also use the WebSphere Message Broker Explorer to change the trace options for execution groups and assigned message flows.

"Checking service trace options" on page 3537
Use the **mqsireporttrace** command or the WebSphere Message Broker Explorer to check what tracing options are currently active for your brokers.

Related reference:

"User trace" on page 6873
User trace is one of two types of optional trace that are available in WebSphere Message Broker and provides more information than that provided by the entries that are written to the Administration log. User trace is inactive by default; you must activate it explicitly by using a command, or by selecting options in the WebSphere Message Broker Toolkit.

"**mqsireporttrace** command" on page 3947
Use the **mqsireporttrace** command to display the trace options currently in effect. Trace can be run only against a broker, or any of its resources.

Changing user trace options

Use the **mqsichangetrace** command to change the trace options that you have set. You can also use the WebSphere Message Broker Explorer to change the trace options for execution groups and assigned message flows.

Procedure

Example: changing user trace from normal to debug:
About this task

To change from a normal level of user trace to a debug level on the default execution group of a broker called MB7BROKER, on distributed systems, enter the command

```
mqsichangetrace MB7BROKER -u -e default -l debug
```

where:

-u specifies user trace
-e specifies the execution group (in this case, the default execution group)
-l specifies the level of trace (in this case, changing it to debug)

z/OS On z/OS, enter the command

```
F MQP1BRK,ct u=yes, e='default', l=debug
```

Example: changing user trace from normal to debug from the WebSphere Message Broker Explorer:
About this task

To change from a normal level of user trace to a debug level for one of your message flows from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the message flow with which you want to work.
2. Click **User trace** > **Debug**.

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Stopping user trace

Use user trace for debugging your applications; you can trace brokers, execution groups, and deployed message flows. Stop user trace facilities by using the **mqsichangetrace** command or the WebSphere Message Broker Explorer.

About this task

Use the **mqsichangetrace** command with a trace level of `none` to stop an active trace. This action stops the trace activity for the component that you specify on the command. It does not affect active traces on other components. For example, if you stop tracing on the execution group `test`, an active trace on another execution group continues.

You can also stop an active trace for execution groups or assigned message flows by using the WebSphere Message Broker Explorer. If you redeploy a component from the WebSphere Message Broker Explorer, trace for that component is returned to its default setting of `none`.

Example: stopping user trace on the default execution group:
About this task

To stop the trace started by the command shown in "Starting user trace" on page 3197, on distributed systems, enter the following command:

```
mqsichangetrace MB7BROKER -u -e default -l none
```

where:

-u specifies user trace
-e specifies the execution group (in this case, the default execution group)
-l specifies the level of trace (in this case, none)

z/OS On z/OS, enter the following command:

```
F MQP1BRK,ct u=yes, e='default', l=none
```

Example: stopping user trace on a message flow from the WebSphere Message Broker Explorer:
About this task

You can stop user trace on individual message flows, or select an execution group and stop user trace on all the message flows in the execution group.

To stop trace for one of your message flows from the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the Brokers folder and right-click the message flow with which you want to work.
2. Click **User trace** > **None**.

"**mqsichangetrace** command" on page 3822
Use the **mqsichangetrace** command to set the tracing characteristics for a broker.

Retrieving user trace

Use the **mqsireadlog** command to access the trace information that is recorded by the user trace facilities.

Procedure

This command retrieves the trace details according to parameters that you specify on the command, and writes the requested records to a file, or to the command line window, in XML format.

Example: retrieving user trace information in XML format:
Procedure

To retrieve information for the user trace activated with the **mqsichangetrace** command and write it to an output file, on distributed systems, enter the command

```
mqsireadlog MB7BROKER -u -e default -o trace.xml
```

where:

-u specifies user trace
-e specifies the execution group (in this case, the default execution group)
-o specifies the output file (in this case, trace.xml)

Results

This sends a log request to the broker to retrieve the user trace log, and stores the responses in the `trace.xml` file. You can view this file using a plain text editor.

Debugging by adding Trace nodes to a message flow

By adding a Trace node to a message flow, you can write debugging messages to a file, to user trace, or to the system log, and review those messages after the message flow has processed some data.

About this task

You must add a Trace node when the message flow is designed. “Viewing the logical message tree in trace output” on page 1481 explains how to view the structure of the logical message tree at any point in the message flow, and contains an example of the message content. You can turn the Trace node off when a message flow is promoted to production to improve performance, but you can turn the node on when required. Performance can be affected when Trace nodes are active. The extent to which performance is affected depends on the destination that you choose for the debugging messages; for example, writing to user trace is typically faster than writing to a file or to the system log.

The debug messages can include writing part or all of the logical message tree, but they can also include hard-coded strings to identify a particular point in the message flow (such as `PRINTF` in a C program). If you write the entire message tree in a Trace node, the behavior of the message flow might be changed. Typically, only the parts of the message that are referenced are parsed, rather than the entire message.

Procedure

- Add a Trace node to your message flow, then set the following properties on the node (as described in detail in "Trace node" on page 4942):
  - Set the destination of the trace record that is written by the node to `User Trace`, `Local Error Log`, or `File`.
  - If you choose `File`, set the file path of the file to which to write records.
  - Use the `Pattern` property to create an ESQL pattern that specifies the data to be included in the trace record.
  - Specify the message catalog from which the error text for the error number of the exception is extracted.
  - Specify the error number of the message that is written.
  -
- After you have added a Trace node to your message flow, you can turn it on or off, as described in "Switching Trace nodes on and off" on page 3555.
- To view the structure of the logical message tree at any point in the message flow, include a Trace node and write some or all of the message (including headers and all four message trees) to the trace output destination. The following topics describes how to view that output: "Viewing the logical message tree in trace output" on page 1481
- If you write debugging messages to user trace, the following topic describes how to retrieve user trace: "Retrieving user trace" on page 3204

Chapter 11. Packaging and deploying

Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

About this task

Read the overview section to learn about the different ways in which you can deploy resources, and the resources and properties associated with deployment:

- "Packaging and deployment overview" on page 3210
  - "Deployment methods" on page 3211
  - "Message flow application deployment" on page 3213

The tasks in this section assume that you have already set up your broker, and connected to it. For information about how to complete those tasks, and other related actions, see "Managing brokers" on page 900.

Refer to the following topics for information about how to package and deploy a message flow application:

- "Packaging resources" on page 3221
  - "Creating a broker archive" on page 3222
  - "Adding files to a broker archive" on page 3223
  - "Refreshing the contents of a broker archive" on page 3233
- "Deploying resources" on page 3234
  - "Deploying a broker archive file" on page 3235
  - "Deploying a message flow that uses WebSphere Adapters" on page 3240
  - "Importing a broker archive file to the WebSphere Message Broker Explorer" on page 3242

Further topics describe other deployment tasks:

- "Checking the results of deployment" on page 3243
- "Renaming objects that are deployed to execution groups" on page 3246
- "Removing a deployed object from an execution group" on page 3246

Related concepts:

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

"Broker archive" on page 3216
The unit of deployment to the broker is the *broker archive* or *BAR* file.

Related tasks:

"**mqsideploy** command" on page 3872
Use the **mqsideploy** command to make a deployment request to the broker.

Packaging and deployment overview

Deployment is the process of transferring data to an execution group on a broker so that it can take effect in the broker. Message flows and associated resources are packaged in broker archive (BAR) files for deployment.

When you create application resources such as message flows in the WebSphere Message Broker Toolkit, you must distribute them to the brokers on which you want them to run. Data for message flows and associated resources is packaged in a broker archive (BAR) file before being sent to the broker.

You can package and deploy message flows and associated resources in one step by using the WebSphere Message Broker Toolkit. You can use this approach when you are developing your flows to make changes and quickly see the results. When you want to deploy to a production environment, you can separate the packaging and deployment steps by first packaging your resources into a BAR file and then deploying that file at a later time. You can create BAR files in the following ways:

- By using the WebSphere Message Broker Toolkit
- By using the **mqsicreatebar** command

For more information about packaging resources, see "Packaging resources" on page 3221.

After you create a BAR file, you can customize the file for deployment to different brokers; for example, to specify queue names or data source names. For more information about customizing your BAR file, see "Configurable properties of a broker archive" on page 3217.

After creating a BAR file and customizing it, you can deploy the BAR file in the following ways:

- From the WebSphere Message Broker Toolkit
- From the WebSphere Message Broker Explorer
- By using the **mqsideploy** command
- By using functions defined by the Administration API (also known as the CMP API)

Depending on your work patterns, you might use all these methods at different times. These options are described in "Deployment methods" on page 3211.

After you read these overview topics, find detailed instructions for the tasks that you want to complete in subsequent topics in this section.

The WebSphere Message Broker Toolkit provides your application development environment on Windows and Linux on x86.

"**mqsideploy** command" on page 3872
Use the **mqsideploy** command to make a deployment request to the broker.

Deployment methods

Choose the appropriate method of deployment to suit the way in which you are working. You can use the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, the **mqsideploy** command, or functions described by the Administration API for WebSphere Message Broker (also known as the CMP API).

Using the WebSphere Message Broker Toolkit

The Brokers view of the WebSphere Message Broker Toolkit displays all the brokers on the local machine that you have defined, and any remote brokers to which you have defined connections. If you expand a broker, all the execution groups in that broker are displayed, as well as deployed message flows and their associated resources. You can drag a message flow or a broker archive (BAR) file from the Broker Development view onto an execution group to deploy it. Alternatively, you can right-click an execution group to select a message flow or BAR file to deploy to the selected execution group.

You would typically use the WebSphere Message Broker Toolkit if your primary role is as an application developer, or if you are new to WebSphere Message Broker.

Using the WebSphere Message Broker Explorer

The Navigator view of the WebSphere Message Broker Explorer displays all the brokers on the local machine that you have defined, and any remote brokers to which you have defined connections. If you expand a broker, all the execution groups in that broker are displayed, as well as deployed message flows and their associated resources. You can import BAR files into the WebSphere Message Broker Explorer. The BAR files are displayed in the Broker Archive Files folder in the WebSphere Message Broker Explorer. You can drag a BAR file from the Broker Archive Files folder onto an execution group to deploy the contents of the broker archive. Alternatively, you can right-click an execution group or BAR file and click **Deploy File** to deploy resources to an execution group. You can also drag BAR files from your file system directly onto an execution group to deploy the contents of the broker archive.

You would typically use the WebSphere Message Broker Explorer if your primary role is as a WebSphere Message Broker administrator.

Using the `mqsideploy` command

You can deploy from the command line by using the **`mqsideploy`** command. On the command line, specify the connection details and parameters that are specific to the deployment.

You would typically use the **`mqsideploy`** command in a script when you are more familiar with WebSphere Message Broker.

Using the CMP API

You can control deployment from a Java program by using functions described by the CMP API. You can also interrogate the responses from the broker and take appropriate action.

Java applications can also use the CMP API to control other objects, such as brokers and execution groups. Therefore, you can use the CMP API to create and manipulate all your brokers and associated resources programmatically.

Deployment results

Whichever deployment method you use, configuration changes are attempted immediately.

- If you are using the WebSphere Message Broker Toolkit, the Deployment Log view is updated to show the results when your deployment completes. If the deployment fails, the reason for the failure is displayed in this view.
- If you are using the WebSphere Message Broker Explorer, you can see the deployment status for all users connected to the broker. The Administration Queue shows all deployments that are currently being processed by the broker, and the Administration Log shows all recent configuration requests and changes made to the broker.
- If you use the **`mqsideploy`** command, the command completes when the broker has processed the deployment request, or when the wait time, defined by the **`-w`** parameter, has expired, whichever occurs first. The results of the deployment are displayed as output from the command.
- If you are using the CMP API, you can view the results of the deployment in the following ways:
  - Review the DeployResult object that is returned from the deployment methods.
  - Access the LogProxy object that represents the administration log.
  - Access the AdminQueueProxy object that represents the administration queue.

Use the **mqsideploy** command to make a deployment request to the broker.

Message flow application deployment

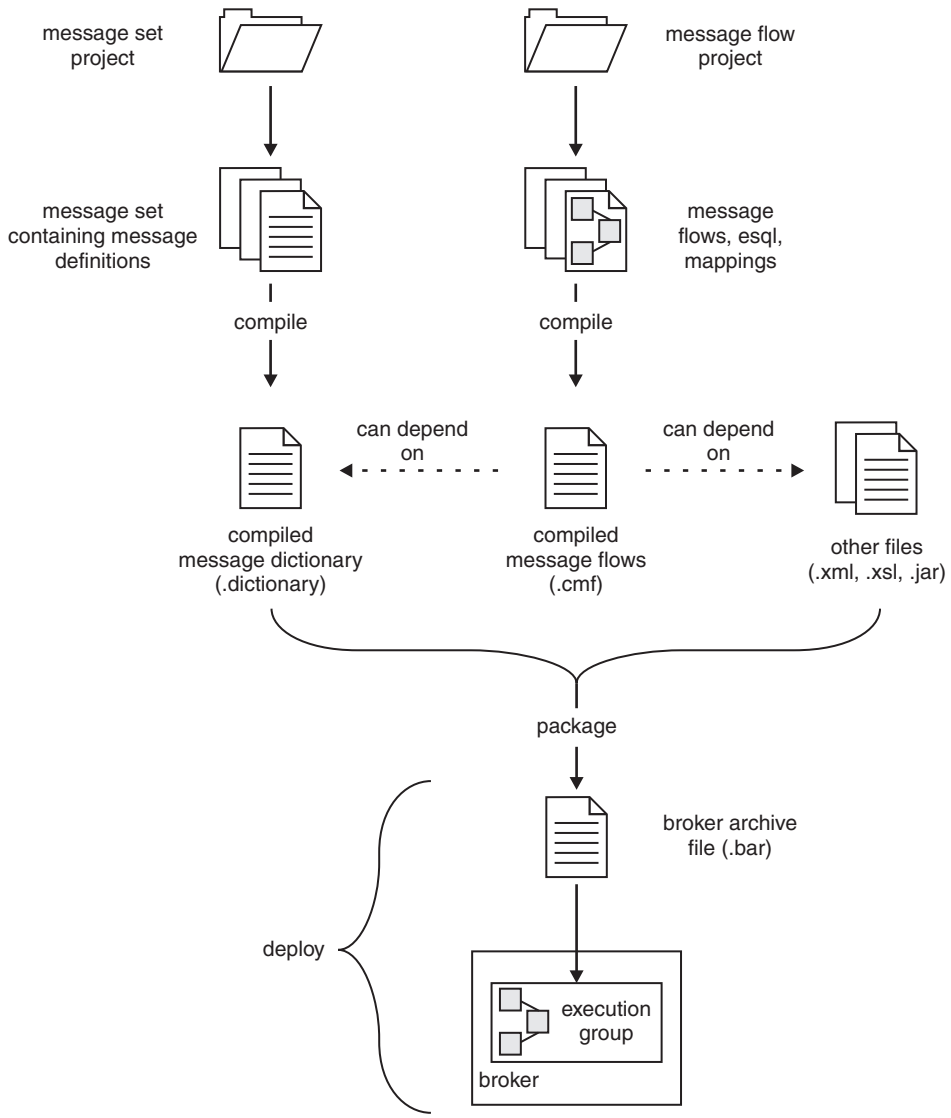
Package all the resources in your message flow into a broker archive (BAR) file for deployment.

When you add files to the broker archive, they are automatically compiled as part of the process. JAR files that are required by JavaCompute nodes in message flows are added automatically from your Java project.

The BAR file is a compressed file that is sent to the broker, where its contents are extracted and distributed to execution groups.

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657.

The following diagram shows the flow of events when you deploy a message flow application.



The diagram illustrates the following sequence of events.

1. You create a broker archive.
2. You add files to the broker archive.
3. You deploy the BAR file by sending it to the broker, from where its contents are distributed to the execution groups.

You can deploy a BAR file in two ways:

- "Incremental BAR file deployment" on page 3215. Deployed files are added to the execution group. Files that exist in the execution group are replaced by the new version.
- "Complete BAR file deployment" on page 3215. Files that are already deployed to the execution group are removed before the entire contents of the BAR file are deployed. Therefore, nothing is left in the execution group from previous deployments.

Incremental BAR file deployment

If you run an incremental deployment of a BAR file, the broker extracts the contents of the BAR file and sends the contents to the specified execution group. The following conditions are applied when a file is deployed to the BAR file.

- If a file in the BAR file has the same name as an object that is already deployed to the execution group, the version that is already deployed is replaced by the version in the BAR file.
- If a file in the BAR file is of zero length, and a file of that name has already been deployed to the execution group, the deployed file is removed from the execution group.

Use incremental BAR file deployment to deploy message flows, message sets, or other deployable objects incrementally to an execution group.

To completely clear the contents of the execution group before the BAR file is deployed, use complete BAR file deployment instead.

Complete BAR file deployment

If you run a complete deployment of a BAR file, the broker extracts the deployable content of the BAR file and sends the contents to the specified execution group, first removing any existing deployed contents of the execution group.

Use a complete BAR file deployment to deploy message flows, message sets, or other deployable objects to an execution group.

To merge the existing contents of the execution group with the contents of the BAR file, use incremental BAR file deployment instead.

Use the JavaCompute node to work with messages by using the Java language.

Broker archive

The unit of deployment to the broker is the *broker archive* or *BAR* file.

The BAR file is a compressed file that can contain a number of different files:

- A `.cmf` file for each message flow. This file is a compiled version of the message flow. You can have any number of these files within your BAR file.
- A `.dictionary` file for each message set dictionary. You can have any number of these files within your BAR file.
- One or more XSD compressed files (`.xsdzip`), if XML schema and WSDL are defined within a message set.
- A `broker.xml` file. This file is called the *broker deployment descriptor*. You can have only one of these files within your BAR file. This file, in XML format, is contained in the `META-INF` folder of the compressed file and can be modified by using a text editor or shell script.
- One or more XML files (`.xml`), style sheets (`.xsl`), and XSLT files (`.xlst`), if required by nodes in the message flows you have added to this BAR file. The XSLTransform node is one that might require these files.
- One or more JAR files, if required by JavaCompute nodes in the message flows you have added to this BAR file.
- One or more inbound or outbound adapter files (`.inadapter` or `.outadapter`), if required by WebSphere Adapter nodes (for example, the SiebelInput node) in the message flows you have added to this BAR file.
- One or more PHP script files (`.php`), if required by PHPCompute nodes in the message flows you have added to this BAR file.
- Other files that you might want to associate with this BAR file. For example, you might want to include Java source files, `.msgflow` files, or `.wsdl` files for future reference. BAR files can contain all files types.

"JavaCompute node" on page 4514
Use the JavaCompute node to work with messages by using the Java language.

Configurable properties of a broker archive

System objects that are defined in message flows can have properties that you can update in the broker archive (BAR) file before deployment.

An administrator can use configurable properties to update target-dependent properties, such as queue names, queue manager names, and database connections.

By changing configurable properties, you can customize a BAR file for a new broker (for example, a test system) without needing to edit and rebuild the message flows or the resources that they work with, such as message mappings, ESQL code, and Java code. Properties that you define are contained in the deployment descriptor, `META-INF/broker.xml` The deployment descriptor is parsed when the BAR file is deployed.

Edit the configurable properties by using either the Broker Archive editor or the **mqsiapplybaroverride** command. In the Broker Archive editor, click a resource on the **Manage** tab to see its properties in the Properties view.

Use the supplied editor and command to ensure that the BAR file contents are correct after the changes are applied. You can also edit the XML-format deployment descriptor manually by using an external text editor or shell script; in this case, you must ensure that you have not invalidated the XML content.

Related tasks:

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

"Editing configurable properties" on page 3227
You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Related reference:

"Configurable message flow properties" on page 4020
When you add a message flow to a broker archive (BAR) file in preparation for deploying it to a broker, you can set additional properties that influence its run time operation. These properties are available for review and update when you select the **Manage and Configure** tab for the broker archive file.

"**mqsiapplybaroverride** command" on page 3684
Use the **mqsiapplybaroverride** command to replace configurable values in the broker archive (BAR) deployment descriptor with new values that you specify in a properties file.

Version and keyword information for deployable objects

Use the Broker Archive editor to view the version and keyword information of deployable objects.

You can display properties of deployed objects, and can modify associated comments:

- "Object version in the Broker Archive editor" on page 1443
- "Version, deployment time, and keywords of deployed objects" on page 1443
- "Path and Comment columns" on page 1444

Object version in the Broker Archive editor

The Version column on the Manage page of the Broker Archive editor displays the version tag for the following objects that have a defined version.

- `.dictionary` files
- `.cmf` files
- Embedded JAR files with a version defined in a `META-INF/keywords.txt` file

You cannot edit the Version column.

You can use the **mqsireadbar** command to list the keywords that are defined for each deployable file within a deployable archive file. For more information, see "**mqsireadbar** command" on page 3697.

Version, deployment time, and keywords of deployed objects

In the WebSphere Message Broker Explorer, the Properties QuickView displays the following properties for all deployed objects:

- Version
- Deployment time
- All defined keywords

For example, you deploy a message flow with the following literal strings:

- `$MQSI_VERSION=v1.0 MQSI$`
- `$MQSI Author=fred MQSI$`
- `$MQSI Subflow 1 Version=v1.3.2 MQSI$`

The Properties view displays these properties:

Property	Description
Deployment Time	Date and time of deployment
Modification Time	Date and time of modification. **Note:** This property has no concept of time zone, therefore it is only meaningful if you know in which time zone it was last modified.
Version	`v1.0`
Author	`fred`
Subflow 1 Version	`v1.3.2`

If the keyword information is not available, a message is displayed in the Properties view to indicate the reason; for example, if keyword resolution has not been enabled at deployment time, the Properties view displays the message `Deployed with keyword search disabled`.

Path and Comment columns

If you add source files, the Path column on the Manage tab is populated automatically.

To add a comment, double-click the Comment column and type the text that you require.

WebSphere Adapters deployment

When you have run the Adapter Connection wizard and created a message flow, you must deploy the resources that are generated by adding them to a broker archive (BAR) file.

To build a WebSphere Message Broker application that integrates with an Enterprise Information System (EIS), such as SAP, Siebel, JD Edwards, or PeopleSoft, you need the following resources:

- A message flow that contains at least one WebSphere Adapters node
- A message set (created by the Adapter Connection wizard) that describes the logical model of the data, as defined by the EIS
- An adapter, which includes two sets of information that are used by the WebSphere Adapters node in the message flow:
  - Connection information
  - Interface information

    The interface information contains a list of methods. For outbound adapters, methods define the operations or services that can be run on the EIS by the WebSphere Adapters request node. For inbound adapters, the method defines callout functions or events from the EIS that cause the WebSphere Adapters input node to propagate a message through the message flow.

    For each method, the information consists of the name of the method, and the name and namespaces of the message types that are used for input and output. To run the method successfully, the message types must be defined in the message set.

Iterative deployment

The message flow can be coded with knowledge of the logical model of the data that is exchanged with the EIS (for example, where Mapping nodes are used to transform the data), but it can also act as a gateway to the EIS, where no transformation of data takes place. When the flow acts as a gateway, you need to be able to run new operations or respond to new events in the EIS without changing or reloading the resources that are already deployed.

You do not need to stop the message flow when you deploy the secondary adapter. During deployment of the secondary adapter, the primary adapter provides connection information, and the secondary adapter supplies additional interface information.

You can use iterative deployment to deploy the resources that are required to support the new methods, without affecting any resources that are already deployed. Iterative deployment is possible by using primary and secondary adapters and message sets.

- The primary adapter for a WebSphere Adapters node contains its connection information and part of its interface; the secondary adapters contain the rest of the interface.
- The primary message set contains message model metadata for the parts of the interfaces that are supported by the node; the secondary message sets define the rest of the model.

You do not need to stop the message flow when you deploy the secondary message set and adapter. During deployment of the secondary adapter, the primary adapter provides connection information, and the secondary adapter supplies additional interface information.

Related tasks:

Packaging resources

Package message flow applications by adding required resources, optionally with their source files, to a broker archive (BAR) file.

Before you begin

Before you start:

Develop and test the message flow applications that you want to package; see Chapter 9, "Developing message flow applications," on page 1019 and Chapter 10, "Testing and debugging message flow applications," on page 3143.

About this task

Before you can deploy your message flow applications to a broker, you must package them into BAR files. If you want to deploy a single message flow, the packaging step can be completed automatically when you deploy the flow; see "Deploying resources" on page 3234.

In most cases, you are working with one or more message flows, one or more message sets, and other objects that you want to deploy with the message flows. In these cases, you can deploy these resources together by packaging them in a BAR file yourself, and deploying just that file. For instructions about how to package resources into a BAR file, see the following topics:

1. "Creating a broker archive" on page 3222
2. "Adding files to a broker archive" on page 3223
3. "Refreshing the contents of a broker archive" on page 3233

You can edit configurable properties for the BAR file in the BAR file editor, or by using the **mqsiapplybaroverride** command. For more details, see "Editing configurable properties" on page 3227.

What to do next

Next:

Deploy your BAR files to a broker; see "Deploying resources" on page 3234.

Related concepts:

"Message flow application deployment" on page 3213
Package all the resources in your message flow into a broker archive (BAR) file for deployment.

Related tasks:

Chapter 11, "Packaging and deploying," on page 3209
Package resources that you create in the WebSphere Message Broker Toolkit, such as message flows, and deploy them to execution groups on brokers.

Creating a broker archive

Create a separate broker archive (BAR) file for each configuration that you want to deploy to execution groups on your brokers.

About this task

You can create a BAR file in two ways:

- "Using the WebSphere Message Broker Toolkit"
- "Using the **mqsicreatebar** command"

Using the WebSphere Message Broker Toolkit

About this task

Follow these steps to create a BAR file by using the WebSphere Message Broker Toolkit:

Procedure

1. Click **File** > **New** > **Message Broker Archive**.
2. Enter a name for the BAR file that you are creating.
3. Click **Finish**.

Results

A file with a `.bar` extension is created and is displayed in the Broker Application Development perspective Navigator view, under the Broker Archives folder. The Content editor for the BAR file opens.

What to do next

Next:

Add files to the BAR file and deploy the BAR file by following the instructions in the following topics:

1. "Adding files to a broker archive" on page 3223
2. "Deploying a broker archive file" on page 3235

Using the `mqsicreatebar` command

About this task

Follow these steps to create a BAR file by using the **mqsicreatebar** command:

Procedure

1. Open a command window that is configured for your environment.
2. Enter the command, typed on a single line. For example:

```
mqsicreatebar -b barName -o filePath -p projectNames -cleanBuild
```

You must specify the **-b** (BAR file name) and **-o** (path for included files) parameters. The **-p** (project names) parameter is optional. For further details, see the "**mqsicreatebar** command" on page 3699.

If you have changed resources in the BAR file by using external tools, add the **-cleanBuild** parameter to refresh all the projects and run a clean build.

A file with a `.bar` extension is created.

What to do next

Next:

Add files to the BAR file and deploy the BAR file by following the instructions in the following topics:

1. "Adding files to a broker archive"
2. "Deploying a broker archive file" on page 3235

Related concepts:

Use the Broker Archive editor to create and manage broker archive (BAR) files.

"**mqsicreatebar** command" on page 3699
Use the **mqsicreatebar** command to create deployable broker archive (BAR) files containing message flows and dictionaries.

Adding files to a broker archive

To deploy files to an execution group, include them in a broker archive (BAR) file.

Before you begin

Before you start:

Create a BAR file for each configuration that you want to deploy. For more details, see "Creating a broker archive" on page 3222.

About this task

You can add any deployable resources from your workspace to a BAR file. If you select **Include source files**, the source and project files for all message flows, message sets, or other deployable resources in the broker archive are included. For more information about the files that you can include in a broker archive, see "Broker archive" on page 3216.

Subflows are not displayed in the BAR file as separate items, and are added automatically. To include these subflows, you have to add only the parent flow.

You can add Flow, ESQL, Java JAR, PHP, MAP, XML, XSLT files and Message Sets manually by following these steps. However, JAR files or .NET assemblies (DLL files) that are required by JavaCompute nodes in message flows are added automatically from your Java project when you add the message flow. XML and XSL files are also added automatically if they are required by the flow.

You do not have to redeploy JAR files unless you have updated them. If one or more JAR files in your BAR file are present on the computer where the broker is running, you can safely remove them from your BAR file before you deploy again. JAR files available to the broker include JAR files that you have deployed and JAR files that exist in the shared-classes directories or the `classes` subdirectory of the installation directory. For example, the files `com.ibm.mq.jar`, `ConfigManagerProxy.jar`, `jplugin2.jar`, and `javacompute.jar` are always visible to the broker, and do not have to be deployed separately.

You cannot read deployed files back from broker execution groups. Therefore, keep a copy of the deployed BAR file, or of the individual files in it.

To add files to a BAR file by using the WebSphere Message Broker Toolkit, complete the following steps.

Procedure

1. Open the BAR file by double-clicking it. The contents of the BAR file are shown in the Broker Archive editor. (If the BAR file is new, this view is empty.)
2. On the Prepare page of the Broker Archive editor, select deployable workspace resources to add to the BAR file.
3. Optional: To include source files, select **Include source files**.
4. Optional: To remove existing content from the BAR file before building the new BAR file, select **Remove contents of Broker Archive before building**.
5. Optional: If you are adding a message flow to a broker archive for a second time, and have used the Manage page to change flow parameters, select **Override configurable property values** to reset configuration settings. If this control is cleared, existing settings are left in place when a flow is replaced.
6. Click **Build broker archive**.

Results

The Manage page lists the files that are now in your BAR file.

You can choose not to display your source files by selecting **Built resources** or **Configurable properties** from the list in the **Filter by** menu.

What to do next

Next:

If you use configurable properties, see “Editing configurable properties” on page 3227.

If you want to have multiple instances of a flow with different values for the configurable properties, see “Adding multiple instances of a message flow to a broker archive” on page 3229.

To make further changes to your BAR file, see “Editing a broker archive file manually.”

When your BAR file is complete, deploy it by following the instructions in “Deploying a broker archive file” on page 3235.

Related concepts:

Editing a broker archive file manually

Edit resources that you want to change, in an editor of your choice, by exporting a broker archive (BAR) file from the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

If you have not already created a BAR file, create one by following the instructions in “Creating a broker archive” on page 3222.

About this task

To edit a BAR file manually by using the WebSphere Message Broker Toolkit, complete the following steps.

Procedure

1. Export the BAR file.
   a. From the WebSphere Message Broker Toolkit, click **File** > **Export**. The Export wizard opens.
   b. Select the export destination, such as your local file system, and click **Next**.
   c. Select the BAR file that you want to export.
   d. Specify the location to which you are exporting the resources, then click **Finish**.

      The BAR file appears at the destination that you have specified.
2. Extract files from the BAR file.
3. Edit the properties that you want to change in an editor of your choice.
4. Save the file.
5. Import the BAR file back into the WebSphere Message Broker Toolkit for deployment.
   a. From the WebSphere Message Broker Toolkit, click **File** > **Import**. The Import wizard opens.
   b. Select the location type of the BAR file, such as the local file system, and click **Next**.
   c. Specify the location of the BAR file; for example, the directory name.
   d. Select the BAR file to import.
   e. Select the project into which you want to import the BAR file.
   f. Click **Finish**.

What to do next

Next:

Deploy the BAR file by following the instructions in "Deploying a broker archive file" on page 3235.

Related concepts:

Editing configurable properties

You can edit configurable properties in the deployment descriptor file (`broker.xml`) of your broker archive.

Before you begin

Before you start:

This topic assumes that you have created a BAR file and added resources to it. For more information, see “Creating a broker archive” on page 3222 and “Adding files to a broker archive” on page 3223.

About this task

You can edit configurable properties in three ways:

- “Using the WebSphere Message Broker Toolkit”
- “Using the WebSphere Message Broker Explorer”
- “Using the **mqsiapplybaroverride** command” on page 3228

Using the WebSphere Message Broker Toolkit:
About this task

To edit properties by using the WebSphere Message Broker Toolkit, complete the following steps.

Procedure

1. Open the BAR file. The resources in your broker archive are listed on the **Manage** page.
2. Optional: You can view the properties that can be configured for your message flows by selecting **Build resources that are configurable** from the **Filter by** list.
3. Expand a message flow to display the nodes that you can configure, then click the node that you want to configure. The values that you can configure for the node are displayed in the **Properties** view.
4. Select the value that you want to edit in the **Properties** view, and enter the new value.

   Repeat these steps for all the properties that you want to configure in your flow.
5. Save your BAR file.

What to do next

Next:

Deploy the BAR file by following the instructions in “Deploying a broker archive file” on page 3235.

Using the WebSphere Message Broker Explorer:
Before you begin

Before you start:

To edit the configurable properties in the WebSphere Message Broker Explorer, you must import a BAR file. To import a BAR file into the WebSphere Message Broker Explorer, see "Importing a broker archive file to the WebSphere Message Broker Explorer" on page 3242.

About this task

To edit properties by using the WebSphere Message Broker Explorercomplete the following steps.

Procedure

1. Open the BAR file. The resources in your broker archive are listed on the **Manage** page.
2. Optional: You can view the properties that can be configured for your message flows by selecting **Build resources that are configurable** from the **Filter by** list.
3. Expand a message flow to display the nodes that you can configure, then click the node that you want to configure. The values that you can configure for the node are displayed in the **Properties** view.
4. Select the value that you want to edit in the **Properties** view, and enter the new value.

   Repeat these steps for all the properties that you want to configure in your flow.
5. Close the BAR file. When you close the BAR file you are prompted to save the file. Click **Yes** to save the changes you made to the BAR file.

What to do next

Next:

Deploy the BAR file by following the instructions in "Deploying a broker archive file" on page 3235.

Using the `mqsiapplybaroverride` command:
About this task

To edit properties by using the **`mqsiapplybaroverride`** command, complete the following steps.

Procedure

1. Open a command window that is configured for your environment.
2. Create a text file with a `.properties` file extension.
3. Enter the command, typed on a single line, specifying the location of your broker archive deployment descriptor (`broker.xml`) and the file that contains the properties to be changed. For examples of how to use the command, see "**`mqsiapplybaroverride`** command" on page 3684.

   A file with a `.bar` extension is created.

What to do next

Next:

Deploy the BAR file by following the instructions in "Deploying a broker archive file" on page 3235.

Use the **mqsiapplybaroverride** command to replace configurable values in the broker archive (BAR) deployment descriptor with new values that you specify in a properties file.

Adding multiple instances of a message flow to a broker archive

Add more than one instance of a message flow to a broker archive and use configurable properties to customize each instance.

About this task

You can deploy multiple instances of the same message flow with different values for configurable properties. By using the same flow with different configurable property values, you can reuse a flow but customize each instance to your requirements. For example, you could use one flow with a particular value for an output queue, then add a second instance of the same flow and use a configurable property to set a different value for the output queue.

If you want to create multiple instances of a message flow to improve performance, see "Optimizing message flow throughput" on page 587.

Procedure

To deploy multiple instances of a message flow with different values for the configurable properties, complete the following steps:

1. In the Broker Development view, create a copy of the message flow of which you want to deploy multiple instances; see "Copying a message flow by using copy" on page 1435.
