WebSphere Message Broker Version 7.0.0.8

Contents

Chapter 14. Reference 3579

Chapter 1. WebSphere Message Broker

This information center provides information for IBM® WebSphere® Message Broker Version 7.0.

The information contained here supports Version 7.0.0.8. This information center is integrated with the WebSphere Message Broker Toolkit and with the WebSphere Message Broker Explorer. It is also available online. Always refer to the WebSphere Message Broker online information center to access the most current information.

Topics that have been added since the previous release of this information, and updated sections within topics, are highlighted with a start of change icon preceding the updated information and an end of change icon following the updated information, as shown in this paragraph.

If you are migrating components and resources from previous versions, see Chapter 3, "Migrating and upgrading," on page 137.

New users: how to find the information you want

The Contents pane on the left lists the categories of task information that are available; for example, **Migrating** and **Developing applications**. Each task category also contains explanations of the concepts related to those tasks, such as "Coexistence", "Message flows", and "Publish/subscribe".

The Start here category in the Contents pane contains topics that provide an introduction for new users to getting started, developing applications, broker administration, and troubleshooting tasks in WebSphere Message Broker. Each topic in the **Start here** category provides overview information and links to relevant topics in the information center. Read the Start here topics and follow the links to help you to navigate through the product documentation and find the information that you want. Alternatively, you can use the following instructions to help you find the information that you want.

Click the top-level topic that you are interested in. If it describes and lists information that covers your area of interest, expand the section to read the associated concepts that give an overview of what you need to understand to perform tasks in this area. Before you start, make sure that you are familiar with the concepts and terminology that are associated with the tasks.

The navigation tree in the Contents pane provides a framework in which you can start to understand the tasks and the context in which you will complete them. Follow the related links at the end of each task to find information about other related tasks. You can move backward and forward to revisit topics, and you can use the **Refresh/Show Current Topic** button if you have moved to a different area of the table of contents, and you want to check where you are.

Expand the **Reference** section to find reference information that is relevant to the task area that you are interested in. You can see that the sections within the Reference section largely correspond to the task categories. You will probably have to refer to one or more of these reference topics to complete any particular task.

For more information, see "Task, concept, and reference topics." When you are more familiar with what information is available, and where to find it, try using the index and the search facility, which are described later in this topic.

Experienced users: how to find the information you want

If you are familiar with what information is available, and where to find it in this information center, you probably have a specific piece of information in mind. You can navigate through to the information in the Content pane, or you can take a more direct route to find specific information:

Search

Enter your search string in the Search box, then click **Go**. If your string includes blanks, and you want the whole string treated as one string, enclose it in quotation marks; for example "search string". The search results are presented in the Search Results pane on the left, and you can switch between the Search Results pane and the Content pane, which contains the navigation tree, by clicking the tabs at the bottom of the pane.

You can limit your search to a particular area of the navigation tree, which can make a search much quicker and produce fewer results. To limit the search, click **Search scope**, then click the **New** button. Select the area or areas you want to include in your new scope and enter a name for the scope so that you can reuse it another time.

Index Find the term that you want in the Index. If more than one entry exists for the subject that you looked up, click the one that is most appropriate for your current task.

Use the letter links at the top of the index to link to the sections that start with that letter; use the letter at the start of a section of index entries to link back to the top of the index.

If you are new to this version of WebSphere Message Broker, you might find some of the information in the Start here category in the Contents pane useful. The Start here topics include links to information about navigating the Information Center, using the WebSphere Message Broker Toolkit, migration and coexistence, and troubleshooting WebSphere Message Broker.

Task, concept, and reference topics

The topics in this information center are divided into task, concept, and reference topics.

Tasks and concepts

Task topics provide steps or actions that tell you how to complete the tasks to establish and maintain your broker environment.

Concept topics provide definitions and background information that help you to understand the product and the ways in which you can use it to solve your business problems. Check the Glossary for a definition of many of the terms introduced in these topics.

• Chapter 2, "WebSphere Message Broker overview," on page 5

These topics provide a good introduction to the product and its facilities. Expand **Product Overview** to read about the product, and what is new in this release. You can also read about, and invoke, the Quick Tour, an online guided introduction to the product components and options. Access the samples that are supplied too, to understand more about how your applications can use the broker function.

- Chapter 6, "Configuring brokers for development environments," on page 563
- Chapter 7, "Configuring brokers for test and production environments," on page 579
- Chapter 8, "Administering brokers and broker resources," on page 899
- Chapter 9, "Developing message flow applications," on page 1019
- Chapter 10, "Testing and debugging message flow applications," on page 3143
- Chapter 11, "Packaging and deploying," on page 3209
- Chapter 12, "Performance and monitoring," on page 3251
- Chapter 13, "Troubleshooting and support," on page 3345

Reference information

Reference topics provide supporting information that help you to complete the tasks. For example, they provide lists of commands, and tables of options and parameters.

- Security
- "Configuration and administration" on page 3657
- "z/OS configuration and administration specific information" on page 3979
- "Message flow development" on page 4015
- "Troubleshooting" on page 6864

Printing topics

You can print a single topic or a section of topics from this information center. Select a topic in the table of contents, then click the printer icon  . You can then choose to print just the selected topic, or the selected topic and all its subtopics.

Feedback

Your feedback on this information center is welcome. For example, you can report errors, identify missing information, or suggest improvement. A feedback link is included at the end of every topic; click this link to display a feedback form for the topic that you are viewing. Your feedback is logged in a database and is forwarded to the author of the topic.

For general feedback on the information center, see Feedback. This topic also contains alternative contact details (postal address, fax number, and email address) that you can use to include attachments with your feedback.

Links to more information

For more information about how to use this information center, and where to find product information about the Web, see the information center home page. The information center home page includes links to the following information:

- Migrating from previous versions
- WebSphere MQ family readme files
- IBM Redbooks®

- Articles on developerWorks®
- SupportPac offerings

Chapter 2. WebSphere Message Broker overview

This section provides introductory information to help you get started with IBM WebSphere Message Broker:

- "WebSphere Message Broker introduction"
- "What's new in Version 7.0?" on page 7
- Technical overview
  - Quick Tour
- Scenarios
- Start here
- "Samples" on page 98
- Legal information
- "Glossary of terms and abbreviations" on page 113
- "Accessibility features for WebSphere Message Broker" on page 135

WebSphere Message Broker introduction

You can use IBM WebSphere Message Broker to connect applications together, regardless of the message formats or protocols that they support.

This connectivity means that your diverse applications can interact and exchange data with other applications in a flexible, dynamic, and extensible infrastructure. WebSphere Message Broker routes, transforms, and enriches messages from one location to any other location:

- The product supports a wide range of protocols: WebSphere MQ, JMS 1.1, HTTP and HTTPS, Web Services (SOAP and REST), File, Enterprise Information Systems (including SAP and Siebel), and TCP/IP.
- It supports a broad range of data formats: binary formats (C and COBOL), XML, and industry standards (including SWIFT, EDI, and HIPAA). You can also define your own data formats.
- It supports many operations, including routing, transforming, filtering, enriching, monitoring, distribution, collection, correlation, and detection.

Your interactions with WebSphere Message Broker can be considered in two broad categories:

- Application development, test, and deployment. You can use one or more of the supplied options to program your applications:
  - Patterns provide reusable solutions that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context. You can use them unchanged or modify them to suit your own requirements.
  - Message flows describe your application connectivity logic, which defines the exact path that your data takes in the broker, and therefore the processing that is applied to it by the message nodes in that flow.
  - Message nodes encapsulate required integration logic, which operates on your data when it is processed through your broker.
  - Message trees describe data in an efficient, format independent way. You can examine and modify the contents of message trees in many of the nodes that are provided, and you can supply additional nodes to your own design.

  - You can implement transformations by using graphical mapping, Java™, PHP, ESQL, and XSL, and can make your choice based on the skills of your workforce without having to provide retraining.
- Operational management and performance. WebSphere Message Broker includes the following features and functionality, which support the operation and performance of your deployment:
  - An extensive range of administration and systems management options for developed solutions.
  - Support for a wide range of operating system and hardware platforms.
  - A scalable, highly performing architecture, based on requirements from traditional transaction processing environments.
  - Tight integration with software products, from IBM and other vendors, that provide related management and connectivity services.

  WebSphere Message Broker is available in several modes, so that you can purchase a solution that meets your requirements. For more information, see "Operation modes" on page 48.

Application development

Your message processing applications, which you can run on more than 30 industry platforms, can connect to the broker by using one of the supported protocols already listed. Platforms from IBM, Microsoft, Oracle, and others are supported.

Diverse applications can exchange information in widely differing formats, with brokers handling the processing required for the information to arrive in the right place in the correct format, according to the rules that you have defined. The applications need only to understand their own formats and protocols, and not standards used by the applications to which they are connected.

Applications also have much greater flexibility in selecting which messages they want to receive, because you can apply filters to control the messages that are made available to them.

WebSphere Message Broker provides a framework that contains a wide variety of supplied, basic, functions along with user-defined enhancements, to enable rapid construction and modification of message processing rules.

Your applications can be integrated by providing message and data transformations in a single place, the broker. This integration helps to reduce the cost of application upgrades and modifications. You can extend your systems to reach your suppliers and customers, by meeting their interface requirements within your brokers. This ability can help you to improve the quality of your interactions, and allow you to respond more quickly to changing or additional requirements.

Messages are manipulated according to the rules that you define by using the WebSphere Message Broker Toolkit.

Operational management

WebSphere Message Broker supports a choice of interfaces for operation and administration of your brokers:

- The WebSphere Message Broker Toolkit

- The WebSphere Message Broker Explorer is a graphical user interface, based on the WebSphere MQ Explorer, for administering your brokers
- Applications that use the Administration API for WebSphere Message Broker (also known as the CMP API)
- A comprehensive set of commands, that you can run interactively or by using scripts

WebSphere Message Broker builds on the WebSphere MQ product, which provides assured, once-only delivery of messages between the applications. WebSphere MQ is included when you purchase WebSphere Message Broker.

WebSphere Message Broker is complemented by a wide variety of other IBM products such as Tivoli® Composite Application Manager for SOA, WebSphere Service Registry and Repository (WSRR), WebSphere Process Server, and WebSphere Transformation Extender (WTX).

Related concepts:

"WebSphere Message Broker technical overview" on page 27
WebSphere Message Broker enables information packaged as messages to flow between different business applications, ranging from large traditional systems through to unmanned devices such as sensors on pipelines.

What's new in Version 7.0?

Learn about the main new functions in IBM WebSphere Message Broker Version 7.0.

Simplicity and productivity

In Version 7.0, both the product and its architecture have been simplified, and the product has fewer prerequisite products.

Streamlined components and prerequisite product requirements

Version 7.0 consists of a single runtime component, the broker. All commands and other programs now connect directly to a broker. The broker security model is now implemented by using WebSphere MQ queues, and therefore handles both brokers and queue managers.

Brokers maintain configuration data in the local file system

Brokers create and manage configuration data in an internal repository in the local file system, and have no requirement for a database. You can back up and restore the broker component and its internal repository by using the commands **mqsibackupbroker** and **mqsirestorebroker**.

Database support for message flows and user data is unchanged; however, supported versions of Relational Database Management Systems (RDBMS) (supplied by IBM and other vendors) have been updated on some platforms.

For more information about database support, see "Supported databases" on page 3591.

Optimized deployment and interactions with the broker

Applications that manage brokers and their resources connect directly to the broker. These applications include:

- The WebSphere Message Broker Explorer, an administration toolkit delivered with Version 7.0, which is described later in this section.
- The WebSphere Message Broker Toolkit.
- Commands; for example, **mqsideploy**, **mqsilist**, and **mqsistartmsgflow**.
- All applications that are written to the Configuration Manager Proxy (CMP) API, including the CMP Exerciser.

  For more details about the CMP API for Version 7.0, see "The Administration API for WebSphere Message Broker" on page 54.

You can control which users and applications are able to run commands against particular brokers or execution groups by using WebSphere MQ security, as described in the following section.

Administration security

Set up broker administration security to control the authority that is required by users to complete specific administrative tasks. You can enable security when you create a broker, or change it later on an existing broker. This option, which uses WebSphere MQ facilities, replaces Access Control Lists (ACLs) that were managed by the Configuration Manager in previous versions.

For further details, see "Broker administration security overview" on page 362.

For details of new and updated commands, see "Commands" on page 3672.

WebSphere Message Broker Explorer

The WebSphere Message Broker Explorer is an administration interface that is integrated as a plug-in into WebSphere MQ Explorer, so that you can administer both brokers and WebSphere MQ queue managers on local and remote computers.

Important status information is always on view, and you can access details about what each broker is doing, and has recently done. Configuration and other changes are monitored, and the user responsible for these changes is recorded.

The WebSphere Message Broker Explorer supports all the function that is provided by the Broker Administration perspective in the WebSphere Message Broker Toolkit in previous versions, and offers additional, more advanced features. Limited administration functionality is still available in the new Brokers view in the WebSphere Message Broker Toolkit to run a subset of operations.

The WebSphere Message Broker Explorer includes the following capabilities:

- You can create, delete, start, and stop local brokers without using the command line.
- You can see the relationships between your brokers and your queue managers.
- You can deploy a broker archive file to multiple execution groups in one step.
- You can see visualizations of your accounting and statistics data.
- You can see visualizations of your resource statistics data.
- You can configure broker properties, including creating and modifying configurable services.
- You can view the broker administration queue, and remove pending tasks that have been submitted to the broker.
- You can connect and configure settings for a DataPower® device.

For further details about the WebSphere Message Broker Explorer, see "WebSphere Message Broker Explorer" on page 57.

For further details about the Brokers view in the WebSphere Message Broker Toolkit, see "Brokers view" on page 6796.

Publish/subscribe support

All topic-based publish/subscribe operations are handled by WebSphere MQ. You can use WebSphere Message Broker facilities to extend publish/subscribe options to include content-based publishers and subscribers.

All applications use a single topic space that is managed by WebSphere MQ, and access control is handled by the queue manager. The concept of broker domains, which is valid in previous versions of WebSphere Message Broker, no longer exists; equivalent function for broker domains, broker topologies, and broker collectives is provided by WebSphere MQ clusters.

The Publication node uses WebSphere MQ publish/subscribe facilities. You can use the *NoMatch* terminal, new in Version 7.0, to identify scenarios in which no subscribers are registered to receive particular topics.

With these changes, your publish/subscribe network requires you to configure a broker only where you have content-based subscribers, not throughout the network. The content-based filters that you can specify can now include full ESQL expressions, including namespace support.

You can migrate JMS applications, and applications that use the MQRFH2 header, directly to WebSphere MQ.

WebSphere MQ Real-time Transport and WebSphere MQ Telemetry Transport nodes are no longer supported. Therefore, the following nodes have been removed:

- Real-timeInput

- Real-timeOptimizedFlow
- SCADAInput
- SCADAOutput

If you use the WebSphere MQ Real-time Transport, your applications can use equivalent qualities of service provided by WebSphere MQ. Migrate JMS real-time publishers and subscribers to the "read-ahead get" and "asynchronous-put" facilities of WebSphere MQ.

Message flows containing these nodes that you have migrated to WebSphere Message Broker Version 7.0 will not start until these nodes have been removed from the flow, and the flow has been redeployed.

Contact your account representative for more information about support for WebSphere MQ Real-time Transport and WebSphere MQ Telemetry Transport.

For more information about the changes to publish/subscribe see "Routing using publish/subscribe applications" on page 2215.

WebSphere Message Broker Toolkit

You can administer local and remote brokers in the Brokers view, which is new in Version 7.0. This view is integrated into the Broker Application Development perspective, so that you can access basic administration tasks while you are developing, deploying, debugging, and testing your applications.

The WebSphere Message Broker Toolkit includes an impact analysis tool that you can use to discover interdependencies between resources, and assess the effects of planned changes to those resources. See "Impact analysis: analyzing the effects of planned changes to your applications" on page 1150.

Samples are now accessible through the Samples and Tutorials page, and from the information center in the WebSphere Message Broker Toolkit. For a full list of the samples, see "Samples" on page 98.

Patterns

A pattern is a reusable solution that encapsulates a top-down tested approach to solving a common architecture, design, or deployment task in a particular context. This approach complements bottom-up development of creating message flows and nodes.

A number of patterns are supplied in the WebSphere Message Broker Toolkit, and you can use the Patterns Explorer, which includes comprehensive help, to simplify creation of common scenarios.

You can configure these patterns with values for use in your own environment to solve specific business problems. The supplied patterns use preferred techniques in message flow design, to produce efficient and reliable flows.

For more information, see "Patterns" on page 1310.

Universal connectivity for SOA

Additional nodes and configurable services expand the interaction of the broker with other products.

SCA nodes for WebSphere Process Server

Five new built-in message flow nodes are provided to improve the interaction between WebSphere Message Broker and WebSphere Process Server Version 6.2 by using Web Services (SOAP over HTTP) or WebSphere MQ bindings.

The nodes are the SCAInput, SCAReply, SCARequest, SCAAsyncRequest, and SCAAsyncResponse nodes.

For more information, see "Service Component Architecture (SCA) overview" on page 2096.

Enhanced support for the PHPCompute node

Support for the PHP scripting language is available on all operating systems on which WebSphere Message Broker is supported, except Solaris on x86-64. The PHPCompute node supports general-purpose transformation logic in the PHP language, and complements the Compute, JavaCompute, XSLTransform, and Mapping nodes. In addition, the set of supported PHP extensions has been increased. For more information, see "Using PHP" on page 2670 and "PHP extensions" on page 5324.

SAP, Siebel, and Peoplesoft enhancements

Version 7.0 improves connectivity with Enterprise Information Systems.

New WebSphere Adapter nodes

Use the SAPReply node to send a reply to an SAP synchronous callout. Use this node with an SAPInput node to implement a message flow application that acts as a remote function call (RFC) destination.

For more information, see "SAPReply node" on page 4682 and "BAPI inbound scenarios" on page 1943.

Generic IDoc routing

By using the SAPInput node in passthrough mode, WebSphere Message Broker can receive any IDoc, and route it according to IDoc type. By using this method, you can also use a single RFC program ID to receive all IDoc types, while still allowing individual IDoc processing.

For more information, see "Generic IDoc routing" on page 1976.

SAP high availability

You can deploy an SAP adapter and a message flow that contains an SAPInput node to two brokers on your network; these brokers can accept IDocs concurrently from the same SAP system so that you can build a highly available environment.

On distributed systems, two brokers share state by using queues on a third queue manager, which is running in multi-instance mode. Each broker has client connections to that queue manager.

On z/OS®, the shared state is stored on a shared queue. Each broker connects to the queue sharing group.

For more information, see "SAP high availability" on page 1947.

Iterative discovery

You can take an adapter component that was created by using the Adapter Connection wizard in WebSphere Message Broker Version

7.0, and update it with newly discovered objects from the Enterprise Information System (EIS) by running the Adapter Connection - Iterative Discovery wizard. This facility is known as *iterative discovery*. You can either add the new objects without modifying existing objects, or replace existing objects.

For more information, see "Enhancing existing adapters with newly discovered objects" on page 2063.

Iterative deployment

If your message flow acts as a gateway to an EIS, you can use it to call new services that did not exist when you developed the flow. You can also create an event handler to an EIS to handle new event types that did not exist when you first developed your message flow. In both cases, if a new service or event is provided by the EIS, you do not have to modify and retest the message flow. This facility is called *iterative deployment*.

For more information, see "WebSphere Adapters deployment" on page 3219.

Sequence and Resequence nodes

WebSphere Message Broker provides support for adding sequence numbers to messages, and for reordering messages in the message flow based on their sequence number. You can use the new Sequence node to add sequence numbers to the messages, and the new Resequence node to reorder the messages into their original sequential order.

For more information, see "Sequence node" on page 4736 and "Resequence node" on page 4651.

New configurable services for EDA nodes

You can use the following configurable services to define the WebSphere MQ queues on which EDA nodes store event state:

- Aggregation
- Collector
- Resequence
- Timer

You can also use these configurable services to specify timeouts for the nodes. For more information, see "Configurable services properties" on page 3766.

Dynamic operation management

Additional features provide better information and control of operations.

Multi-instance brokers

WebSphere Message Broker builds on the multi-instance queue manager support introduced in WebSphere MQ Version 7.0.1 to provide a highly available configuration with active and passive brokers.

Multi-instance brokers and queue managers store their configurations on shared network storage so that if a failure occurs in an active component, the passive component assumes the configuration and operation of the

active component. The use of queue managers in this way avoids the requirement for a high availability solution, such as HACMP™, supplied by a vendor software company.

For further information, see "Configuring for high availability" on page 826.

Audit and monitoring

You can now generate comprehensive audit and monitoring events from message flows, either at design time or operationally, for new and existing message flows. These events can be consumed by a diverse range of applications and systems, including WebSphere Business Monitor, WebSphere MQ and JMS applications, and vendor applications. In addition to business monitoring, you can use these events for business intelligence, and audit scenarios.

See "Business-level monitoring" on page 3319 for an overview of monitoring.

The following improvements to the monitoring of message flows are introduced:

- A filter can be applied to every event source, to control whether the event is emitted. See "Configuring monitoring event sources using monitoring properties" on page 3327 and "Monitoring profile" on page 6768.
- You can export the monitoring information about a message flow from the WebSphere Message Broker Toolkit, and import it into WebSphere Business Monitor Version 7.0 to generate a monitor model for your message flow. See "Creating a monitor model for WebSphere Business Monitor V7" on page 3341.
- You can choose whether the emission of monitoring events by a message flow is coordinated with the message flow transaction, is in an independent unit of work, or is not in a unit of work, which improves overall monitoring performance; see "Monitoring basics" on page 3320.
- Monitoring events now contain an integer counter, as well as the creation time of the events, for use in sequencing events. The Sequence tab has been removed from the WebSphere Message Broker Toolkit.

Resource statistics

You can collect statistics for some of the resources that are used by execution groups in the broker to help with problem diagnosis and broker optimization. Supported resources are the Java Virtual Machine (JVM), and the outbound sockets. For example, you can monitor the sockets that are used by SOAP nodes in your message flows.

You can start and stop statistics collection at broker or execution group level by using the WebSphere Message Broker Explorer, the CMP API, or the **mqsichangeresourcestats** command.

The resource statistics framework is based on the existing accounting and statistics for message flows, and generates periodic messages as publications that your programs can subscribe to. You can also view these statistics in the WebSphere Message Broker Explorer, which provides both numeric and graphical representations.

For further details, see "Monitoring resource performance" on page 3305.

Service Federation Management enablement

You can enable brokers for Service Federation Management. For further information, see “Working with Service Federation Management (SFM)” on page 911.

Platforms and environments

The Version 7.0 broker operates in 64-bit mode on z/OS and all distributed platforms, except Linux on x86 and Windows systems.

Platforms

- The following platforms now support only 64-bit operation, and have a smaller installation footprint:
  - AIX®
  - Linux on x86-64
  - Solaris on SPARC

  See “Migrating a Version 6.1 broker to Version 7.0 on distributed operating systems” on page 173 or “Migrating a Version 6.0 broker to Version 7.0 on distributed operating systems” on page 194 for configuration details.
- WebSphere Message Broker Version 7.0 is not supported on HP-UX on PA-RISC. If you use this platform, retain Version 6.1, and speak to your IBM representative about your requirements.

Java

Java 1.6 (Version 6) is supported in all environments. On IBM platforms, the IBM J9 engine is supplied, which benefits from reduced startup time and memory footprint.

Migration

You can migrate to WebSphere Message Broker Version 7.0 from WebSphere Message Broker Version 6.1, WebSphere Message Broker Version 6.0, and WebSphere Event Broker Version 6.0. You can also install WebSphere Message Broker Version 7.0 to coexist with previous versions on the same computer.

For details about how to migrate your components and data, and how components from different versions can interact, see Chapter 3, “Migrating and upgrading,” on page 137.

Related concepts:

“New function added in Version 7.0 fix packs” on page 15
Some fix packs and other maintenance packs deliver new functions.

Related tasks:

Chapter 3, “Migrating and upgrading,” on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Related reference:

“Reviewing technical changes in Version 7.0” on page 205
Some minor changes in behavior are present in WebSphere Message Broker Version 7.0; for example, those changes caused by defects that have been fixed between versions.

New function added in Version 7.0 fix packs

Some fix packs and other maintenance packs deliver new functions.

The "What's new in Version 7.0?" on page 7 topic introduces you to the main new function in WebSphere Message Broker Version 7.0. This topic introduces you to the additional function that has been added in fix packs.

For detailed information about the contents of fix packs and other maintenance packs, see the WebSphere Message Broker support web page. Click **Download**, then **Recommended Fixes**, and select your product to view available fixes. The description of each fix pack includes links to **Release notes** (details of its content) and **Problems fixed** (a list of PMRs, APARs, and defects that are included).

To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command, as shown in the following example:

```
mqsichangebroker MB7BROKER -f 7.0.0.7
```

For more information about this command, see "**mqsichangebroker** command" on page 3723.

Fix pack V7.0.0.7 enhancements

Setting up the JNDI interface for the proxy servlet

The proxy servlet initialization parameters must be configured for the broker environment that the proxy servlet is connecting to each time the proxy servlet is deployed to the servlet container. It is now possible to configure the `web.xml` parameters only once through the JNDI in WebSphere Application Server, regardless of how many future deployments there might be of the proxy servlet. Because the JNDI configuration parameters take precedence over the initialization parameters in the `web.xml` file, using this method means that you need to set up at the application server side only once for any future deployments of the proxy servlet.

These setup tasks must all be completed in the WebSphere Application Server administrative console. For a full list of the steps, see "Setting up the JNDI interface for the proxy servlet" on page 886.

Configuring the XPath cache

An Execution Group keeps a cache of compiled XPath expressions to help reduce the processor usage of parsing and re-creating XPath expressions that are used repeatedly during Message Flow execution. This cache is shared by all Message Flows within an Execution Group. However, this default size might become a performance bottleneck for customers who use many XPath expressions with a single flow invocation completely invalidating the cache. Altering the size of the XPath cache might improve message flow performance. For examples and information about altering the default cache size, see "Configuring the XPath cache" on page 765.

Fix pack V7.0.0.6 enhancements

Setting FTP and SFTP servers dynamically

You can override the `Remote server and port` property on the FileOutput node by setting a value in the local environment.

For more information, see “Local environment overrides for the FileOutput node” on page 4443.

Verify the ODBC environment on Linux and UNIX systems

The **mqsicvp** command is run automatically when you start a broker by using the **mqsistart** command. The command checks that the broker environment is set up correctly. This checking has been enhanced to verify that the ODBC environment is configured correctly on Linux and UNIX systems. When you run this command from the command line on Linux and UNIX systems, it also validates the connection to all data sources that are listed in the `odbc.ini` file that have been associated with the broker by using the **mqsisetdbparms** command.

For more information, see “**mqsicvp** command” on page 3857.

Display the full content of BIP messages

You can view the full content of a runtime BIP message, including the user response and explanation sections, by using the **mqsiexplain** command.

For more information, see “**mqsiexplain** command” on page 3879.

Start an execution group with a different user ID to a broker on z/OS systems

On z/OS systems, you can change the user ID under which an execution group runs so that it can access resources according to the permissions assigned to it, rather than the permissions assigned to the main broker user ID.

For more information, see “Execution group user IDs on z/OS” on page 560.

New `ConnectionIdleTimeoutSec` property on the IMSConnect configurable service

You can use the **ConnectionIdleTimeoutSec** property on the IMSConnect configurable service to specify the idle connection timeout for cached IMS Connections. If a cached IMS connection is inactive for more than the specified **ConnectionIdleTimeoutSec**, then this connection becomes ineligible for reuse, and is removed from the cache, and closed cleanly.

For more information, see “Configurable services properties” on page 3766.

Configure the properties of an execution group while it is in offline mode

You can use the **-f** parameter on the **mqsireportproperties** and **mqsichangeproperties** commands to view and change properties on an execution group while it is in offline mode.

For more information, see “**mqsichangeproperties** command” on page 3756.

Additional problem collector for IBM Support Assistant Data Collector

Use the broker problem collector, which is installed with IBM Support Assistant Data Collector, to gather more extensive broker diagnostic documents.

For more information, see “Selecting a problem collector for IBM Support Assistant Data Collector” on page 3568.

New `timeoutThreads` property

An optional property that assigns additional processing threads to enable processing of timed out aggregation messages in the AggregateReply node. For more information, see "Processing timed out aggregation messages" on page 2739.

Fix pack V7.0.0.5 enhancements

Updates to the FileOutput node Basic properties

Support has been added for writing directly to an output file; see "FileOutput node" on page 4430 for more information.

Java shared classloader

A new shared classloading option has been introduced:

- **Execution group classloading** – allows only a single defined execution group to access and load any JAR files that are placed in the execution group `shared-classes` directory.

A new classloading precedence order is also defined.

For more information, see "Java shared classloader" on page 2637.

Support for `mqsimode` command on z/OS

The **`mqsimode`** command can be run on z/OS by customizing and submitting BIPMODE; see "**`mqsimode`** command" on page 3899 for more information.

New `jdbcProviderXASupport` property

An optional property that controls whether the broker connects to a database server using XA Protocol. For more information, see "Setting up a JDBC provider for type 4 connections" on page 684.

IBM Support Assistant Data Collector

Using IBM Support Assistant Data Collector, which is installed with WebSphere Message Broker, you can collect diagnostic documents and submit a problem report to IBM.

For more information, see "IBM Support Assistant Data Collector" on page 3565.

WebSphere MQ Version 7.1 and Version 7.5

This fix pack introduces support for WebSphere MQ Version 7.1 and Version 7.5 within WebSphere Message Broker, with the following restrictions.

- WebSphere MQ Version 7.1 and Version 7.5 must be configured as the primary installation.
- WebSphere MQ Version 7.1 and Version 7.5 must be installed in the default install location on AIX, HP-UX, Linux, and Solaris.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

Fix pack V7.0.0.4 enhancements

New nodes for IBM Sterling Connect:Direct®

IBM Sterling Connect:Direct is a managed file transfer product that transfers files between, and within, enterprises. The following new nodes have been added to implement the additional features:

- "CDInput node" on page 4305
- "CDOutput node" on page 4312

WebSphere Message Broker nodes work as clients, connecting to an external Connect:Direct server through the IBM Sterling Connect:Direct Java Application Interface. For an overview of IBM Sterling Connect:Direct, see "IBM Sterling Connect:Direct overview and concepts" on page 1810.

Using LocalEnvironment variables with JMSOutput and JMSReply nodes
Use the DestinationData element with DestinationName and DestinationType child elements to specify the name and type of the JMS Destination. For more information, see "Using LocalEnvironment variables with JMSOutput and JMSReply nodes" on page 4242.

Creating a security profile for LDAP
Use the rejectBlankpassword property when configuring a security profile for Lightweight Directory Access Protocol (LDAP), to specify whether the security manager rejects a user name that has an empty password token without passing it to LDAP. For more information, see "Creating a security profile for LDAP" on page 435, "Configurable services properties" on page 3766, and "SecurityProfiles configurable service properties" on page 3801.

New HTTPConnector property autoRespondHTTPHEADRequests
Use the autoRespondHTTPHEADRequests property to specify if the connector handles HEAD requests for HTTP traffic in the same way that it does for SOAP traffic. For more information, see "Execution group HTTP listener parameters (SOAP and HTTP nodes)" on page 3805.

Millisecond timeouts on HTTPRequest and SOAPRequest nodes
Use the TimeoutMillis local environment setting to define a timeout in milliseconds and override the Request timeout (sec) property on the node. For more information, see "HTTPRequest node" on page 4488 and "Local environment overrides for the SOAPRequest node" on page 4850.

Proxy servlet configuration for SSL connections
Use the SSL connection options when deploying the proxy servlet `web.xml` to the servlet container. For more information, see "Proxy servlet configuration parameters" on page 878.

Support for additional data types on DB2®
GRAPHIC, VARGRAPHIC, LONGVARGRAPHIC, and DBCLOB data type support on DB2 is now provided for the broker. For more information, see "Support for Unicode and DBCS data in databases" on page 3668.

Fix pack V7.0.0.3 enhancements

HTTP Transport property hostnameChecking
Use the HTTP Transport property hostnameChecking to specify whether the host name of the server that is receiving the request must match the host name in the SSL certificate. For more information, see "HTTPRequest node" on page 4488, "SOAPRequest node" on page 4828, and "SOAPAsyncRequest node" on page 4750.

TDS Mnemonics
Use the TDS mnemonic string <X12_ERS> as an element repetition separator for X12. For more information, see "TDS Mnemonics" on page 5391.

Policy Sets and Policy Set Bindings editor
Use the **mustUnderstand** attribute in the Policy Sets and Policy Set Bindings editor to configure the security header of the consumer message. For more information, see "Policy Sets and Policy Set Bindings editor: Advanced panel" on page 6863.

New configurable service properties

The following configurable service properties are new for 7.0.0.3:

- Use the JDEdwardsConnection configurable service property assuredOnceDelivery to specify whether to provide assured once-only delivery for inbound events. For more information, see "Configurable services properties" on page 3766.
- Use the MonitoringProfiles configurable service property useParserNameInMonitoringPayload to determine when the payload is included in a monitoring message. For more information, see "Configurable services properties" on page 3766 and "Configuring monitoring event sources using a monitoring profile" on page 762.
- Use the IMSConnect configurable service property CodedCharSetID to change your IMS system or IMSConnect CCSID from the default value. For more information, see "Changing connection information for the IMSRequest node" on page 732 and "Configurable services properties" on page 3766.
- Use the FtpServer configurable service property preserveRemoteFileDate to specify whether files that are retrieved from a remote server by the FileInput node retain the last modified date on the server. For more information, see "FtpServer configurable service properties" on page 3794 and "Configurable services properties" on page 3766.

Fix pack V7.0.0.2 enhancements

Simplicity and productivity

To simplify the product and increase productivity, WebSphere MQ Telemetry Transport is now supported by WebSphere MQ, and you can do more with patterns.

WebSphere MQ Telemetry Transport

WebSphere MQ Telemetry Transport is supported from WebSphere MQ. For more information, see "Changes to nodes in WebSphere Message Broker Version 7.0" on page 2217.

Modifying pattern instances by using Java or PHP

Use Java or PHP code to modify pattern instances when the pattern user generates an instance of a user-defined pattern. For example, to modify the structure of a message flow that is based on the values of pattern parameters.

For more information, see "Modifying pattern instances by using Java or PHP" on page 1364.

Share your user-defined patterns with other users

Package your user-defined pattern into a pattern archive so that the user-defined pattern can be distributed to pattern users by adding the pattern archive to a pattern community site.

For more information, see "Packaging and distributing pattern plug-ins" on page 1397.

Universal connectivity for SOA

Additional nodes and configurable services expand the interaction of the broker with other products.

CICSRequest node enhancements

- You can specify a mirror transaction name on the CICSRequest node, which you can use to run CICS® Transaction Server for z/OS tasks and programs. This grouping greatly assists in collecting statistics, accounting, and aids decision making about task priority. For more information about mirror transactions, see "CICS Transaction Server for z/OS mirror transactions" on page 2189.
- The CICSRequest node support in WebSphere Message Broker provides direct communication with CICS (two-tier connection) by sending Distributed Program Link (DPL) requests over TCP/IP-based IP InterCommunications (IPIC) protocol, or communication with CICS through CICS Transaction Gateway for Multiplatforms (three-tier connection). For more information about the two-tier and three-tier connection models, see "CICS Transaction Server for z/OS overview" on page 2173 for a high-level overview, or "CICS Transaction Server for z/OS two-tier connectivity" on page 2177 and "CICS Transaction Server for z/OS three-tier connectivity" on page 2181 for detailed conceptual information.
- You can specify either a COMMAREA data structure or a channel data structure on the CICSRequest node to use as input for linking to CICS programs. The data structure that is specified as input returns the same data structure as output. Channels are an alternative for COMMAREAs, providing relief from the COMMAREA maximum size of 32766 bytes, and allowing greater flexibility in input and output data structures. For more information about using a COMMAREA or channel data structure, see "COMMAREA or channel data structures" on page 2183.
- The CICS Transaction Server for z/OS Channel Connectivity sample demonstrates how to call a channel-based CICS program. A CICS channel structure can be represented in WebSphere Message Broker by a message collection. This sample demonstrates how to create and populate a message collection for the CICSRequest node and how to process the collection after the call.

New EmailInput node

Use the EmailInput node to retrieve an email, with or without attachments, from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

For more information, see "EmailInput node" on page 4394.

A sample that demonstrates how you can use the EmailInput node is also provided. For more information, see Email.

New JDEdwardsInput and JDEdwardsRequest nodes

Use the JDEdwardsInput and JDEdwardsRequest nodes to interact with a JD Edwards EnterpriseOne server. For example, you can use the JDEdwardsRequest node to discover JD Edwards EnterpriseOne business functions, XML lists, and real-time events.

For more information, see "JDEdwardsInput node" on page 4519 and "JDEdwardsRequest node" on page 4524.

A sample that demonstrates how you can use the "JDEdwardsRequest node" on page 4524 node is also provided. For more information, see JD Edwards Connectivity.

New FileRead node

Use the FileRead node to read one record, or the entire contents of a file, from within a message flow.

For more information, see "FileRead node" on page 4444.

The Message Routing sample has been enhanced, and now demonstrates how to use the FileRead node. For more information about how to process messages that are based on the contents of an XML or CSV file, see Message Routing.

FileInput node

Skip the first record in a file. The FileInput node reads the first record in the file but does not propagate the record to the Out terminal. Records are propagated as normal, from the second record onwards. Use this option when the first record is a header that does not need to be processed. It is not valid to use this option when using the whole file.

For more information, see "FileInput node" on page 4415.

SSL for TCP/IP nodes

You can configure the broker to use SSL for TCP/IP connections; see "Configuring TCP/IP client nodes to use SSL" on page 551.

HTTP compression for HTTP and SOAP nodes

You can configure HTTP nodes to use HTTP compression and decompression when sending and receiving messages. Similar HTTP compression functionality was introduced for the SOAP nodes in fix pack 7.0.0.1. For more information, see "Using compression with HTTP and SOAP nodes" on page 1597.

JMS transport for SOAP nodes

The SOAPAsyncRequest and SOAPAsyncResponse nodes support JMS as well as HTTP transport. You can import WSDL with bindings for both JMS and HTTP transport, and switch transports for the SOAPAsyncRequest node during a message flow. WS-Security and WS-Addressing are supported for SOAP/JMS, as well as transactionality. WebSphere Message Broker supports both W3C (standard) and IBM (proprietary) WSDL formats for SOAP/JMS. For more information, see "WSDL URI formats for JMS" on page 1668 and "SOAP over JMS" on page 6698.

Web services gateway

The SOAP nodes support a web services gateway mode, which does not require a WSDL to configure the SOAP nodes, and allows WebSphere Message Broker to handle generic SOAP request/response and one-way messages when used as a web services provider or consumer. WebSphere Message Broker can also act as a façade between multiple web service clients and multiple back-end web service providers.

For more information, see "Gateway operation mode for SOAP nodes" on page 1645.

A sample that demonstrates how you can use a web services gateway is also provided. For more information, see Web Services Gateway.

DatabaseInput node

The DatabaseInput node can now generate the code for a simple database query. After code generation, you can add custom code; see “Configuring a DatabaseInput node” on page 2120. By using an MQInput node with the built-in DatabaseInput node the WBI JDBC Adapter Migration sample re-creates a scenario of migrating a JDBC adapter to invoke a message flow.

A sample that demonstrates how you can use the DatabaseInput node is also provided. For more information, see DatabaseInput Node.

JSON domain

Fix pack V7.0.0.2 provides support for a JSON domain. Messages in the JSON domain are processed by the JSON parser and serializer. The JSON parser interprets a bit stream by using the JSON grammar, and generates a corresponding JSON domain logical message tree in the broker.

For more information, see “JSON parser and domain” on page 1128.

RESTful Web Service Using JSON sample

This sample shows how you can use WebSphere Message Broker to front an existing service as a RESTful web service, providing a JSON message format interface. The sample also shows how to consume the RESTful Web Service from a message flow.

For more information, see RESTful Web Service Using JSON.

Web Service Aggregation sample

The sample demonstrates how you can invoke a number of web services and amalgamate the results by using WebSphere Message Broker aggregation nodes. The sample illustrates how you can use aggregation for transports other than WebSphere MQ, and highlights any issues of which to be aware. For more information, see Web Service Aggregation.

Improved *order by* **support for the MQInput node**

You can now sort by any element in the message. For each value of that element, the messages are processed in arrival order. See “Optimizing message flow throughput” on page 587 and “MQInput node” on page 4594.

Dynamic operation management

Additional features provide better information and control of operations.

Resource statistics for parsers

View the statistics for a parser to view the number of input and output messages that are processed by a message flow, and determine if message flow parsers are using large amounts of memory. For more information, see “Resource statistics” on page 3306.

Platforms and environments

You can interact with more platforms and environments.

Configuring JMS nodes with Oracle AQ

You can configure the JMS nodes to communicate with Oracle AQ (Oracle 11g and above).

For more information, see “Configuring JMS nodes to communicate with Oracle AQ” on page 1712.

Integrating with the Rational® Team Concert client
You can integrate the Rational Team Concert client with the WebSphere Message Broker Toolkit.

For more information, see "Integrating the Rational Team Concert client with the WebSphere Message Broker Toolkit" on page 576

Execution group profiles
You can create and use profiles that apply to a specific execution group.

For more information, see "Execution group-specific command environment: Windows systems" on page 309 and "Execution group-specific command environment: Linux and UNIX systems" on page 312.

Fix pack V7.0.0.1 enhancements

- "Simplicity and productivity"
- "Universal connectivity for SOA" on page 24
- "Platforms and environments" on page 26

Simplicity and productivity

Additional patterns are provided to help solve specific business problems.

User-defined patterns
User-defined patterns extend the function of WebSphere Message Broker so that you can create patterns that you can reuse within your organization.

For more information, see "User-defined patterns" on page 1334.

Solar Pattern Authoring sample
This sample shows how you can build a user-defined pattern. The sample provides an example message flow project that calculates the sunrise and sunset times in a PHPCompute node. The sample also provides a pattern authoring project that configures a pattern.

For more information, see "Samples" on page 98.

Service Access from WebSphere MQ: one-way pattern
Use this pattern to process WebSphere MQ XML messages by using the data that the pattern contains to call a web service. Use this pattern to bridge the reliable WebSphere MQ messaging protocols of a client application with the synchronous requests to services to handle updates with an assurance that service failures, including timeouts, are reliably reported.

This pattern provides loose coupling between client applications and service providers in timing, protocols, and transport. It is appropriate for service interfaces to existing systems.

For more information, see "Built-in patterns" on page 1332.

Using a subflow as a user-defined node
Develop a user-defined node that packages a subflow, either in the same way that you create any other user-defined node that has its implementation based on Java, or by basing it on an existing subflow.

For more information, see "Using a subflow as a user-defined node" on page 3008.

Universal connectivity for SOA

Additional nodes and configurable services expand the interaction of the broker with other products.

New CORBARequest node
Use the CORBARequest node to call an external CORBA application over Internet Inter-Orb Protocol (IIOP). You can use this node to create a new external interface for existing CORBA applications.

For more information, see "CORBARequest node" on page 4349.

A sample that demonstrates how to use the CORBARequest node is also provided. For more information, see "Samples" on page 98.

New CICSRequest node
Use the CICSRequest node to call an external CICS Transaction Server for z/OS application over TCP/IP-based IP InterCommunications (IPIC) protocol. By using the CICS support that is provided in WebSphere Message Broker you can deploy CICS applications into a service-oriented architecture (SOA).

For more information, see "CICSRequest node" on page 4321.

A sample that demonstrates how to use the CICSRequest node is also provided. For more information, see "Samples" on page 98.

New WebSphere MQ File Transfer Edition nodes
The FTEOutput and FTEInput nodes transfer files across an existing WebSphere MQ File Transfer Edition network in a timely and reliable manner.

For more information, see "Managed file transfers using WebSphere MQ File Transfer Edition" on page 1869.

A sample that demonstrates how to use the FTEOutput and FTEInput nodes is also provided. For more information, see "Samples" on page 98.

New DatabaseInput node
The DatabaseInput node enables a message flow to respond to changes to data in a database.

For more information, see "Event-based database integration" on page 2118.

Samples that demonstrate how to use the DatabaseInput node are also provided. For more information, see "Samples" on page 98.

You can now create a message definition from a database definition (`.dbm` file); see "Creating a message definition from a database definition" on page 2941.

The New Message Set wizard now includes an option to specify database records; see "Creating a message set" on page 2842.

New SecurityPEP node
The SecurityPEP node enables you to invoke the message flow security manager at any point in the message flow between an input node and an output or request node.

For more information, see "SecurityPEP node" on page 4729.

A sample that demonstrates how to use the SecurityPEP node is also provided. For more information, see "Samples" on page 98.

JMS transport for SOAP nodes

The SOAPInput, SOAPReply, and SOAPRequest nodes support JMS as well as HTTP transport. You can import WSDL with bindings for both JMS and HTTP transport, and switch transports during a message flow. WS-Security and WS-Addressing are supported for SOAP/JMS. WebSphere Message Broker supports both W3C (standard) and IBM (proprietary) WSDL formats for SOAP/JMS. For more information, see "WSDL URI formats for JMS" on page 1668.

For more information, see "SOAP over JMS" on page 6698.

Querying WSDL with ?wsdl

A web service client can send an HTTP GET request with a `?wsdl` query string to message flows implementing web services, and receive a representation of the WSDL that was used to configure the input node that provides the endpoint for the service.

For more information, see "Using WSDL to configure message flows" on page 1664.

HTTP nodes can use the embedded listener in an execution group

You can configure your broker and execution groups so that the HTTP nodes use the listener within the execution group to communicate with clients and servers, in preference to the broker-wide listener. The latter configuration remains the default option, but the execution group listener might enhance message flow throughput.

For more information, see "HTTP listeners" on page 1589.

New HTTP Timeout terminal on HTTPInput and SOAPInput nodes

You can configure your HTTPInput and SOAPInput nodes to connect timeout processing nodes to the HTTP Timeout terminal.

On SOAPInput nodes, messages are propagated through this terminal only when you are using an HTTP binding. On HTTPInput nodes, messages are propagated through this terminal only when you have configured your broker and execution groups such that the HTTPInput node is using the embedded execution group listener.

For more information, see "Using timeouts with HTTP and SOAP nodes" on page 1595, "SOAPInput node" on page 4795, and "HTTPInput node" on page 4474.

Securing the connection to IMS by using SSL

You can use the IMSConnect configurable service to configure the IMSRequest node to use Secure Sockets Layer (SSL) protocol. For more information, see "Securing the connection to IMS by using SSL" on page 549.

Propagating security credentials to IMS

The IMSRequest node can use an identity that is present on an input message, and propagate it to IMS, by using the `Propagate` property on the security profile that is defined for the node. For more information, see "Propagating security credentials to IMS" on page 2144.

Closing unused connections to Enterprise Information Systems

To effectively maintain the pool of connections to SAP, Siebel, or PeopleSoft, you can set a connection timeout value on a configurable

service. The value determines how long a connection can be idle before it is closed. For more information, see “Configuring EIS connections to expire after a specified time” on page 726.

Propagating security credentials to SAP

The SAPRequest node can use an identity that is present on an input message, and propagate it to SAP, by using the `Propagate` property on the security profile that is defined for the node. For more information, see “Propagating security credentials to an SAP request” on page 2065.

New WS-Trust V1.3 compliant security token server (STS) support for message flow security

You can use a WS-Trust V1.3 compliant STS, such as Tivoli Federated Identity Manager (TFIM) V6.2, for message flow security to provide authentication, mapping, and authorization of the following additional security tokens:

- SAML assertions
- Kerberos tickets
- LTPA tokens
- RACF® PassTickets
- Universal WSSE tokens

This support is in addition to the existing support for Username, Username and password, and X.509 certificates. For more information, see “Identity” on page 390.

The support for this new security provider is in addition to the existing support for Lightweight Directory Access Protocol (LDAP) and TFIM V6.1. For more information, see “Message flow security” on page 382.

New WS-Security support for SOAP nodes

You can use the SOAP node support for Kerberos and SAML pass-through to provide SOAP message security. For more information, see “WS-Security” on page 765.

Platforms and environments

Support for the Windows platform is enhanced, to include Windows 7 and Windows Server 2008 R2. You can also now create 64-bit brokers and execution groups with the new Windows on x86-64 version of the product.

WebSphere Message Broker ODBC Database Extender package

This package is required when you are using WebSphere Message Broker to interface with an ODBC data source that is not supported through the DataDirect ODBC drivers.

For further information, see “Installing the WebSphere Message Broker ODBC Database Extender (IE02)” on page 273 and “Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02)” on page 682

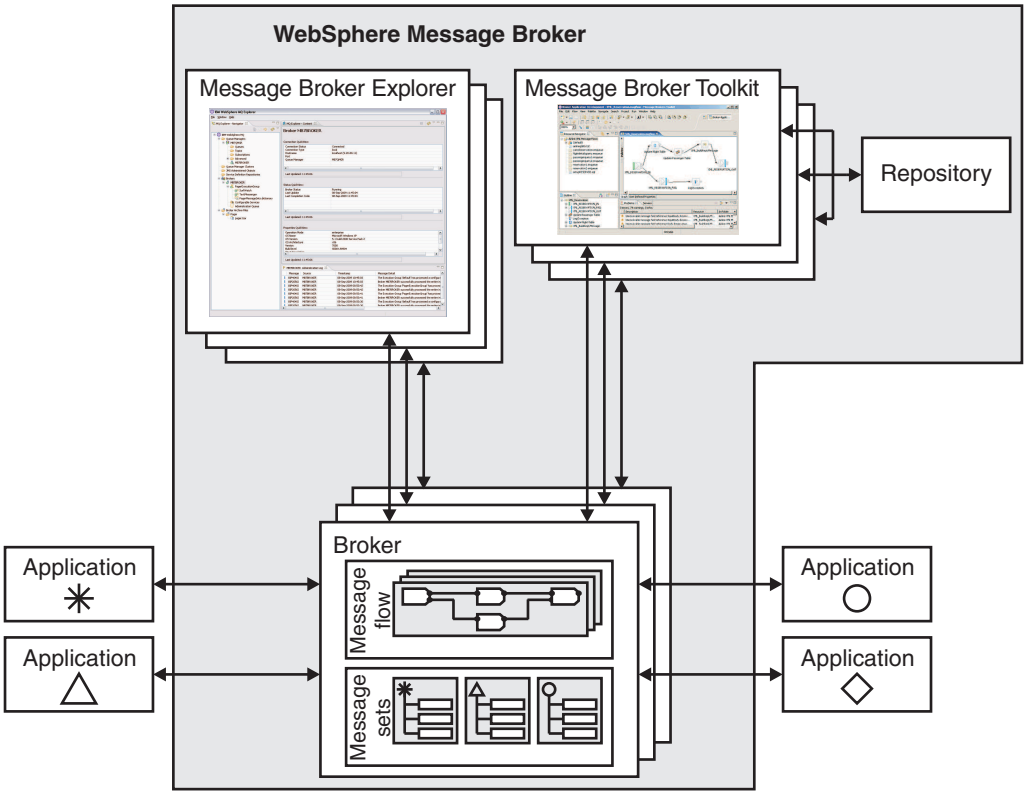
Some minor changes in behavior are present in WebSphere Message Broker Version 7.0; for example, those changes caused by defects that have been fixed between versions.

WebSphere Message Broker technical overview

WebSphere Message Broker enables information packaged as messages to flow between different business applications, ranging from large traditional systems through to unmanned devices such as sensors on pipelines.



For an animated introduction to the basic concepts and features of WebSphere Message Broker shown in the diagram, run the Quick Tour.

WebSphere Message Broker processes messages in two ways: message routing and message transformation.

Message routing

Messages can be routed from sender to recipient based on the content of the message.

The message flows that you design control message routing. A message flow describes the operations to be performed on the incoming message, and the sequence in which they are carried out.

Each message flow consists of the following parts:

- A series of steps used to process a message; see "Message flow nodes" on page 1024.
- Connections between the nodes, defining routes through the processing; see "Message flow connections" on page 1032.

IBM supplies built-in nodes and samples for many common functions. If you require additional functions, you can write your own user-defined nodes; see "User-defined extensions overview" on page 2971.

You create message flows in the WebSphere Message Broker Toolkit which is an integrated development and administration console.

Message transformation

Messages can be transformed before being delivered:

- They can be transformed from one format to another, perhaps to accommodate the different requirements of the sender and the recipient.
- They can be transformed by modifying, combining, adding, or removing data fields, perhaps involving the use of information stored in a database. Information can be mapped between messages and databases. More complex manipulation of message data can be achieved by writing code, for example in Extended SQL (ESQL) or Java, within configurable nodes.

Transformations can be made by various nodes in a message flow. Before a message flow node can operate on an incoming message, it must understand the structure of that message.

- Some messages contain a definition of their own structure and format. These messages are known as self-defining messages, which you can handle without the need for additional information about structure and format; see "Self-defining elements and messages" on page 1198.
- Other messages do not contain information about their structure and format. To process them, you must create a model of their structure; see "Message definition files" on page 1171.

The message definitions that you design are created within a message set which contains one or more message definitions. Message sets also categorize message definitions. The category facility, which you can extend using XSLT scripts, is used for generating Web Services Description Language (WSDL) and documentation; see "Message categories" on page 1200.

Like message flows, you create message models in the WebSphere Message Broker Toolkit. They can contain two types of information:

- The logical structure: the abstract arrangement and characteristics of the data, represented as a tree structure; see "The message model" on page 1160.

- One or more physical formats: the way the data is represented and delimited in the physical bit stream; see “Physical formats in the MRM domain” on page 1211.

Create the broker environment

The work of routing and transforming messages takes place in a broker. Within the broker, you can define one or more execution groups, which are processes in which message flows run.

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See “Restrictions that apply in each operation mode” on page 3657.

You can install and create one or more brokers on one or more computers that are running a supported operating system. If you create multiple brokers, you can configure your environment to provide protection against failure, and you can separate work across different divisions in a business.

You administer the broker by using product commands, the WebSphere Message Broker Explorer, the Brokers view within the WebSphere Message Broker Toolkit, or the Administration API for WebSphere Message Broker (also known as the CMP API) in your own applications.

Develop applications

After your system administrator has created your brokers, your application developers can create and modify message flows and message definitions by using the WebSphere Message Broker Toolkit.

Different perspectives in the WebSphere Message Broker Toolkit are used to develop message flows, message sets, and other related resources; see “WebSphere Message Broker Toolkit” on page 31.

You can use a repository to provide access control and version control of your development resources. A repository also allows multiple developers to work on the same resources in parallel; see “Development repository” on page 45.

Your applications can communicate with the broker by using a range of protocols that includes WebSphere MQ, JMS 1.1, HTTP and HTTPS, Web Services (SOAP and REST), File, Enterprise Information Systems (including SAP and Siebel), and TCP/IP. For more information about connecting applications, see “Nodes for connectivity” on page 1028.

Deploy applications to the runtime environment

When you have created and configured your message flows, message sets, and associated resources by using the Broker Application Development perspective of the WebSphere Message Broker Toolkit, you can deploy the executable data to one or more brokers; see “Packaging and deployment overview” on page 3210.

You can deploy data in the following ways:

- From the Brokers view of the WebSphere Message Broker Toolkit
- From the stand-alone administrative interface, the WebSphere Message Broker Explorer
- From the Test Client environment in the WebSphere Message Broker Toolkit

- By using a command
- By creating applications that use the Administration API application programming interface

When you deploy message flows and message sets, they are compiled and enveloped in a broker archive (BAR) file, and sent to the target broker; see "Packaging and deployment overview" on page 3210. The BAR file has configurable system properties. You can override properties such as queue and database names, without the need to change source files or redevelop the message flow. This configuration makes it easier to move definitions between systems.

The broker opens the BAR file, removes the contents, makes a record of the information that it has received, and discards the envelope. It retains the information in its local storage area within the computer file system, so that it can restore the application resources and restart messages flows if and when required.

Publish/Subscribe

Publish/subscribe is a style of messaging for which WebSphere Message Broker provides limited support; in WebSphere Message Broker Version 7.0 this support was transferred to WebSphere MQ. If you have been connecting publish/subscribe applications to brokers in previous versions, see "Migrating publish/subscribe information to WebSphere MQ" on page 141.

Further information

For a basic introduction to WebSphere Message Broker, see the IBM Redbooks publication WebSphere Message Broker Basics.

A message set is a container for grouping messages and associated message resources (elements, types, groups).

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

"Publish/Subscribe" on page 2215
Publish/subscribe is a style of messaging application in which the providers of information (publishers) are decoupled from the consumers of that information (subscribers).

"ESQL overview" on page 2371
Extended Structured Query Language (ESQL) is a programming language defined by WebSphere Message Broker to define and manipulate data within a message flow.

"Generate WSDL" on page 1274
A *Web Services Description Language* (WSDL) document specifies the interface to a web service, and enables a web service client to start it. A WSDL document that is generated from a message model defines web service requests and responses in terms of the messages that you have defined in that message model.

WebSphere Message Broker supports general industry standards that are associated with message processing.

WebSphere Message Broker Toolkit

The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform.

Application developers work in separate instances of the WebSphere Message Broker Toolkit to develop resources associated with message flows. The WebSphere Message Broker Toolkit connects to one or more brokers to which the message flows are deployed.

You can install the WebSphere Message Broker Toolkit only on Windows and Linux on x86. You can only view and interact with brokers that you have created in WebSphere Message Broker Version 7.0.

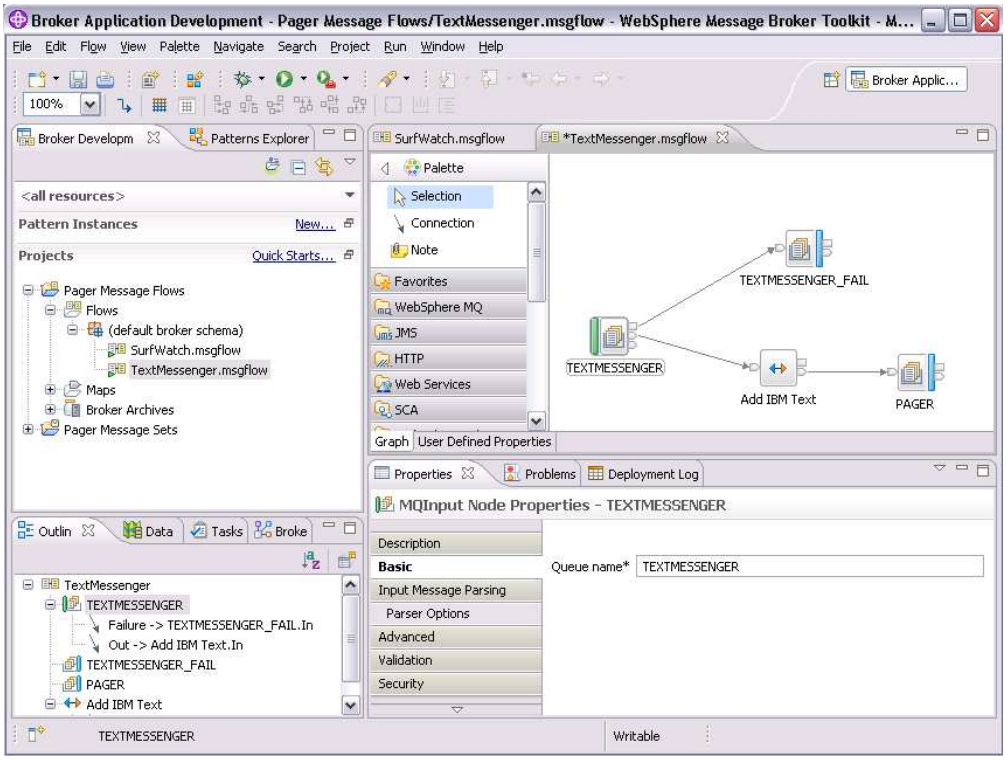
The WebSphere Message Broker Toolkit

When you start the WebSphere Message Broker Toolkit, a single window is displayed. This window is the WebSphere Message Broker Toolkit, which contains one or more perspectives.

A perspective is a collection of views and editors that you use to complete a specific task, or work with specific types of resource. The two significant perspectives in the WebSphere Message Broker Toolkit are the Broker Application Development perspective for application development, and the Debug perspective for debugging message flows. The first time that you start the WebSphere Message Broker Toolkit, the Broker Application Development perspective is displayed.

An additional stand-alone component, the WebSphere Message Broker Explorer, is supplied for advanced administrative users, and enables additional administration tasks that you cannot perform in the WebSphere Message Broker Toolkit.

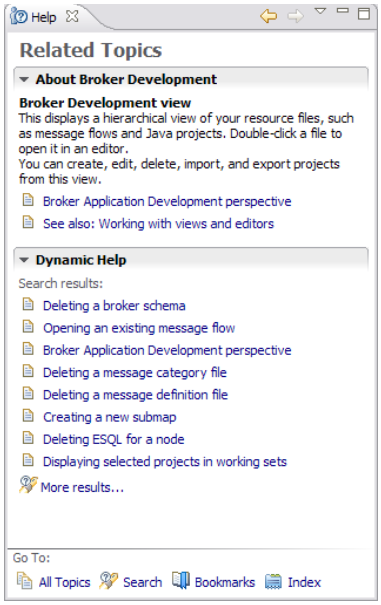
The following figure shows the Broker Application Development perspective with a message flow open in the Message Flow editor on Windows.



Accessing context-sensitive help

The Help view provides context-sensitive help throughout the WebSphere Message Broker Toolkit. You can display the Help view for most aspects of the user interface (for example, on the Broker Development view, the Message Flow editor, or a properties page) by bringing focus to the object and pressing F1 (on Windows) or SHIFT+F1 (on Linux). The Related Topics page shows description and help topics that are related to the selected object. The About section shows context help that is specific to your current context, and the Dynamic Help section shows some search results that might be related.

The following figure shows the Related Topics page of the Help view that is displayed when you press F1 in the Broker Development view.



Use the other pages in the Help view to view and search the contents of the information center. The All Topics page shows the table of contents of all the books in the information center. The Index provides an index of keywords of all the books in the information center. You can enter a keyword in the text field on the Index page to highlight the best match in the list of keywords. You can use the Search page to locate topics, samples, and remote documents using keywords in a search query. You can bookmark topics and other documents of interest, and view them in the Bookmarks page.

For a basic introduction to using the WebSphere Message Broker Toolkit, see the IBM Redbooks publication WebSphere Message Broker Basics.

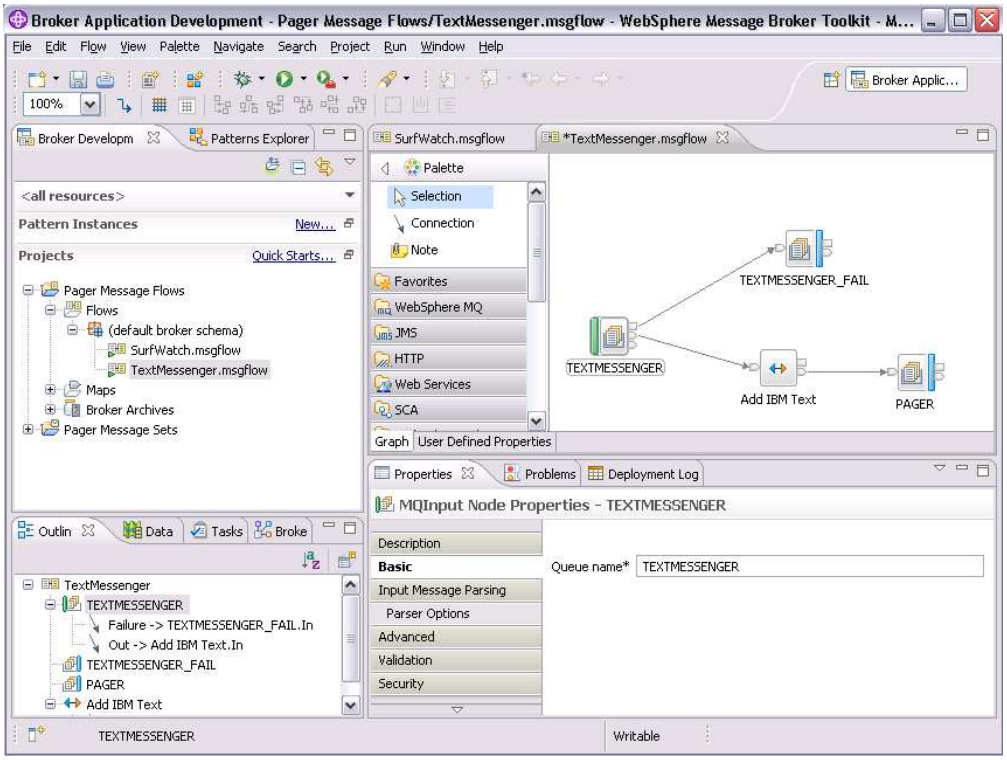
WebSphere Message Broker Toolkit perspectives

A perspective is a group of views and editors that shows various aspects of the resources in the WebSphere Message Broker Toolkit.

You can switch perspectives, depending on the task at hand, and customize the layout of views and editors. Switch between perspectives by clicking **Window** > **Open Perspective** > **Other**, then clicking the perspective to which you want to switch.

The following figure shows the Broker Application Development perspective in the WebSphere Message Broker Toolkit.



The WebSphere Message Broker Toolkit offers the following perspectives:

Broker Application Development perspective

The Broker Application Development perspective is the default perspective that is displayed the first time that you start the WebSphere Message Broker Toolkit.

Application developers work in this perspective to develop and modify message sets, message flows, and other associated resources. You can also import relational database schemas for ESQL content assist and validation, and interact with databases by using the Data Project Explorer view and Data Source Explorer view.

The preceding figure shows the Broker Application Development perspective with a message flow open in the Message Flow editor.

You can use the Brokers view in the Broker Application Development perspective to create new brokers and deploy resources to connected brokers. Some of the administrative tasks that are available through the WebSphere Message Broker Explorer, which is supplied as a separate component that you can install on computers on which you intend to perform only administrative tasks, are also supported by the Brokers view.

Debug perspective

The Debug perspective is where application developers test and debug message flows.

Plug-in Development perspective

The Plug-in Development perspective is where application developers develop plug-ins for user-defined extensions.

Related concepts:

Workbench User Guide - Working with Perspectives

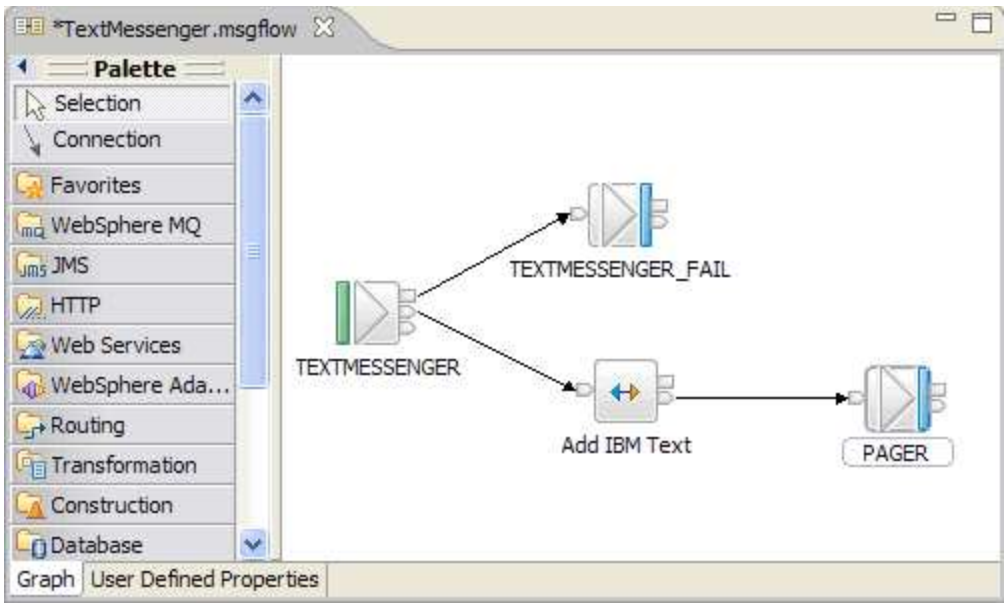
Editors

An editor is a component of the WebSphere Message Broker Toolkit. Editors are typically used to edit or browse resources, which are the files, folders, and projects that exist in the workbench.

When you open a file for editing, for example by double-clicking it in the Broker Development view, the default editor associated with that file opens in the editor area of the current perspective. By default, the editor area is in the upper-right corner of the WebSphere Message Broker Toolkit window.

Open resources with the default editor because other editors might not validate the changes correctly.

The following diagram shows the `TextMessenger.msgflow` file from the Pager sample opened in the Message Flow editor, which is part of the Broker Application Development perspective.



You can open any number of editors at the same time, but only one editor is active at a time. The main menu bar and main toolbar display the operations that apply to the active editor. By default, editors are stacked in the editor area, but you can tile them to view source files simultaneously. Tabs in the editor area indicate the names of the resources that are open for editing. An asterisk (*) indicates that an editor has unsaved changes. If you attempt to close the editor or exit the WebSphere Message Broker Toolkit with unsaved changes, you are prompted to save the changes.

To find out about the Pager sample, click the following link:

- Pager

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Resources

The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored

with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

The default locations for the workspace are in the following places:

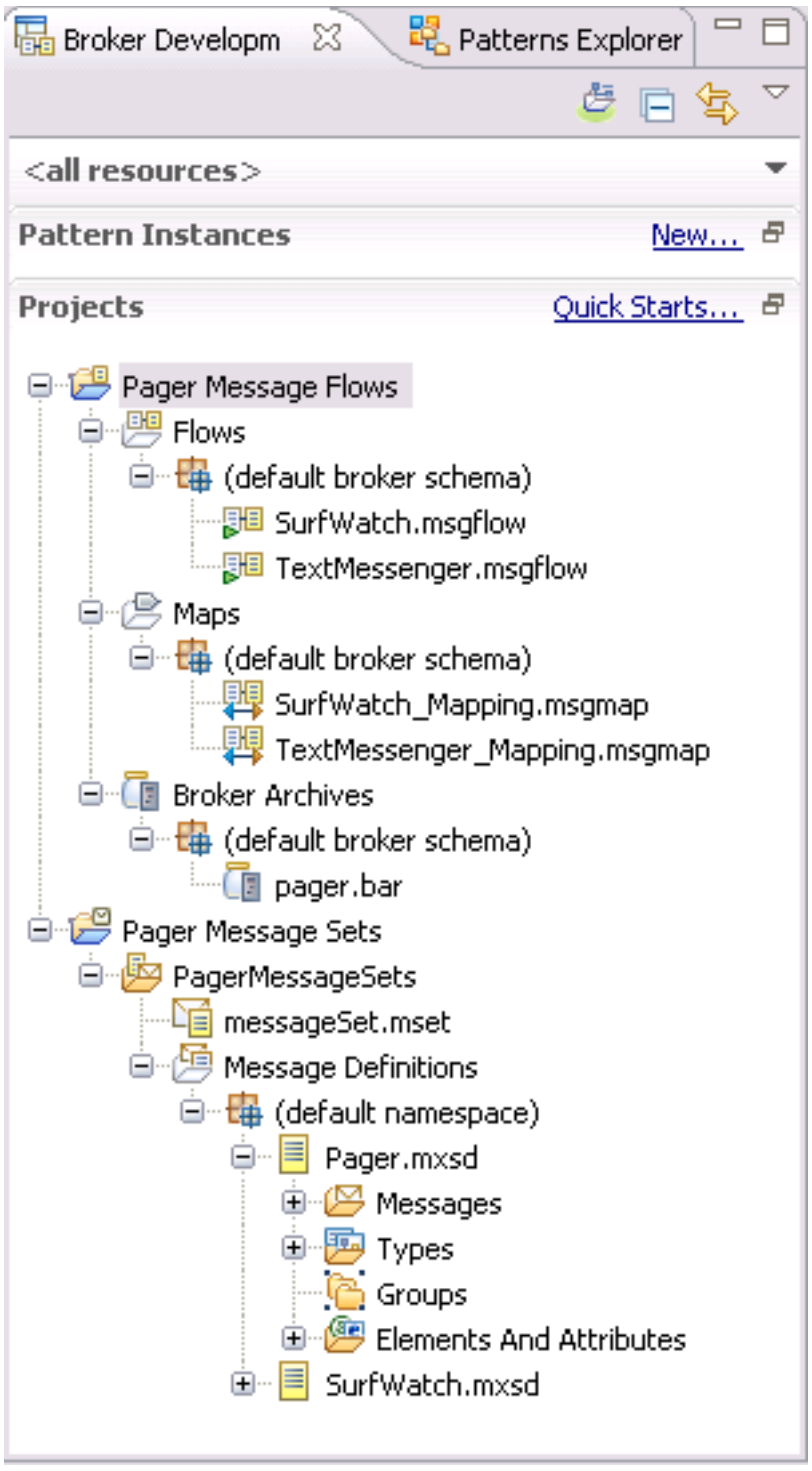
- On Linux on x86, the default workspace directory is created at `/home/user_ID/IBM/wmbt70/workspace`.
- On Windows XP and Windows Server 2003, the default workspace directory is created at `C:\Documents and Settings\user_ID\IBM\wmbt70\workspace`.
- On Windows Vista and Windows Server 2008, the default workspace directory is created at `C:\Users\user_ID\IBM\wmbt70\workspace`.

  where *user_ID* is the user name with which you are logged on.

You can create projects in other directories in addition to the workspace directory. You can maintain multiple workspaces by specifying a new location at the prompt when you start your WebSphere Message Broker Toolkit session.

Typically, you edit and view WebSphere Message Broker Toolkit resources in the Broker Development view in the Broker Application Development perspective.

The following figure shows a message flow project and a message set project in the Broker Development view of the Broker Application Development perspective.



Resource editors do not automatically reflect the changes that you make in one window in additional windows that you have opened to view the same resource. Close and reopen additional windows each time that you update a resource in an editor session.

Types of resource: You can create and work with three basic types of resource:

Source files
Source files are included in your workspace and are accessible from the

Broker Application Development perspective. When you create source files, they are grouped by file type in *folders*, in the same way as the directories of a file system. You can also group folders or files in *projects*. Projects are used for building, version control, sharing, and resource organization.

The following source files can exist:

- `.msgflow` files contain the message nodes and connections that you create to form a message flow. These files are displayed in the Broker Application Development perspective in a folder called Flows. The Flows folder is always created and displayed.
- `.esql` files are optional and contain ESQL code that performs specific processing steps within a message node. You can code ESQL to tailor message processing in Compute, Database, and Filter nodes. If you have created ESQL files, they are displayed in the Broker Application Development perspective in a folder called ESQLs.
- `.msgmap` files are optional and map the relationships between different data sources (typically database tables and messages) that you have created by using the graphical mapping tools. You can create maps to tailor message processing in DataDelete, DataInsert, DataUpdate, and Warehouse nodes. If you have created mapping files, they are displayed in the Broker Application Development perspective in a folder called Maps.
- `.category` files are optional and contain a group of messages, either related to WSDL operations, or to a user-specific purpose or message flow. If you have created category files, they are displayed in the Broker Application Development perspective in a folder called Message Categories.
- `.mxsd` files are optional and contain definitions of the messages you have modeled. If you have created message models, they are displayed in the Broker Application Development perspective in a folder called Message Definitions.
- `.wsdl` files are optional and contain WSDL definitions which you have imported into the workspace to use as a source for message definitions. If you have created WSDL files, they are displayed in the Broker Application Development perspective in a folder called Deployable WSDL, and are grouped by namespace.
- `.insca` and `.outsca` files are optional Broker SCA definition files. A `.insca` file contains an SCA import component and is used to configure SCAInput and SCAReply nodes. A `.outsca` file contains an SCA export component and is used to configure SCAAsyncRequest, SCAAsyncResponse, and SCARequest nodes. They are displayed in the Broker Application Development perspective in a folder called Broker SCA Definitions, in the message set project.

You can create resources from a pattern more than once to give unique pattern instances with different configurations, see “Patterns” on page 1310. The resources for each pattern instance are contained within a single pattern instance project. The pattern instance project contains links to all projects containing the resources that are created as a result of generating a pattern instance from your configuration, such as message flows, Java classes for JavaCompute nodes, ESQL modules, message maps, test client, XML files, and style sheet files.

Helper files

Helper files maintain information that supports other activities:

- `.broker` files contain definitions of broker connections.
- `.bar` files contain deployable and other files that you have chosen to send to a broker.
- `.mbtest` files contain the steps that define a test that you use with the Test Client to debug your applications.

Deployable files

Deployable files are included in a broker archive (BAR) file and deployed to the broker where they are involved in some way in the processing of messages. A BAR file might contain the following files:

- A `.cmf` file for each message flow. This file is a compiled version of the message flow. You can have any number of these files within your BAR file.
- A `.dictionary` file for each message set dictionary. You can have any number of these files within your BAR file.
- One or more XSD compressed files (`.xsdzip`), if XML schema and WSDL are defined within a message set.
- A `broker.xml` file. This file is called the *broker deployment descriptor*. You can have only one of these files within your BAR file. This file, in XML format, is contained in the `META-INF` folder of the compressed file and can be modified by using a text editor or shell script.
- One or more XML files (`.xml`), style sheets (`.xsl`), and XSLT files (`.xlst`), if required by nodes in the message flows you have added to this BAR file. The XSLTransform node is one that might require these files.
- One or more JAR files, if required by JavaCompute nodes in the message flows you have added to this BAR file.
- One or more inbound or outbound adapter files (`.inadapter` or `.outadapter`), if required by WebSphere Adapter nodes (for example, the SiebelInput node) in the message flows you have added to this BAR file.
- One or more PHP script files (`.php`), if required by PHPCompute nodes in the message flows you have added to this BAR file.
- Other files that you might want to associate with this BAR file. For example, you might want to include Java source files, `.msgflow` files, or `.wsdl` files for future reference. BAR files can contain all files types.

References between files:

Source files can refer to content in other files. For example, a message flow can require an ESQL file. The files on which the message flow depends must be present when that message flow is compiled; see "By name linking" on page 43.

If you are considering changing a resource, you can see a list of other resources that refer to it. To search for these resources, you must first enable indexing by following the instructions in "Enabling and disabling indexing" on page 1454. Then you can right-click a resource in the Broker Development view and click **Show all references**. The search results view shows, in a tree structure, all references of your resource, including its location, such as a node property or the line number in an ESQL file. You can double-click a resource to open it in an appropriate editor, or you can right-click a resource and click **Open with** to choose the editor in which to open it. Note that dependent files can be found in another project. See "Project references" on page 44.

To see which files are dependent on which other files, see "Showing resource references" on page 1447.

If you are considering renaming or moving a resource and you know the new name or location, you can run an impact analysis. For more information, see “Impact analysis: analyzing the effects of planned changes to your applications” on page 1150.

Working sets:

A *working set* is a logical collection of projects, which you can use to limit the number of resources that are displayed in the Broker Development view. By creating and using a working set, you can reduce the visual complexity of what is displayed in the Broker Development view, making it easier to manage and work with your projects.

The *active working set* is the current working set of projects that you choose to display. If you do not create any working sets, the default active working set contains all your resources and are contained in the <all resources> section of the Broker Development view, which displays all of your projects.

The Broker Development view has three sections: the working set selection list, Pattern Instances (initially collapsed), and Projects (initially expanded). Pattern instance projects are shown only in the Pattern Instances section, and all other project types are shown in the Projects section. If no projects exist, the Projects section contains a list of Quick Start Wizard links.

You can create a new working set in the Broker Development view in one of the following three ways:

- You can create a new working set and add existing projects to it.
- You can use a Quick Start wizard to set up the basic resources that are required to develop a message flow. The wizard provides the option of creating a new working set for the resources.
- You can create a pattern instance project, and a working set of the same name is created automatically.

When you use the Broker Application Development perspective to create a file or new project, the new file or project is automatically added to the current active working set. If you have not identified an active working set, the new file or project is displayed in the <all resources> section of the Broker Development view, but is not added to a working set.

Workbench User Guide - Resources

Workbench User Guide - Working with projects, folders, and resources

By name linking:

You identify objects using a combination of a *namespace* and a name, referred to as a *fully qualified name*. The use of fully qualified names, called *by name linking*, makes it easy to identify and locate objects, and to correct broken references.

For example, if you rename an object, all references to that object are broken. If you substitute another object with the same name, all the broken references are corrected.

This concept is important when you are working in a team environment. With by name linking, you can share files in a repository and concurrently modify, add, and delete objects in your message flow application. When you integrate the various parts of the message flow application, you can detect and resolve broken references to objects that have been moved, renamed, or deleted.

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. "Project references"
When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

"Namespaces in the message model" on page 1201
Use namespaces to qualify message model object names.

Related reference:

"Rules for naming workspace objects" on page 6827

Project references:

When a projects refers to other projects in the workspace, this is called a *project reference*. When one project references another, the files in the referenced project are available for use by the referring project. For example to configure certain nodes, to create libraries of reusable message flows, and to enable Content Assist in the ESQL editor.

The following scenarios in the WebSphere Message Broker Toolkit give examples of project references:

- When configuring a Mapping node in a message flow, you must select source and target messages for the map. The messages are contained within one or more message sets. In order to select messages, the message flow project must have a reference to the message sets. You must also have a reference to a data design project if you want to map to or from a database.
- When configuring a node, such as an MQInput node, you can define the message template for the message type that the node processes. If you have chosen MRM, SOAP, XMLNSC, DataObject, or IDOC as the `Message domain` property of the node, you must also specify the name of the message sets that contains the message model. To pre-populate the list of message sets in the `Message set` property, the message flow project must have a reference to the message sets.
- You might want to create a library of reusable ESQL subroutines in a message flow project, or create a library of message flows to reuse in other flows. A message flow that you want to use these subroutines or message flows in, must have a reference to the message flow project from its parent message flow project.
- You can also use project references to enable Content Assist in the ESQL editor. ("Content Assist" is context-sensitive help that displays valid ways in which a code statement can be completed.) If you set up a project reference from a message flow project containing ESQL code to a message sets, the ESQL editor is able to display a list of valid message references.
- If you use the Patterns Explorer to generate a pattern instance from a pattern specification, the generated pattern instance project contains references to all the other projects generated from the pattern. See "Using patterns" on page 1312.

To create or remove a project reference manually, right-click the project name in the Broker Development view and select the **Properties** menu item. Select **Project References** from the Properties window, and a list of all regular projects in the workspace is displayed from which you can select or clear project references. Message flow, message sets and pattern instance projects have an additional menu item **Add or Remove Project References** that launches the Add or Remove Project References window where you can select or clear project references.

If you later close or delete a referenced project, or delete an object within it, it is no longer available to the referencing project and an error is generated. You can correct the error by opening the closed project or adding the missing object, with the correct name, and saving.

Development repository

Use a development repository to benefit from features such as version control and access control of files, which make it easier for teams to work on shared resources.

The WebSphere Message Broker Toolkit is based on the Eclipse platform, therefore you can access Eclipse-supported repositories directly from the WebSphere Message Broker Toolkit. You can use all repositories that are supported by Eclipse with WebSphere Message Broker.

You can take the version numbers of resources from the repository, and associate that version number with the message flows and message sets when they are deployed. This association allows you to display which version of the flow is deployed in the WebSphere Message Broker Toolkit. An alternative method of assigning a version number to a message flow is to specify one in the WebSphere Message Broker Toolkit when the message flow is created; see "Message flow version and keywords" on page 1445.

- For information about how to set up the WebSphere Message Broker Toolkit to run with CVS, see "Configuring CVS to run with the WebSphere Message Broker Toolkit" on page 573.
- For information about how to integrate the Rational Team Concert client, see "Integrating the Rational Team Concert client with the WebSphere Message Broker Toolkit" on page 576.
- For information on how to enable Rational ClearCase®, see "Configuring the WebSphere Message Broker Toolkit to run Rational ClearCase" on page 574.
- For information about other repositories, read about other team repositories that are supported by Eclipse.

Related concepts:

The broker environment

A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Create more than one broker, on one or more computers, to support your applications; creating more than one broker can provide load balancing, or a division of responsibilities. For example, you might have one broker that handles all your financial applications, and another that handles your order processing and fulfillment.

Application programs connect to and send messages to the broker, and receive messages from the broker. Code your applications to use one of the supported protocols for interacting with the broker; for example, WebSphere MQ queues and connections, Web services, or WebSphere Adapters. The broker routes each message by using the rules that you have defined in message flows and message sets, and transforms the data into the structure required by the receiving application.

You can install the broker component on one or more of the supported platforms, which are listed in "Operating system requirements" on page 3590. You can create a broker only on the computer on which you have installed the broker component. You can use the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit, or the command line to create local brokers.

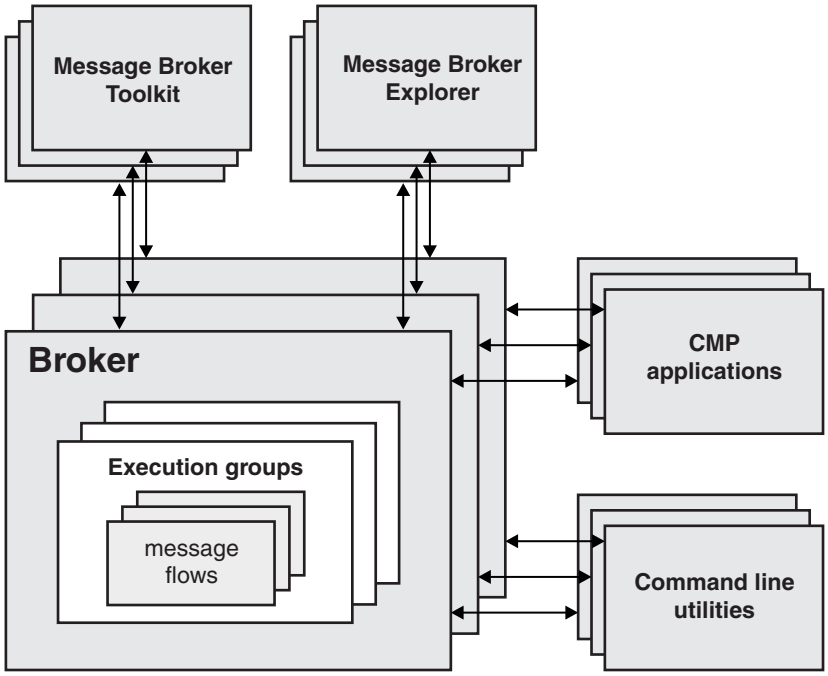
When you create a broker, it operates in one of a number of modes: `enterprise`, `adapter`, `starter`, or `entry`. You must run the broker in the mode that matches the license that you have purchased; see "Operation modes" on page 48.

Administer the broker by using the WebSphere Message Broker Explorer, the Broker view in the WebSphere Message Broker Toolkit, or the product commands. Alternatively, you can write your own programs to use the Administration API for WebSphere Message Broker (also known as the CMP API).

Manage the application resources of the broker, which include message flows and message sets, by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer; these two applications connect to the broker by using a WebSphere MQ server connection, which is defined to the broker queue manager when you create the broker.

The following figure shows the relationship between the resources that exist at run time, and how they interact with the WebSphere Message Broker Explorer and

WebSphere Message Broker Toolkit.



Resources associated with a broker

When you create a broker, the following resources are also defined and created:

- A WebSphere MQ queue manager, if one does not exist.
- A set of fixed-name queues that are defined to the WebSphere MQ queue manager.
- A default WebSphere MQ SVRCONN channel with a fixed name SYSTEM.BKR.CONFIG, which is used by the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, and applications that use the Administration API (CMP API).

Related concepts:

"Operation modes" on page 48
The operation mode that you use for your broker is determined by the license that you purchase.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

Operation modes

The operation mode that you use for your broker is determined by the license that you purchase.

The following modes are supported:

- “Trial Edition mode” on page 49. All features are enabled, but you can use the product for only 90 days after installation.
- “Entry Edition mode” on page 49. Entry node features are enabled and the types of node that you can use, and the number of execution groups that you can create, are limited.
- “Starter Edition mode” on page 49. All features are enabled for use with a single execution group. The number of message flows that you can deploy are unlimited.
- “Enterprise mode” on page 49. All features are enabled and no restrictions or limits are imposed. This mode is the default mode, unless you have the Trial Edition.
- “Remote Adapter Deployment mode” on page 50. Only adapter-related features are enabled, and the types of node that you can use, and the number of execution groups that you can create, are limited.

You must ensure that your brokers are running in the operation mode for which you have purchased a license. You can set the operation mode when you create a broker by using the **mqsicreatebroker** command.

If you have purchased a license for the full package, the Starter Edition, or the Remote Adapter Deployment mode, the broker is automatically created in `enterprise` mode unless you specify the correct mode for your license.

Change the mode of your broker to conform to your license if necessary; see “Changing the operation mode of your broker” on page 655. You can also report the current mode of your broker; see “Checking the operation mode of your broker” on page 657.

The WebSphere Message Broker Toolkit remains the same in all modes. All the capabilities of the WebSphere Message Broker Toolkit are available in all modes. If you try to deploy too many message flows or execution groups for the mode, or try to use a node that is not valid in the mode, the operation is rejected, and an error message is displayed indicating the reason for the failure; see “Restrictions

that apply in each operation mode" on page 3657. Node restrictions for a given mode also apply to the use of message flows generated by WebSphere Message Broker patterns.

Fix packs are identical for all modes, and can be applied without affecting the validity of the mode. The expiry of a Trial Edition is not affected by applying service; in Trial Edition, by default new brokers continue to be in Trial Edition mode.

Trial Edition mode

In `trial` mode, the broker operates with all features enabled. You can use all available function, and are not limited in the number of resources that you create and maintain. All capability is available for 90 days after installation.

You cannot revert to Trial Edition from any other mode.

You can download Trial Edition at no charge, from the following website: WebSphere Message Broker Trial package.

Entry Edition mode

In `entry` mode, the broker operates with a limited set of nodes available for deployed flows. You are also limited to one execution group. For a list of nodes that can be deployed to a broker running in Entry Edition mode, see "Restrictions that apply in each operation mode" on page 3657. If you attempt to exceed the limits of this mode, the deployment is rejected. Use this edition for simple use cases only.

Because the functions that are enabled and the number of execution groups that you can create are limited, not all samples work in Entry Edition mode. To run samples, see "Development and unit test" on page 50.

Starter Edition mode

In `starter` mode, the broker operates with all features enabled. Use this edition if you expect to use all or most of the features that are available, but intend to configure a limited environment because of low capacity requirements.

You can use all the available functions, but are limited in the number of resources that you can create and maintain. You are limited to creating one execution group; for more information, see "Restrictions that apply in each operation mode" on page 3657. If you attempt to exceed the limits of this mode, the deployment is rejected.

You cannot use all the samples when your broker is in `starter` mode, because of the preceding restrictions. If you want to run samples, see "Development and unit test" on page 50.

Enterprise mode

In `enterprise` mode, the broker operates with all features enabled, and no operational limits on the creation of execution groups or on the number of flows deployed to an individual execution group are enforced. If you want to set up a full broker environment that uses most or all the features available, your brokers must operate in this mode, and you therefore require the full license. If you do not

specify another mode, your brokers have the mode set to the default value `enterprise`.

Remote Adapter Deployment mode

In `adapter` mode, the broker operates with a limited set of nodes available for deployed flows. Use this edition if you expect your typical use of the broker to be integration with Enterprise Information Systems (EIS). This edition supports the subset of development resources that provide EIS interaction. For a list of nodes that can be deployed to a broker running in Remote Adapter Deployment mode, see "Restrictions that apply in each operation mode" on page 3657.

You can create up to two execution groups, with no limit on the number of deployed message flows in each of these execution groups; see "Restrictions that apply in each operation mode" on page 3657. If you attempt to exceed the limits of this mode, the deployment is rejected.

You cannot use all the patterns and samples when your broker is in `adapter` mode, because of the preceding restrictions. If you want to run samples, see "Development and unit test."

Development and unit test

Your license also covers use of the product for development and unit test purposes, but check the license to ensure that you conform to any restrictions for development and unit test. All developers in your organization who are working on resources and applications for the WebSphere Message Broker environment can install all components on their computer. They can create and configure a broker environment without any functional or resource restrictions, but they can use only a single broker per WebSphere Message Broker Toolkit. Installation of the WebSphere Message Broker Toolkit limits this use to Windows and Linux on x86 computers. Developers can create and use development and unit test brokers in `enterprise` mode.

You can also install the supplied WebSphere MQ and DB2 products on the computers on which your developers perform their development and unit test, regardless of the license agreement that you have purchased.

If you want to run samples to explore and understand the features of the product, install them on your development and unit test computers.

Integration with Tivoli License Manager

If you use IBM Tivoli License Manager to control and manage your licensed software products, you must ensure that you choose the correct license for the WebSphere Message Broker edition that you have purchased. For more information, see "Installing Tivoli License Manager" on page 301.

Controlling the functional level of WebSphere Message Broker

You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

About this task

The default functional level of the broker represents the level for WebSphere Message Broker Version 7.0.0.0. At this level, some functionality added by later fix packs is not supported by the broker.

Nodes and parsers that are added in later fix packs are available in the WebSphere Message Broker Toolkit, and you can include these nodes and parsers in a message flow. You can deploy the message flow to a broker only if you have set the functional level of that broker to the value that represents the fix pack in which the nodes and parsers were first delivered.

You can control the functional level of each broker, therefore you can try out new nodes on test brokers without affecting the operation of your production brokers. When you are satisfied that the nodes provide the functions that you require, and work as you expect, you can set the functional level of other brokers in your domain when appropriate.

To change the function level of a broker, use the **mqsichangebroker** command and set the **-f** parameter to the appropriate value. For more information about the use of the **mqsichangebroker** command, see "**mqsichangebroker** command" on page 3723.

You can check the functional level of a broker by using the **mqsireportbroker** command (see "**mqsireportbroker** command" on page 3919) or through the WebSphere Message Broker Explorer.

If you enable a certain functional level, you also enable all the functions added at lower levels. For example, if you enable new fix pack 3 functions, you automatically enable new functions for fix packs 1 and 2.

You can enable all new functionality by setting the function level to all.

The list of functions that are enabled for each function level is described in the following sections.

Version 7.0.0.1

You can install Version 7.0.0.1 as a full, generally available version, or as a fix pack. Version 7.0.0.1 has the functions enabled for V7.0.0.1 regardless of the installation route chosen.

Version 7.0.0.2

- JDEdwardsInput node (see "JDEdwardsInput node" on page 4519)
- JDEdwardsRequest node (see "JDEdwardsRequest node" on page 4524)
- EmailInput node (see "EmailInput node" on page 4394)
- FileRead node (see "FileRead node" on page 4444)
- JSON parser (see "JSON parser and domain" on page 1128)
- Execution group profiles (see "Execution group-specific command environment: Windows systems" on page 309 and "Execution group-specific command environment: Linux and UNIX systems" on page 312)

Use the **mqsireportbroker** command to display broker registry entries.

System management interfaces

The brokers provide a service for independent system management agents.

This service enables a central management facility to access information about a network that includes one or more brokers. Therefore, you can extend your existing system management agents to include WebSphere Message Broker resources.

Brokers publish event messages, using fixed topics, in response to configuration changes, state changes, and user actions such as subscription registrations. Brokers also use architected messages to publish events related to their operational status, and changes in that status. These messages are published using the reserved topic root `$SYS` in code page 1208.

An example of a fixed topic is:

```
$SYS/Broker/<brokerName>/Status/ExecutionGroup/<executionGroupName>
```

The topic structure is fixed in this case, but obviously `<brokerName>` and `<executionGroupName>` are replaced with the appropriate values.

An example of the actual message data for this publication is:

```
<Broker uuid="12345678-1234-1234-1234-123456789012">
        <ExecutionGroup uuid="12345678-1234-1234-1234-123456789012">
                <Stop>
                        <AllMessageFlows/>
                </Stop>
        </ExecutionGroup>
</Broker>
```

A system management agent can subscribe to these topics, or to a subset of these topics, to receive the detailed information about activity and state changes in the WebSphere Message Broker components.

The event messages have a fixed structure, defined in *XML (Extensible Markup Language)*. The format of these messages, constructed in XML, is detailed in "The XML message body" on page 4262. The messages cover configuration changes, state changes, error notifications, and detailed subscription and topic information (for example, a subscription registration).

You can develop or purchase system management adapters or customized administrative applications. These applications subscribe to the system management topics generated by WebSphere Message Broker to receive information about the activity of its resources.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

"Installing Tivoli License Manager" on page 301
IBM Tivoli License Manager (ITLM) enables you to monitor the use of IBM (and other) software products. WebSphere Message Broker includes support for ITLM Version 2.1.

Brokers publish messages on reserved topics after significant events within the broker. By subscribing to these topics, a client can be informed when these events occur.

Execution groups

An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

Each execution group is started as a separate operating system process, providing an isolated runtime environment for a set of deployed message flows. Within an execution group, the assigned message flows run in different thread pools. You can specify the size of the thread pool (that is, the number of threads) that are assigned for each message flow by specifying the number of additional instances of each message flow.

The mode that your broker is working in can affect the number of execution groups that you can use; see "Restrictions that apply in each operation mode" on page 3657.

A single default execution group is set up ready for use when you create a reference to a broker in the WebSphere Message Broker Toolkit. By setting up additional execution groups, you can isolate message flows that handle sensitive data such as payroll records, or security information, or unannounced product information, from other non-sensitive message flows.

If you create additional execution groups, you must give each group a name that is unique within the broker, and assign and deploy one or more message flows to each one.

You can create and deploy execution groups either in the WebSphere Message Broker Toolkit, or using commands.

An execution group process is also known as a DataFlowEngine (DFE); this term is typically used in problem determination scenarios (trace contents, diagnostic messages, and so on). A DFE is created as an operating system process, and has a one-to-one relationship with the named execution group. If more than one message flow runs within an execution group, multiple threads are created within the DFE process.

WebSphere Message Broker operates in 32-bit mode or 64-bit mode, on supported operating systems.

The Administration API for WebSphere Message Broker

The Administration API for WebSphere Message Broker is a programming interface that your applications can use to control brokers and their resources through a remote interface.

The Administration API for WebSphere Message Broker is also known as the Configuration Manager Proxy, or CMP API

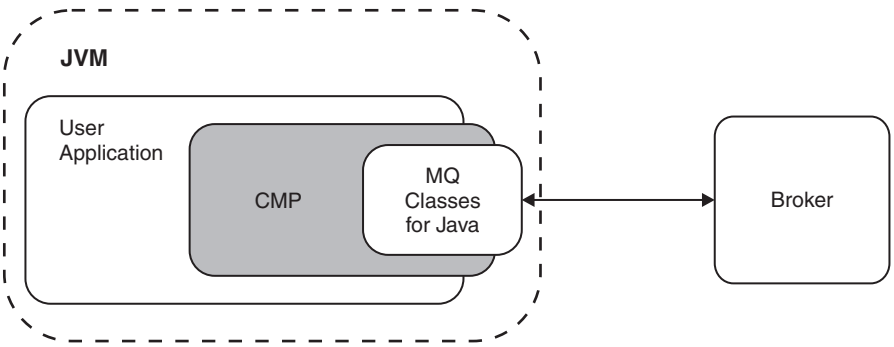
The Configuration Manager has been removed from Version 7, and the full name of the API has changed. However, the terms CMP application and

CMP API have been retained, and are used in this information center to refer to the Administration API, for continuity and consistency with the JAR file `ConfigManagerProxy.jar` that supplies all the classes.

The Administration API for WebSphere Message Broker (CMP API) consists solely of a Java implementation, and is referred to as the Message Broker Java API. Your applications have complete access to the broker functions and resources through the set of Java classes that constitute the CMP. Use the CMP API to interact with the broker to perform the following tasks:

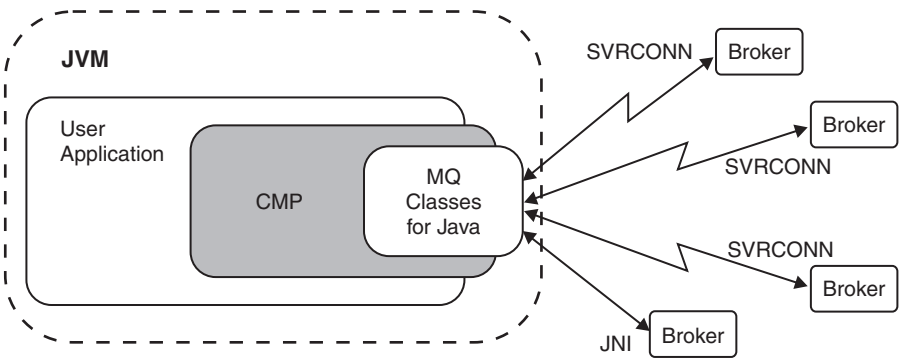
- Deploy BAR files
- Change the broker configuration properties
- Create, modify, and delete execution groups
- Inquire and set the status of the broker and its associated resources, and to be informed if status changes
  - Execution groups
  - Deployed message flows
  - Deployed files used by the message flows (for example, JAR files)
- View the Administration log

Interaction between CMP applications and the broker: The Java classes sit logically between the user application and the broker, inside the Java Virtual Machine (JVM) of the user application. The API requires the WebSphere MQ Classes for Java for connectivity, as shown in the following diagram.



The CMP application can be on the same physical computer as the broker, connected by a JNI (Java Native Interface) connection to the queue manager that uses the WebSphere MQ Java Bindings transport. If appropriate, you can distribute your applications over an Internet Protocol (TCP/IP) network, and connected to the broker by using a WebSphere MQ SVRCONN channel through the WebSphere MQ Java Client transport.

You can use the CMP API to communicate with more than one broker from within the same application, as shown in the following diagram.



Migrating from earlier versions of WebSphere Message Broker: If you are migrating to Version 7.0 from Version 6.1, the CMP is largely compatible, but you must take the following actions before you run your applications in a Version 7.0 environment:

- Check the source of your existing applications against the CMP Javadoc information that is provided with Version 7.0. Although a significant number of the classes and methods have been deprecated, they are still tolerated by the CMP, and appropriate action is taken if possible. For example, if your code connects to a Configuration Manager, the same connection properties are used by the CMP to connect to a broker.

  If appropriate action is not available, the behavior is undefined. Rework your applications to remove such classes and methods.
- Recompile your applications against the Version 7.0 libraries, even if you have not changed the source, to ensure that your code can take advantage of improvements in the updated classes.

You can work only with Version 7.0 brokers from your CMP API applications; earlier versions are not compatible and are not supported.

For further information about new and deprecated classes and methods, see "Administration API" on page 3672.

WebSphere Message Broker Explorer

The WebSphere Message Broker Explorer is a graphical user interface based on the Eclipse platform for administering your brokers.

The WebSphere Message Broker Explorer is an extension to the WebSphere MQ Explorer.

You can install the WebSphere Message Broker Explorer only on Windows and Linux on x86. You can view and interact only with brokers that you have created in WebSphere Message Broker Version 7 or later.

The WebSphere Message Broker Explorer

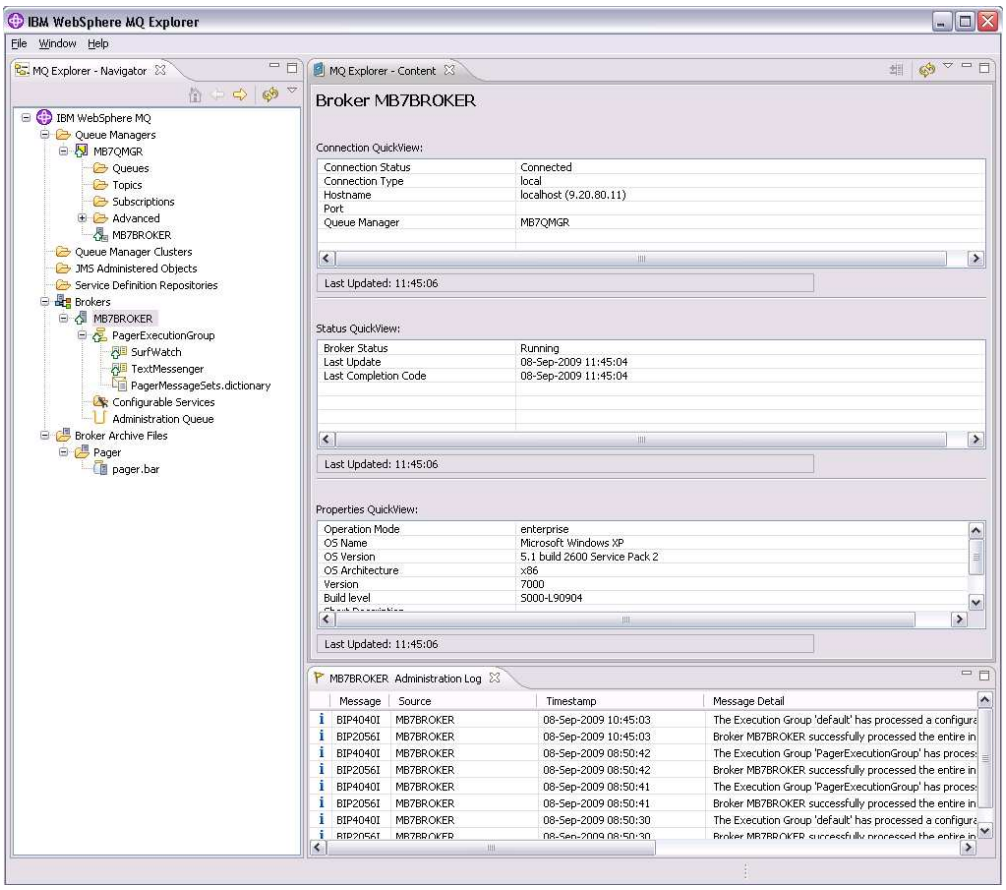
To use the WebSphere Message Broker Explorer, you must start the WebSphere MQ Explorer. The WebSphere Message Broker Explorer adds the Brokers and Broker Archive Files folders to the MQ Explorer - Navigator view:

- Use the Brokers folder to create, view, and modify brokers
- Use the Broker Archive Files folder to import, view, and modify broker archive files before deploying them to your brokers

If you cannot see these two folders in your MQ Explorer session, you have not installed the broker-specific plug-ins that are provided by WebSphere Message Broker Explorer. Close your MQ Explorer session, follow the instructions to install the WebSphere Message Broker Explorer, then start the MQ Explorer again.

The WebSphere Message Broker Explorer provides several QuickViews that you can use to view the properties of brokers and their resources. These QuickViews are automatically displayed when you click the resource in the Brokers folder in the MQ Explorer - Navigator view. A QuickView is also available for viewing the details of broker archive files that you have imported into the WebSphere Message Broker Explorer.

The following figure shows the QuickViews that are displayed when a broker is selected in the WebSphere Message Broker Explorer.



The following views and editors are provided for working with brokers in the WebSphere Message Broker Explorer:

Broker Archive editor
Use the Broker Archive editor to create and manage broker archive (BAR) files.

Broker Statistics and Broker Statistics Graph views
Use the Broker Statistics and Broker Statistics Graph views to view snapshot accounting and statistics data as it is produced by the broker.

Policy Sets and Policy Set Bindings editor
Use the Policy Sets and Policy Set Bindings editor to edit, save, import, and export policy sets or bindings.

Security Profiles editor
Use the Security Profiles editor to create a security profile for use with Lightweight Directory Access Protocol (LDAP) or Tivoli Federated Identity Manager (TFIM).

DataPower Security wizard
Use the DataPower Security wizard to configure an external DataPower appliance to handle the WS-Security Policy for your HTTP, HTTPS, and SOAP nodes within your message flow.

Administration Log view
Use the Administration Log view to view the results of deployment actions on brokers.

Accessing context-sensitive help

The Help view provides context-sensitive help throughout the WebSphere Message Broker Explorer. You can display the Help view for most aspects of the user interface by bringing focus to the object and pressing F1 (on Windows) or SHIFT+F1 (on Linux). The Related Topics page shows description and help topics that are related to the selected object. The About section shows context help that is specific to your current context, and the Dynamic Help section shows some search results that might be related.

The following figure shows the Related Topics page of the Help view that is displayed when you press F1 when the Brokers folder is selected in the WebSphere Message Broker Explorer.

"Broker Archive editor" on page 6794
Use the Broker Archive editor to create and manage broker archive (BAR) files.

"Administration Log view" on page 6840
The Administration Log view shows administration requests and their results, changes made to objects, and the result of deployment actions on brokers. The Administration Log view can also describe configuration changes that have been automatically applied as a result of moving the broker from one version to another; for example, after applying maintenance.

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

External systems and resources

You can configure WebSphere Message Broker resources to interact with a wide range of external systems and resources, such as WebSphere Process Server, and databases.

The products and standards listed here are for guidance only; for details of supported versions, you must check the WebSphere Message Broker Requirements Web page.

External systems

WebSphere Message Broker interfaces with other IBM products, and with products from other software vendors, to provide services that enhance message processing in the broker:

- IBM WebSphere Service Registry and Repository
- IBM WebSphere Process Server
- IBM WebSphere Integration Developer
- IBM WebSphere Business Monitor
- IBM WebSphere Transformation Extender
- IBM WebSphere MQ File Transfer Edition
- Enterprise Information Systems
  - SAP
  - Siebel
  - Peoplesoft
- Security
  - Tivoli Federated Identity Manager (TFIM)
  - Lightweight Directory Access Protocol (LDAP)
  - RACF and other External Security Managers, on z/OS only
- Management
  - Tivoli License Manager
- Citrix Presentation Server

External resources

WebSphere Message Broker interfaces with other IBM resources, and with resources from other software vendors, to provide extensions to message processing:

- Databases and ODBC support
  - IBM DB2
  - Oracle
  - Sybase
  - Microsoft SQL Server
  - IBM Informix®
- Databases and JDBC support
  - IBM DB2 Driver for JDBC and SQLJ
  - Microsoft SQL Server 2005 JDBC driver
  - Oracle JDBC Driver
  - Sybase jConnect for JDBC
  - IBM Informix JDBC
- File systems
  - FTP
  - SFTP
- Email systems
- Development repositories
  - Rational ClearCase
  - CVS
  - Other repositories supported by Eclipse

- Compilers (C and Java)
- Browsers
  - Microsoft Internet Explorer
  - Mozilla
- Adobe Flash Player for Quick Tour
- Adobe Acrobat for reading PDF files

External standards

Products and applications that adhere to certain specifications can also interact with WebSphere Message Broker:

- Java and JMS providers
- XSD
- WSDL
- SOAP
- XSLT
- WS-Addressing
- WS_Security

For further information about standards, see "General industry standards supported by WebSphere Message Broker" on page 3607.

WebSphere Message Broker business scenario

WebSphere Message Broker manages the flow of information in your business, applying message processing rules to route, store, retrieve, and transform the information as required by the different systems in your business and the systems of your customers, suppliers, partners, and service providers.

The following scenario outlines an example of how WebSphere Message Broker can be used to solve IT infrastructure problems in a business.

Mergers and acquisitions scenario

This scenario describes how WebSphere Message Broker is used by a fictitious insurance company to manage two disparate IT infrastructures after a small, Internet-based insurance company is acquired by a large, more traditional, insurance company. The description focuses on what happens when a potential customer requests a motor insurance quotation by using the merged company Web site. This scenario is based on a larger, more complex scenario that was published on developerWorks. To read the full scenario see the links at the end of the scenario description.

Background

Company A is a motor and general insurance company that has been in business for approximately 50 years and currently has approximately 5 million policyholders. The company uses agents and a call center to communicate with customers. The company has a large established IT infrastructure, which includes CICS Transaction Server for z/OS and IBM DB2 Universal Database™ on z/OS.

Company B is small Internet-based motor insurance company, which currently has less than 1 000 000 policyholders, and is expanding. The IT infrastructure managed

by the company includes WebSphere Application Server on Microsoft Windows Server 2003, and Oracle Enterprise and IBM DB2 Universal Database on Windows XP.

The problems

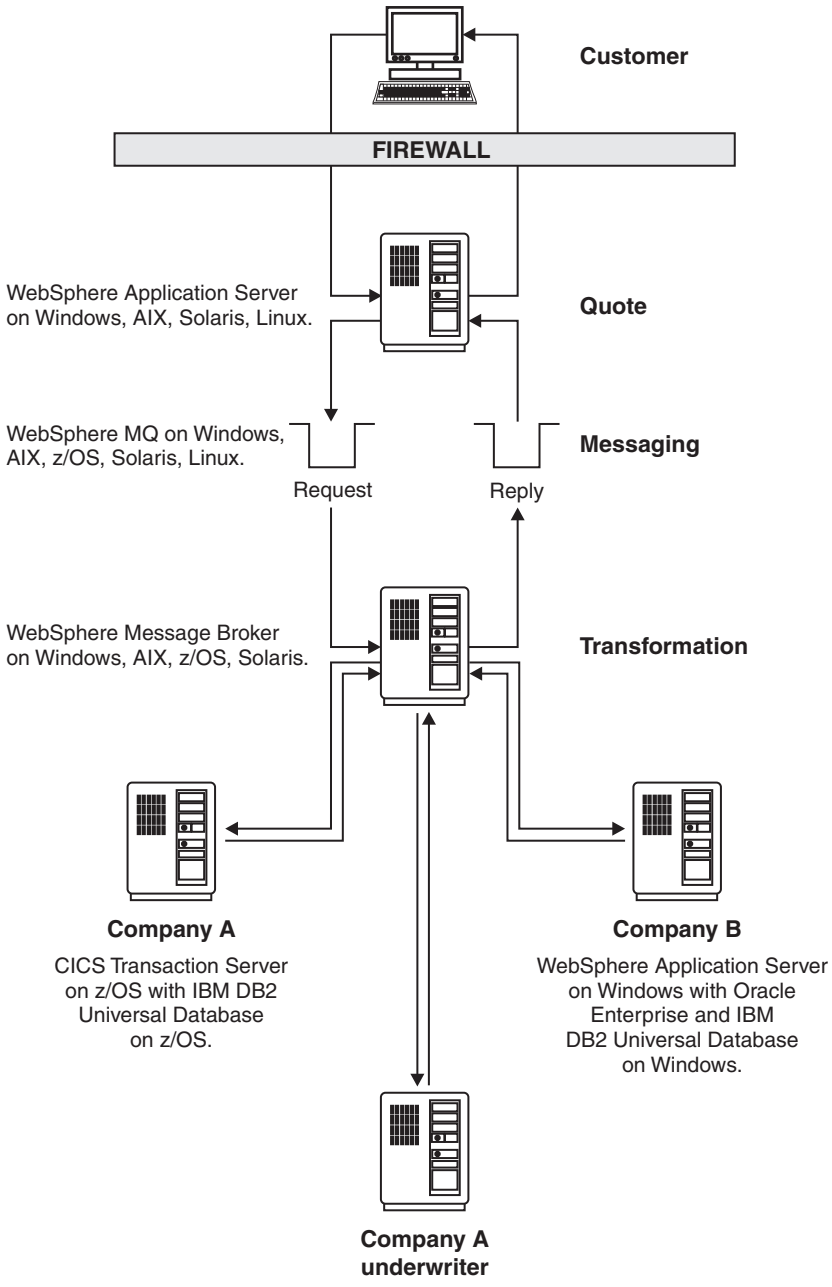
Company A acquired Company B to gain access to the Internet-based insurance market and to use the Internet-based skills and IT infrastructure established in Company B. The two companies have customer and policy data of different formats but, for legal reasons, the data from the separate companies cannot be merged. However, the administration costs of managing the separate IT infrastructures are high. Also, customers, agents, and call center staff need a single administration process to interact with the company data.

The solution

Now that the two companies have merged, users can request an insurance quotation by giving some basic personal information in a form on the Web site of the new company. WebSphere Application Server, on which the Web site runs, forwards the request in XML format to WebSphere Message Broker using the request queue in a WebSphere MQ cluster. WebSphere Message Broker transforms the XML request to the COMMAREA format that is used by Company A systems, then routes the request to those systems. WebSphere Message Broker also routes the request, in XML format, to Company B systems. Both systems return a quotation to WebSphere Message Broker.

Logic within WebSphere Message Broker also requests a risk assessment from the internal underwriter and applies the returned risk to the quotations from systems within Company A and Company B. The broker detects that, in this instance, the best or lowest quotation for the customer has been generated by Company A systems. Therefore, the broker transforms the quotation from Company A from COMMAREA to XML, and routes the quotation back to WebSphere Application Server to a reply queue in the WebSphere MQ cluster, where the quotation is stored for up to 14 days. WebSphere Application Server returns the quotation to the customer.

The following diagram shows the flow of information in this scenario.



Welcome to WebSphere Message Broker

New users: Use this topic to help you navigate through the WebSphere Message Broker information center:

- If you are new to WebSphere Message Broker, look at the Getting started section first.
- If you are ready to start developing message flows for WebSphere Message Broker, look at the Developing message flow applications section.
- If you are ready to design and configure your brokers, look at the WebSphere Message Broker administration section.
- The Additional information section includes links that might be of interest to all users.

Use the links in the following sections to go to start here topics that contain useful links into the information center or to external information. You can recognize the start here topics by the blue background, as shown in this paragraph. To return to this page, click **Navigation view** ( ) to display the contents of the information center, then select **Start here**. To find out where the page that you are currently viewing is located in the contents of the information center, click **Show in Table of Contents** ( ). You can use **Back** ( ) to go back through the pages you have previously viewed.

Some of the links in the start here topics work only if you are accessing this information center from the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer. The links that work only in the WebSphere Message Broker Toolkit are displayed with this icon . Some of the links in the start here topics work only if you have a connection to the internet, and these links are displayed with this icon .

WebSphere iconGetting started

WebSphere Message Broker provides an advanced enterprise service bus, delivering universal connectivity and data transformation. The following introductory information describes the high-level concepts of the product and some basic tasks, including how to use this information center and how to use the WebSphere Message Broker Toolkit.

- "How do I use the information center?" on page 67 Find out how to use this information center, including navigation and searching techniques.
- "Where can I get an overview of WebSphere Message Broker?" on page 69 Get links to introductory information about WebSphere Message Broker.
- "How do I use the WebSphere Message Broker Toolkit?" on page 70 Find out how to use the WebSphere Message Broker Toolkit.
- "How can I check that my installation was successful?" on page 90 Find out how to check that your installation was successful.

WebSphere iconDeveloping message flows

Use the links in this section to help you to start developing your own message flows. Links are also included to help you to understand WebSphere Message Broker concepts that might be useful when you develop your own message flows. You can also use the Samples to help you to develop your own message flows. Most samples provide working examples of message flows, and demonstrate the features that are available in WebSphere Message Broker. To run samples, or deploy and test your own message flows, you must first create a broker.

You can use the Default Configuration wizard available in the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer to create a basic broker configuration for testing message flows, see "Creating the Default Configuration" on page 106.

- "What do I need to know to start developing applications?" on page 72 Find out about the WebSphere Message Broker concepts you might want to know before developing your own message flows.
- "How do I design and develop applications?" on page 72 Start to develop your own message flows and associated resources.

- "How do I deploy and test message flows?" on page 86 Find out how to deploy your message flows to a broker and how to test them.
- How do I debug and troubleshoot my applications? Find out how to debug message flows and troubleshoot problems.

WebSphere iconWebSphere Message Broker Administration

To test and run your message flows, you must create and configure your brokers. Use the links in this section to find out how to configure and administer your brokers and message flows:

- "How do I plan and configure brokers?" on page 91 Find out how to plan and configure brokers for your business.
- "How do I deploy and configure message flow applications?" on page 94 Find out how to configure your message flows and get them running.
- "How do I administer and monitor brokers?" on page 93 Find out about day to day administrative tasks and about monitoring the performance of your message flows.

WebSphere iconAdditional information

Use the following links to get additional information about using WebSphere Message Broker:

- Where can I find out about the accessibility functions of WebSphere Message Broker? Find out about accessibility features in WebSphere Message Broker and shortcut keys to use in the information center.
- How can I troubleshoot any problems? Find out how to debug message flows and troubleshoot problems.
- "What information is available for users of previous versions?" on page 91 Find out about migration and what is new for users of previous versions of the product.

How do I use the information center?

New users: Use this topic to find out how to use the WebSphere Message Broker information center.

To view most of the following links you must be running the information center from within the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

- What is the information center?

  Find out what the information center is, and the alternative ways that you can use to access it.
- How do I navigate the information center?

  Learn how to find your way around the information center.
- What are the accessibility features and keyboard shortcuts in the information center?

  Find out about accessibility in the information center and how to navigate using keyboard shortcuts.
- How do I search the information center?

  Learn how to search the information center, limiting your search scope and making your searches more effective.
- How do I set bookmarks and print topics?

Find out how to bookmark information to make it easier to find later. Also find out how to print topics for reading offline.

- How do I view information in different languages?

  Find out how to view the information center in different languages.

- Where can I find other sources of help information?

  Find out how the documentation is structured, and what other sources of help are provided in the information center and the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Where can I find other sources of help information?

New users: Use this topic to find out about the resources available in the information center. You can also find out about other ways that you can get help when using WebSphere Message Broker.

What resources are available in the information center?

The Contents pane in the WebSphere Message Broker information center lists high-level categories of information based on tasks that you might want to perform, such as configuring, administering, and developing applications. In each of the high-level categories, concept topics provide definitions and background information to help you understand the tasks in the product. Task topics provide the actions or steps that you complete for the associated tasks. You can find reference topics in the Reference category that provide supporting information to help you complete the tasks, for example lists of options and parameters for commands.

Use the following links as alternative ways to help you find the information that you want:

- Where can I find a glossary of terms and abbreviations?

  The glossary contains a list of terms and abbreviations that are used in the WebSphere Message Broker information center.

- Where can I find the information center index?

  Search for information about particular subjects or terms by using the Index.

- Where can I find support and technical documents on IBM Web sites?

  Search for WebSphere Message Broker support and technical documents on IBM Web sites. You must have an Internet connection to use the links on this page.

- Where can I find information about diagnostic messages?

  Search for information about diagnostic messages that might be generated when you use WebSphere Message Broker.

What other sources of help are there in WebSphere Message Broker?

User assistance is provided in WebSphere Message Broker, in the form of messages, context-sensitive help on wizards, and information provided on the product interfaces, including the WebSphere Message Broker Toolkit and in the command-line environment.

- How do I get context-sensitive help in the WebSphere Message Broker Toolkit?

  Context-sensitive help and links into the information center are available in the WebSphere Message Broker Toolkit in the Help view. The Help view can be launched by selecting an object in the WebSphere Message Broker Toolkit and pressing the F1 key (on Windows) or SHIFT+F1 (on Linux).

- How do I get context-sensitive help in the WebSphere Message Broker Explorer?

Context-sensitive help and links into the information center are available in the WebSphere Message Broker Explorer in the Help view. The Help view can be launched by selecting an object in the WebSphere Message Broker Explorer and pressing the F1 key (on Windows) or SHIFT+F1 (on Linux).

- **How do I get assistance when I am developing my applications?**

  You can get assistance when you develop your applications by using content assist. Content assist provides a list of available code options, for example the XPath functions to use in a message map, or a list of available references, for example to assist with constructing message references in ESQL. Content assist is available in the following editors when developing applications:

  – ESQL Editor
  – Java Editor
  – Message Mapping Editor

  You can also use content assist to help construct XPath expressions in the properties of some message flow nodes. Content assist can be displayed in the properties fields, and in the XPath Expression Builder.

  To access content assist, either select **Edit** > **Content Assist** or press Ctrl+Space to display a list of available options. To use content assist to help with constructing messages, you must have defined the message to the WebSphere Message Broker Toolkit and linked it to your message flow project; see "Project references" on page 44.

- **How do I get help when I am using commands?**

  You can get usage information for the commands by entering the command without any parameters, or alternatively entering the command followed by `/?`, for example:

  ```
  mqsilist /?
  ```

Where can I get an overview of WebSphere Message Broker?

New users: Use the links in this topic to get introductory information about WebSphere Message Broker.

- Where can I get a quick tour of the product?

  Learn about the basic concepts and features of WebSphere Message Broker with this animated tour.

- Where can I get a technical overview of the product?

  Learn about the capabilities and components of WebSphere Message Broker with this technical overview.

- Where can I find a WebSphere Message Broker example scenario?

  Learn how WebSphere Message Broker can be used to solve a business problem with this example scenario.

I am a developer; what tasks am I interested in?

If you are a developer, you will be involved in the tasks to create, test, debug, and run message flow applications.

Before you start

New users: Read the following introductory topics to the product, and the information center, before you start application development:

- "How do I use the information center?" on page 67
- "Where can I get an overview of WebSphere Message Broker?"

- "How do I use the WebSphere Message Broker Toolkit?"

Returning users: Find out what new features are supported for application development:

- "What's new in Version 7.0?" on page 7

WebSphere iconDeveloping message flow applications

Use the links in this section to help you to start developing your own message flow applications. Links are also included to help you to understand WebSphere Message Broker concepts that might be useful when you develop your own message flow applications.

You can also use the Samples to help you to develop your own message flow applications. Most samples provide working examples of message flow applications, and demonstrate the features that are available in WebSphere Message Broker. To run samples, or deploy and test your own message flow applications, you must first create a broker; use the Default Configuration wizard available in the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer, to create a basic broker configuration for testing message flow applications. For more information about the Default Configuration wizard, see "Creating the Default Configuration" on page 106.

- "What do I need to know to start developing applications?" on page 72 Find out about the WebSphere Message Broker concepts you might want to know before developing your own message flow applications.
- "How do I design and develop applications?" on page 72 Start to develop your own message flow applications and associated resources.
- "How do I deploy and test message flows?" on page 86 Find out how to deploy your message flow applications to a broker and how to test them.

What else might I be interested in?

When you develop message flow applications, you might also be interested in the following questions:

- How can I troubleshoot problems? Find out how to debug message flow applications and troubleshoot problems.
- Where can I find out about the accessibility functions of WebSphere Message Broker? Find out about accessibility features in WebSphere Message Broker and shortcut keys to use in the information center.

How do I use the WebSphere Message Broker Toolkit?

New users: Use the links in this topic to help you get started using the WebSphere Message Broker Toolkit.

The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface based on the Eclipse platform. You can use the WebSphere Message Broker Toolkit for developing, testing, and debugging your applications.

Some of the links in this topic work only if you are accessing this information center from the WebSphere Message Broker Toolkit, or from the WebSphere Message Broker Explorer.

How do I navigate and customize the WebSphere Message Broker Toolkit?

Use the links in this section to find out how to navigate the WebSphere Message Broker Toolkit. You can also find information about the different resources that you can create in the WebSphere Message Broker Toolkit.

- What are the perspectives in the WebSphere Message Broker Toolkit?

  A perspective defines the initial set and layout of windows in the workbench. Each perspective provides a set of functionality aimed at accomplishing a specific type of task or working with specific types of resources. Follow this link to find out about the WebSphere Message Broker Toolkit perspectives.
- What are the editors in the WebSphere Message Broker Toolkit?

  Follow this link to find out about the different editors in the WebSphere Message Broker Toolkit.
- What are the views in the WebSphere Message Broker Toolkit?

  Use this link to find out how views are used in the Eclipse workbench. You can use the following links to find out more about the views that are used in association with different editors in the WebSphere Message Broker Toolkit:
  - Project Explorer view
  - Problems view
  - Tasks view
  - Outline view
  - Properties view
- What types of resource can I create in the WebSphere Message Broker Toolkit?

  Find out about the types of resources and files that you can create and develop in the WebSphere Message Broker Toolkit.
- What are the keyboard shortcuts in the WebSphere Message Broker Toolkit?

  Find out how to navigate by using keyboard shortcuts in the WebSphere Message Broker Toolkit.

How can I customize the Eclipse workbench?

You can use the instructions in these links to learn how to use any application running in the Eclipse workbench, including the WebSphere Message Broker Toolkit and Rational Application Developer.

- How do I work with perspectives?

  Find out how to work with perspectives.
- How do I work with views and editors?

  Find out how to work with views and editors such as rearranging views and opening files for editing.
- How do I customize the workbench?

  Find out how to work to further customize the Eclipse workbench such as rearranging the main toolbar and changing the placement of the tabs.

How can I change the WebSphere Message Broker Toolkit preferences?

You can change a number of settings in the WebSphere Message Broker Toolkit to suit your requirements. Use these links to get more information about these settings and how to change them.

- What WebSphere Message Broker Toolkit preferences can I change?

  Use this link to find out about WebSphere Message Broker Toolkit preferences that you can change, and get links to information about preferences that might be useful when you develop applications.
- How do I change the WebSphere Message Broker Explorer preferences?

  Follow this link to get an overview of how you change preferences to alter the behavior of the WebSphere Message Broker Explorer.
- How do I change the standard Eclipse preferences?

  Follow this link to find out about the standard preferences in the Eclipse workbench.

How do I design and develop applications?

New users: Use the links in this topic to get information about how to design and develop message flow applications and related resources.

- "What do I need to know to start developing applications?"

  Use this link to get information that it is useful to know before you start developing your message flow applications.
- How do I design a message flow?

  Follow this link to get a comprehensive list of the decisions that you need to make when designing a message flow.
- "How do I construct message flows?" on page 76

  Find out how to construct message flows.
- "How do I program message flows?" on page 78

  Find out how to program you message flow nodes by using ESQL, Java, message mappings, and XML transformations.
- "How do I design and develop a message model?" on page 83

  Find out how to develop message models.
- "How do I develop publish/subscribe applications?" on page 86

  Find out how to design and develop publish/subscribe applications.
- How do I develop user-defined extensions?

  Find out how to develop your own user-defined extensions such as nodes and parsers.

What do I need to know to start developing applications?:

New users: Before you start developing your applications, use the links in this topic to get information about concepts that you must understand.

This topic contains the following sections:

- "Basic application development concepts"
- "Advanced application development concepts" on page 76

Basic application development concepts:
What types of resources can I develop?

You can develop the following kinds of resources:

- Message flows

  A message flow is a sequence of processing steps that run in the broker when an input message is received. You define a message flow by including a number of

message flow nodes, each of which represents a set of actions that define a processing step. For more information about message flow nodes, see message flow nodes.

- Message models

  You can define the structure of messages for use with your message flows.

What is WebSphere Message Broker typically used for?

Use the links in this section to find out about the tasks that WebSphere Message Broker is commonly used for. You can also find out about the alternative ways to implement message flows for these tasks.

- **How can I use WebSphere Message Broker to route messages?**

  You can select from a number of ways of routing messages using message flows:

  – Using a Filter node

    You can route messages through a message flow based on the content of the message using a Filter node. The nodes that are connected to the different terminals of the Filter node can be used to apply different processing and routing to messages based on their content.

  – Using a Route node

    You can route messages through different paths in a message flow, based on the content of the message using a Route node. The Route node uses XPath expressions to control processing.

  – Using the destination list to route messages

    You can create a destination list to define the recipients of output messages using a Compute, Mapping, PHPCompute, or JavaCompute node. This list can then be used to route messages using RouteToLabel and Label nodes. Alternatively, a single message can be sent to many locations using a destination list for the destination mode, on some output nodes.

  You can see examples of how message flows can be used for routing in the following samples.

  – Message Routing
  – Airline Reservations
  – Simplified Database Routing

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

- **How can I use WebSphere Message Broker to transform and enrich messages?**

  You can select from a number of different ways of transforming and enriching messages using different nodes in message flows. Messages can be enriched with content from databases, applications, and files. The following methods of programming nodes in your message flows can be used to transform messages:

  – Databases

    WebSphere Message Broker supports various database managers so that you con configure your brokers to interact with databases on behalf of your message flows. Follow this link to get instructions on how to create and configure databases and connections.

  – ESQL

Extended Structured Query Language (ESQL) is a programming language based on Structured Query Language (SQL) that is typically used to work with databases. ESQL is extended to access and manipulate data in messages and databases. You can code ESQL to transform and enrich messages using the Compute node.

- Java

  Use the JavaCompute node to add valid Java code to your message flow. You can access, create, and transform messages in your message flows by using Java.

- Message mappings

  Message mappings use a drag-and-drop interface to transform messages. You can use conditional logic, ESQL functions, Java functions, and XPath functions to create complex mappings and transformations. You can also use message mapping to select and manipulate data in database tables. You can create message mappings to transform and enrich messages using the Mapping node.

- PHP

  Use the PHPCompute node to add valid PHP code to your message flow. You can access, create, and transform messages in your message flows by using PHP.

- XML transformation

  You can use the XSLTransform node to transform from one type of XML message to another, based on rules provided by an Extensible Stylesheet Language (XSL) style sheet.

The Airline Reservations demonstrates message enrichment, and the following samples demonstrate message transformation.

- Video Rental
- XSL Transform

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

- **How can I use WebSphere Message Broker with Web services?**

  WebSphere Message Broker provides a number of ways to work with Web services:

  - "WebSphere Message Broker and Web services" on page 1602

    Find out how WebSphere Message Broker can be used to integrate applications using Web services.

  - Web services scenarios

    Find out about the different Web services scenarios that WebSphere Message Broker supports.

  - "Processing Web service messages" on page 1601

    Find out more about working with Web services in WebSphere Message Broker.

  - Web services using HTTP nodes
  - SOAP Nodes

How can I connect my applications?

Use the links in this section to find out how you can connect your applications to WebSphere Message Broker.

- What are the application communication models?

  Find out about the differences between the two types of application communication model that WebSphere Message Broker supports.
- What application programming interfaces are supported?

  Find out about the many programming interfaces supported by WebSphere Message Broker.
- Connecting applications

  Find out about the communication transports and protocols that WebSphere Message Broker supports.
- "Publish/Subscribe" on page 2215

  Publish/subscribe is a style of messaging in which the providers of information (publishers) are decoupled from the consumers of that information (subscribers).

What is a logical message tree?

Use the links in this section to find out about the logical message tree and the internal representation of messages within message flows. When a message is received by a message flow, a logical structure is created, known as the logical message tree or the message assembly. The message assembly contains a message tree, which is the internal representation of the physical message, and a number of other trees that are used to store information during the processing of the message in the message flow.

- What is the logical message tree?

  Use this link to get more information about the logical message tree and how it is used in application development. You can get information about the four subtrees from the following links:
  - "Message tree structure" on page 1045
  - "Environment tree structure" on page 1055
  - "Local environment tree structure" on page 1056
  - "Exception list tree structure" on page 1066
- How is the message tree populated?

  Follow this link to get detailed information about how the message tree is populated when a message enters a message flow, and how the structure of the message tree is affected by the transport protocol that the message is received on.

What are physical message formats?

Use the links in this section to get information about the physical messages received by message flows, and to find out how the different structures and formats are handled by your applications.

- What are the differences between predefined and self-defining messages?

  Find out about the differences between predefined and self-defining messages in WebSphere Message Broker. The design of your applications can be influenced by your decision to use predefined or self-defining messages. If you use predefined messages, you must create a message model to define the logical

message structure to be used by the nodes in your message flows, but you can use self-defining messages instead, or as well.

- "Why model messages?" on page 1158

  Find out about the benefits of modeling messages, even if you use self-defining messages in your system.

- Where can I find an introduction to message modeling?

  Follow this link to get introductory information about message modeling.

- What is a parser?

  A parser is used to interpret the physical structure of an incoming message and create an internal representation of the message in a tree structure - the logical message tree. Follow this link to get an introduction to parsers.

- Which message domain and format can I use?

  A message model has one or more domains that determine which parser is used to construct the logical tree structure from the physical message. Follow this link for guidance on selecting a domain and parser for your message model.

- How can I define a physical format for my message?

  Follow this link to find out how you can define the physical structure for your messages. The following links provide information about specific types of message format:

  – What is a Custom Wire Format?
  – What is an XML Wire Format?
  – What is a Tagged/Delimited String Format?

Advanced application development concepts:
What other resources can I develop?

- "Developing message flows that use WebSphere Adapters" on page 2033

  You can develop applications that connect to an Enterprise Information System (EIS) using WebSphere Adapters.

- "User-defined extensions overview" on page 2971

  A user-defined extension is an optional component that is designed by the user to extend the functions provided by WebSphere Message Broker. A user-defined extension can be either a node or a parser.

- Administration API applications

  The Administration API for WebSphere Message Broker (also known as the CMP API) is an application programming interface (API) that you can program to control brokers by using a remote interface to the appropriate broker.

How do I construct message flows?:

New users: when you have considered the various factors involved in designing a message flow you are ready to create one.

Use the links in this topic to learn how to construct message flows and work with related resources.

How do I create message flow resources?

- How do I create a message flow project?

  A message flow project is a specialized container in which you create and maintain all the resources associated with one or more message flows. You can group together related message flows and resources in a single message flow project to provide an organizational structure to your message flow resources.

You must create a project before you can create a message flow. Use this link to learn how to create a message flow project.

- How do I create a broker schema?

  If you want to organize your message flow project resources, and to define the scope of resource names to ensure uniqueness, you can create broker schemas. When you first create a message flow project, a default broker schema is created in the project. Use this link to learn how to create a broker schema.

- How do I create a message flow?

  You create a message flow to specify how to process messages in the broker. You can create any number of message flows and deploy them to one or more brokers. Use this link to learn how to create a message flow.

How do I construct a message flow?

- How do I add a node?

  When you create a message flow, the first action to take to define its function is to add nodes. A message flow node is a processing step in a message flow. A message flow node can be a built-in node, a user-defined node, or a subflow node; see “Message flow nodes” on page 1024. Select the nodes to add to your message flow from the node palette, see “Message flow node palette” on page 1027.

- How do I rename a message flow node?

  To make your message flows easier to understand and to maintain, you can change the name of any type of node that you have added to your message flow. For example, you might change the name of an MQInput node to match the input queue name defined in the node.

-

  When you have included an instance of a node in your message flow, you can customize its function. Each node has a set of properties that are specific to the function of that node. For a list of nodes that are provided with WebSphere Message Broker, see “Built-in nodes” on page 4293. Select the required node from this list to view details of the terminals, and properties, and how to configure the node. For more information about nodes that can be programmed, such as the JavaCompute, Compute, and Mapping nodes, see “How do I program message flows?” on page 78.

- How do I connect nodes?

  You connect the nodes in your message flow to indicate how the flow of control passes from input to output, and the route that messages can take through the message flow. A message flow node has a fixed number of input and output points known as terminals. You can connect the failure or catch terminals of nodes to add error handling to your message flows, see “Handling errors in message flows” on page 2823.

- How do I align and arrange nodes in a message flow?

  You can change the way that the nodes in your message flow are displayed and arranged, to make them easier to read. You can add a bend point to make the flow of control easier to follow where node connections cross each other, see “Adding a bend point” on page 1527.

- How do I save a message flow?

  Save the message flow when you want to do any of the following actions:

  – Close the workbench
  – Work with another resource
  – Validate the contents of the message flow

How do I manage my message flows?

- How do I delete a message flow node?

  Learn how to remove a node from your message flow.
- How do I delete a node connection?

  Learn how to remove a node connection between nodes in your message flow.
- How do I delete a message flow?

  Learn how to delete your message flow.
- How do I rename a message flow?

  Learn how to rename your message flow.
- How do I delete a message flow project?

  Learn how to delete your message flow project.
- How do I move a message flow?

  Learn how to move your message flow between broker schemas or message flow projects.
- How do I add a subflow?

  After you have created message flows, you can embed them in other message flows as subflows. You can use subflows to reuse function across message flow projects, reduce development time, and increase the maintainability of your message flows.
- How do I back up my message flow projects and related resources?

  Your message flow projects and other resources are stored in the WebSphere Message Broker Toolkit workspace and other locations in your file system. You can use the export function in Eclipse, or take copies of the directories on your file system, to back up your resources. Alternatively, you can set up the WebSphere Message Broker Toolkit to work with a repository, see "Development repository" on page 45.

Related tasks:

"Designing a message flow" on page 1455
A message flow can perform a wide range of operations, depending on your business and operational requirements. For best performance and capability, you must design it to include the most appropriate nodes.

How do I program message flows?:

New users: Use the links in this topic to get information about the concepts and tasks associated with programming message flows.

This topic contains the following sections:

How do I use message mappings?: Message mappings use a drag-and-drop interface to create and transform messages. You can use conditional logic, ESQL functions, and XPath functions to create complex mappings and transformations. You can also use message mapping to select and manipulate data in database

tables. You must create a message definition for any messages that you include in a message mapping. Message map files are stored in message flow projects.

- How do I create a message map file?

  Follow this link for instructions on how to create a message map in the Broker Application Development perspective. You can also create a message map from the nodes that support message mapping including:

  – Mapping node
  – DataInsert node
  – DataUpdate node
  – DataDelete node

- What does the Message Mapping editor look like?

  You create and modify message mappings in the Message Mapping editor. Use this link to discover information about the Message Mapping editor.

- How do I configure message mappings?

  When you configure message mappings, you can drag content from a source to a target. The source can be a message, a database, or both, and the target can be messages, database tables, or both. If your target is a database, you can select the database operation (insert, update, or delete) that you want to perform on the table. You can set the value for your target to be a constant, or you can use a function or expression to produce the value. Additionally, you can configure conditional mappings to set different values for targets based on the content of the sources, and to handle repeating elements in sources and targets. Follow this link to discover more about message mappings.

- **Message mapping syntax**

  When you use an expression to set the value of a target in a message map, the expression must be in XPath format.

  – What syntax is used in mapping nodes?

    Use this link to discover more about the XPath syntax used in message maps.

  – How do I use expressions in my message maps?

    Use this link to discover more about the type of functions that you can use in expressions in your message maps.

  – How can I find out more about XPath query syntax?

    To discover more about XPath, follow this link to the W3C recommended XPath 1.0 query syntax reference document. This link works only if you have an active internet connection.

- How do I create and call submaps and routines?

  You can reuse message maps between different message flows and message flow projects by using a submap. You can also use a submap to create message mappings for a wildcard source so that you can select replacement elements, for example to select the appropriate body element from a SOAP message. In addition to calling a submap from a message map, you can call a submap from ESQL. You can also call ESQL routines from a message map. Use this link to discover more information about creating and using submaps and ESQL routines.

How do I use ESQL?: Extended Structured Query Language (ESQL) is a programming language based on Structured Query Language (SQL), which is commonly used with relational databases such as DB2. ESQL extends the constructs of the SQL language to provide support for you to work with both message and database content. ESQL can be used with the Compute, Database, and Filter nodes.

Many of the WebSphere Message Broker "Samples" on page 98 show how to use ESQL in message flows.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

The following samples contain example ESQL code:

- Airline Reservations
- Large Messaging
- Message Routing

Use the following links to discover how to use ESQL in your message flows:

- How do I create an ESQL file?

  The ESQL code for each of your nodes is contained within a module in an ESQL file. Use this topic to discover how to create an empty ESQL file in your message flow project. Alternatively, you can select **Open ESQL** to create an ESQL file when you configure the first node in a message flow that uses ESQL. This action creates an ESQL file with skeleton ESQL code for a module associated with the selected node. You can also select an ESQL module for a node from a different message flow project by creating "Project references" on page 44.
- What is the ESQL editor?

  You can create and modify your ESQL code in the ESQL editor. You can change the way that code is displayed in the ESQL editor, and modify the way in which the ESQL editor validates code, by changing your ESQL preferences.
- How do I create ESQL for a node?

  Follow this link to get an overview of how to create ESQL for your node, including more information about the differences between the skeleton ESQL code generated for the modules associated with the Compute, Database, and Filter nodes.
- How do I modify ESQL for a node?

  Follow this link to discover how to modify the skeleton ESQL module code.
- How do I save an ESQL file?

  Discover how to save your ESQL file.
- How do I write ESQL code?

  Follow this link to get introductory information about writing ESQL code for your message flows. Discover how to manipulate the message tree, transform data, access databases, and work with messages from different message domains using ESQL.
- **ESQL language**

  Use the following the links to get concept and reference information about the ESQL language:

  – "ESQL data types" on page 2373
  – "ESQL variables" on page 2374
  – "ESQL operators" on page 2382
  – "ESQL field references" on page 2381
  – "ESQL statements" on page 2383
  – "ESQL functions" on page 2385

- "ESQL procedures" on page 2386
- "Special characters, case sensitivity, and comments in ESQL" on page 5305
- "ESQL modules" on page 2388
- "ESQL reserved keywords" on page 5307
- "ESQL non-reserved keywords" on page 5307

How do I use Java?: You can create a Java class file for a JavaCompute node and code Java functions to tailor the behavior of the node. You can add any valid Java code to your JavaCompute nodes and use the Java user-defined node API to process messages. You manage Java files through the Java perspective.

The following sample provides a collection of message flows that show how to use the JavaCompute node:

- JavaCompute Node

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
- How do I use a JavaCompute node?

  You can use the JavaCompute node to examine the content of an input message, transform a message, and build new messages. Follow this link to discover how to use and configure the JavaCompute node in your message flows.
- How do I create Java code for a JavaCompute node?

  Discover how to create a Java class file using the JavaCompute node wizard. The JavaCompute node wizard creates a Java class with skeleton Java code that is based on the options that you select in the wizard. You can then modify the skeleton code to perform your own processing.
- How do I open an existing Java file?

  You can modify existing Java code that you have created in a Java Project.
- How do I save a Java file?

  Discover how to save your Java file.
- How do I write Java for message flow applications?

  Get introductory information about writing Java code for your message flow applications, including how to manipulate the message tree, access databases, handle errors, and access broker properties.
- What views and editors do I use when programming Java?

  Get a list of concept, task, and reference topics that relate to editors and views for working with Java.
- Where can I get assistance when programming Java?

  You can use code assist to provide a list of available command completions that you can select to insert into the editor. You can also use command assist to access Javadoc information about code in the Java editor.
- How do I add Java code dependencies?

  Discover how to include references to other Java projects and JAR files in your JavaCompute node code.
- Where can I find the Java user-defined node API?

  Follow this link to the Java API for the WebSphere Message Broker classes for creating a Java user-defined node, which you can also use to code your JavaCompute node.

How do I use XML transformations?: You can use the XSLTransform node to transform an XML message into another form of XML according to the rules provided by an XSL (Extensible Stylesheet Language) style sheet. You can specify the location of the style sheet to apply to this transformation in three ways:

- By using the content of the XML data within the message itself, which transforms the message according to a style sheet that the message itself defines.
- By setting a value within the LocalEnvironment folder.
- By using node properties, which ensures that the transformation that is defined by this single style sheet is applied to every message that is processed by this node.

You can discover links to information about using XML transformation in this section.

- Where can I find a sample that shows XML transformations?

  If you have installed the WebSphere Message Broker Toolkit, you can use this link to display the XSL Transform sample. The XSL Transform sample is a message flow sample that shows how to use a message flow to transform an XML message to another form of XML message according to the rules provided by an XSL stylesheet.

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
- How do I use the XSLTransform node?

  Follow this link to discover how to use and configure the XSLTransform node to transform an XML message into another form of XML.
- Where can I find out more about XSL Transformations?

  To discover more about XML Transformations, follow this link to the W3C specification of the syntax and semantics of the XSL Transformations language for transforming XML documents into other XML documents.

How do I use PHP?: PHP is a scripting language that you can code to route and transform messages. You can use PHP in the PHPCompute node, which is supported only on Windows.

- Where can I get an overview of PHP?

  Follow this link for an overview of PHP, and links to further information about how you can use this scripting language.
- Where can I find a sample that shows how to use PHP?

  If you have installed the WebSphere Message Broker Toolkit, you can use this link to display the PHP sample. The PHP sample is a message flow sample that shows how to use PHP code to transform an XML message.

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
- How do I use a PHPCompute node?

  Follow this link to discover how to use and configure the PHPCompute node in your message flows.
- How do I create PHP code for a PHPCompute node?

Discover how to create a PHP script file for the PHPCompute node in your message flows.

How do I use XPath?: The XML Path Language (XPath) is a language used to uniquely identify or address parts of an XML document. An XPath expression can be used to search through an XML document, and extract information from the nodes (any part of the document, such as an element or attribute) in it. XPath expressions can be used in message maps, and in the properties of some of the nodes. Typically, you might use XPath when you are using Java, XML, or PHP.

- Where can I get an overview of XPath?

  Follow this link for an overview of XPath, and how you can use XPath with nodes.
- How do I use the XPath Expression Builder?

  You can use the XPath Expression Builder to add XPath expressions to your node properties. Follow this link for information about how to use the XPath Expression Builder.

How do I design and develop a message model?:

New users: how to design and create message models.

If the format of the messages that you want to use with your applications is not self-defining, you must create a message model that defines the structure of your messages. If your messages are self-defining, you might want to create a message model to take advantage of runtime validation of messages, reuse of messages, automatic generation of documentation, and code completion on the message structure when you use ESQL. If you want to use message mapping, you must also create a message model for your messages.

You can obtain prebuilt models for common industry standard message formats such as SWIFT, EDIFACT, X12, FIX, HL7, and TLOG to use with WebSphere Message Broker. You can also create message models from C header files, COBOL copybooks, XML Schema and DTDs, and WSDL files. Alternatively, you can use the Message Definition editor to create your own message models.

For further information, read the logical and physical message structure sections in "What do I need to know to start developing applications?" on page 72.

What are the components of a message model?

Use the links in this section to learn how to create and configure message set projects and message set files.

- Use the following links to learn about the different components that are used to build a message model:
  - What is a message set project?

    A message set project is a container in which you create and maintain all of the resources that are associated with a single message set. A message set can contain one or more message models.
  - What is a message set?

    A message set is a logical grouping of messages and the objects that comprise them (elements, types, and groups). A message set can contain one message set file, message definition files, and message category files.
  - What is a message definition file?

A message definition file contains the messages, elements, types, and groups that make up a message model. The message definition file contains the logical model and associated physical model in XML Schema form for a group of related messages.

– What is a message model object?

  Get an overview of the objects that make up a message model.

– What is a message category?

  You can use message categories to group your messages for documentation purposes.

– What is a multipart message?

  You can define a message that contains one or more embedded messages within its structure.

– How can I control the number of occurrences of an element or attribute in a message?

  You can define a message that contains repeating, optional, and mandatory elements.

How do I create and configure a message model?

Use the links in this section to learn how to create and configure message set projects and message set files. The following sample provides step-by-step instructions about how to create a simple message model. The sample also demonstrates message transformation between three different message formats.

- Video Rental

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

- How can I use the Quick Start wizards to help create resources?

  You can use the Quick Start wizards to help you to create a message model and to set up the resources that you require to develop a WebSphere Message Broker application.

- How do I create a message set?

  You must create a message set before you can add any content to your message model. When you create a message set, a message set project is also created.

- **How do I configure a message set file?**

  After you have created a message set, you must configure the logical and physical properties of the message set. You can use the Message set editor to configure the properties of a message set. See “Message set editor” on page 6819.

  – How do I configure the logical properties of my message set?

    Learn how to configure logical properties of a message set.

  – How do I configure the physical formats of my message set?

    Learn how to add and configure different physical format layers in a message set.

- How do I create a message definition file?

  You must create a message definition file before you can create the message model objects. You can use the New message definition file wizard to create an empty message definition file, or you can populate a message definition by

using existing application message formats by importing data structures. See "New message definition file wizards" on page 6360 and "Working with data structures" on page 2930.

- How do I configure the properties of my message definition files?

  When you have created a message definition file, you can configure the message definition file properties described in this topic by using the Message Definition editor. See "Message Definition editor" on page 6804.

- **How do I add and configure message model objects?**

  When you have created a message definition file you can add message model objects to your message definition file, to define the structure of your message. You can also add objects to existing message definition files. You must then configure the logical, physical, and other properties of the message model objects.

  – How do I add message model objects?

    Follow this link to learn how to add different message model objects to a message definition file.

  – How do I configure message model objects?

    Follow this link to learn how to configure message model objects.

  – What properties do message model objects have?

    Follow this link to get reference information about logical, physical, and documentation properties for all types of message model objects.

  – How do I create a multipart message?

    You can create a message model that includes a multipart (embedded) message. Use this link to learn how to create a multipart message.

  – How do I link from one message definition file to another?

    Follow this link to learn how to link one message definition file to another.

- How are namespaces used in the message model?

  Objects in the message model such as elements, attributes, types, and groups are identified by their name. No two objects in the same scope are allowed to have the same name. If namespaces are enabled for a message set, each message definition file within it can specify a namespace. Global objects within namespaces can share the same name, therefore namespaces provide a way to avoid name clashes between objects.

How do I manage my message models?

Learn about how to manage your message models:

- **How do I generate model representations from message models?**

  When you have created and populated a message set, you can generate a message model in different representations for use both by WebSphere Message Broker and your applications. Use the following links to learn about the types of model representations that you can generate from your message models:

  – "Generate message dictionaries" on page 1271

  – "Generate XML schema" on page 1272

  – "Generate WSDL" on page 1274

- How do I configure message set preferences?

  Follow this link to learn how to make changes to preferences that relate to message set processing.

- How do I change my viewing preferences for message model editors?

You can change your viewing preferences for the Message Set editor and the Message Definition editor, to make it easier to view message definition files.

How do I develop publish/subscribe applications?:

New users: use the links in this topic to get concept and reference information that is useful when you develop publish/subscribe applications.

Publish/subscribe is a style of messaging application in which the providers of information (publishers) are decoupled from the consumers of that information (subscribers) using a broker. The following samples are examples of simple publish/subscribe message flows, and include associated user applications. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

- Pager
- Scribble

A publish/subscribe application can consist of a network of brokers connected together. By connecting brokers together, publications can be received by a client on any broker in the network.

- Where can I find an overview of publish/subscribe?

  For an overview of publish/subscribe, see the following topics:
  - "Publishers" on page 2218
  - "Publications" on page 2219
  - "Subscription points" on page 2222
  - "Subscribers" on page 2220
- How do I use a publication node?

  Use the Publication node in your message flows to filter output messages and transmit them to subscribers who have registered an interest in a particular set of topics.
- What are command messages?

  Different types of command messages can be sent from an application to instruct the broker to perform the required task; for example to publish a message, or register a subscriber.

How do I deploy and test message flows?:

New users: Use this topic to get information about deploying and testing your message flows during development. When you have developed your message flows, message models, and other resources, you are ready to deploy them to a broker.

You can use features provided in the WebSphere Message Broker Toolkit to help you test your message flows. Read "How do I deploy and configure message flow applications?" on page 94 for information about deploying and configuring message flows for use in a production environment.

Before you can deploy and test your message flows, you must create and configure at least one broker.

You can create the Default Configuration to create a broker environment that is suitable for testing message flows during development, see "Creating the Default

Configuration" on page 106. You can create the Default Configuration only if you are accessing the information center from the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

How do I deploy message flows and related resources?

Use the links in this section to get instructions on how to deploy your message flows, message sets, and related resources to a broker. Read "Message flow application deployment" on page 3213 for an overview of the concepts of deployment of message flow resources.

- How do I create a broker archive?

  A broker archive file is a compressed file that contains compiled message flows, message dictionaries, and other application development resources. Use this link for instructions about how to create a broker archive file. You can use the "Broker Archive editor" on page 6794 to add or remove message flows and message sets to, or from, your broker archive. You can also use the Broker Archive editor to edit the configurable properties in your broker archive.
- How do I add files to a broker archive?

  You can add message flows and message sets to a broker archive file. The message flows, message sets, and related resources are compiled when they are added to the broker archive file. You can also choose to add the source files to the broker archive file. You cannot add resources to a broker archive file from a project that contains an error.
- How do I deploy a broker archive?

  Find out about the different ways that you can deploy a broker archive file to a broker. For deploying message flows for development to a test environment, the simplest method is to use the WebSphere Message Broker Toolkit.
- How do I check the results of the deployment?

  Find out about the ways that you can check the results of deployment. When you deploy message flows to a test environment, the simplest method is to use the WebSphere Message Broker Toolkit. You can also use the "**mqsilist** command" on page 3882 with the name of the broker and execution group to which you deployed your broker archive file.
- How do I edit configurable properties?

  System objects that are defined in message flows have configurable properties that you can update within the broker archive before deployment. By changing configurable properties, you can customize a broker archive for a new domain, without needing to edit and rebuild the message flows or other resources.
- How do I refresh the contents of a broker archive?

  You can refresh the contents of a broker archive by removing resources from it and, having made required changes, add them back again. Alternatively, you can use the Refresh option in the Broker Archive editor.

How can I test my message flows?

Use the links in this section provide information about the different features provided in the WebSphere Message Broker Toolkit to help you to test your message flows.

- How do I test a message flow using the Test Client?

  You can test message flows that use WebSphere MQ or HTTP input and output nodes. If you have a message sets defined for the input nodes in your message

flow, the message flow test tool can provide an input message template in XML format, that you can use to develop test messages.

- How can I put a test message onto a WebSphere MQ queue?

  Get instructions about how to create and use an enqueue file to put a test message on to a WebSphere MQ queue.
- How can I get a test message from a WebSphere MQ queue?

  Get instructions about how to read a message from a WebSphere MQ queue by using the Dequeue Message dialog box.
- How can I test my message flows?

  You can use the flow debugger to help test your message flows by tracking the path a message takes through your message flow. You can also step through the ESQL, Java, and message mappings in your message flows, to view the output messages that are being constructed.
- "How can I diagnose problems?" on page 96

  If you are having difficulty deploying your message flows and other resources, or receiving unexpected results when you test your message flows, look at the problem determination information in this topic.

I am an administrator; what tasks am I interested in?

If you are an administrator, you will be involved in the tasks to configure brokers and associated resources, and support your application developers.

Before you start

New users: Read the following introductory topics to the product, and the information center, before you start configuration:

- "How do I use the information center?" on page 67
- "Where can I get an overview of WebSphere Message Broker?" on page 69
- "How do I use the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit?" on page 89

Returning users: Find out what new features are supported for configuration and administration:

- "What's new in Version 7.0?" on page 7

WebSphere iconWebSphere Message Broker Administration

To test and run your message flow applications, you must create and configure your brokers. Use the links in this section to find out how to configure and administer your brokers and message flow applications:

- "How can I check that my installation was successful?" on page 90 Find out if your installation has been successful.
- "What information is available for users of previous versions?" on page 91 Find out what you need to know if you are a user of a previous version or release.
- "How do I plan and configure brokers?" on page 91 Find out how to plan and configure brokers for your business.
- "How do I administer and monitor brokers?" on page 93 Find out about day to day administrative tasks and about monitoring the performance of your message flow applications.
- "How do I deploy and configure message flow applications?" on page 94 Find out how to configure your message flow applications and get them running.

What else might I be interested in?

When you configure and administer your brokers, you might also be interested in the following questions:

- How can I troubleshoot problems? Find out how to debug message flow applications and troubleshoot problems.
- Where can I find out about the accessibility functions of WebSphere Message Broker? Find out about accessibility features in WebSphere Message Broker and shortcut keys to use in the information center.

How do I use the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit?

New users: use the links in this topic to help you get started using the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit.

The WebSphere Message Broker Explorer is an administration environment and graphical user interface based on the Eclipse platform, and integrated with the WebSphere MQ Explorer. You can configure, administer, view, and monitor your brokers, and their associated resources, by using the options in this workbench.

The WebSphere Message Broker Toolkit enables you to complete some basic administration functions for testing and debugging your message flow applications.

Some of the links in this topic work only if you are accessing this information center from the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit.

How do I navigate and customize the WebSphere Message Broker Explorer?

Use the links in this section to find out how to navigate the WebSphere Message Broker Explorer.

- What are the keyboard shortcuts?

  Find out how to navigate by using keyboard shortcuts in the WebSphere Message Broker Explorer.

How can I customize the Eclipse workbench?

You can use the instructions in these links to learn how to use any application running in the Eclipse workbench, including the WebSphere Message Broker Explorer and Rational Application Developer.

- How do I work with perspectives?

  Find out how to work with perspectives.
- How do I work with views and editors?

  Find out how to work with views and editors such as rearranging views and opening files for editing.
- How do I customize the workbench?

  Find out how to work to further customize the Eclipse workbench such as rearranging the main toolbar and changing the placement of the tabs.

How can I change the WebSphere Message Broker Toolkit preferences?

You can change a number of settings in the WebSphere Message Broker Toolkit to suit your requirements. Use these links to get more information about these settings and how to change them.

- What WebSphere Message Broker Toolkit preferences can I change?

  Use this link to find out about WebSphere Message Broker Toolkit preferences that you can change, and get links to information about preferences that might be useful when you develop message flow applications.
- How do I change WebSphere Message Broker Explorer preferences?

  Follow this link to get an overview of how you change preferences to alter the behavior of the WebSphere Message Broker Explorer.
- How do I change the standard Eclipse preferences?

  Follow this link to find out about the standard preferences in the Eclipse workbench.

How can I check that my installation was successful?

New users: Use the links in this topic to help you to check that your installation of WebSphere Message Broker was successful.

Most links in this topic work only if you are accessing this information center from the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

- "Creating the default configuration" on page 564

  Use the Default Configuration wizard from the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer to create a broker to run the WebSphere Message Broker samples. The default configuration also provides a useful environment to test and debug your own message flow applications. You can run a wizard to remove the default configuration when you have finished with it.
- Where can I find samples?

  The WebSphere Message Broker samples are a set of sample message flow applications and associated resources that demonstrate some of the capabilities of WebSphere Message Broker. Use the Where can I find samples? link to view a description of all the samples. You must create the default configuration before you can run the samples.

  You can use the following samples to quickly check that your installation was successful:

  – Pager

  – Scribble

  You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

  The Starter Edition and Entry Edition modes of operation restrict you to a single execution group. Also, the Entry Edition mode restricts the set of nodes you can use. As a result, not all samples can be used in these modes of operation. For more information, see "Restrictions that apply in each operation mode" on page 3657.

For more information about how to check that your installation of the WebSphere Message Broker or the WebSphere Message Broker Explorer was successful, see "Verifying your WebSphere Message Broker installation" on page 290. This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

What information is available for users of previous versions?

If you are a user of a previous version of WebSphere Message Broker, use the links in this topic to get information about what is new in WebSphere Message Broker Version 7.0, and how to migrate from previous versions.

What's new?

Use the links in this section to find out about the main enhancements and changes in this release. You can find out more about the new functions and capabilities of this release by looking at the new WebSphere Message Broker Version 7.0 samples.

- "What's new in Version 7.0?" on page 7

  Find out about the main new function in this release, and new features added at Version 7.0.
- Where can I find sample applications?

  Look at the new samples introduced in Version 7.0 that demonstrate WebSphere Message Broker capabilities. Follow this link to get a description of all the samples and a direct link to each one. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

What do I need to know about migration and coexistence?

Use the links in this section to find out how to migrate to WebSphere Message Broker Version 7.0 from previous versions of the product.

- How does WebSphere Message Broker Version 7.0 coexist with previous versions?

  WebSphere Message Broker Version 7.0 can coexist with previous versions. You can therefore perform a staged migration when you want to migrate from a previous version. See this topic for details about coexistence on a single computer.
- How do I migrate from Version 6.1 products?

  If you are migrating from Version 6.1 products, see this topic for information about planning for migration, and the steps involved in carrying out a migration from your specific product.
- How do I migrate from Version 6.0 products?

  If you are migrating from Version 6.0 products, see this topic for information about planning for migration, and the steps involved in carrying out a migration from your specific product.

How do I plan and configure brokers?

New users: Use the links in this topic to find out how to plan and configure brokers.

You can create a broker for testing purposes on your WebSphere Message Broker Toolkit computer by using the Default Configuration wizard. When you are ready

to create brokers for testing on platforms other than Windows or Linux on x86, or for production purposes, you must plan your configuration carefully, by using the information provided in the WebSphere Message Broker information center.

What do I need to know about brokers?

Use the links in this section to find information that you might find useful before planning and designing your brokers.

- What is a broker?

  A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in-flight messages. Follow this link to get information about brokers, and the resources that you need to create and configure your brokers.

- What is an operation mode?

  The operation mode that you use is determined by the license that you purchased when you bought the product. The mode can either give you the full operating capabilities of your broker, that is, `enterprise` mode, or restrict the operating capabilities of your broker, that is, `starter`, `adapter`, or `entry` modes.

  You can set the operation mode when you create a broker, however, brokers are created, or migrated from previous versions, in `enterprise` mode by default. Follow this link to get information about the various modes that are available.

- What do I need to know about databases?

  You can configure your message flows to access data in databases; you can read from, write to, and update the information in a supported database. Follow this link to find out more about databases and how to create connections to them.

What do I need to know about authorization and security?

You must set up access and authorization credentials for some of the resources that you use with WebSphere Message Broker; for example, databases. Follow the links in this section to get information about authorization, access control, and security for your broker.

- What authorizations are needed for configuration tasks?

  Authorization is the process of granting or denying access to a system resource. Use this link to get examples of the tasks in WebSphere Message Broker that require authorization. Use the following links to get more details about the security requirements for administrative tasks on the different platforms:

  - "Security requirements for Linux and UNIX platforms" on page 3648
  - "Security requirements for Windows systems" on page 3651
  - "Security requirements for z/OS" on page 3655

- What authorizations are required for access to runtime resources?

  If you want to set up administrative authority for the resources managed by the broker (including the broker itself), you must set up WebSphere MQ authorizations for brokers and execution groups.

- Where can I find out about security for publish/subscribe?

  Follow this link to get an overview of publish/subscribe security.

How do I plan brokers and configure prerequisites?

Use the following links to find out how to plan your brokers. You can also find out about tasks you must complete before you can configure your brokers.

- How do I plan brokers?

Follow this link to find out what you must consider when you plan your brokers, and your WebSphere MQ infrastructure.

- How do I set up broker security?

  Follow this link for information about how to set up security for your brokers. Each link comprises a list of reminders or questions about the security tasks to consider for your broker configuration. The answers to the questions provide the security information that you need to configure your brokers, and also give you further information about other security controls that you might want to deploy.

How do I create and configure brokers?

You can create one or more brokers on one or more computers. The use of multiple brokers can help you to spread the load of the message processing that you want to achieve, or to allocate different functions to different brokers or computers. For example, you might set up a broker to run personnel applications, and another to run financial or order systems. To support each broker, you must create a WebSphere MQ queue manager, and you might need to create a WebSphere MQ infrastructure of channels or a WebSphere MQ cluster to connect the brokers together.

You might also create several execution groups on each broker to manage the message flow applications that you deploy to the broker.

To create a broker, complete the following tasks in order:

1. How do I create a broker?

   On Windows and Linux on x86, you can create brokers in the WebSphere Message Broker Toolkit. On all platforms, you can create the brokers by using the command-line commands. Create as many brokers as you require.
2. How do I verify that the broker has been created successfully?

   You can use the **mqsilist** command to check that your brokers were created successfully
3. How do I start a broker?

   Follow this link to get instructions on how to start a broker.

How do I administer and monitor brokers?

New users: Use the links in this topic to get information about administering brokers.

How do I administer my brokers?

Use the links in this section to find out about the tasks that you operate frequently to activate and run your brokers.

- How do I start and stop a broker?

  Use this link to find out how to start and stop a broker on the different platforms. You can stop and start a broker by using the command line.
- How do I connect to a broker?

  Use the following links to find out how to connect to your broker:
  - Using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer
  - Using the Administration API (CMP API)
  - On z/OS
- How do I start and stop message flows?

Use the following links to find out how to start and stop message flows:
  - Using the WebSphere Message Broker Explorer in stand-alone mode (link to follow)
  - Start and Stop message flows using the command line
  - Using the CMP API
- How do I deploy a broker archive file?

  Use this link to find out how to deploy a broker archive file to a broker by using the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, the **mqsideploy** command, and the CMP API.
- How do I submit batch requests using the CMP API?

  You can use the CMP API to group multiple requests destined for the same broker together, and submit them as a single unit of work.
- How do I modify my broker?

  You might want to change the configuration of your broker. See How do I modify a broker? and follow the link for your broker platform.
- How do I delete my broker?

  You might want to delete your broker. See How do I delete a broker? for a link to your platform.
- How do I back up my resources?

  Follow this link to find out how to back up your broker and application resources.

How can I monitor my brokers?

Use the links in this section to find out how you can monitor the events and performance of your brokers.

- How can I view administration log information?

  The "Administration Log view" on page 6840 in the WebSphere Message Broker Toolkit contains information about events that occur during operation. These events can be information, errors, or warnings, and relate to your own actions.
- How can I view message flow accounting and statistics data?

  Message flow accounting and statistics data is the information that can be collected by a broker to record performance and operating details of message flow execution. Follow this link to get an overview of message flow accounting and statistics, and links to further information.
- What are the system management interfaces?

  The brokers provide a service for independent system management agents so that a central management facility can access information about a network that includes one or more brokers. Use this link to find out how you can use the system management publications from WebSphere Message Broker to develop or use system management adapters or customized administrative applications to receive information about broker activity.

How do I deploy and configure message flow applications?

New users: Use the links in this topic to get information about deploying and configuring message flow applications and related resources.

What do I need to know about deployment?

Deployment is the process of transferring data to an execution group that belongs to a broker, so that it can take effect in the broker. Use the following links to find out more about deployment.

- Where can I get an overview of deployment?

  Use this link to find out about the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, the **mqsideploy** command, and the Administration API (also known as the CMP API) as environments for deployment.
- What do I need to know about message flow application deployment?

  Use this link to find out more about deploying message flow applications and related resources.
- What is a broker archive?

  You add message flow applications and related resources to a broker archive to deploy the resources to an execution group. Use this link to find out about the files that can be associated with a broker archive file.
- What are configurable properties of broker archives?

  System objects that are defined in message flows can have configurable properties that you can update within the broker archive file before deployment. You can use configurable properties to update target-dependent properties, such as queue names, queue manager names, and database connections.
- How do I view version and keyword information for deployable resources?

  Follow this link to find out how to view the version and keyword information of deployable objects. You can use version and keyword information to track resources that have been deployed to a broker.

How do I deploy message flow applications?

You must create, configure, and start at least one broker to deploy message flow applications to an execution group. Use the links in this section to find out how to deploy your message flow applications and related resources to an execution group.

- **How do I add an execution group?**

  An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes. You can create more execution groups in a number of different ways:

  – Using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer
  – Using the command line
  – Using the CMP API
- How can I create a broker archive?

  A broker archive file (BAR file) is a compressed file that contains compiled message flows, message dictionaries, and other development resources. Use this link to find out how to create a broker archive. You can use the “Broker Archive editor” on page 6794 to add or remove message flows and message sets to or from your broker archive, and to edit the configurable properties within your BAR file.
- How can I add resources to a broker archive?

You can add message flows and message sets to a broker archive file. The message flows, message sets, and related resources are compiled when they are added to the broker archive file. You can also choose to add the source files to the broker archive file. You cannot add resources to a broker archive file from a project that contains an error.

- How can I deploy a broker archive file?

  Find out about the different ways that you can deploy a broker archive file to a broker. For deploying message flow applications during development to a test environment, the simplest method is to use the WebSphere Message Broker Toolkit. When you deploy to a broker, you select an execution group to deploy to.

- How do I check the results of deployment?

  Use this link to find out how you can check the results of a deployment.

- How do I refresh the contents of a broker archive?

  You can refresh the contents of a broker archive by removing resources from it and, having made required changes, add them back again. Alternatively, you can use the Refresh option in the Broker Archive editor.

How can I configure message flow applications?

Use the links in this section to find out how to configure your message flow applications for use in a production environment.

- How do I edit configurable properties?

  System objects that are defined in message flows can have configurable properties that you can update within the broker archive file before deployment. By changing configurable properties, you can customize a broker archive file for a new broker, without needing to edit and rebuild the message flows or other resources.

- How do I configure message flows at deployment time using user-defined properties?

  User-defined properties (UDPs) give you the opportunity to configure message flows at deployment time, without modifying program code.

- How can I optimize message flow throughput?

  Use this link to find out how you can optimize the throughput of messages in your message flows using parallel processing.

- How do I add multiple instances of a message flow to a broker archive?

  You can edit the name of your files in the broker archive so that you can deploy multiple instances of a message flow with different values for the configurable properties.

- How do I configure global coordination of transactions?

  To ensure data integrity during transactions, you can globally coordinate message flow transactions with a WebSphere MQ queue manager. Follow this link to find out how to configure your databases, queue managers, and message flow applications for global coordination.

How can I diagnose problems?

New users: Use the links in this topic to find out how to debug message flow applications and get help with troubleshooting problems.

How can I debug and troubleshoot my message flow applications?

A number of tools and sources of information are available to help you solve problems with your message flow applications. If you can see errors or warnings in the Problems view in the WebSphere Message Broker Toolkit, your message flow applications and related resources might have problems that prevent you from adding them to a broker archive file. Also, your message flow applications might not work as you expect when they are deployed.

Use the information in the error or warning messages to fix the problem. If you have difficulty deploying message flow application resources, see **How can I troubleshoot problems when deploying message flow applications?** in this topic for more information. If you have successfully deployed your message flow applications, you can use the following links to debugging and troubleshooting topics to help you solve any problems.

- How do I use the flow debugger?

  You can test and debug your message flow applications by using the debugger in the WebSphere Message Broker Toolkit. By adding breakpoints to your message flows, you can use the debugger to view the path that messages take through your message flow. You can also view the contents of the message passing through the flow, and step through code to view the output messages being constructed. The debugger is launched from the "Debug perspective" on page 6789.
- Where can I find useful logs?

  Find out where to find useful logs that are used in WebSphere Message Broker.
- How do I use trace?

  User trace can be used to get further information about problems with messages passing through your message flows. You can use the following sequence of tasks to get user trace to troubleshoot a problem with a message flow:

  1. "Starting user trace" on page 3197
  2. "Retrieving user trace" on page 3204
  3. "Formatting trace" on page 3543
  4. "Interpreting trace" on page 3546
- How can I resolve problems when developing message flows?

  Follow this link for information about some common problems when developing message flows.
- How can I resolve problems when developing message models?

  Follow this link for information about some common problems when developing message models.

How can I troubleshoot problems when deploying message flow applications?

If your message flow applications or related resources contain an error, they cannot be added to a broker archive file. Sometimes message flow applications that are successfully added to a broker archive file can fail to be deployed, for example, because of a problem with the broker or with the message flow applications. Use the following links to find out how to check the results of deployment and get help solving problems.

- How can I check the results of deployment?

  Find out how to check the results of a deployment by using the "Administration Log view" on page 6840, the **mqsideploy** command, and the Administration API (also known as the CMP API).
- How can I resolve problems when deploying message flows or message sets?

Follow this link to find tips on resolving problems when deploying message flows and message sets.

Where can I get other help on troubleshooting and solving problems?

Use the links in this section to find out more information about troubleshooting and how to get support.

- What initial checks can I make?

  Follow this link to get more in-depth advice on checks to make if you have problems with WebSphere Message Broker.
- How do I deal with problems?

  Use the links in this topic to find out about common problems that you might see when you use WebSphere Message Broker. Check to see if one of these problems match the symptoms you are observing.
- Where can I get more help with problems?

  View this topic for links to more techniques for diagnosing problems with WebSphere Message Broker, and links to information about getting support.

Samples

The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Use the samples to learn how to use WebSphere Message Broker.

- You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
- Not all samples work in all modes. If you try to use a sample in a mode that is restricted, you receive a message indicating the reason; see "Restrictions that apply in each operation mode" on page 3657. You can run all samples in a development and unit test broker; see "Development and unit test" on page 50.
- You might receive the following error:

  ```
  SEVERE: Could not find the connection files.
  ```

  If you receive this error, copy the `.broker` file for your default broker from the runtime workspace in which you created your default configuration to your current runtime workspace.
- To ensure that all available samples are displayed in the **Samples and Tutorials** tab in the WebSphere Message Broker Toolkit, in the "More samples" panel in the **Samples and Tutorials** tab click **Retrieve** and select the sample categories that you want to display.

The samples are categorized as either Application or Technology samples.

Application samples

The Application samples are small end-to-end WebSphere Message Broker message flow applications that show how to transform and route messages through message flows.

- Application samples

Technology samples

The Technology samples are small WebSphere Message Broker message flow applications that each show a specific feature of WebSphere Message Broker.

- Controlling and Routing samples
- File Processing samples
- Industry samples
- Message Formats samples
- Message Transformation samples
- Monitoring samples
- Security samples
- Transports and Connectivity samples
- Web Service samples

Before you can use the samples you must create the Default Configuration, see "Creating the Default Configuration" on page 106.

The following table lists the Application samples that are available in WebSphere Message Broker.

Sample name	Description
Airline Reservations	This sample shows how to use a range of nodes, including nodes for aggregation, routing, tracing, filtering, and updating database tables.
Coordinated Request Reply	This sample shows how two applications with different message formats communicate with each other through the use of WebSphere MQ messages in a request-reply processing pattern, coordinated by the use of an MQGet node.
DatabaseInput Node	This sample demonstrates how to take data from a database, as it is being updated, and process the data within WebSphere Message Broker.
Data Warehouse	This sample contains a message flow that archives data, such as sales data, to a database.
Error Handler	This sample contains a message flow and a subflow to show error handling in message flow applications.
Large Messaging	This sample shows how to process messages that contain repeating structures, and how to minimize the virtual storage requirements for the message flow.
Message Routing	This sample shows how to use a message flow to route messages to different WebSphere MQ queues based on data stored in a database table or a file.
Pager	This sample shows simple point-to-point messaging and publish/subscribe messaging. Use graphical interfaces to send text messages to a pager application, or to subscribe to publications about the surf on selected beaches.
Scribble	This sample is a small, graphical whiteboard application on which you draw by using your mouse pointer. Depending on the options you choose, you can see the effects of message transformation by using WebSphere MQ transport or RealTime transport.

Sample name	Description
Solar Pattern Authoring	This sample shows how to build a WebSphere Message Broker pattern. The sample provides an example message flow project that calculates the sunrise and sunset times in a PHPCompute node. The sample also provides a pattern authoring project that configures a pattern.
User-defined Extension	These two samples show the use of user-defined nodes written in the C and Java programming languages.
Video Rental	This sample shows message transformation between three different formats: XML, Custom Wire Format (CWF), and Tagged/Delimited String (TDS) Format.
WBI JDBC Adapter Migration	This sample re-creates a scenario of migrating a JDBC adapter to invoke a message flow, by using an MQInput node with the built-in DatabaseInput node.
Web Service Aggregation	This sample demonstrates how to invoke a number of web services and amalgamate the results by using WebSphere Message Broker aggregation nodes. The sample illustrates how aggregation can be used for transports other than WebSphere MQ, and highlights issues to be aware of. The sample also shows how you can use message flow monitoring to audit data across the aggregation fan-out and fan-in by using Collector node techniques.

The following tables list the Technology samples that are available in WebSphere Message Broker.

Control and Routing samples

Sample name	Description
Aggregation	This sample shows how to use the Aggregation nodes to perform a basic four-way aggregation operation, with simple fan-out and fan-in message flows.
Collector Node	This sample shows how to configure the Collector node to gather input from different input sources. It also shows some alternative methods for completing collections.
Simplified Database Routing	This sample shows how to use the following range of simplified (non-programming) message flow nodes: Route, DatabaseRoute, and DatabaseRetrieve. The sample illustrates how to access databases by using JDBC, and how to use values held in an acquired result set, gathered from a database query, to either dynamically route messages or update the content of the messages.
Timeout Processing	This sample shows how to use the timeout nodes to add timeouts to message flows.

File Processing samples

Sample name	Description
Batch Processing	This sample shows how to use the FileInput and FileOutput nodes to read different input files and append them to one output file. It also shows you how to read a file "as is" from one local input directory and write the file to a different local output directory.
File Output	This sample shows how a FileOutput node can write a message to a file during a message flow. The sample shows a flow updating a SOAP message, the FileOutput node writing this updated message to a file, and the message being sent back to the sender by using HTTP as the transport mechanism.
Managed File Transfer	This sample shows how the FTEOutput node writes a message to a file by using WebSphere MQ File Transfer Edition to manage the transfer of the file. The sample shows a Retail HQ to Branch product provisioning scenario. The flow receives a stream of WebSphere MQ messages with product data, and a file is created with an FTEOutput node. The built-in FTEAgent operates with the FTEOutput node to manage the transfer of the file to a remote location.
WildcardMatch	This sample shows how to access the LocalEnvironment.Wildcard.WildcardMatch variable set in the FileInput node. The sample then gives an example of how, by using this variable, you can dynamically override the output file name and directory properties set in the FileOutput node.

Industry samples

Sample name	Description
Healthcare	This sample is a development accelerator, decreasing the time an integration developer within the healthcare industry requires to deliver integration solutions. This sample provides a number of Healthcare assets that solve key healthcare-specific integration problems.
TLOG Processor	This sample is a set of customized message sets, subflows, message flows, and style sheets that process transaction log (TLOG) data from retail stores. These samples provide sample TLOG input messages that are generated by various IBM Retail applications to test the TLOG message flows. Customers and service teams can customize or extend the TLOG Processor samples by modifying the message sets and flows, or by recombining these components in alternative ways.

Message Formats samples

Sample name	Description
Comma Separated Value (CSV)	This sample shows how to model common CSV message variants, and how to transform the sample CSV messages to and from XML.
EDIFACT	This sample shows an industry-standard message set for Edifact messages.

Sample name	Description
FIX	This sample shows an industry-standard message set for Fix messages.
SWIFT	This sample shows an industry-standard message set for Swift messages.
X12	This sample shows an industry-standard message set for X12 messages.
XMLNSC Namespaces	This sample shows how to change the existing namespace of a message, remove a namespace from a message, and add a namespace to a message.
XMLNSC Validation	This sample shows the capability of the XMLNSC parser to validate messages against an XML schema.

Message Transformation samples

Sample name	Description
JavaCompute Node	This sample shows how to use the JavaCompute node to perform tasks such as calling an external service and propagating a new message based on the results of the call.
Message Map	This sample shows how to author message maps in the WebSphere Message Broker Toolkit.
PHPCompute Node	This sample shows how to use the PHPCompute node in a message flow to transform an XML message.
XSL Transform	This sample shows how to use a message flow to transform an XML message to another form of XML message according to the rules provided by an XSL stylesheet.

Monitoring samples

Sample name	Description
WebSphere Business Monitor	This sample provides resources to help you use the monitoring events produced by your message flows for business process modeling by using WebSphere Business Monitor.

Security samples

Sample name	Description
Security Identity Propagation	This sample shows how to use Identity Security features to extract the security credentials from the messages on the MQInput and HTTPInput nodes. So that the sample can run stand-alone, the sample does not include security validation with an external security provider system, such as LDAP or TFIM. The sample also shows how to manipulate the security credentials by using ESQL, then how to propagate the identity to the MQOutput and HTTPRequest nodes.
Security Policy Enforcement Point (PEP)	This sample demonstrates how to use the SecurityPEP node as the Policy Enforcement Point in a message flow.

Transports and Connectivity samples

Sample name	Description
Browsing WebSphere MQ Queues	This sample shows how a message flow can browse WebSphere MQ messages that are in a queue, therefore retrieving the messages non-destructively. This sample also shows how to examine the contents of the browsed message to determine whether to get the message. Getting the message is a destructive process that removes the message from the queue.
CICS Transaction Server for z/OS Connectivity	This sample is based on a scenario in which a business wants to retrieve a record from a file resource on CICS Transaction Server for z/OS. The sample demonstrates how to use the CICSRequest node. With this node, you can run CICS applications, and retrieve data from CICS regions.
CICS Transaction Server for z/OS Channel Connectivity	This sample demonstrates how to call a channel-based CICS program. A CICS channel structure can be represented in WebSphere Message Broker by a message collection. This sample demonstrates how to create and populate a message collection for the CICSRequest node and how to process the collection after the call.
CORBA nodes	This sample is based on a product warehouse scenario where a stock administrator wants to manage a stock control management system hosted on a CORBA server. The sample demonstrates how to use the CORBARequest node to invoke CORBA server applications.
Email	This sample consists of three message flow applications that show the use of sending and receiving emails. The emailform message flow provides an HTML input form to construct and submit an email message. The sendemail message flow receives the message and processes all the details that are associated with the email message. The recipients specified on the form receive the message as an email in the appropriate format, with any attachments. The getemail message flow processes the email that is sent and filters the email either to a WebSphere MQ queue, or saves the attachment to a file by using the FileOutput node.
HTTPHeader node	This sample consists of three message flows that show the different ways in which you can use an HTTPHeader node. The three message flows are: • Single WebService in MQ flow sample. This sample message flow shows how to create an interface between a WebSphere MQ application and web-based applications by using the HTTPHeader and MQHeader nodes. • Multiple WebService requests sample. This sample shows how to create and reset HTTP headers by using the HTTPHeader node. • Set Cookie HTTP reply sample. This sample shows how to add an HTTPReply header by using the HTTPHeader node in a request-reply session.

Sample name	Description
IMS Synchronous Request	This sample shows how to call an IBM Information Management System (IMS) transaction synchronously from within a message flow. The sample uses the IMSRequest node to make the synchronous calls by using IMS Connect. This sample uses the IMS sample transaction DSPALLI (Display All Invoices), which is typically available on all IMS systems. The DSPALLI transaction can call a REXX or COBOL program, although REXX is the default that is typically installed on IMS.
JD Edwards Connectivity	This sample consists of a message flow application that demonstrates the use of the JDEdwardsRequest node. This sample message flow uses the JD Edwards business function call "retrieve" to fetch a record from a JD Edwards EnterpriseOne server. The record is then put on a WebSphere MQ queue.
JMS Nodes	This sample shows how to use the JMS nodes as a JMS Consumer and Producer to an external JMS provider.
JMSHeader node	This sample shows how to use the JMSHeader node in a JMS coordinated request-reply scenario.
MQHeader node	This message flow sample shows how to use the MQHeader node to add and remove an MQMD header.
SAP callout to a synchronous system	This sample consists of a single message flow application that demonstrates the use of the SAPInput node with the SAPReply node to enable a message flow to act as a synchronous BAPI. The message flow is used to service requests for four different BAPIs that create, update, retrieve, and delete customer details.
SAP callout to an asynchronous system	This sample consists of three message flow applications that demonstrate the use of the SAPInput node with the SAPReply node to enable a message flow to act as a synchronous BAPI that wraps an asynchronous application. The message flows are used to service requests for four different BAPIs that create, update, retrieve, and delete customer details.
SAP Connectivity	This sample consists of two message flow applications that show the use of the SAPInput node and the SAPRequest node. The SAPInput node scenario shows how to use a message flow to receive IDocs from the SAP Material Master, then send the data to a WebSphere MQ output queue for processing by another message flow or application. The SAPRequest node scenario shows how to use a message flow to create a customer in SAP, then update and retrieve the customer details.

Sample name	Description
SCA nodes	This sample shows how to use the SCAInput, SCAReply, SCAAsyncRequest, and SCAAsyncResponse nodes to exchange message requests and responses with a business process in WebSphere Process Server. The sample re-creates a scenario in which a savings account is linked to a current account, and money can be transferred between the two accounts. In the outbound scenario, WebSphere Message Broker passes money transfer requests to WebSphere Process Server, which hosts the savings account. This sample can be extended to include an inbound scenario where WebSphere Process Server passes requests onto WebSphere Message Broker, which hosts the current account.
TCPIP Client Nodes	This sample consists of three message flows that show both synchronous and asynchronous communication from the WebSphere Message Broker to a TCP/IP server. It also includes a simple message flow to simulate the TCP/IP server.
TCPIP Handshake	This sample shows how to implement an application-level handshake protocol for a synchronous request reply model of communication between a client and a server. The sample also includes two other message flows to emulate the client and server applications. You can replace these applications by external applications which use the same interfaces.
Twineball Example EIS Adapter	This sample shows how to use the WebSphere Adapter nodes by using the Twineball adapter, a self contained EIS, to synchronize a C system with an EIS.

Web Service samples

Sample name	Description
Address Book	This sample shows how to use the SOAPInput, SOAPReply, and SOAPRequest nodes to provide and consume a web service. Two sets of example input messages are provided: one set to call the consumer flow which in turn calls the provider flow, and one set to call the provider flow directly. This sample can also be extended to show how to set up WS-Security for existing message flows for both a provider and a consumer.
Asynchronous Consumer	This sample shows how to use the asynchronous SOAP nodes when you call a web service. The web service simulates an order service, and the client shows how existing WebSphere MQ interfaces can be extended to make web service requests.

Sample name	Description
RESTful Web Service Using JSON	This sample shows how to front an existing service as a RESTful web service providing a JSON message format interface. The sample also shows how to consume the RESTful web service from a message flow.
SOAP Nodes	This sample shows the use of SOAP nodes to both provide and consume a web service.
Web services using HTTP nodes	This sample shows how to use WebSphere Message Broker to front an existing application as a web service.
Web Services Gateway	This sample demonstrates how to use the SOAP nodes in a Web Services Gateway mode, which allows WebSphere Message Broker to handle generic SOAP request/response and one-way messages when used as a web services provider or consumer.
WebSphere Service Registry and Repository Connectivity	This sample shows how to retrieve documents by using the WebSphere Service Registry and Repository nodes. You can use these nodes to query Service Registry information, and to use this information at run time. You can also use these nodes to acquire WSDL or other generic descriptions of available services.

Related tasks:

"Creating the Default Configuration"
You can create the Default Configuration of WebSphere Message Broker by using the Default Configuration wizard. You can also remove the Default Configuration by using the link provided.

"Resolving problems when running samples" on page 3366
Use the advice given here to help you to resolve common problems that can arise when you run or remove samples.

Related reference:

"What the Default Configuration wizard creates" on page 107
A table of the components that are created by the wizard, details of how to resolve problems, and how to view errors.

Creating the Default Configuration

You can create the Default Configuration of WebSphere Message Broker by using the Default Configuration wizard. You can also remove the Default Configuration by using the link provided.

About this task

The Default Configuration wizard creates all the components that you need to import and deploy the WebSphere Message Broker samples, and to build your own samples. For more information about the Default Configuration wizard and the authorities your user account must have to successfully create the Default Configuration, see "What the Default Configuration wizard creates" on page 107.

You can use the following links only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Procedure

Click the following link to start the Default Configuration wizard:

- Start the Default Configuration wizard

What to do next

When you have finished using the Default Configuration, you can remove it by clicking the following link:

- Remove the Default Configuration wizard

Related concepts:

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Creating a default configuration" on page 564
Use the Default Configuration wizard to create and test a basic broker configuration.

Related reference:

"What the Default Configuration wizard creates"
A table of the components that are created by the wizard, details of how to resolve problems, and how to view errors.

What the Default Configuration wizard creates

A table of the components that are created by the wizard, details of how to resolve problems, and how to view errors.

Purpose

The components that are created by the Default Configuration wizard are listed in the following table.

Component	Name
broker	MB7BROKER
queue manager	MB7QMGR

- WebSphere Message Broker automatically scans for a free queue manager port starting at 2414.
- The HTTP listener port that is automatically used is 7080.

Target environment of the wizard

The target environment contains the default components that are created by the Default Configuration wizard.

```
Target Environment of Wizard
------------------------------------------------
Summarized resource updates listed below will be
applied to installation
[C:\Program Files\IBM\MQSI\7.0]
```

```
All actions are logged to file
[DefaultConfigurationWizard.log]
in the workspace directory
[C:\Documents and Settings\Administrator\IBM\wmbt70\
workspace\.metadata]

All actions are applied under account:
LocalSystem
Queue manager name: MB7QMGR
Queue manager port: 2414

Default broker details
Broker name: MB7BROKER
Queue manager name: MB7QMGR

HTTP listener port: 7080
```

Resolving problems when creating and running the Default Configuration

If you have problems when you run the Default Configuration wizard, consider whether the following issues apply to you:

- If you have any existing brokers that are using the default HTTP listener port of 7080, you must ensure that the existing brokers are stopped before you create and deploy to the Default Configuration. If a sample does not run as you expect, check the Event Log for errors such as BIP3144:

  ```
  BIP3144
  (MB8BROKER.HTTPListener) An error has occurred during HTTP
  listener startup:
  the specified TCPIP port ('7080') is already in use.

  The HTTP listener needs to bind to a TCPIP port for correct
  operation to be possible.
  The broker-specific TCPIP port number '7080' is in use by
  another application.

  Stop other applications from using the specified port,
  or change the broker-specific port.
  ```

- Linux On Linux: Ensure that your user account belongs to the mqbrkrs group.

Viewing errors

To view errors generated by the Default Configuration wizard look at the `DefaultConfigurationWizard.log` file:

- Windows On Windows: This file is, by default, in `C:\Documents and settings\`*`user_name`*`\IBM\wmbt70\workspace\.metadata\DefaultConfigurationWizard.log`
- Linux On Linux: This file is, by default, in `/home/`*`user_name`*`/IBM/wmbt70/workspace/.metadata/DefaultConfigurationWizard.log`

To view Eclipse errors that are caused by the Default Configuration wizard look at the Eclipse Error log, see “Viewing the Eclipse error log” on page 3532. The Error Log view opens in the perspective in which you are currently working.

Related concepts:

"Samples" on page 98
The WebSphere Message Broker Toolkit provides samples that show the features that are available in WebSphere Message Broker, and how to use them. This topic provides links to the information about the individual samples.

Related tasks:

"Creating a default configuration" on page 564
Use the Default Configuration wizard to create and test a basic broker configuration.

"Creating the Default Configuration" on page 106
You can create the Default Configuration of WebSphere Message Broker by using the Default Configuration wizard. You can also remove the Default Configuration by using the link provided.

"Viewing the Eclipse error log" on page 3532
The Eclipse error log captures internal errors that are caused by the operating system or your code.

Legal information for WebSphere Message Broker

- Trademarks

This information center provides links or references to non-IBM Web sites and resources. IBM makes no representations, warranties, or other commitments whatsoever about any non-IBM Web sites or third-party resources (including any Lenovo Web site) that may be referenced, accessible from, or linked to any IBM site. A link to a non-IBM Web site does not mean that IBM endorses the content or use of such Web site or its owner. In addition, IBM is not a party to or responsible for any transactions you may enter into with third parties, even if you learn of such parties (or use a link to such parties) from an IBM site. Accordingly, you acknowledge and agree that IBM is not responsible for the availability of such external sites or resources, and is not responsible or liable for any content, services, products, or other materials on or available from those sites or resources. When you access a non-IBM Web site, even one that may contain the IBM-logo, be aware that it is independent from IBM, and that IBM does not control the content on that Web site. It is up to you to take precautions to protect yourself from viruses, worms, trojan horses, and other potentially destructive programs, and to protect your information as you deem appropriate.

Notices for WebSphere Message Broker

Read the legal notices for WebSphere Message Broker.

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this information in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this information. The furnishing of this information does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Programming License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information includes examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

Privacy policy considerations

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is described below.

For WebSphere Message Broker, the Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at http://www.ibm.com/privacy and IBM's Online Privacy Statement at http://www.ibm.com/privacy/details/us/en

sections entitled "Cookies, Web Beacons and Other Technologies" and "Software Products and Software-as-a Service".

COPYRIGHT LICENSE

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

Glossary of terms and abbreviations

This glossary defines WebSphere Message Broker terms and abbreviations that are used in this online information center.

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

A

active working set
The logical collection of application projects that is currently displayed in the Broker Application Development perspective. See also working set.

adapter
An intermediary software component that allows two other software components to communicate with one another.

Administration API (CMP)
An application programming interface that your applications can use to control brokers through a remote interface. For continuity and consistency, this API is referred to as the CMP, its name in previous versions.

aggregation
See message element aggregation.

AMI See Application Messaging Interface.

Application Messaging Interface (AMI)
The programming interface, provided by WebSphere MQ, that defines a high-level interface to message queuing services. See also Message Queue Interface (MQI) and Java Message Service (JMS). Applications that use the AMI connect to the broker using WebSphere MQ Enterprise Transport.

attribute
A characteristic or trait of an entity that describes the entity; for example, the telephone number of an employee is one of the employee attributes.

An attribute may have a type, which indicates the range of information given by the attribute, and a value, which is within that range. In XML, for example, an attribute consists of a name-value pair within a tagged element, that modifies features of the element.

attribute group
A set of attributes that can appear in a complex type.

TOP

B

BAR file
See broker archive file.

bend point
A point that is introduced in a connection between two message flow nodes at which the line that represents the connection changes direction. A bend point can be used to make node alignment and processing logic clearer and more effectively displayed.

binary large object (BLOB)
A block of bytes of data (for example, the body of a message) that has no discernible meaning, but is treated as one entity that cannot be interpreted.

BLOB See binary large object.

BLOB domain
The message domain that includes all messages with content that cannot be interpreted or subdivided into smaller sections of information. Messages in this domain are processed by the BLOB parser. See also DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

BLOB parser
A program that interprets a message that belongs to the BLOB domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output.

broker
A set of execution processes that host one or more message flows. Also known as a message broker.

broker archive file
The unit of deployment to the broker; also known as a BAR file. The broker archive file contains a number of different files, including compiled message flows (`.cmf`) and message sets (`.dictionary` and `.xsdzip` files), that are used by the broker at run time. It can also contain additional user-provided files that your message flows might need at run time, if the file extension does not overlap with extensions that are used by the broker.

broker schema
A symbol space that defines the scope of uniqueness of the names of resources that are defined within it. The resources include message flows, ESQL files, and mapping files.

built-in node
A message flow node that is supplied by the product. Some of the supplied nodes provide basic processing such as input and output.

built-in pattern
A pattern that covers a set of commonly encountered message flow scenarios and that is packaged and released with WebSphere Message Broker.

business component
This term is specific to the WebSphere Adapters. A component that defines the structure, behavior, and information that is displayed by a particular subject, such as a product, contact, or account, in Siebel Business Applications.

business graph
This term is specific to the WebSphere Adapters. A wrapper that is added around a simple business object or a hierarchy of business objects to provide additional capabilities. For example, a wrapper might carry change summary and event summary information related to the business objects in the business graph. See also business object.

business object
A software entity that represents a business entity, such as an invoice. A business object includes persistent and nonpersistent attributes, actions that can be performed on the business object, and rules that the business object is governed by. See also business graph.

TOP

C

callback function
See implementation function.

cardinality
See mapping cardinality.

certificate authority
A trusted third-party organization or company that issues the digital certificates. The certificate authority typically verifies the identity of the individuals who are granted the unique certificate.

cmf See compiled message flow.

compiled message flow (cmf)
A message flow that has been compiled to prepare it for deployment to the broker. A `cmf` file is sent to the broker within a BAR file.

complex element
A named structure that contains simple elements within the message. Complex elements can contain other complex elements, and can also contain groups. The content of a complex element is defined by a complex type. See also simple element.

complex type
A type that can contain elements, attributes, and groups organized into a hierarchy.

A complex type structure within a message contains elements, attributes, and groups organized into a hierarchy. See also simple type.

component
A set of processes that perform a specific set of functions. WebSphere Message Broker consists of two components, the broker and the WebSphere Message Broker Toolkit.

component directory
In z/OS, the root directory of the component's runtime environment.

component name
The external name of a component. Each component requires a name, which is used, for example, in the WebSphere Message Broker Toolkit and in commands.

component PDSE
In a z/OS environment, a PDSE that contains jobs to define resources to WebSphere MQ, DB2, and the broker started task. See partitioned data set.

connection
See message flow node connection. For broker-to-broker connections, see publish/subscribe topology.

connection factory
A set of configuration values that produces connections that enable a Java EE component to access a resource. Connection factories provide on-demand connections from an application to an enterprise information system (EIS).

content-based filter
In publish/subscribe, an expression that is included as part of a subscription to determine whether a publication message is received based on its content. The expression can include wildcards.

Custom Wire Format (CWF)
The physical representation of a message in the MRM domain that is composed of a number of fixed-format data structures or elements. In CWF, these structures are not separated by delimiter characters.

CWF See Custom Wire Format.

TOP

D

data element separation
For a complex type, defines to the MRM parser TDS physical format which method of identifying data elements is to be used, and how the data elements are constructed. The following separation types are supported: data pattern separation, delimited separation, fixed-length separation, and tagged separation

DataFlowEngine (DFE)
See execution group.

datagram
A form of asynchronous messaging in which an application sends a message, but does not want a response. Also known as send-and-forget. Contrast with request/reply.

DataObject domain
The message domain that includes all messages that are exchanged between the broker and enterprise information system applications such as SAP, PeopleSoft, and Siebel. Messages in this domain are processed by the DataObject parser. You must create a message model for messages that you process in this domain. See also BLOB domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

DataObject parser
A program that interprets a message that belongs to the DataObject domain, and generates the corresponding tree from the business object on input, or the business object from the tree on output.

debugger
See flow debugger.

deploy
To place files or install software into an operational environment.

The process of transferring data to an execution group on a broker.

For deploying message flows and associated resources, the data is packaged in a broker archive (BAR) file before being sent to the broker, which unpacks and stores the data.

destination list
See local environment.

digital certificate
An electronic document used to identify an individual, a system, a server, a company, or some other entity, and to associate a public key with the entity. A digital certificate is issued by a certificate authority and is digitally signed by that authority.

digital signature
Information that is encrypted with a private key and is appended to a message or object to assure the recipient of the authenticity and integrity of the message or object. The digital signature proves that the message or object was signed by the entity that owns, or has access to, the private key or shared-secret symmetric key.

distribution list
A list of WebSphere MQ queues to which a message can be put with a single statement.

document type definition (DTD)
The rules that specify the structure for a particular class of SGML or XML documents. The DTD defines the structure with elements, attributes, and notations, and it establishes constraints for how each item can be used within the particular class of documents. A DTD is analogous to a database schema in that the DTD completely describes the structure for a particular markup language.

DOM See Document Object Model.

DTD See document type definition.

TOP

E

editor area
The area in the WebSphere Message Broker Toolkit where files are opened for editing.

EIS See Enterprise Information System.

element
A named piece of information, or a field, within a message, with a business meaning agreed by the applications that create and process the message. See also simple element and complex element.

embedded message
See multipart message.

EMD See Enterprise Metadata Discovery.

endpoint
A JCA application or other client consumer of an event from the enterprise information system.

Enterprise Information System (EIS)
The applications that comprise an existing enterprise system for handling company-wide information. An enterprise information system offers a well-defined set of services that are exposed as local or remote interfaces or both. (Sun)

Enterprise Metadata Discovery (EMD)
A specification that defines how you can examine an Enterprise Information System (EIS) and get details of business object data structures and APIs. An EMD stores the definitions as XML schemas by default, and builds components that can access the EIS.

environment
A structure within the message tree that is user-defined and can contain variable information that is associated with a message while it is being processed by a message flow.

ESM See external security manager.

ESQL See Extended SQL.

ESQL data type
A characteristic of an item of data that determines how that data is processed. ESQL supports six data types (Boolean, datetime, null, numeric, reference, and string). Data that is retrieved from a database or is defined in a message model is mapped to one of these basic ESQL types when it is processed in ESQL expressions.

ESQL field reference
A sequence of values, separated by periods, that identify a specific field (which might be a structure) within a message tree or a database table. An example of a field reference is `Body.Invoice.InvoiceNo`.

ESQL function
A single ESQL expression that calculates a resultant value from a number of specified input values. The function can take input parameters but has no output parameters; it returns to the caller the value that results from the implementation of the expression. The ESQL expression can be a compound expression such as BEGIN END.

ESQL module
A sequence of declarations that define MODULE-scope variables and their initialization, and a sequence of subroutine (function and procedure) declarations that define a specific behavior for a message flow node. A module must begin with the `CREATE node_type MODULE` statement and end with an `END MODULE` statement. The `node_type` must be one of Compute, Database, or Filter. The entry point of the ESQL code is the module scope procedure named MAIN.

ESQL procedure
A subroutine that has no return value. It can accept input parameters from and return output parameters to the caller.

ESQL variable
A local temporary field that is used to assist in the processing of a message.

event A change to a state, such as the completion or failure of an operation, business process, or human task, that can trigger a subsequent action, such as persisting the event data to a data repository or invoking another business process.

event store
A persistent cache where event records are saved until a polling adapter can process them.

exception list
A list of exceptions, with supporting information, that has been generated during the processing of a message.

execution group
A named grouping of message flows that have been assigned to a broker.

The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they execute in separate address spaces, or as unique processes.

An execution group process is also known as a DataFlowEngine (DFE). This term is typically used in problem determination scenarios; for example, trace contents or diagnostic messages). A DFE is created as an operating system process, and has a one-to-one relationship with the named execution group. If more than one message flow runs within an execution group, multiple threads are created within the DFE process.

exemplar
A project that contributes most of its content to a pattern. An exemplar contains message flows and other resources, such as source code.

Extended SQL (ESQL)
A specialized set of SQL functions and statements that are based on regular SQL, and extended with functions and statements that are unique to WebSphere Message Broker.

Extensible Markup Language (XML)
A standard metalanguage for defining markup languages that is based on Standard Generalized Markup Language (SGML).

Extensible Stylesheet Language (XSL)
A language for specifying style sheets for XML documents. Extensible Stylesheet Language Transformation (XSLT) is used with XSL to describe how an XML document is transformed into another document.

External Security Manager (ESM)
In a z/OS environment, a security product that performs security checking on users and resources. RACF is an example of an ESM.

TOP

F

field reference
See ESQL field reference.

file splitting
The division of an event file, based on a delimiter or based on size, to separate individual business objects within the file and send them as if they are each an event file to reduce memory requirements.

filter An ESQL expression that is applied to the content of a message to determine whether the message matches certain criteria.

For example, a Filter node uses a filter to determine how a message is to be processed. Alternatively, a filter is applied to the content of a publication message to determine whether it is to be passed to a subscriber.

flow debugger
A facility to debug message flows that is provided in the Debug perspective in the WebSphere Message Broker Toolkit.

TOP

G

graphical user interface (GUI)
A type of computer interface that presents a visual metaphor of a real-world scene, often of a desktop. A GUI combines high-resolution graphics, pointing devices, menu bars and other menus, overlapping windows, icons, and the object-action relationship.

GUI See graphical user interface.

TOP

I

IBM Runtime Environment for Java
A subset of the IBM Developer Kit for the Java Platform that contains the core executable files and other files that constitute the standard Java platform. The IBM Runtime Environment includes the Java virtual machine (JVM), core classes, and supporting files.

IBM Software Developer Kit for Java
A software package that can be used to write, compile, debug, and run Java applets and applications.

IDOC domain
The message domain that includes all messages that are exchanged between the broker and SAP R3 clients by the MQSeries® link for R/3. Messages in this domain are processed by the IDOC parser. See also BLOB domain, DataObject domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

The IDOC domain is deprecated; use the MRM domain for new messages.

IDOC parser
A program that interprets a message that belongs to the IDOC domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output.

implementation function
A function written for a user-defined node or message parser; also known as a callback function.

inbound processing
The process by which changes to business information in an enterprise information system (EIS) are detected, processed, and delivered to a runtime environment by a JCA Adapter. An adapter can detect EIS changes by polling an event table or by using an event listener.

input node
A message flow node that represents a source of messages for a message flow or subflow. See also output node.

installation directory
In a z/OS environment, a file system into which all product data is installed, and from which it is referenced and retrieved during the customization phase.

TOP

J

J2EE See Java 2 platform, Enterprise Edition.

Java 2 Platform, Enterprise Edition (J2EE)
An environment for developing and deploying enterprise applications, defined by Sun Microsystems Inc. The Java EE platform consists of a set of services, application programming interfaces (APIs), and protocols that provide the functionality for developing multi-tiered, Web-based applications. (Sun)

Java Database Connectivity (JDBC)
An industry standard for database-independent connectivity between the Java platform and a wide range of databases. The JDBC interface provides a call-level API for SQL-based and XQuery-based database access. See also Open Database Connectivity.

Java EE Connector Architecture (JCA)
A standard architecture for connecting the J2EE platform to heterogeneous enterprise information systems (EIS).

Java Message Service (JMS)
An application programming interface that provides Java language functions for handling messages. See also Application Messaging Interface (AMI) and Message Queue Interface (MQI).

Java virtual machine (JVM)
A software implementation of a processor that runs compiled Java code (applets and applications).

JCA See Java EE Connector Architecture.

JCL See Job Control Language

JDBC See Java Database Connectivity.

JMS See Java Message Service.

JMS domain
The message domain that includes all messages that are produced by the WebSphere MQ implementation of the Java Message Service standard. These messages, which have a message type of either JMSMap or JMSStream, are supported in the same way as messages in the XML domain, and are parsed by the XML parser. See also BLOB domain, DataObject domain, IDOC domain, MIME domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

Job Control Language (JCL)
Job Control Language (JCL) comprises a set of Job Control Statements that are used to define work requests called jobs. JCL tells the operating system what program to run, and defines its inputs and outputs.

TOP

K

keystore
In security, a storage object, either a file or a hardware cryptographic card, where identities and private keys are stored, for authentication and encryption purposes. Some keystores also contain trusted, or public, keys.

TOP

L

LIL See loadable implementation library.

loadable implementation library (LIL)
The implementation module for a node or parser written in C. This library file is implemented in the same way as a dynamic link library, but has a file extension of `.lil` not `.dll`.

local environment
A structure within the message tree that contains broker and, optionally, user information associated with a message while it is being processed by a message flow.

In previous releases, the local environment structure was known as the Destination list; the latter term is retained for compatibility.

local error log
A generic term that refers to the logs to which WebSphere Message Broker writes records on the local system. Also known as the system log.

TOP

M

map (1) A complete transformation that has source objects that define the structure of the inputs and target objects that define the structure of the outputs. A map is represented as a `.msgmap` file.

(2) To associate a source to a target in a message map.

mapping
A target value expression.

mapping cardinality
The granularity of the way in which message elements are mapped from message source to message target. For example:

- One-to-one: associates a single source with a single target
- One-sided: associates a value with a target
- Many-to-one: associates multiple sources with a single target

message
Data that is passed from one application to another. Each message must have a structure and format that is compatible with both the sending and receiving applications.

message broker
See broker.

message category
An optional grouping of messages that are related in some way. For example, messages that relate to a particular application might be included in a single category.

message definition
An annotated XML Schema model of a message format. A message definition is a structured collection of elements, types, and groups.

message definition file
A file in a message set that contains one or more message definitions.

message dictionary
A data structure that describes all the messages in a message set in a form suitable for use by the MRM parser.

message domain
A grouping of messages that share certain characteristics. A message domain has an associated parser that interprets messages that are received and generated by a broker. WebSphere Message Broker supports messages in the BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain. You can create additional parsers known as user-defined parsers to support messages that do not conform to the supported domains.

message element aggregation
A mapping in which all the repeatable elements in one instance are mapped to another instance. It is not possible to map the repeatable elements themselves, only the instances. This aggregation is useful when mapping all possible inputs to one or more outputs, and can be used for copying an array, or for assigning a scalar, such as a summation. Use message element aggregation when the following conditions are met:
- A single source and target are selected.
- Source and target are of simple numeric type.
- The source repeats.

message flow
A sequence of processing steps that run in the broker when an input message is received. A message flow is created in the WebSphere Message Broker Toolkit by including a number of message flow nodes that each represents a set of actions that define a processing step. The connections in the flow determine which processing steps are carried out, in which order, and under which conditions. A message flow must include an input node that provides the source of the messages that are processed. Message flows are then ready to deploy to a broker for execution. See also subflow.

message flow node
A processing step in a message flow, also called a message processing node. A message flow node can be a built-in node, a user-defined node, or a subflow node.

message flow node connection
An entity that connects an output terminal of one message flow node to an input terminal of another. A message flow node connection represents the flow of control and data between two message flow nodes.

message format
The definition of the internal structure of a message, in terms of the fields and the order of those fields. When a message format is self-defining, the message is interpreted dynamically when it is read.

message group
A list of elements with information about how those elements can appear in a message. Message groups can be ordered, unordered, or selective.

message model
See message definition.

message parser
A program that interprets an incoming message and creates an internal representation of the message in a tree structure, and that regenerates a bit stream for an outgoing message from the internal representation.

message processing node
See message flow node.

Message Queue Interface (MQI)
The programming interface that is provided by WebSphere MQ queue managers. Application programs use the programming interface to access message queuing services. See also Application Messaging Interface (AMI) and Java Message Service (JMS). Applications that use the MQI, connect to the broker using WebSphere MQ Enterprise Transport.

message set
A folder in a message set project that contains one or more message definition files. It can be deployed to a broker in a broker archive file.

message set project
The eclipse container for a message set.

message template
A means of identifying a message format within the broker. It consists of four parts: message domain, message set, message type, and physical format.

message tree
The logical tree structure that represents the content and structure of a message in the broker. The message tree is created by a message parser from the input message received by a message flow, according to a message template.

message type
The name given to a message definition in a message definition file.

metadata
The data that describes the characteristic of stored data.

metadata tree
A list in a tree structure that presents all the objects discovered from the enterprise information system (EIS) by the enterprise service discovery process. These objects can be selected from the tree to generate a business object.

MIME See Multipurpose Internet Mail Extensions.

MIME domain
The message domain that includes all messages that conform to the MIME standard. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MRM domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

MIME parser
A program that interprets a message that belongs to the MIME domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output.

MQI See Message Queue Interface.

MQRFH
An architected message header that is used to provide metadata for the processing of a message. This header is supported by the WebSphere MQ (MQSeries) Publish/Subscribe SupportPac.

MQRFH2
An extended version of MQRFH, providing enhanced function in message processing.

MRM domain
The message domain that can parse, and write, a wide variety of message

formats. This domain is primarily intended for non-XML message formats, but it can also parse and write XML messages. Message models are created in the WebSphere Message Broker Toolkit, with one or more physical formats. Messages in the MRM domain are processed by the MRM parser. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, SOAP domain, XML domain, XMLNS domain, and XMLNSC domain.

MRM parser
A program that interprets a message that belongs to the MRM domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output. Its interpretation depends on the physical format that you have associated with the input or output message.

multilevel wildcard
A wildcard that can be specified in subscriptions to match any number of levels in a topic.

multipart message
A message that contains one or more other messages within its structure. The contained message is sometimes referred to as an embedded message.

Multipurpose Internet Mail Extensions
An Internet standard that defines different forms of data, including video, audio, or binary data, that can be attached to email without requiring translation into ASCII text.

TOP

N

namespace
In XML and XQuery, a uniform resource identifier (URI) that provides a unique name to associate with the element, attribute, and type definitions in an XML schema, or with the names of elements, attributes, types, functions, and errors in XQuery expressions.

XML instance documents, XML Schemas, and message definitions can use namespaces.

node (1) An endpoint or junction used in a message flow. See message flow node.

(2) Any element in a tree. See tree node.

TOP

O

ODBC
See Open Database Connectivity.

Open Database Connectivity (ODBC)
A standard application programming interface (API) for accessing data in both relational and non-relational database management systems. By using this API, database applications can access data stored in database management systems on various computers, even if each database management system uses a different data storage format and programming interface.

operation mode
A property of a broker that determines what operations it can perform.

outbound processing
The process by which a calling client application uses the adapter to update or retrieve data in an enterprise information system (EIS). The adapter uses operations such as create, update, delete, and retrieve to process the request.

output node
A message flow node that represents a point at which messages leave the message flow or subflow. See also input node.

TOP

P

package group
A group of one or more packages that are designed to work together and can be installed to one directory. In WebSphere Message Broker, this term refers to the group of products that are installed and maintained by Installation Manager, which includes the WebSphere Message Broker Toolkit. Products that are installed into a package group share common files and resources. You can create multiple package groups on a single computer.

parser See message parser.

partitioned data set (PDS, PDSE)
In a z/OS environment, a data set in direct-access storage that is divided into partitions, which are called members. A partitioned data set (extended) (PDSE) is an extension to a PDS that contains an indexed directory in addition to the members.

pattern
A reusable solution that encapsulates a tested approach to solving a common architecture, design, or deployment task in a particular context.

pattern archive
An archive file that contains all the installable pattern resources. The pattern archive can be distributed by using a pattern community site.

pattern author
The developer that creates a pattern to meet a business or technical requirement.

pattern authoring
The process of configuring one or more regular projects to turn them into a pattern.

pattern authoring project
A project that contains the information used to create a pattern.

pattern categories
Categories that are based on pattern classification and that structure the display in the Patterns Explorer view.

pattern community site
An application that supports uploading, browsing, searching, and downloading pattern archives. The application can be either a website or a shared file system directory.

pattern instance
The implementation of a pattern, consisting of a pattern instance project and one or more regular WebSphere Message Broker projects that implement the pattern. A pattern instance is generated by providing appropriate customization values to the parameters available in the pattern.

pattern instance project
A project that contains project references to all other projects in the workspace, relating to a specific pattern instance. A pattern instance project also contains a pattern instance configuration file that stores the pattern parameter values.

pattern parameter
A parameter that customizes and configures a pattern. For example, a queue name from which messages are read.

pattern user
A user who configures a pattern that the pattern author has created. The pattern is available to a pattern user in the Patterns Explorer view.

PDS, PDSE
See partitioned data set.

perspective
A group of views that show various aspects of the resources in the WebSphere Message Broker Toolkit. See also view.

physical format
The physical representation of a message within the bit stream. The supported physical formats are Custom Wire Format, XML Wire Format, and Tagged/Delimited String Format. Physical format information is used only by the MRM parser and the IDOC parser.

point-to-point
A style of messaging application in which the sending application knows the destination of the message. Contrast with publish/subscribe.

predefined element and message
An element or message for which a matching definition exists in the message model. See also self-defining element and message.

principal
An individual user ID (for example, a login ID) or a group. A group can contain individual user IDs and other groups, to the level of nesting that is supported by the underlying facility.

property
A characteristic of an object that describes the object. A property can be changed or modified. Properties can describe the name, type, value, or behavior of an object, and various other characteristics.

Resources that are created and maintained in the WebSphere Message Broker Toolkit and components have properties; for example, message flow nodes, deployed message flows, and brokers.

publication
In publish/subscribe messaging, a piece of information about a specified topic that is available to a queue manager, for delivery to subscribed applications.

publication node
An end point of a specific path through a message flow to which a client application subscribes, identified to the client by its subscription point.

publisher
An application that makes information about a specified topic available to a broker in a publish/subscribe system.

publish/subscribe
A style of messaging application in which the providers of information (publishers) are de-coupled from the consumers of that information (subscribers) using a broker. See also topic. Contrast with point-to-point messaging.

publish/subscribe topology
The brokers, and the connections between them, that support publish/subscribe applications.

TOP

Q

queue A WebSphere MQ object to which message queuing applications can put messages, and from which message queuing applications can get messages.

queue manager
A system program that provides queuing services to applications. A queue manager provides an application programming interface (the MQI) that enables programs to access messages on the queues that the queue manager owns.

TOP

R

request/reply
A type of messaging application in which a request message is used to request a reply from another application. Contrast with datagram.

Resource Recovery Services (RRS)
A z/OS facility that provides two-phase sync point support by participating resource managers.

retained publication
A published message that is kept at the broker for propagation to clients that subscribe in the future.

RRS See Resource Recovery Services.

TOP

S

SCADA
See Supervisory, Control, And Data Acquisition.

SCA See Service Component Architecture (SCA).

schema
See XML Schema.

self-defining element and message
An element or message for which no matching definition exists in a message model, but which can be parsed without reference to a model. For example, a message that is coded in XML can be self-defining. See also predefined element and message.

send-and-forget
See datagram.

Service Component Architecture (SCA)
An architecture in which all elements of a business transaction, such as access to Web services, Enterprise Information System (EIS) service assets, business rules, workflows, databases, and so on, are represented in a service-oriented way.

shared resources directory
The directory that contains software files or plug-ins that are shared by packages. In WebSphere Message Broker, this term refers to the directory that contains Eclipse plug-ins and features, and other common files and resources, that are used by all products on the computer that are installed and maintained by Installation Manager, which include the WebSphere Message Broker Toolkit. The contents of this directory are used by all products in all the package groups that are defined on the computer.

simple element
A field in a message that is based on a simple type. A simple element can repeat, and it can define a default or a fixed value. See also complex element.

simple type
A characteristic of a simple element that defines the type of data within a message (for example, string, integer, or float). A simple type can have value constraints which place limits on the values of any simple elements based on that simple type. See also complex type.

single-level wildcard
A wildcard that can be specified in subscriptions to match a single level in a topic.

SOAP A lightweight, XML-based protocol for exchanging information in a decentralized, distributed environment. SOAP can be used to query and return information and invoke services across the Internet.

SOAP domain
The message domain that includes all messages that conform to the SOAP standard. You must create a message model for messages that you process in this domain. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, XML domain, XMLNS domain, and XMLNSC domain.

SOAP parser
A program that interprets a message that belongs to the SOAP domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output. The bit stream is a representation of an XML file.

SQL See Structured Query Language.

SQLJ A Java extension that supports static Structured Query Language statements embedded within Java code.

stream
A method of topic partitioning that is used by applications that connect to WebSphere MQ Publish/Subscribe brokers.

Structured Query Language (SQL)
A standardized programming language that is used to define and manipulate data in a relational database. ESQL, the language that is used by WebSphere Message Broker, is based on SQL, and has many similar constructs.

style sheet
A specification of formatting instructions that, when applied to structured information, provides a particular rendering of that information (for example, online or printed). Different style sheets can be applied to the same piece of structured information to produce different presentations of the information.

subflow
A sequence of processing steps, implemented by message flow nodes, that is designed to be embedded in a message flow or in another subflow. A subflow must include at least one Input or Output node. A subflow can be started by a broker only as part of the message flow in which it is embedded, and therefore cannot be deployed.

subflow node
A message flow node that represents a subflow.

subscriber
A publish/subscribe application that requests information about a topic.

subscription
A record that contains the information that a subscriber passes to its local broker to describe the publications that it wants to receive.

subscription filter
A predicate that specifies the subset of messages that are to be delivered to a particular subscriber.

subscription point
The name that a subscriber uses to request publications from a particular set of publication nodes. It is the property of a publication node that differentiates that publication node from other publication nodes in the same message flow.

substitution group
An XML Schema feature that provides a means of substituting one element for another in an XML message. A substitution group contains a list of global elements that can appear in place of another global element, called the head element.

Supervisory, Control, And Data Acquisition (SCADA)
A term used to describe any form of remote telemetry system that is used to gather data from remote sensor devices (for example, flow rate meters on an oil pipeline) and for the near real-time control of remote equipment (for example, pipeline valves).

system log
See local error log.

TOP

T

Tagged/Delimited String (TDS) Format
The physical representation of a message in the MRM domain that has a number of data elements separated by tags and delimiters.

target property
A message flow property that is selected by the pattern author to be configured by the pattern.

TDS Format
See Tagged/Delimited String Format.

terminal
The point at which one node in a message flow is connected to another node. You can connect terminals to control the route that a message takes, dependent on the outcome of the operation that is performed on that message by the node.

topic A character string that describes the nature of the data that is published in a publish/subscribe system.

topic-based subscription
A subscription specified by a subscribing application that includes a topic that filters publications.

tree node
An element in a mapping tree; a container for the mapping type such as a message, database table, a column, or a basic element.

truststore
In security, a storage object, either a file or a hardware cryptographic card, where public keys are stored in the form of trusted certificates, for authentication purposes in Web transactions. In some applications, these trusted certificates are moved into the application keystore to be stored with the private keys.

type A characteristic of a message element that describes its data content. See also simple type and complex type.

TOP

U

Unicode Transformation Format, 8-bit encoding form (UTF-8)
A transformation format that is designed for ease of use with existing ASCII-based systems. UTF-8 is an encoding of Unicode character strings that optimizes the encoding of ASCII characters in support of text-based communication.

uniform resource identifier (URI)
An encoded address that represents any resource, such as an HTML document, image, video clip, or program, on the Web; a URI is an abstract superclass compared with a Uniform resource locator or a Uniform resource name, which are concrete entities.

uniform resource locator (URL)
The unique address of an information resource that is accessible in a network such as the Internet. The URL includes the abbreviated name of the protocol used to access the information resource and the information used by the protocol to locate the information resource.

A Web server typically maps the request portion of the URL to a path and file name. Also known as universal resource locator.

uniform resource name (URN)
A name that uniquely identifies a Web service to a client.

URI See uniform resource identifier.

URL See uniform resource locator.

URN See uniform resource name.

user-defined extension
An optional component that is designed by the user to extend the functions of WebSphere Message Broker. A user-defined extension can be either a node or a message parser. See also user-defined node and user-defined parser.

user-defined node
An extension to the broker that provides a new message flow node in addition to the nodes that are supplied with the product. See also implementation function and utility function.

user-defined parser
An extension to the broker that provides a new message parser in addition to the parsers that are supplied with the product. See also implementation function and utility function.

user-defined pattern
A pattern that is created by a pattern author.

UTF-8 See Unicode Transformation Format.

utility function
A function provided by the broker that can be used by developers who write user-defined nodes or parsers.

TOP

V

value constraint
A limit that sets a restriction on the values that a simple type can represent.

view In Eclipse-based user interfaces, a pane that is outside the editor area, which can be used to look at or work with the resources in the WebSphere Message Broker Toolkit. For example, you can view and edit your project files in the Broker Development view (previously called the Resource Navigator view). See also perspective.

TOP

W

warehouse
A persistent, data store for historical events (or messages). The Warehouse node within a message flow supports the recording of information in a database for subsequent retrieval and processing by other applications.

Web service
A self-contained, self-describing modular application that can be published, discovered, and invoked over a network using standard network protocols.

Typically, XML is used to tag the data, SOAP is used to transfer the data, WSDL is used for describing the services available, and UDDI is used for listing what services are available.

Web Services Description Language (WSDL)
An XML-based specification for describing networked services as a set of endpoints that operate on messages that contain either document-oriented or procedure-oriented information. A WSDL document enables a Web services client to invoke a Web service using the messages defined in a message definition.

WebSphere Adapters
WebSphere Adapters facilitate the exchange of business objects between Enterprise Information Systems (such as SAP Software, PeopleSoft Enterprise, and Siebel Business Application systems) and other applications.

WebSphere Message Broker Explorer
A graphical user interface based on the Eclipse platform for administering your brokers.

WebSphere Message Broker pattern
A pattern in the WebSphere Message Broker Toolkit that exposes one or more pattern parameters for a pattern user to complete.

WebSphere Message Broker Toolkit
A graphical user interface built on Eclipse that is used to provide integration and connectivity solutions by developing resources associated with message flows.

WebSphere MQ Enterprise Transport
A transport protocol supported by WebSphere Message Broker that enables WebSphere MQ application clients to connect to brokers.

WebSphere MQ Everyplace®
A generally available WebSphere MQ product that provides proven WebSphere MQ reliability and security for mobile and wireless devices. WebSphere MQ Everyplace applications connect to the broker using WebSphere MQ Mobile Transport.

WebSphere MQ Mobile Transport
A transport protocol supported by WebSphere Message Broker that enables WebSphere MQ Everyplace application clients to connect to brokers.

WebSphere MQ Web Services Transport
A transport protocol supported by WebSphere Message Broker that enables HTTP-compliant application clients to connect to brokers.

wildcard
A character that can be specified in subscriptions to match a range of topics. See also multilevel wildcard and single-level wildcard.

work_path
The location in the local file system in which the component stores internal and working data. For example, the default location on Windows XP systems is `C:\Documents and Settings\All Users\Application Data\IBM\MQSI\`.

working set
A logical collection of application projects, that you can use to limit the number of resources that are displayed in the Broker Application Development perspective. See also active working set.

World Wide Web Consortium (W3C)
An international industry consortium set up to develop common protocols to promote the evolution and interoperability of the World Wide Web.

WSDL
See Web Services Description Language.

W3C See World Wide Web Consortium.

TOP

X

XML See Extensible Markup Language.

XML domain
The message domain that includes all messages that conform to the W3C XML standard. Messages in this domain are processed by the XML parser. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XMLNS domain, and XMLNSC domain.

The XML domain is deprecated; use the XMLNSC domain for new messages.

XML parser
A program that interprets a message that belongs to the XML domain and JMS domains, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output. The bit stream is a representation of an XML file.

XMLNS domain
An extension of the XML domain that contains messages that conform to the W3C XML standard, and that can also use the namespaces specification. Messages in this domain are processed by the XMLNS parser. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, and XMLNSC domain.

XMLNS parser
A program that interprets a message that belongs to the XMLNS domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output. The bit stream is a representation of an XML file.

XMLNSC domain
An extension of the XML domain that provides high-performance XML parsing and offers optional XML Schema validation. Messages in this domain are processed by the XMLNSC parser. You can create a message model for messages that you process in this domain, but a model is required only if you want to validate the message. See also BLOB domain, DataObject domain, IDOC domain, JMS domain, MIME domain, MRM domain, SOAP domain, XML domain, and XMLNS domain.

XMLNSC parser
A program that interprets a message that belongs to the XMLNSC domain, and generates the corresponding tree from the bit stream on input, or the bit stream from the tree on output. The bit stream is a representation of an XML file.

XML Path Language (XPath)
A language designed to uniquely identify or address parts of a source XML document, for use with XSLT. XPath provides basic facilities for the manipulation of strings, numbers, and Boolean values in message flow resources. For example, it can be used by Java programs within a JavaCompute node, or as the expression language within a Mapping node, or by the properties of several other nodes.

XML Schema
An international standard that defines a language for describing the structure of XML documents. An XML Schema formally describes and constrains the content of XML documents by indicating which elements are valid and in which combinations. (An XML Schema is an alternative to a document type definition (DTD), and can be used to extend functionality in the areas of data typing, inheritance, and presentation.) The XML Schema language is ideally suited to describing the messages that flow between business applications, and is widely used in the business community for this purpose. Message definitions are annotated XML Schema.

XML Schema Definition Language (XSD)
A language for describing XML files that contain XML Schema.

XML Wire Format
The physical representation of a message in the MRM domain that can be parsed as XML.

XPath See XML Path Language.

XSD See XML Schema Definition Language (XSD).

XSL See Extensible Stylesheet Language.

TOP

Accessibility features for WebSphere Message Broker

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in WebSphere Message Broker. You can use screen-reader software to hear what is displayed on the screen.

- Supports keyboard-only operation
- Supports interfaces commonly used by screen readers

Tip: This information center, and its related publications, are accessibility-enabled for the IBM Home Page Reader. You can operate all features using the keyboard instead of the mouse.

If you are reading a PDF file with a screen reader, the default reading option typically returns the best results. In some cases, the way in which the PDF file has been generated might require you to select one of the other reading options; for example, `Use reading order in raw print stream`.

Keyboard navigation

This product uses standard Linux and Microsoft Windows navigation keys.

Visit the IBM Accessibility Center for more information about the commitments that IBM makes towards accessibility.

Related reference:

"WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit keyboard shortcuts" on page 6828
You can navigate all interfaces in the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit by using the keyboard.

Workbench User Guide - Keyboard shortcuts for the Workbench, Java development tools, and the debugger

Chapter 3. Migrating and upgrading

To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Before you begin

Migration information is regularly updated on the WebSphere Message Broker support web page with the latest details available. Click **Troubleshoot** and look for the document "Problems when migrating".

You can migrate your existing components and resources to WebSphere Message Broker Version 7.0 from previous versions of both WebSphere Message Broker and WebSphere Event Broker.

The architecture of WebSphere Message Broker Version 7.0 has been simplified:

- The broker has no requirement for a database. When you migrate from a previous version, the following changes apply:
  - Because a database is no longer a mandatory requirement for a broker, DB2 and DB2 Runtime Client (the Derby database supported only on Windows systems) are not supplied when you purchase WebSphere Message Broker Version 7.0.
  - The **mqsicreatebroker** and **mqsichangebroker** commands have been updated to remove the specification of database parameters.
  - The DatabaseInstanceMgr that was available on Windows systems to manage Derby and DB2 databases has been removed for Version 7.0. Commands that control the DatabaseInstanceMgr and the Derby database have been removed:

    mqsicreatedb

    mqsideletedb

    mqsichangedbimgr
- The broker security model is implemented by using WebSphere MQ queues. The Configuration Manager component has been removed and you cannot migrate existing components of this type. All operational data maintained by the Configuration Manager components is retrieved when you migrate your brokers.

  The commands that controlled this component have been removed:

  mqsichangeconfigmgr
  mqsicreateconfigmgr
  mqsideleteconfigmgr
  mqsireportconfigmgr
- All topic-based publish/subscribe operations are handled by WebSphere MQ. Because access control for publishers and subscribers is managed by WebSphere MQ, the User Name Server component is no longer required, and has been removed; you cannot migrate existing components of this type. The following commands are no longer available:

  mqsichangeusernameserver
  mqsicreateusernameserver
  mqsideleteusernameserver

After you have migrated, you can control brokers only from the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit Version 7.0.

You can migrate from Version 6.1 or Version 6.0 only to a full edition of Version 7.0, Remote Adapter Deployment, Entry Edition, or Starter Edition. Do not migrate brokers from an earlier version to the Trial Edition. If you choose to migrate brokers by using the **mqsimigratecomponents** command, the brokers are migrated in enterprise mode. If you have purchased the Remote Adapter Deployment, Entry Edition, or Starter Edition, you must change the mode of all your migrated brokers to comply with the terms of your license. For more information, see "Changing the operation mode of your broker" on page 655.

Procedure

1. Check that your current installation of WebSphere Message Broker (Version 6.1 or Version 6.0) or WebSphere Event Broker (Version 6.0 only) is at a supported level for migration. Details are provided in "Supported migration paths" on page 3579.
2. Understand the options that are available to install Version 7.0 components on the same computer as components from previous versions. These options are described in "Coexistence with previous versions and other products" on page 139.
3. You must migrate your queue managers to a supported version of WebSphere MQ before you can migrate your brokers. For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
4. If your configuration includes publish/subscribe applications, support has transferred from WebSphere Message Broker to WebSphere MQ. You must take additional steps to migrate publish/subscribe information from your current WebSphere Message Broker or WebSphere Event Broker configuration. Details are provided in "Migrating publish/subscribe information to WebSphere MQ" on page 141.
5. If you are currently working with WebSphere Message Broker or WebSphere Message Broker with Rules and Formatter Extension , follow the instructions in "Migrating from Version 6.1 products" on page 163.
6. If you are currently working with WebSphere Message Broker Version 6.0 or WebSphere Message Broker with Rules and Formatter Extension Version 6.0, follow the instructions in "Migrating from Version 6.0 products" on page 183.
7. If you are currently working with WebSphere Event Broker Version 6.0, and you only use publish/subscribe functions, you can migrate to WebSphere MQ. This migration path is documented in the *Migration* section of the WebSphere MQ Version 7 Information Center online.

   If you currently use, or plan to use, additional broker functions, and you want to migrate to WebSphere Message Broker Version 7.0, follow the instructions in "Migrating from Version 6.0 products" on page 183. The tasks that you must complete are the same as those tasks documented for WebSphere Message Broker Version 6.0.
8. When you have migrated your components and resources, check if the post-migration tasks apply to your configuration. Guidance is provided in "Post-migration tasks" on page 204.

"Supported migration paths" on page 3579
You can migrate to WebSphere Message Broker Version 7.0 from previous versions of the product.

Related information:

WebSphere Message Broker Requirements

WebSphere Message Broker Support

WebSphere MQ Version 7 Information Center online

Coexistence with previous versions and other products

WebSphere Message Broker Version 7.0 supports restricted coexistence with previous versions and with other products.

WebSphere Message Broker Version 7.0 requires a specific minimum supported version of WebSphere MQ. For systems other than z/OS that allow only one version of WebSphere MQ on a single computer, you must first install a supported version of WebSphere MQ and migrate your WebSphere MQ resources to this version. You can then install WebSphere Message Broker Version 7.0. For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

Coexistence with previous versions of the product installed on the same computer

WebSphere Message Broker Version 7.0 can coexist with a Version 6.1 product, a Version 6.0 product, or both, on the same computer.

Component names must be unique on the computer, regardless of version.

When you migrate from a Version 6.1 or Version 6.0 product to Version 7.0, you do not have to uninstall the Version 6.1 or Version 6.0 product before installing Version 7.0. You can install Version 7.0 in a different location on the same computer, migrate your components and resources to Version 7.0, and uninstall the Version 6.1 or Version 6.0 product later, when you are sure that you no longer need it.

For details of default locations for installations of each version, see "Coexistence and migration" on page 239.

If you attempt to install the broker into a directory that already contains an installation of the broker at a previous version, you are prompted to confirm that you want to continue with the installation, because it will overwrite the existing installation. Cancel the installation and select a different directory to preserve your existing configuration.

If you install more than one version on a single computer, and you create multiple components, check that sufficient memory and disk space are available.

When you have installed Version 7.0, you can test your configuration.

Coexistence of Version 7.0 components with components from previous versions

The following restrictions apply:

- The WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit work only with brokers that you have migrated to, or created in, Version 7.0. If you try to connect to brokers at an earlier version, the connection attempt fails.
- You can run all programs that you have written to the CMP API to interact with a CMP API at Version 6.1 or Version 6.0 to interact with brokers that you have migrated to, or have created in, Version 7.0. Programs that start, stop, delete, and monitor deployed resources continue to work with Version 7.0.
- You can deploy BAR files that you have created in an earlier version of the WebSphere Message Broker Toolkit from the WebSphere Message Broker Toolkit Version 7.0 to a broker at Version 7.0, without change.
- You cannot deploy resources that you have created in the WebSphere Message Broker Toolkit Version 7.0 to brokers that are at Version 6.1 or Version 6.0.

Coexistence with SupportPac IS02

The SupportPac IS02, WebSphere Message Broker Explorer Plug-in, cannot coexist with the WebSphere Message Broker Explorer in WebSphere Message Broker Version 7.0. If you have previously installed SupportPac IS02, you must uninstall the SupportPac before installing the WebSphere Message Broker Explorer. To remove SupportPac IS02, delete or move the directory to which you extracted the `IS02 zip` file supplied with the SupportPac. Delete the `BrokerExplorer.link` file which you copied into the `C:\Program Files\IBM\WebSphere MQ\eclipseSDK33\eclipse\links\` directory.

Migrating publish/subscribe information to WebSphere MQ

These tasks give an overview of how to migrate publish/subscribe information from WebSphere Message Broker or WebSphere Message Broker Version 6.0 to WebSphere MQ.

Before you begin

Before you start

- Read about publish/subscribe on WebSphere MQ.
- For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- Plan your migration, and pay specific attention to your Access Control List (ACL) authorities.

  The migration tool accepts and modifies only your positive ACL entries. Therefore, you must inspect your ACL entries and modify all that do not meet the appropriate criteria; see "Access Control List (ACL) migration - publish/subscribe" on page 146
- Back up your Version 6.1 resources.

To migrate publish/subscribe information to WebSphere Message Broker Version 7.0 you must have WebSphere MQ installed on your system.

About this task

To migrate your existing publish/subscribe information to WebSphere MQ, complete the following steps.

Procedure

1. Install WebSphere MQ on your system. This step upgrades your queue managers; for instructions about how to install this product, see the WebSphere MQ documentation.

2. Install WebSphere Message Broker Version 7.0. This installation must be alongside your existing WebSphere Message Broker Version 6.1 or Version 6.0 system.
3. Explicitly enable content-based filtering if you are using this option. For further information, see "Enabling content-based filtering with publish/subscribe" on page 2224.
4. Use a WebSphere MQ command prompt to run the **migmbbrk** command. This command copies data from your WebSphere Message Broker Version 6.1 or Version 6.0 system to your WebSphere MQ system.
5. Use a WebSphere Message Broker Version 7.0 command prompt to run the **mqsimigratecomponents** command; for further information, see "**mqsimigratecomponents** command" on page 3894.
6. If you have existing MQRFH format retained publications in WebSphere Message Broker Version 6.0 or Version 6.1, see "Retained publications with headers in MQRFH format" on page 149 for further migration considerations.

What to do next

Next: Follow the instructions detailed in "Migrating publish/subscribe from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 146

Related concepts:

"Access Control List (ACL) migration - publish/subscribe" on page 146
The function that migrates publish/subscribe configuration data from WebSphere Event Broker Version 6.0 and WebSphere Message Broker to WebSphere MQ produces a file containing suggested security commands, and creates topic objects as required.

Related tasks:

"Migrating publish/subscribe from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 146
You can migrate publish/subscribe configuration data from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ.

"**mqsimigratecomponents** command" on page 3894
Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

WebSphere MQ migmbbrk command

Migrate the publish/subscribe information from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ

Purpose

Use the WebSphere MQ **migmbbrk** command to migrate the publish/subscribe information from a WebSphere Message Broker Version 6.0 or WebSphere Message Broker broker to a WebSphere MQ queue manager. The command runs a migration process that migrates the following publish/subscribe information to the queue manager that is associated with the named broker:

- Subscriptions
- Subscription points (subscription points are supported only when RFH2 messages are used)
- Streams

- Retained publications

When you run the **migmbbrk** command, you must use the profile for the version of WebSphere Message Broker from which you are migrating.

The **migmbbrk** command does not migrate the Access Control List (ACL). Instead, running the migration with the **-t** or **-r** parameters produces a file containing suggested **setmqaut** commands to set up a security environment in the queue manager that is equivalent to the security environment that existed in the broker. You must review and modify the security command file as needed and run the commands to set up a security environment in the queue manager, equivalent to the one that existed in the broker, before you run the migration with the **-c** parameter to complete the migration.

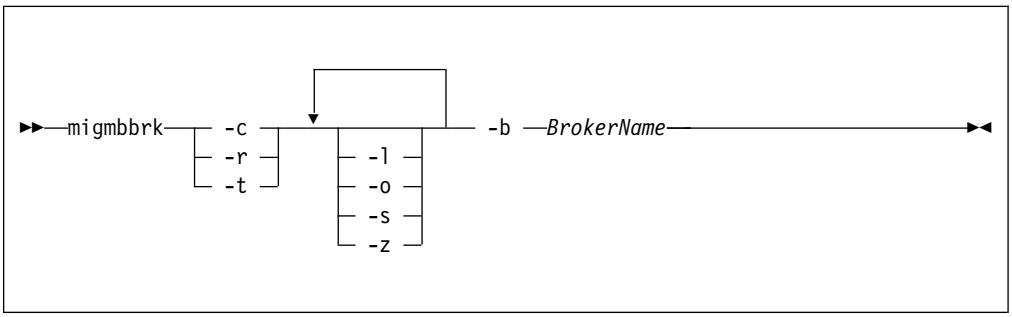
Note: On UNIX systems, all authorities are held by user groups internally, not by principals, which has the following implications:

- If you use the **setmqaut** command to grant an authority to a principal, the authority is granted to the primary user group of the principal. Therefore, the authority is effectively granted to all members of that user group.
- If you use the **setmqaut** command to revoke an authority from a principal, the authority is revoked from the primary user group of the principal. Therefore the authority is effectively revoked from all members of that user group.

You must issue the **migmbbrk** command from a command environment that can process both WebSphere MQ and WebSphere Message Broker commands successfully. Typically, you can issues these commands from a WebSphere Message Broker command console.

The WebSphere Message Broker Version 6.0, WebSphere Event Broker Version 6.0, or WebSphere Message Broker publish/subscribe configuration data, which is stored in the subscription database tables, is not deleted by the migration process. This configuration data is therefore available to use until you explicitly delete it.

Syntax



Parameters

-b *BrokerName*
(Required) The name of the broker that is the source of the publish/subscribe information that is to be migrated. The queue manager to which the publish/subscribe information is migrated is the queue manager that is associated with the named broker.

-c

(Required) Complete the migration of the publish/subscribe configuration data. The completion phase of the migration uses the topic objects that are created in the initial **-t** phase. The broker state might have changed since the initial phase was run, and new additional topic objects might now be required. If this is the case, the completion phase creates these new topic objects as necessary. The completion phase does not delete any topic objects that have become unnecessary; you might need to delete any topic objects that you do not require.

Before you complete the migration you must review and modify the security command file produced in the **-r** or **-t** phase as required and run the commands to set up a security environment in the queue manager, equivalent to the one that existed in the broker.

Before you run this completion phase you must run the initial **-t** phase. You cannot use the **-c** parameter with the **-r** parameter or the **-t** parameter. This phase also creates a migration log.

-r

(Required) Rehearse the migration process but do not change anything. You can use this before running the migration with the **-t** parameter, to create a migration log, including any errors, so that you can observe what the result of the migration process would be, but without changing the current configurations.

Rehearsing the migration also produces a file containing suggested **setmqaut** commands to set up a security environment in the queue manager that is equivalent to the security environment that existed in the broker. Before you complete the migration with the **-c** parameter you must review and modify the security command file as required and run the commands to set up a security environment in the queue manager, equivalent to the one that existed in the broker.

You cannot use the **-r** parameter with the **-c** parameter or the **-t** parameter.

-t

(Required) Create topic objects that might be needed in the queue manager, based on the ACL entries that are defined in the broker.

Use of the **-t** parameter also produces a file containing suggested **setmqaut** commands to set up a security environment in the queue manager that is equivalent to the security environment that existed in the broker. The topic objects are created in anticipation of you running the security commands to create ACLs for the topic objects. Before you complete the migration with the **-c** parameter you must review and modify the security command file as required and run the commands to set up a security environment in the queue manager, equivalent to the one that existed in the broker.

You must run this phase before you run the completion phase with the **-c** parameter. You cannot use the **-t** parameter with the **-c** parameter or the **-r** parameter. This phase also creates a migration log.

-l

(Optional) Leave the broker running. If you do not specify this parameter, the broker is shut down by default at the end of the migration process.

-o

(Optional) Overwrite subscription or retained publication that already exists in the queue manager and that has the same name as a subscription or retained

publication that is being migrated from the broker, with the publish/subscribe information that was retrieved from the broker. The **-o** parameter has no effect if you use it with the **-r** parameter.

-s
(Optional) Discard intermediate information that was retained from a previous instance of the migration process that failed or was interrupted. The migration process populates private queues with temporary data. If the migration process completes successfully, the temporary data is deleted. If you do not specify this parameter and the migration process fails or is interrupted, the temporary data is retained and is used by the migration process if you restart it, so that the process resumes at the point where it previously failed or was interrupted.

-z
(Optional) Run the migration process, regardless of whether it has previously run to a successful completion. If you do not specify this parameter and the migration process has previously run to a successful completion, the process recognizes this fact and exits. You can use the **-o** parameter with the **-z** parameter, but this is not mandatory. A previous rehearsal of the migration using the **-r** parameter does not count as a successful completion.

Return codes

0	Migration completed successfully
20	An error occurred during processing

Output files

The migration process writes two output files to the current directory:

amqmigrateacl.txt
A file containing a list of **setmqaut** commands, for you to review, change, and run if appropriate, to help you to reproduce your ACLs.

amqmigmbbrk.log
A log file containing a record of the details of the migration.

Examples

This command migrates the publish/subscribe information of broker BRK1 into its associated queue manager and specifies that the migration process runs regardless of whether it has previously run to a successful completion. It also specifies that any subscription or retained publication that already exists in the queue manager, that has the same name as a subscription or retained publication that is being migrated from the broker, must be overwritten.

```
migmbbrk -r -z -o -b BRK1
```

Supported operating systems

The **migmbbrk** command is supported only on the following platforms that support WebSphere Event Broker Version 6.0 or WebSphere Message Broker :

Microsoft Windows XP Professional with SP2, 32–bit versions only
Solaris on x86-64: Solaris 10
Solaris on SPARC: Solaris 9 (64–bit)
AIX Version 5.2 or later, 64–bit only
HP-Itanium: HP-UX 11i
Linux on IBM z Systems (64-bit)

Linux on POWER® (64–bit)
Linux on x86
Linux on x86-64

On z/OS the equivalent function to the migmbbrk command is provided by the CSQUMGMB utility.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

Access Control List (ACL) migration - publish/subscribe

The function that migrates publish/subscribe configuration data from WebSphere Event Broker Version 6.0 and WebSphere Message Broker to WebSphere MQ produces a file containing suggested security commands, and creates topic objects as required.

On WebSphere Event Broker Version 6.0 and WebSphere Message Broker , the default behavior is for all user IDs to have access to any topic unless the ACL explicitly restricts access. In WebSphere MQ the default behavior is for no user ID to have access to any topic unless the ACL explicitly authorizes access, and it is not possible to explicitly restrict access. Because of this difference in security approaches, the migration process cannot directly migrate WebSphere Event Broker Version 6.0 and WebSphere Message Broker ACLs to the WebSphere MQ queue manager.

If the rehearsal or initial phase of the migration finds an ACL entry that denies access, the process cannot produce a WebSphere MQ equivalent command. Instead, it reports it in the security command file and advises that the ACL migration must be performed manually.

You can modify the:

- Broker security settings to match the WebSphere MQ security approach, and run the rehearsal or initial phase of the migration again to produce a new security command file, or
- Security command file as needed. You must set up a security environment in the queue manager, equivalent to the one that existed in the broker, before you run the completion phase of the migration.

WebSphere Event Broker Version 6.0 and WebSphere Message Broker provide the capability to define topic trees, but there is no capability to set specific attributes for a particular individual topic in a topic tree. WebSphere MQ supports the concept of topic objects that allow you to set specific, nondefault attributes for a topic. An Access Control List is a property of a topic object. The initial phase of the migration creates topic objects speculatively, based on the ACL entries that are defined in the broker and in anticipation of you subsequently running the security commands to create ACLs for the topic objects. When you have resolved what security settings you need, you might need to delete the topic objects that you do not require.

Migrating publish/subscribe from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ

You can migrate publish/subscribe configuration data from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ.

Before you begin

Before you start:

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

This topic assumes the following prerequisite steps:

- You have installed WebSphere MQ.
- You want to migrate publish/subscribe support from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ.
- You want to upgrade from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere Message Broker Version 7.0. You are currently using the broker as an interface for functions other than, but in addition to, publishing and subscribing, and you want to continue to use those other functions after you migrate publish/subscribe information to WebSphere MQ.
- On distributed systems, you have set up and initialized a command environment in which WebSphere MQ and WebSphere Message Broker commands can run.
- The WebSphere MQ queue manager is not currently handling any publish or subscribe messages.
- The queue manager attribute **PSMODE** is set to COMPAT; run the command **ALTER QMGR PSMODE(COMPAT)**.

Note: WebSphere MQ publish/subscribe functionality might alter the header chains in your published message. The message body is not affected, but avoid assumptions about the value of the **CodedCharSetId** field in MQRFH2 headers when subscribing.

About this task

This task upgrades your enterprise from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere Message Broker Version 7.0.

Procedure

1. Uninstall WebSphere MQ Version 6.X from your system.
2. Install WebSphere MQ on your system.
3. Install WebSphere Message Broker Version 7.0 on your system. Do not remove your existing WebSphere Message Broker installation until you have migrated your current publish/subscribe data.
4. Start the broker on your WebSphere Message Broker Version 6.0 or Version 6.1 system.
5. Run the migration process with the **-r** parameter.

   For more information, see "WebSphere MQ migmbbrk command" on page 142. This option rehearses the migration of the publish/subscribe configuration data from the broker to its underlying queue manager without changing either of the configurations. For example, on supported systems other than z/OS, use the following command to rehearse the migration from a broker named BRK1:

   ```
   migmbbrk -r -b BRK1
   ```

   On z/OS use the equivalent parameters with the **CSQUMGMB** utility.
6. Run the following command:

```
migmbbrk -t  -b brokername
```

then run the security commands that set up the security environment. If you do not run these commands, migration fails.

7. To check what is to be migrated in a real migration, review the contents of the log file.
8. Back up the file that contains the security commands, and create your own copy of the file.
9. Review and, if necessary, edit the commands in your copy of the security commands file to ensure that they create a security environment that is like your broker security environment.
10. Run the migration process with the **-o** parameter.

    The migration process migrates the publish/subscribe configuration data to the queue manager, and creates a log file and a new security commands file.

    For example, on supported systems other than z/OS, use the following command:

    ```
    migmbbrk -c -o -b BRK1
    ```

    This command completes the following actions:

    - Migrates the publish/subscribe configuration data from broker BRK1
    - Overwrites any subscription or retained publication that exists in the queue manager
    - Creates a file that has the same name as a migrating subscription or retained publication

    On z/OS use the equivalent parameters with the CSQUMGMB utility.
11. Stop the broker and check the Administration log to confirm that the broker has stopped.

    Note: After you have stopped the broker, the queue manager is in COMPAT mode. As a result, the publish/subscribe state cannot be changed in WebSphere MQ or WebSphere Message Broker, allowing the migration to proceed.
12. Check the contents of the new security commands file against your backup copy to make sure that nothing related to the ACL has changed since you rehearsed the migration. If anything has changed, you might need to edit your copy of the security commands file.
13. Run the commands that are in your copy of the security commands file.
14. Optional: Remove WebSphere Message Broker Version 6.0 or WebSphere Message Broker from your system if necessary. Carry out this step only if you are sure that you are not going to require your WebSphere Message Broker Version 6.0 or WebSphere Message Broker system in the future.

    To reverse the migration process, see “Migrating publish/subscribe information from WebSphere MQ to WebSphere Message Broker Version 6.0 or WebSphere Message Broker ” on page 150.
15. Run the **mqsimigratecomponents** command; for more information, see “**mqsimigratecomponents** command” on page 3894.
16. To set the **PSMODE** queue manager attribute to ENABLED, run the following command:

    ```
    ALTER QMGR PSMODE(ENABLED)
    ```

This command starts the queued publish/subscribe interface so that the queue manager deals with all subsequent publish/subscribe processing.

17. If appropriate, enable content-based filtering on at least one execution group. For more information, see "Enabling content-based filtering with publish/subscribe" on page 2224.
18. Restart the broker.

    When the broker restarts, it continues to provide message services other than publish and subscribe functions.

Migrate the publish/subscribe information from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ

Retained publications with headers in MQRFH format

Retained publications in MQRFH format might lose data when migrated to WebSphere MQ.

WebSphere Message Broker applications that communicate with one another using publish/subscribe can do so regardless of the message format that they use. WebSphere Message Broker delivers the message in the format of the subscription and provides automatic conversion to ensure that a subscriber receives messages in the requested format.

WebSphere Message Broker applications generally use the MQRFH2 message header, but it is possible that an application might have used the MQRFH format.

The migration of publish/subscribe information from WebSphere Message Broker to WebSphere MQ requests messages in MQRFH2 format. It is rare for WebSphere Message Broker client applications to use messages in MQRFH format. However, if an application does use retained messages in MQRFH format, it is possible that some truncation of data might occur upon migration. In particular, data passed using the MQPSStringData and MQPSIntData name/value pairs is not migrated.

The migration function checks for two conditions in the data that is returned from the broker:

1. That there is at least one retained message stored in the broker
2. That there is at least one MQRFH subscription

If both these conditions are true, the migration function displays a warning message and writes a warning message in the migration log stating that MQRFH retained publications have been migrated with a possible loss of data.

MQRFH2 retained publications are migrated correctly.

Migrating publish/subscribe information from WebSphere MQ to WebSphere Message Broker Version 6.0 or WebSphere Message Broker

Complete these tasks to migrate publish/subscribe configuration data from WebSphere MQ to WebSphere Message Broker Version 6.0 or WebSphere Message Broker .

Before you begin

Before you start:

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

This task assumes the following prerequisites:

- You want to migrate publish/subscribe support from WebSphere MQ back to WebSphere Message Broker Version 6.0 or WebSphere Message Broker .
- On distributed systems, you have set up and initialized a command environment in which WebSphere MQ and WebSphere Message Broker commands can run.
- The WebSphere MQ queue manager is not currently handling any publish or subscribe messages.

Procedure

1. Run **mqsimigratecomponents** on WebSphere Message Broker Version 7.0, specifying the broker that you want to migrate. For further information about running this command, see "**mqsimigratecomponents** command" on page 3894.

   This step resets the information to your original specifications in WebSphere Message Broker Version 6.0 or WebSphere Message Broker .
2. Use the command: **ALTER QMGR PSMODE(COMPAT)** to set the **PSMODE** queue manager attribute to COMPAT. This step starts the queued publish/subscribe interface so that the queue manager deals with all subsequent publish/subscribe processing.
3. Restart the broker.

Related tasks:

"WebSphere MQ migmbbrk command" on page 142
Migrate the publish/subscribe information from WebSphere Message Broker

Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ

Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Before you begin

Before you start:

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

This task assumes the following prerequisites:

- You have installed WebSphere MQ
- You want to migrate publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue manager clusters.
- You want to upgrade from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere Message Broker Version 7.0.
- On distributed systems, you have set up and initialized a command environment in which WebSphere MQ and WebSphere Message Broker commands can run.
- The WebSphere MQ queue manager is not currently handling any publish or subscribe messages.

You must migrate each broker separately, and if you have a large number of brokers to migrate, you can administer the process from a WebSphere Message Broker WebSphere Message Broker Toolkit, using a Configuration Manager to a mixed environment of WebSphere Message Broker brokers and migrated WebSphere Message Broker Version 7.0 brokers.

This process is for migration only. You cannot administer new WebSphere Message Broker Version 7.0 brokers or update, for example, publish/subscribe topologies, or Access Control Lists

If you inadvertently initiate a publish/subscribe topology deploy, any brokers already migrated to WebSphere Message Broker Version 7.0 ignore this part of the deployment and issue a BIP2082 warning message to the system log.

If you use this mixed environment, you must use the “WebSphere MQ migmbbrk command” on page 142 as part of the migration for each broker.

To migrate each broker separately:

Procedure

1. Remove each broker from the collective.
2. Migrate each broker, as described in “Migrating publish/subscribe from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ” on page 146.

3. Restart all the brokers. When you have migrated all the brokers you can place the brokers in a queue manager cluster. See "Setting up a new queue-manager cluster" for more information on how you carry out this procedure.

Related concepts:

"Setting up a new queue-manager cluster"
Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe information to WebSphere MQ" on page 141
These tasks give an overview of how to migrate publish/subscribe information from WebSphere Message Broker or WebSphere Message Broker Version 6.0 to WebSphere MQ.

Setting up a new queue-manager cluster

Initial points to consider when setting up a new queue-manager cluster

Scenario:

- You are setting up a new WebSphere MQ network for a chain store. The store has two branches, one in London and one in New York. The data and applications for each store are hosted by systems running separate queue managers. The two queue managers are called LONDON and NEWYORK.
- The inventory application runs on the system in New York, connected to queue manager NEWYORK. The application is driven by the arrival of messages on the INVENTQ queue, hosted by NEWYORK.
- The two queue managers, LONDON and NEWYORK, are to be linked in a cluster called INVENTORY so that they can both put messages to the INVENTQ.
- Examples are given using TCP/IP only.
- Example UNIX systems commands are shown for AIX only.

Carry out the following tasks to set up a new cluster:

1. "Decide on the organization of the cluster and its name" on page 153
2. "Determine which queue managers should hold full repositories" on page 153
3. "Alter the queue-manager definitions to add repository definitions" on page 154
4. "Define the CLUSRCVR channels" on page 154
5. "Define the CLUSSDR channels" on page 155
6. "Define the cluster queue INVENTQ" on page 156
7. "Verify and test the cluster" on page 158

When you have set up your initial cluster you can add further queue managers; see "Adding a new queue manager to a cluster" on page 159 for further information.

For further information about setting up queue-manager clusters, refer to the WebSphere MQ information center.

Note: You can also use one of the wizards supplied with WebSphere MQ Explorer to create a new cluster similar to the one created by this task. Right-click the Queue Manager Clusters folder, then click **New** > **Queue Manager Cluster**, and follow the instructions given in the wizard.

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Decide on the organization of the cluster and its name

Start by linking two queue managers into a cluster. You can use this as a basis for expansion at a later date.

You have decided to link the two queue managers, LONDON and NEWYORK, into a cluster. A cluster with only two queue managers offers only marginal benefit over a network that is to use distributed queuing, but is a good way to start and provides scope for future expansion. When you open new branches of your store, you will be able to add the new queue managers to the cluster easily and without any disruption to the existing network. "Adding a new queue manager to a cluster" on page 159 describes how to do this.

For the time being the only application you are running is the inventory application. The cluster name is INVENTORY.

Related concepts:

"Adding a new queue manager to a cluster" on page 159
How to add a queue manager to the cluster you have set up.

"Setting up a new queue-manager cluster" on page 152
Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Determine which queue managers should hold full repositories

In any cluster you need to nominate at least one queue manager, or preferably two, to hold full repositories.

See "Selecting queue managers to hold full repositories" on page 161 for more information. In this example there are only two queue managers, LONDON and NEWYORK, both of which hold full repositories.

Note:

1. You can perform the remaining steps in any order.
2. As you proceed through the steps, warning messages might be written to the queue-manager log or the z/OS system console if you have yet to make some expected definitions.

```
Examples of the responses to the commands are shown in a box
like this after each step in this task.
These examples show the responses returned by WebSphere MQ for AIX.
The responses vary on other platforms.
```

3. Before proceeding with these steps, make sure that the queue managers are started.

Related concepts:

"Setting up a new queue-manager cluster" on page 152
Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Alter the queue-manager definitions to add repository definitions

On each queue manager that is to hold a full repository, you need to alter the queue-manager definition.

To alter the queue-manager definition, use the ALTER QMGR command and specifying the REPOS attribute:

```
ALTER QMGR REPOS(INVENTORY)
```

If you enter:

```
     1 : ALTER QMGR REPOS(INVENTORY)
AMQ8005: Websphere MQ queue manager changed.
```

1. C:\..runmqsc LONDON
2. ALTER QMGR REPOS(INVENTORY) (as shown above)

LONDON will be changed to a full repository.

Note: If you just runmqsc and enter the ALTER QMGR command, the local queue manager will be changed.

Related concepts:

"Setting up a new queue-manager cluster" on page 152
Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Define the CLUSRCVR channels

On every queue manager in a cluster you need to define a cluster-receiver channel on which the queue manager can receive messages.

This definition defines the queue manager's connection name and the CLUSTER keyword shows the queue manager's availability to receive messages from other queue managers in the cluster. The queue manager's connection name is stored in the repositories, where other queue managers can refer to it.

Using transport protocol TCP/IP to define the channel:

On the LONDON queue manager, define:

```
DEFINE CHANNEL(TO.LONDON) CHLTYPE(CLUSRCVR) TRPTYPE(TCP)
CONNAME(LONDON.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('TCP Cluster-receiver channel for queue manager LONDON')
```

```
    1 : DEFINE CHANNEL(TO.LONDON) CHLTYPE(CLUSRCVR) TRPTYPE(TCP)
        CONNAME(LONDON.CHSTORE.COM) CLUSTER(INVENTORY)
        DESCR('TCP Cluster-receiver channel for queue manager LONDON')
AMQ8014: Websphere MQ channel created.
07/09/98  12:56:35  No repositories for cluster 'INVENTORY'
```

In this example the channel name is TO.LONDON, and the connection name (CONNAME) is the network address of the machine the queue manager resides on, which is LONDON.CHSTORE.COM. The network address can be entered as an alphanumeric DNS hostname, or an IP address in either in IPv4 dotted decimal form (for example 9.20.9.30) or IPv6 hexadecimal form (for example fe80:43e4:0204:acff:fe97:2c34:fde0:3485). Do not allow the CONNAME to specify a generic name. The port number is not specified, so the default port (1414) is used.

On the NEWYORK queue manager, define:

```
DEFINE CHANNEL(TO.NEWYORK) CHLTYPE(CLUSRCVR) TRPTYPE(TCP)
CONNAME(NEWYORK.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('TCP Cluster-receiver channel for queue manager NEWYORK')
```

Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Define the CLUSSDR channels

On every queue manager in a cluster you need to define one cluster-sender channel on which the queue manager can send messages to one of the full repository queue managers.

In this case there are only two queue managers, both of which hold full repositories. They must each have a CLUSSDR definition that points to the CLUSRCVR channel defined at the other queue manager. Note that the channel names given on the CLUSSDR definitions must match those on the corresponding CLUSRCVR definitions.

Using transport protocol TCP/IP:

On the LONDON queue manager, define:

```
DEFINE CHANNEL(TO.NEWYORK) CHLTYPE(CLUSSDR) TRPTYPE(TCP)
CONNAME(NEWYORK.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('TCP Cluster-sender channel from LONDON to repository at NEWYORK')
```

```
    1 : DEFINE CHANNEL(TO.NEWYORK) CHLTYPE(CLUSSDR) TRPTYPE(TCP)
        CONNAME(NEWYORK.CHSTORE.COM) CLUSTER(INVENTORY)
        DESCR('TCP Cluster-sender channel from LONDON to repository at NEWYORK')
AMQ8014: Websphere MQ channel created.
07/09/98  13:00:18    Channel program started.
```

On the NEWYORK queue manager, define:

```
DEFINE CHANNEL(TO.LONDON) CHLTYPE(CLUSSDR) TRPTYPE(TCP)
CONNAME(LONDON.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('TCP Cluster-sender channel from NEWYORK to repository at LONDON')
```

Related concepts:

Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Define the cluster queue INVENTQ

Define the INVENTQ queue on the NEWYORK queue manager, specifying the CLUSTER keyword.

```
DEFINE QLOCAL(INVENTQ) CLUSTER(INVENTORY)
```

```
    1 : DEFINE QLOCAL(INVENTQ) CLUSTER(INVENTORY)
AMQ8006: Websphere MQ queue created.
```

The CLUSTER keyword causes the queue to be advertised to the cluster. As soon as the queue is defined it becomes available to the other queue managers in the cluster. They can send messages to it without having to make a remote-queue definition for it.

Now that you have completed all the definitions, if you have not already done so start the channel initiator on WebSphere MQ for z/OS and, on all platforms, start a listener program on each queue manager. The listener program listens for incoming network requests and starts the cluster-receiver channel when it is needed.

All cluster queue managers need a channel initiator to monitor the system-defined initiation queue SYSTEM.CHANNEL.INITQ and a channel listener program on each queue manager. A channel listener program 'listens' for incoming network requests and starts the appropriate receiver channel when it is needed; see "Channel listener" on page 157 for more information.

Channel initiator: This is the initiation queue for all transmission queues including the cluster transmission queue.

WebSphere MQ for z/OS

There is one channel initiator for each queue manager and it runs as a separate address space. You start it using the MQSC START CHINIT command, which you issue as part of your queue manager startup.

Platforms other than z/OS

When you start a queue manager, a channel initiator is automatically started if the queue manager attribute SCHINIT is set to QMGR. Otherwise it can be started using the MQSC START CHINIT command or the runmqchi control command.

Channel listener:

The implementation of channel listeners is platform specific, however there are some common features. On all WebSphere MQ platforms, the listener can be started using the MQSC command START LISTENER. On Windows systems and UNIX systems, you can make the listener start automatically with the queue manager by setting the CONTROL attribute of the LISTENER object to QMGR or STARTONLY.

Platform-specific details follow:

WebSphere MQ for z/OS

Use the channel listener program provided by WebSphere MQ. To start a WebSphere MQ channel listener, use the MQSC command START LISTENER, which you issue as part of your channel initiator startup. For example:

```
START LISTENER PORT(1414) TRPTYPE(TCP)
```

As well as a listener for each queue manager, members of a queue-sharing group can make use of a shared listener. Do not use shared listeners in conjunction with clusters. Specifically, do not make the CONNAME of the queue manager's CLUSRCVR channel the address of the queue sharing group's shared listener. If you do, queue managers might receive messages for queues for which they do not have a definition.

WebSphere MQ for Windows

Use either the channel listener program provided by WebSphere MQ, or the facilities provided by the operating system.

To start the WebSphere MQ channel listener use the RUNMQLSR command. For example:

```
RUNMQLSR -t tcp -p 1414 -m QM1
```

WebSphere MQ on UNIX systems

Use either the channel listener program provided by WebSphere MQ, or the facilities provided by the operating system (for example, inetd for TCP communications).

To start the WebSphere MQ channel listener use the runmqlsr command. For example:

```
runmqlsr -t tcp -p 1414 -m QM1
```

To use inetd to start channels, configure two files:

1. Edit the file /etc/services. (To do this you must be logged in as a superuser or root.) If you do not have the following line in that file, add it as shown:

   ```
   MQSeries       1414/tcp      # Websphere MQ channel listener
   ```

   where 1414 is the port number required by WebSphere MQ. You can change this, but it must match the port number specified at the sending end.

2. Edit the file /etc/inetd.conf. If you do not have the following line in that file, add it as shown:

   For AIX:

   ```
   MQSeries stream tcp nowait mqm /usr/mqm/bin/amqcrsta amqcrsta
   -m queue.manager.name
   ```

   The updates become active after inetd has reread the configuration files. Issue the following commands from the root user ID:

   On AIX:

   ```
   refresh -s inetd
   ```

You need to delete the remote queue definition at LONDON for the INVENTQ queue.

As the INVENTQ is defined to the cluster, the queue managers no longer need remote-queue definitions for the INVENTQ. At every queue manager, issue the command:

```
DELETE QREMOTE(INVENTQ)
```

Until you do this, the remote-queue definitions will continue to be used and you will not get the benefit of using clusters.

Related concepts:

"Setting up a new queue-manager cluster" on page 152
Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Verify and test the cluster

Issue some DISPLAY commands to verify the cluster that you have set up.

The responses you see should be similar to those shown in the examples that follow.

From the NEWYORK queue manager, issue the command:

```
dis clusqmgr(*)
```

```
     1 : dis clusqmgr(*)
AMQ8441: Display Cluster Queue Manager details.
   CLUSQMGR(NEWYORK)              CLUSTER(INVENTORY)
   CHANNEL(TO.NEWYORK)
AMQ8441: Display Cluster Queue Manager details.
   CLUSQMGR(LONDON)               CLUSTER(INVENTORY)
   CHANNEL(TO.LONDON)
```

Now issue the corresponding DISPLAY CHANNEL STATUS command:

```
dis chstatus(*)
```

```
     1 : dis chstatus(*)
AMQ8417: Display Channel Status details.
   CHANNEL(TO.NEWYORK)           XMITQ( )
   CONNAME(9.20.40.24)           CURRENT
   CHLTYPE(CLUSRCVR)             STATUS(RUNNING)
   RQMNAME(LONDON)
AMQ8417: Display Channel Status details.
   CHANNEL(TO.LONDON)            XMITQ(SYSTEM.CLUSTER.TRANSMIT.QUEUE)
   CONNAME(9.20.51.25)           CURRENT
   CHLTYPE(CLUSSDR)              STATUS(RUNNING)
   RQMNAME(LONDON)
```

Because the INVENTQ queue has been advertised to the cluster there is no need for remote-queue definitions. Applications running on NEWYORK and applications running on LONDON can put messages to the INVENTQ queue. They can receive responses to their messages by providing a reply-to queue and specifying its name when they put messages.

At every queue manager, issue the command:

```
DELETE QREMOTE(INVENTQ)
```

Note: The definition for the local queue LONDON_reply does not need the CLUSTER attribute. NEWYORK replies to this queue by explicitly specifying the queue manager name.

Adding a new queue manager to a cluster

How to add a queue manager to the cluster you have set up.

Scenario:

- The INVENTORY cluster has been set up as described in "Setting up a new queue-manager cluster" on page 152. It contains two queue managers, LONDON and NEWYORK, which both hold full repositories.
- A new branch of the chain store is being set up in Paris and you want to add a queue manager called PARIS to the cluster.
- Queue manager PARIS will send inventory updates to the application running on the system in New York by putting messages on the INVENTQ queue.
- Network connectivity exists between all three systems.
- The network protocol is TCP.

Procedure

Follow these steps to add a new queue manager to a cluster.

1. Determine which full repository PARIS should refer to first

Every queue manager in a cluster must refer to one or other of the full repositories in order to gather information about the cluster and so build up its own partial repository. Choose either of the repositories, because as soon as a new queue manager is added to the cluster it immediately learns about the other repository as well. Information about changes to a queue manager is sent directly to two repositories. In this example we choose to link PARIS to the queue manager LONDON, purely for geographical reasons.

Note: Perform the remaining steps in any order, after queue manager PARIS is started.

2. Define a CLUSRCVR channel on queue manager PARIS

Every queue manager in a cluster needs to define a cluster-receiver channel on which it can receive messages. On PARIS, define:

```
DEFINE CHANNEL(TO.PARIS) CHLTYPE(CLUSRCVR) TRPTYPE(TCP)
CONNAME(PARIS.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('Cluster-receiver channel for queue manager PARIS')
```

This advertises the queue manager's availability to receive messages from other queue managers in the cluster INVENTORY. There is no need to make definitions on other queue managers for a sending end to the cluster-receiver channel TO.PARIS. These will be made automatically when needed.

3. Define a CLUSSDR channel on queue manager PARIS

Every queue manager in a cluster needs to define one cluster-sender channel on which it can send messages to its initial full repository. On PARIS, make the following definition for a channel called TO.LONDON to the queue manager whose network address is LONDON.CHSTORE.COM.

```
DEFINE CHANNEL(TO.LONDON) CHLTYPE(CLUSSDR) TRPTYPE(TCP)
CONNAME(LONDON.CHSTORE.COM) CLUSTER(INVENTORY)
DESCR('Cluster-sender channel from PARIS to repository at LONDON')
```

Now that you have completed all the definitions, if you have not already done so, start the channel initiator on WebSphere MQ for z/OS and, on all platforms, start a listener program on queue manager PARIS. The listener program listens for incoming network requests and starts the cluster-receiver channel when it is needed.

By making only two definitions, a CLUSRCVR definition and a CLUSSDR definition, the queue manager PARIS has been added to the cluster.

Now the PARIS queue manager learns, from the full repository at LONDON, that the INVENTQ queue is hosted by queue manager NEWYORK. When an application hosted by the system in Paris tries to put messages to the INVENTQ, PARIS automatically defines a cluster-sender channel to connect to the cluster-receiver channel TO.NEWYORK. The application can receive responses when its queue-manager name is specified as the target queue manager and a reply-to queue is provided.

4. Issue the REFRESH CLUSTER command

If you are adding a queue manager to a cluster that has previously been removed from the same cluster, you must issue the **REFRESH CLUSTER** command on the queue manager you are adding. This completes the task of adding the queue manager.

```
REFRESH CLUSTER(INVENTORY) REPOS(YES)
```

Selecting queue managers to hold full repositories

In each cluster you must select at least one, preferably two, or possibly more of the queue managers to hold full repositories.

A cluster can work quite adequately with only one full repository but using two improves availability. You interconnect the full repository queue managers by defining cluster-sender channels between them.

- The most important consideration is that the queue managers chosen to hold full repositories need to be reliable and well managed. For example, it would be far better to choose queue managers on a stable z/OS system than queue managers on a portable personal computer that is frequently disconnected from the network.
- You should also consider the planned outages of the systems hosting your full repositories, and ensure that they do not have coinciding outages.
- You might also consider the location of the queue managers and choose ones that are in a central position geographically or perhaps ones that are located on the same system as a number of other queue managers in the cluster.
- Another consideration might be whether a queue manager already holds the full repositories for other clusters. Having made the decision once, and made the necessary definitions to set up a queue manager as a full repository for one cluster, you might choose to rely on the same queue manager to hold the full repositories for other clusters of which it is a member.

When a queue manager sends out information about itself or requests information about another queue manager, the information or request is sent to two full repositories. A full repository named on a CLUSSDR definition handles the request whenever possible, but if the chosen full repository is not available another full repository is used. When the first full repository becomes available again it collects the latest new and changed information from the others so that they keep in step.

If all of the full repository queue managers go out of service at the same time, queue managers continue to work using the information they have in their partial repositories. The repositories are limited to using the information that they have. New information and requests for updates cannot be processed. When the full repository queue managers reconnect to the network, messages are exchanged to bring all repositories (both full and partial) back up-to-date.

The full repositories republish the publications they receive through the manually-defined CLUSSDR channels, which must point to other full repositories in the cluster. You must make sure that a publication received by any full repository ultimately reaches all of the other full repositories. This is done by manually defining CLUSSDR channels between the full repositories. Having more interconnection of full repositories will make the cluster more robust.

Having only two full repositories is sufficient for all but very exceptional circumstances

Initial points to consider when setting up a new queue-manager cluster

Related tasks:

"Migrating publish/subscribe collectives from WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ" on page 151
Complete these tasks to migrate the configuration data from publish/subscribe collectives in WebSphere Message Broker Version 6.0 or WebSphere Message Broker to WebSphere MQ queue-manager clusters.

Migrating existing z/OS applications

You must migrate your existing z/OS applications to be 64-bit before you can use them in WebSphere Message Broker Version 7.0.

You must recompile and link your C code and user exits on z/OS using XPLINK, ensuring that you use the:

- `LP64` flag
- IEEE Floating Point format

Therefore, the options you require are:

- LP64
- FLOAT (IEEE) - the default when you use LP64
- XPLINK - the default when you use LP64

When you make WebSphere MQ calls from within your C code or user exits, you need to link against the following stub:

```
++WMQHLQ++.SCSQDEFS(CSQBMB2X)
```

where `++WMQHLQ++` refers to the high level qualifier for the WebSphere MQ datasets.

You must use the `cmqcmb.h` header file sipped in WebSphere Message Broker Version 7.0 to recompile code that uses WebSphere MQ structures.

Using the `cmqc.h` header file provided by WebSphere MQ results in compilation errors, as `cmqc.h` explicitly disallows 64-bit compilation.

Note, that compilation using the `cmqcmb.h` header file, and linking against `CSQBMB2X` are supported only for user extensions running within the WebSphere Message Broker Version 7.0 address space.

See "Compiling a C user-defined extension" on page 3047 for examples of 64-bit compilation.

Compile user-defined extensions in C for all supported operating systems.

Migrating from Version 6.1 products

Migrate your components and resources to WebSphere Message Broker Version 7.0.

Before you begin

Before you start:

Read “Preparing for migration from Version 6.1” on page 165.

About this task

You can migrate to WebSphere Message Broker Version 7.0 from the following products:

- WebSphere Message Broker
- WebSphere Message Broker with Rules and Formatter Extension

For full product version and release levels, see “Supported migration paths” on page 3579.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

The instructions in this section apply to all operating systems that are supported by Version 6.1.

You can migrate to WebSphere Message Broker Version 7.0 only if you do not use the additional features provided by Rules and Formatter, or you choose not to use them after migration. If you want to use the additional features provided by Rules and Formatter, you can migrate to WebSphere Message Broker Version 7.0.0.6 with WebSphere Message Broker with Rules and Formatter Extension Version 7.0.

Complete the following migration tasks in the order shown to reduce the possibility of problems:

1. Back up your components and resources to ensure that you can return to your previous version if necessary. See the information center for your current product for more information and instructions.

   Consider backing up the following resources:

   - The internal configuration repository maintained by the Configuration Manager.
   - The broker database.
   - Other critical databases that are accessed by your message flows.
   - All your development resources; for example, message flows and message sets.

If you use a repository to manage these resources, check that the product you use provides sufficient features for you to recover your resources at a specific version.

2. Migrate your WebSphere MQ installation to a supported version.
3. Optional: In WebSphere Message Broker Version 7.0, publish/subscribe is controlled by WebSphere MQ. If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate your broker.

   Information about how to run the **migmqbrk** command to migrate and complete other tasks that might be required, is provided in "Migrating publish/subscribe information to WebSphere MQ" on page 141.

   When you complete this step, all your subscriptions are migrated to WebSphere MQ; subsequently, you must use WebSphere MQ facilities to change subscriptions. A subscription related to the SYSTEM.BROKER.ADMIN.REPLY queue has to be removed manually.

   If you are using cloned WebSphere Message Broker support in Version 6.1, you must change to use WebSphere MQ Clustering for Publish and Subscribe.
4. Migrate the WebSphere Message Broker Toolkit.

   If the users of your toolkit operate in a team environment and share resources with each other, upgrade all users to Version 7.0 at the same time to ensure continued access to all resources. Because toolkit resources are stored in a different format when they are first saved in Version 7.0, your users might experience compatibility problems in some circumstances if some of their colleagues are using Version 7.0 and they are still working with a previous version.
5. Migrate the broker.
6. Optional: If you are migrating from a secure domain, you cannot directly migrate security settings for brokers. You must set up equivalent security by using the facilities provided by Version 7.0. To set up administration security for a broker:
   a. Activate broker administration security.
   b. Set up your security based on existing ACLs.
7. Start the broker by using the **mqsistart** command.
8. Review the changes of behavior that are introduced in Version 7.0.
9. Consider the list of post-migration tasks, and follow the guidance provided if these tasks apply to your environment.

Related concepts:

"Coexistence with previous versions and other products" on page 139
WebSphere Message Broker Version 7.0 supports restricted coexistence with previous versions and with other products.

WebSphere Message Broker Information Center online

Preparing for migration from Version 6.1

Plan the order and extent of the migration of components and resources to Version 7.0.

Before you begin

Before you start: Check that your current installation of WebSphere Message Broker Version 6.1 is at a supported level for migration. Details are provided in "Supported migration paths" on page 3579.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

About this task

Complete the following steps:

Procedure

1. Decide how you want to migrate the WebSphere Message Broker Version 6.1 product components:
   a. Find out what is new in Version 7.0, and learn about new and changed function. These changes might affect how you want to use your migrated components in the future.
   b. Plan your migration of WebSphere MQ to a supported version. It is a requirement that a supported version of WebSphere MQ is installed before installing WebSphere Message Broker Version 7.0.

      Publish/subscribe functions are no longer supported in the broker; WebSphere MQ provides this support. If your applications use the publish/subscribe communication model, you must migrate your subscriptions to a supported version of WebSphere MQ before you migrate your brokers.
   c. Check the requirements for other products on which Version 7.0 components might depend. If you have configured your message flows to use external resources, such as databases, or event monitoring applications, you might have to modify your configuration. You can find details of supported versions of optional products on the WebSphere Message Broker Requirements web page.
   d. Decide where you will migrate the product components; you can migrate them to a different location on the same computer or to a second computer. For example, you might want to migrate components to another location to maintain availability during the migration.

e. Decide when to migrate the product components. You might want to preserve some components at the Version 6.1 level for now, and migrate them later. Each migration task includes steps for installing WebSphere Message Broker Version 7.0, so you might decide to carry out the tasks in parallel, rather than completing one task before starting the next task.

f. Decide the order in which you will migrate your components. No required order is defined, but your specific circumstances might mean that you decide to migrate components in a particular order.

   A typical order might be:

   1) Install the WebSphere Message Broker Toolkit Version 7.0 on a single computer.
   2) Create a Version 7.0 broker, or migrate an existing broker to Version 7.0.
   3) Migrate further brokers and toolkits.

"Coexistence with previous versions and other products" on page 139 explains how WebSphere Message Broker Version 7.0 can coexist on the same computer with previous versions of the product. It also describes the extent to which Version 7.0 components can operate with components from previous versions.

2. Decide how you will use your existing development resources with WebSphere Message Broker Version 7.0.

   You do not have to perform specific tasks to migrate your development and deployment resources, such as message flow files, message set definition files, ESQL files, XML Schema files, and broker archive files. You can start using these resources with WebSphere Message Broker Version 7.0 immediately.

   However, some migration actions are performed automatically when you open or rebuild resources in the WebSphere Message Broker Toolkit; see "Migrating the WebSphere Message Broker Toolkit development resources from Version 6.1 to Version 7.0" on page 170 for details.

3. Decide what testing you will do to ensure a successful migration.

   The purpose of testing your migration is to identify problems that might arise during migration. For example, if problems arise you might need to restore some migrated resources to the Version 6.1 level that you backed up before you started the migration; all post-migration changes to these resources are lost in this situation. If you migrate your development and test domains before you migrate your production domain, you can identify potential problems and develop a strategy for dealing with further problems.

   Each new release can include changes to address product defects that affect external behavior. If your resources depend on undocumented or incorrect behavior (for example, the ESQL code in a Compute node), you might need to make changes and test these resources to understand the implications in your business scenarios. Read the guidance provided in "Reviewing technical changes in Version 7.0" on page 205 to see if your configuration is affected.

4. Optional: When you are ready to migrate, run the **mqsimigratecomponents** command with the **-c** parameter. Use this form of the command to run a premigration check against the Version 6.1 components to ensure that they can be migrated. The premigration check identifies potential problems so that you can correct them before you continue with migration.

5. Optional: Consider adding time to your migration plan to update development resources in response to changes in product behavior. If you have identified changes that you must make to one or more of your resources in step 3, you must allow time during your migration schedule to make the necessary changes and test those applications.

What to do next

Next: After you have planned your migration, back up your resources.

Related concepts:

Backing up WebSphere Message Broker resources

Back up your resources before you start to migrate components to Version 7.0.

Before you begin

Before you start:

Read "Preparing for migration from Version 6.1" on page 165 to plan your migration strategy.

About this task

Before you carry out migration tasks, back up your WebSphere Message Broker resources by completing the following steps:

Procedure

1. Back up the broker database tables. On z/OS, customize and submit the JCL member BIPBUDB. On other platforms, use the documented procedures that are provided by your database supplier.
2. Optional: If your message flows access user databases through an ODBC connection, back up the ODBC files that you use for these connections. Take a copy of these files and store them safely in a different location.
3. Optional: If you have created or configured configurable services for your message flows, record the properties of all your configurable services. For example, a message flow might access user databases through a JDBC

connection, for which you have set up a JDBCProvider configurable service. Run the **mqsireportproperties** for these services, take a copy of the output, and store it safely in a different location.

4. Back up your WebSphere Message Broker Toolkit workspace and resources; for example, message flow files, message set definition files, Java files, ESQL files, mapping files, XML Schema files, and broker archive (BAR) files.
   - Export all your projects from your WebSphere Message Broker Toolkit Version 6.1.
   - Archive your workspace resources:
     - If you manage your workspace resources in a shared repository, for example CVS, follow standard backup procedures for safeguarding versions. Create a version for storing Version 7.0 resources.
     - If you maintain your workspace resources on a local or shared disk, copy your workspace directory to a different location.

Results

For detailed instructions on how to back up these resources, see the WebSphere Message Broker information center.

What to do next

Next: After you have backed up your WebSphere Message Broker resources, update your ODBC definitions.

Related tasks:

"Migrating from Version 6.1 products" on page 163
Migrate your components and resources to WebSphere Message Broker Version 7.0.

Related information:

WebSphere Message Broker Information Center online

Updating ODBC definitions when migrating

Before you migrate a broker, create ODBC definitions for user databases that specify appropriate database drivers for WebSphere Message Broker Version 7.0.

About this task

The database drivers that are supported by Version 7.0 are at a later version than the drivers used by Version 6.1 and Version 6.0.

Complete this update before you run the **mqsimigratecomponents** command for the broker that uses these ODBC connections.

Follow the instructions provided for your operating system:

Windows systems

To change the ODBC connection definitions:

1. Open the ODBC Data Source Administrator window.
2. Open the System DSN page.
3. For each Oracle and Sybase database that is accessed by the broker, associate the data source name with the new ODBC driver:

a. Delete the data source by clicking **Remove**.
b. Re-create the data source with the new ODBC driver by clicking **Add**.

The following table displays the name of the new ODBC driver for each database management system (DBMS).

DBMS	New ODBC driver
Oracle	WebSphere Message Broker DataDirect Technologies 6.00 32-BIT Oracle Wire Protocol
Sybase	WebSphere Message Broker DataDirect Technologies 6.00 32-BIT Sybase Wire Protocol

To change the XA resource manager definitions:

1. Open the **Properties** window of the broker queue manager using the WebSphere MQ Services snap-in.
2. Open the **Resources** page.
3. For each Oracle and Sybase database that participates in a global unit of work, coordinated by the broker queue manager, change the contents of the **SwitchFile** field. For changes to the switch file configuration to take effect, you must restart the broker queue manager.

   The following table specifies what you must change for each database management system (DBMS). *WBIMB* represents the fully qualified path name of the directory in which you have installed WebSphere Message Broker.

DBMS	Change ...	To ...
Oracle	*WBIMB*\bin\ukor8dtc20.dll or*WBIMB*\bin\ukor8dtc22.dll or*WBIMB*\bin\ukor8dtc23.dll	*WBIMB*\bin\ukora24.dll
Sybase	*WBIMB*\bin\ukase20.dll or*WBIMB*\bin\ukase22.dll or*WBIMB*\bin\ukase23.dll	*WBIMB*\bin\ukase24.dll

Linux and UNIX systems

To change the ODBC connection definitions:

Create an ODBC definitions file by following the instructions in "Connecting to a database from Linux and UNIX systems using the DataDirect drivers" on page 674. Before you run the commands at the new service level, check that your ODBCINI environment variable points to the new file and not to the existing file.

To change the XA resource manager definitions:

To change the XA resource manager definitions, edit the queue manager configuration file (`qm.ini`) of the queue manager that is associated with the broker. The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`, where *queue_manager_name* is the name of the queue manager that is associated with the broker.

In the *XAResourceManager* stanza for each Oracle and Sybase database that participates in a global unit of work that is coordinated by the broker queue manager, change the entry for the

switch file. For changes to the switch file configuration to take effect, you must restart the broker queue manager.

The following table specifies what you must change for each broker operating system and database management system (DBMS).

DBMS	Change ...	To ...

Oracle	`SwitchFile=UKor8dtc20.so`
	`orSwitchFile=UKor8dtc22.so`
	`orSwitchFile=UKoradtc22.so`
	`orSwitchFile=UKor8dtc23.so`
	`orSwitchFile=UKoradtc23.so`
		`SwitchFile=UKoradtc24.so`

Sybase (not supported on Linux on IBM z Systems)	`SwitchFile=UKasedtc20.so`
	`orSwitchFile=UKasedtc22.so`
	`orSwitchFile=UKasedtc23.so`
		`SwitchFile=UKasedtc24.so`

To check that your ODBC environment is set up correctly on Linux and UNIX systems, run the **mqsicvp** command. This command also validates the connection to all data sources that are listed in the `odbc.ini` file that have been associated with a broker by using the **mqsisetdbparms** command. For more information, see "**mqsicvp** command" on page 3857.

Results

If you revert to a previous version of WebSphere Message Broker, you must reverse the changes that you make to the ODBC definitions. Update your ODBC files after you have run the **mqsimigratecomponents** command, but before you restart the broker at the earlier version.

Migrating the WebSphere Message Broker Toolkit development resources from Version 6.1 to Version 7.0

You cannot migrate the WebSphere Message Broker Toolkit component from WebSphere Message Broker Version 6.1, but you can install Version 7.0 to coexist with Version 6.1, and migrate the development resources that you have created in your workspace.

About this task

- You cannot deploy resources from the WebSphere Message Broker Toolkit Version 7.0 to brokers at a previous version that you have not migrated to Version 7.0.
- If any of the following actions have caused an error in the project:
  - Creating the metadata information for the user-defined node project
  - Correcting the plug-in identifier if it does not match the project name
  - Ensuring all the user-defined nodes are in the same category

  The WebSphere Message Broker Toolkit flags the error, and you can use a Quick Fix to rectify the error, see "Applying a Quick Fix to a task list error" on page 2862.However, if you have different user-defined nodes that depend on different resources that have identical names, the broker archive (BAR) file compiler produces an error indicating a naming conflict in the dependent resources. Quick Fix cannot be used to resolve BAR file compiler errors.
- You cannot migrate a deployable JAR file for a user-defined node that was created in Version 7.0, or before Version 7.0.

To migrate your WebSphere Message Broker Toolkit workspace to Version 7.0, complete the following steps:

Procedure

1. Install WebSphere Message Broker Toolkit Version 7.0 in a different location from WebSphere Message Broker Toolkit Version 6.1 or Version 6.0. For detailed instructions, see "Installing the WebSphere Message Broker Toolkit" on page 276, or refer to the "Installation Guide" on page 233.
2. When you start the WebSphere Message Broker Toolkit Version 7.0 for the first time, you are prompted to enter a workspace location. Enter the directory that contains the WebSphere Message Broker Toolkit Version 6.1 or Version 6.0 workspace that you want to migrate and click **OK**. The workspace and resources are now available in the WebSphere Message Broker Toolkit Version 7.0.
3. In the Broker Application Development perspective, select **Window** > **Reset Perspective** to ensure that all views and menus are updated for Version 7.0.
4. You must migrate any user-defined node source projects that were developed in Version 7.0, or before Version 7.0. An error is displayed on all projects that require migration. You can use a Quick Fix to clear these errors, see "Applying a Quick Fix to a task list error" on page 2862. After fixing the errors, you must package the user-defined node source projects and redistribute to the users, see "Packaging and distributing a user-defined node project" on page 3121.

Results

You can now view and modify existing resources, and create resources. You can deploy your workspace resources to Version 7.0 brokers.

What to do next

When you have migrated the resources associated with the WebSphere Message Broker Toolkit, you must migrate your brokers, see "Migrating a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0" on page 172.

When you have completed these tasks, for information about tasks that you might want to perform after migration, see "Post-migration tasks" on page 204.

Related concepts:

After you have migrated to Version 7.0, finish setting up your environment.

Migrating a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0

Migrate one or more brokers to Version 7.0.

Before you begin

Before you start: Read "Preparing for migration from Version 6.1" on page 165.

About this task

To migrate a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0, see the appropriate topic for your operating system:

- "Migrating a Version 6.1 broker to Version 7.0 on distributed operating systems" on page 173
- "Migrating a Version 6.1 broker to Version 7.0 on z/OS" on page 177

Results

You do not have to redeploy resources to a broker that you have migrated. When you start the broker, it starts all existing message flows.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Coexistence with previous versions and other products" on page 139

You can migrate to WebSphere Message Broker Version 7.0 from previous versions of the product.

Migrating a Version 6.1 broker to Version 7.0 on distributed operating systems

Migrate a broker to use the enhanced facilities available in Version 7.0.

Before you begin

Before you start:

- Back up your broker resources.
- For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- Install WebSphere MQ and migrate your queue managers and other resources, following the instructions provided by WebSphere MQ.
- Optional: If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate the broker.
- Migrate the WebSphere Message Broker Toolkit from Version 6.1 to Version 7.0.
- Check that you have no aggregations in progress on this broker. When you migrate a broker to Version 7.0, all live data that is being stored for aggregations in progress is lost.
- If the broker runs in a locale that is not listed in "Locales" on page 3629, check that the code page is one of the supported code pages, and that the locale is set up correctly.

About this task

If you stop the broker, you can migrate it immediately to the new version on the same computer. If you prefer not to stop the broker to avoid problems for your business applications, or if you want to reproduce the broker function on another computer, you can associate the application logic on your Version 6.1 broker with a separate Version 7.0 broker.

Select the topic that is appropriate to your environment:

- "Migrating a Version 6.1 broker to Version 7.0"
- "Migrating application logic to a Version 7.0 broker" on page 174

Migrating a Version 6.1 broker to Version 7.0:
About this task

To migrate a Version 6.1 broker on a distributed operating system to Version 7.0 on the same computer, complete the following steps:

Procedure

1. Install WebSphere Message Broker Version 7.0 on the same computer as Version 6.1. Install at least the Broker component; other components are optional. You must specify a new location for this installation.
2. Open the WebSphere Message Broker Toolkit Version 6.1, and remove the broker from the domain configuration.
3. Stop all channels that are connected to the Version 6.1 broker.

4. Open a Version 6.1 command environment, and stop the Version 6.1 broker by using the **mqsistop** command.
5. Optional: If your message flows access user databases by using ODBC connections, update the ODBC definitions to Version 7.0 format.
6. Set up the correct Version 7.0 command environment:
   - Linux UNIX On Linux and UNIX systems, open a new shell and run the environment profile **mqsiprofile** for this Version 7.0 installation.
   - Windows On Windows, click **Start**, and open the Command Console that is associated with this Version 7.0 installation.

     On Windows 7 and Windows Server 2008 systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.
7. Run the **mqsimigratecomponents** command to migrate the broker. For example:

   ```
   mqsimigratecomponents Broker1
   ```

   All configuration data is retrieved from the Version 6.1 broker database. If you had set a default user ID and password for your Version 6.1 broker by using the **-u** and **-p** options on the **mqsicreatebroker** command, these values are migrated with the broker. You can change these values for your Version 7.0 broker by using the **mqsisetdbparms** command.
8. On the AIX, Linux on x86-64, and Solaris on SPARC platforms, support has changed from both 32-bit and 64-bit support to 64-bit support only. 32-bit execution groups are converted to 64-bit. These platforms now require 64-bit libraries and 64-bit ODBC configurations for databases.
   a. Recompile C/C++ user-defined nodes, parsers, and exits to 64-bit, if the existing ones are 32-bit only.
   b. Configure the broker to point at these recompiled extensions by using the following command:

      ```
      mqsichangebroker -l userLilPath -x userExitPath
      ```

      where *userLilPath* defines one or more paths to your LIL files, and *userExitPath* defines one or more paths to your user exit programs.

   The following changes are made to environment variables, for all platforms:

Previous version	Version 7
MQSI_LILPATH64 and MQSI_LILPATH32	MQSI_LILPATH
MQSI_USER_EXIT_PATH64 and MQSI_USER_EXIT_PATH	MQSI_USER_EXIT_PATH
MQSI_SECURITY_PROVIDER_PATH64 and MQSI_SECURITY_PROVIDER_PATH32	MQSI_SECURITY_PROVIDER_PATH

   Update all custom profiles that set these environment variables.
9. Copy all additional custom environment settings from your previous environment into your Version 7.0 environment; for example, MQSI_FILENODES_ROOT_DIRECTORY.
10. Start the Version 7.0 broker by using the **mqsistart** command.

Migrating application logic to a Version 7.0 broker:

About this task

To migrate application logic from a Version 6.1 broker on a distributed operating system to a different Version 7.0 broker on the same computer, or on a different computer, complete the following steps:

Procedure

1. Install WebSphere Message Broker Version 7.0 on the same computer as Version 6.1, or on a different computer. Install at least the Broker component; other components are optional. If you are installing on the same computer, you must specify a different location.
2. Optional: If your message flows access user databases by using ODBC connections, update the ODBC definitions to Version 7.0 format.
3. Set up the correct Version 7.0 command environment:
   - Linux UNIX On Linux and UNIX systems, open a new shell and run the environment profile **mqsiprofile** for this Version 7.0 installation.
   - Windows On Windows, click **Start**, and open the Command Console that is associated with this Version 7.0 installation.

     On Windows 7 and Windows Server 2008 systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.
4. Create a Version 7.0 broker by using the **mqsicreatebroker** command; give it a name and a queue manager name that are different from the names of the Version 6.1 broker and queue manager. If you have installed one or both of these components on this computer, you can also create a local broker by using the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit.
5. Start the Version 7.0 broker by using the **mqsistart** command. If you have installed one or both of these components on this computer, you can also start a local broker by using the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit.
6. Write a list of the execution groups that you have on the Version 6.1 broker, and create these same execution groups on the Version 7.0 broker. Use the WebSphere Message Broker Explorer, the Version 7.0 WebSphere Message Broker Toolkit, or the **mqsicreateexecutiongroup** command to complete this step. On the AIX, Linux on x86-64, and Solaris on SPARC platforms, you can create only 64-bit execution groups.
7. Deploy the message flows and message sets that are in use by the Version 6.1 broker to the Version 7.0 broker from the Version 7.0 WebSphere Message Broker Toolkit. You cannot complete this step unless you have already migrated the WebSphere Message Broker Toolkit resources.
8. Configure all other relevant properties of the Version 6.1 broker on the Version 7.0 broker.
9. If you want to delete your Version 6.1 broker at this time, or later:
   a. In a Version 6.1 command environment, stop the Version 6.1 broker by using the **mqsistop** command.
   b. Remove the Version 6.1 broker from the Version 6.1 WebSphere Message Broker Toolkit.
   c. Redeploy the Version 6.1 topology from the Version 6.1 WebSphere Message Broker Toolkit to update the configuration data held by the Configuration Manager.

d. In a Version 6.1 command environment, delete the Version 6.1 broker by using the **mqsideletebroker** command.

What to do next

When you have completed these tasks, see the post-migration tasks for information about tasks that you might want to perform after migration.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Migrating a Version 6.1 broker to Version 7.0 on z/OS

Migrate a broker to use the enhanced facilities available in Version 7.0.

Before you begin

Before you start:

- Backup your broker resources.
- For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- Install WebSphere MQ and migrate your queue managers and other resources, following the instructions provided by WebSphere MQ.
- Optional: If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate the broker.
- Ensure that you are familiar with the steps involved in creating a broker on z/OS.
- Ensure that you are familiar with the **mqsimigratecomponents** command which the JCL (Job Control Language) file uses to migrate a broker.
- Check that you have no aggregations in progress. When you migrate a broker to Version 7.0, any live data that is being stored for aggregations in progress is lost.
- If the broker runs in a locale that is not listed in "Locales" on page 3629, check that the code page is one of the supported code pages and that the locale is set up correctly.

About this task

To migrate a WebSphere Message Broker Version 6.1 broker to Version 7.0 on z/OS:

Procedure

1. Stop the Version 6.1 broker and the Version 6.1 Configuration Manager.
2. Create a new broker PDSE.
3. Copy all broker JCL files from the Version 7.0 installed SBIPPROC and SBIPSAMP PDSEs to the new broker PDSE. You can then customize these files. Some customization is required for migration, as described in the following sub-steps. You can update these and other files at a later date, if required. See "Customizing the broker JCL" on page 625 for more information.

   You must take a backup copy of your Version 6.1 `ENVFILE` file before you submit the `BIPGEN` job from the Version 7.0 component data set. The `ENVFILE` file is stored in the directory referenced by the ++*HOME*++ JCL variable. Subsequently, if you want to migrate back to Version 6.1, restore the `ENVFILE` file, either from the backup file location, or by submitting the `BIPGEN` job from the Version 6.1 component data set, before you start the Version 6.1 broker.

   a. Customize the `BIPEDIT` file by using the values that are defined in the Version 6.1 `BIPEDIT` file.

b. Copy all additional changes that you have made to the Version 6.1 version of the BIPBPROF and BIPDSNAO files to these files in the Version 7.0 component data set. Submit the BIPGEN job to create the environment file ENVFILE.

c. Customize and submit the BIPMGCMP (**mqsimigratecomponents**) job. This job migrates the registry, queue, and broker database; connection to the broker database of the previous broker is required to complete this action.

   After migration, all information in the broker database is stored in an internal repository in Version 7.0; the Version 7.0 broker does not require a database.

4. Copy the renamed started task JCL file BIPBRKP to the procedures library. When you copy the started task, keep a second copy of the original in a safe place for backup purposes.
5. Start the Version 7.0 broker. The verification program checks the configuration of the broker.

What to do next

When you have completed these tasks, see the post-migration tasks for information about tasks that you might want to perform after migration.

Related concepts:

Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

Migrating Configuration Manager ACLs

If you are migrating from WebSphere Message Broker , WebSphere Message Broker Version 6.0, or WebSphere Event Broker Version 6.0, you can use the Access Control Lists (ACLs) that you set up in the Configuration Manager as the basis for your security model in Version 7.0.

Before you begin

Before you start:

- Migrate your broker by following the instructions in "Migrating a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0" on page 172 or "Migrating a broker from WebSphere Message Broker Version 6.0 to WebSphere Message Broker Version 7.0" on page 193.
- Activate broker administration security by following the instructions in "Enabling broker administration security" on page 368.

Administration security for a broker in Version 7.0 is disabled by default. Because no security details are migrated, when you migrate a broker from a previous version security is disabled, even if you had set up security in the previous version.

About this task

The Configuration Manager has been removed as a result of the architectural and security model changes in Version 7.0, therefore the commands that controlled this component and its ACLs have been removed:

mqsichangeconfigmgr
mqsicreateconfigmgr
mqsideleteconfigmgr
mqsireportconfigmgr
mqsicreateaclentry
mqsideleteaclentry
mqsilistaclentry

Although you can use the ACLs that you set up in previous versions as the basis for your security model in Version 7.0, you might choose to reconsider your security model, and set up different levels of control that match the facilities available in this version.

If you choose to use your existing ACLs as a basis for your security model in Version 7.0, consider the following factors:

- You can obtain a list of existing ACLs maintained by your Configuration Manager by using the **mqsilistaclentry** command.
- You can migrate existing groups, users, or both, subject to the following factors:
  - You must define the user ID on the same computer as the queue manager associated with the Version 7.0 broker.
  - On Linux and UNIX systems, you can grant authority only to the primary group of a user. All users that you have defined with the same primary group

automatically get the same level of security access. You must therefore consider the membership of all your groups to ensure that you give the required level of control to each user.

- You can grant only broker and execution level authorities for Version 7.0 brokers.
- If you grant read, write, and execute authority to a user ID for a Version 7.0 broker, this permission is equivalent to full control access in previous versions.
- If you grant read authority to a user ID for a Version 7.0 broker, this permission is equivalent to view access in previous versions.
- Check the authority that write and execute permissions grant for a Version 7.0 broker to determine the best match for edit and deploy access levels in previous versions.
- Although you can set up access for a particular computer or domain name in previous versions, you can use only user IDs and groups in Version 7.0. If you want to establish a more secure environment, consider the use of WebSphere MQ security exits and SSL.

To set up authorization for your Version 7.0 broker, complete the following steps.

Procedure

1. Review the authorizations that are required for specific tasks and commands. Details are provided in "Tasks and authorizations for broker administration security" on page 3645 and "Commands and authorizations for broker administration security" on page 3646.
2. Grant the authorities that your users require.
   - For details of this task on distributed systems, with examples, see "Granting and revoking authority on Linux, UNIX, and Windows systems" on page 374.
   - For details of this task on z/OS, with examples, see "Granting and revoking authority on z/OS systems" on page 376.

What to do next

Next: Start the broker in the WebSphere Message Broker Explorer, or run the **mqsistart** command.

"Commands" on page 3672
All WebSphere Message Broker Toolkit and runtime commands that are provided on distributed systems are listed, grouped by function, with references to command details.

Related information:

WebSphere MQ Version 7 Information Center online

Migrating a Microsoft Windows WebSphere Message Broker that is configured using Microsoft Cluster Services (MSCS)

You must complete a specific set of steps to migrate your MSCS cluster to WebSphere Message Broker Version 7.0.

Before you begin

Read the topics in the section "Migrating from Version 6.1 products" on page 163, and the topic "Using a broker with an existing high availability manager" on page 843.

About this task

Use the following procedure to migrate a WebSphere Message Broker that is configured using MSCS.

Migrating from WebSphere Message Broker to WebSphere Message Broker Version 7.0 .

Procedure

1. Install WebSphere Message Broker Version 7.0 onto each node. You must specify a new location for this installation.
2. Stop all channels that are connected to the WebSphere Message Broker broker.
3. In MSCS bring the broker resource offline, keeping the cluster disk and WebSphere MQ resource online on your primary node
4. In a WebSphere Message Broker Version 7.0 command console run the following command:

   ```
   mqsimigratecomponents BROKER1 -m
   ```

   where BROKER1 is the name of your broker
5. Move the broker cluster group to the secondary node. Note that the broker resource should remain stopped.
6. In a WebSphere Message Broker Version 7.0 command console run the following command:

   ```
   mqsimigratecomponents BROKER1 -m -1
   ```
7. Copy all additional custom environment settings from your previous environment into your WebSphere Message Broker Version 7.0 environment; for example: MQSI_FILENODES_ROOT_DIRECTORY.
8. Bring the cluster disk and WebSphere MQ resource offline.
9. Start the WebSphere Message Broker cluster group on its primary node.

What to do next

Migrating from WebSphere Message Broker Version 7.0 to WebSphere Message Broker .

1. In MSCS bring the broker resource offline, keeping the cluster disk and WebSphere MQ resource online on your primary node.
2. In a WebSphere Message Broker Version 7.0 command console run the following command:

   ```
   mqsimigratecomponents BROKER1 -s 7.0 -t 6.1
   ```
3. In a WebSphere Message Broker command console run the following command:

   ```
   mqsistart BROKER1
   ```

   This is required to update the Windows service to point at the WebSphere Message Broker binary files.
4. In a WebSphere Message Broker command console run the following command:

   ```
   mqsistop BROKER1
   ```
5. Move the broker cluster group to the secondary node. Note that the broker resource should remain stopped.
6. In a WebSphere Message Broker Version 7.0 command console run the following command:

   ```
   mqsimigratecomponents BROKER1 -m -s 6.1 -t 7 -1
   ```
7. In a WebSphere Message Broker Version 7.0 command console run the following command:

   ```
   mqsimigratecomponents BROKER1 -s 7.0 -t 6.1 -1
   ```
8. In a WebSphere Message Broker command console run the following command:

   ```
   mqsistart BROKER1
   ```

   This is required to update the Windows service to point at the WebSphere Message Broker binary files
9. In a WebSphere Message Broker command console run the following command:

   ```
   mqsistop BROKER1
   ```
10. Bring the cluster disk and WebSphere MQ resource offline.
11. Start the broker cluster group on its primary node.

Due to changes in the file security model used in WebSphere Message Broker Version 7.0, you might need to alter the file permissions of the shared resource.

If necessary, create a domain group, add the `userID` of your broker to this group, and give the group full access to the shared files.

Related tasks:

"Migrating from Version 6.1 products" on page 163
Migrate your components and resources to WebSphere Message Broker Version 7.0.

"Using a broker with an existing high availability manager" on page 843
You can use WebSphere Message Broker Version 7.0 with an existing high availability manager, for example HACMP, HA/XD, VCS, or HP-UX Serviceguard.

Migrating from Version 6.0 products

Migrate your components and resources to WebSphere Message Broker Version 7.0.

About this task

You can migrate to WebSphere Message Broker Version 7.0 products from the following products:

- WebSphere Event Broker Version 6.0
- WebSphere Message Broker Version 6.0
- WebSphere Message Broker with Rules and Formatter Extension Version 6.0

For full product version and release levels, see "Supported migration paths" on page 3579.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

The instructions in this section apply to all operating systems that are supported by Version 6.0. The instructions are the same for both WebSphere Event Broker Version 6.0 and WebSphere Message Broker Version 6.0; in the interests of readability, only WebSphere Message Broker Version 6.0 is shown.

If your current installation is WebSphere Message Broker with Rules and Formatter Extension Version 6.0, you can migrate to WebSphere Message Broker Version 7.0 only if you do not use the additional features provided by Rules and Formatter, or you choose not to use them after migration. If you want to use the additional features provided by Rules and Formatter, you need to migrate to WebSphere Message Broker Version 7.0.0.1 or later, with WebSphere Message Broker with Rules and Formatter Extension Version 7.0.

Some of the migration tasks that you must complete are dependent on the order in which you start them. Complete these tasks in the order shown, to reduce the possibility of problems:

1. Read "Preparing for migration from Version 6.0" on page 185.
2. Back up your components and resources to ensure that you can return to your previous version, if necessary. See the information center for your current product for more information and instructions.

   Consider backing up the following resources:

   - The internal configuration repository maintained by the Configuration Manager.
   - The broker database.
   - Other critical databases that are accessed by your message flows.
   - All your development resources; for example, message flows and message sets.

     If you use a repository to manage these resources, check that the product you use provides sufficient features for you to recover your resources at a specific version.
3. If you have installed SupportPac IA9Q, you must uninstall it before you install WebSphere Message Broker Version 7.0; see "Migrating from SupportPac IA9Q" on page 190.
4. Migrate your WebSphere MQ installation to a supported version.

5. Optional: If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate your broker.

   In WebSphere Message Broker Version 7.0, publish/subscribe is controlled by WebSphere MQ.

   Information about how to run the **migmqbrk** command to perform this migration and other tasks that might be required, is provided in "Migrating publish/subscribe information to WebSphere MQ" on page 141.

   When you have completed this step, all your subscriptions have been migrated to WebSphere MQ; in future, you must use WebSphere MQ facilities to change subscriptions.
6. Migrate the WebSphere Message Broker Toolkit.

   If your toolkit users operate in a team environment, and share resources with each other, upgrade all users to Version 7.0 at the same time to ensure continued access to all resources. Because toolkit resources are stored in a different format when they are first saved in Version 7.0, your users might experience compatibility problems in some circumstances if some of their colleagues are using Version 7.0 and they are still working with a previous version.
7. Migrate the broker.
8. Optional: If you are migrating from a secure domain, you cannot directly migrate security settings for brokers. You must set up equivalent security by using the facilities provided by Version 7.0. To set up administration security for a broker:
   a. Activate broker administration security.
   b. Set up your security based on existing ACLs.
9. Start the broker by using the **mqsistart** command.
10. Review the changes of behavior that are introduced in Version 7.0.
11. Consider the list of post-migration tasks, and follow the guidance provided if these tasks apply to your environment.

Related concepts:

"Coexistence with previous versions and other products" on page 139
WebSphere Message Broker Version 7.0 supports restricted coexistence with previous versions and with other products.

Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

Related information:

WebSphere Message Brokers Version 6.0 Information Center online

Preparing for migration from Version 6.0

Plan the order and extent of the migration of components and resources to Version 7.0.

Before you begin

Before you start: Check that your current installation of WebSphere Message Broker or WebSphere Event Broker Version 6.0 is at a supported level for migration. Details are provided in "Supported migration paths" on page 3579.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

About this task

Complete the following steps:

Procedure

1. Decide how you want to migrate the WebSphere Message Broker Version 6.0 product components:
   a. Find out what is new in Version 7.0 and learn about new and changed function. These changes might affect how you want to use your migrated components in the future.
   b. Plan your WebSphere MQ migration. A supported version of WebSphere MQ is required; you must install it before you install WebSphere Message Broker Version 7.0.

      Publish/subscribe functions are no longer supported in the broker; WebSphere MQ provides this support. If your applications use the publish/subscribe communication model, you must migrate your subscriptions to WebSphere MQ before you migrate your brokers.
   c. Check the requirements for other products on which Version 7.0 components might depend. If you have configured your message flows to use external resources, such as databases, or event monitoring applications, you might have to modify your configuration. You can find details of supported versions of optional products on the WebSphere Message Broker Requirements Web page.
   d. Decide where you will migrate the product components. Migrate them to a different location on the same computer or to a second computer. For example, you might want to migrate components to another location to maintain availability during the migration.
   e. Decide when to migrate the product components. You might want to preserve some components at the Version 6.0 level for now, and migrate them later. Each migration task includes steps for installing WebSphere Message Broker Version 7.0, so you might decide to carry out the tasks in parallel, rather than completing one task before starting the next task.
   f. Decide the order in which you will migrate your components. You can migrate components in any order, but your specific circumstances might mean that you need to migrate components in a particular order.

      A typical order might be:

1) Install a Version 7.0 toolkit.
2) Create a Version 7.0 broker, or migrate an existing broker to Version 7.0.
3) Migrate further brokers and toolkits.

"Coexistence with previous versions and other products" on page 139 explains how WebSphere Message Broker Version 7.0 can coexist on the same computer with previous versions of the product. It also describes the extent to which Version 7.0 components can operate with components from previous versions.

2. Decide how you will use your existing resources with WebSphere Message Broker Version 7.0.

   You do not have to perform specific tasks to migrate your development and deployment resources, such as message flow files, message set definition files, ESQL files, XML Schema files, and broker archive files. You can start using these resources with WebSphere Message Broker Version 7.0 immediately.

   However, some migration actions are performed automatically when you open or rebuild resources in the WebSphere Message Broker Toolkit; see "Migrating the WebSphere Message Broker Toolkit development resources from Version 6.0 to Version 7.0" on page 192 for details.

3. Decide what testing you will do to ensure a successful migration.

   The purpose of testing your migration is to identify any problems that might arise during migration. For example, if problems arise you might need to restore some migrated resources to the Version 6.0 level that you backed up before you started the migration, and all post-migration changes to these resources are lost. If you migrate your development and test domains before you migrate your production domain, you can identify potential problems and develop a strategy for dealing with further problems.

   Each new release can include changes to address product defects that affect external behavior. If your resources depend on undocumented or incorrect behavior (for example, the ESQL code in a Compute node), you might need to change and test these resources to understand the implications in your business scenarios. Read the guidance provided in "Reviewing technical changes in Version 7.0" on page 205 to see if your configuration is affected.

4. Optional: When you are ready to migrate, run the **mqsimigratecomponents** command with the **-c** parameter. Use this form of the command to run a premigration check against the Version 6.0 components to ensure that they can be migrated. The premigration check identifies potential problems so that you can correct them before you continue with migration.

5. Optional: Consider adding time to your migration plan to update resources in response to changes in product behavior. If you have identified changes that you must make to one or more of your resources in step 3, you must allow time during your migration schedule to make the necessary changes and test those applications.

What to do next

Next: After you have planned your migration, back up your resources.

Related concepts:

"Coexistence with previous versions and other products" on page 139
WebSphere Message Broker Version 7.0 supports restricted coexistence with previous versions and with other products.

Related tasks:

WebSphere Message Broker Requirements

WebSphere Message Broker Support

WebSphere MQ Version 7 Information Center online

Backing up WebSphere Message Broker Version 6.0 resources

Back up your resources before you start to migrate components to Version 7.0.

Before you begin

Before you start:

Read "Preparing for migration from Version 6.0" on page 185 to determine your migration strategy.

About this task

Before you carry out migration tasks, back up your WebSphere Message Broker Version 6.0 resources by completing the following steps:

Procedure

1. Back up the configuration repository. Use the **mqsibackupconfigmgr** command.
2. Back up the broker database tables. Use the documented procedures that are provided by your database supplier.
3. Optional: If your message flows access user databases through an ODBC connection, back up the ODBC files that you use for these connections. Take a copy of these files and store them safely in a different location.
4. Optional: If you have created or configured configurable services for your message flows, record the properties of all your configurable services. For example, a message flow might include a JMSInput node, for which you have set up a JMSProviders configurable service. Run the **mqsireportproperties** for these services, take a copy of the output, and store it safely in a different location.
5. Back up your WebSphere Message Broker Toolkit workspace and resources; for example, message flow files, message set definition files, Java files, ESQL files, mapping files, XML Schema files, and broker archive (BAR) files.
   - Export all your projects from your WebSphere Message Broker Toolkit Version 6.0.
   - Archive your workspace resources:

- If you manage your workspace resources in a shared repository, for example CVS, follow standard backup procedures for safeguarding versions. Create a version for storing Version 7.0 resources.
- If you maintain your workspace resources on a local or shared disk, copy your workspace directory to a different location.

Results

For detailed instructions on how to back up these resources, see the WebSphere Message Broker Version 6.0 information center.

What to do next

Next: After you have backed up your WebSphere Message Broker Version 6.0 resources, update your ODBC definitions.

Related tasks:

"Migrating from Version 6.0 products" on page 183
Migrate your components and resources to WebSphere Message Broker Version 7.0.

Related information:

WebSphere Message Brokers Version 6.0 Information Center online

Updating your ODBC definitions when migrating

As part of migrating a broker, create ODBC definitions for user databases that specify appropriate database drivers for Version 7.0.

About this task

The database drivers that are supported by Version 7.0 are at a later version than the drivers used by Version 6.1 and Version 6.0.

Complete this update before you run the **mqsimigratecomponents** command for the broker that uses these ODBC connections.

Follow the instructions provided for your operating system:

Windows systems

To change the ODBC connection definitions:

1. Open the ODBC Data Source Administrator window.
2. Open the System DSN page.
3. For each Oracle and Sybase database that is accessed by the broker, associate the data source name with the new ODBC driver:
   a. Delete the data source by clicking **Remove**.
   b. Re-create the data source with the new ODBC driver by clicking **Add**.

   The following table displays the name of the new ODBC driver for each database management system (DBMS).

DBMS	New ODBC driver
Oracle	WebSphere Message Broker DataDirect Technologies 6.00 32-BIT Oracle Wire Protocol
Sybase	WebSphere Message Broker DataDirect Technologies 6.00 32-BIT Sybase Wire Protocol

To change the XA resource manager definitions:

1. Open the **Properties** window of the broker queue manager using the WebSphere MQ Services snap-in.
2. Open the **Resources** page.
3. For each Oracle and Sybase database that participates in a global unit of work, coordinated by the broker queue manager, change the contents of the **SwitchFile** field. For changes to the switch file configuration to take effect, you must restart the broker queue manager.

   The following table specifies what you must change for each database management system (DBMS). *WBIMB* represents the fully qualified path name of the directory in which you have installed WebSphere Message Broker.

DBMS	Change ...	To ...
Oracle	*WBIMB*\bin\ukor8dtc20.dll or*WBIMB*\bin\ukor8dtc22.dll or*WBIMB*\bin\ukor8dtc23.dll	*WBIMB*\bin\ukora24.dll
Sybase	*WBIMB*\bin\ukase20.dll or*WBIMB*\bin\ukase22.dll or*WBIMB*\bin\ukase23.dll	*WBIMB*\bin\ukase24.dll

Linux and UNIX systems

To change the ODBC connection definitions:

Create an ODBC definitions file by following the instructions in "Connecting to a database from Linux and UNIX systems using the DataDirect drivers" on page 674. Before you run the commands at the new service level, check that your ODBCINI environment variable points to the new file and not to the existing file.

To change the XA resource manager definitions:

To change the XA resource manager definitions, edit the queue manager configuration file (`qm.ini`) of the queue manager that is associated with the broker. The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`, where *queue_manager_name* is the name of the queue manager that is associated with the broker.

In the *XAResourceManager* stanza for each Oracle and Sybase database that participates in a global unit of work that is coordinated by the broker queue manager, change the entry for the switch file. For changes to the switch file configuration to take effect, you must restart the broker queue manager.

The following table specifies what you must change for each broker operating system and database management system (DBMS).

DBMS	Change ...	To ...
Oracle	SwitchFile=UKor8dtc20.so orSwitchFile=UKor8dtc22.so orSwitchFile=UKoradtc22.so orSwitchFile=UKor8dtc23.so orSwitchFile=UKoradtc23.so	SwitchFile=UKoradtc24.so
Sybase (not supported on Linux on IBM z Systems)	SwitchFile=UKasedtc20.so orSwitchFile=UKasedtc22.so orSwitchFile=UKasedtc23.so	SwitchFile=UKasedtc24.so

To check that your ODBC environment is set up correctly on Linux and UNIX systems, run the **mqsicvp** command. This command also validates the connection to all data sources that are listed in the `odbc.ini` file that have been associated with a broker by using the **mqsisetdbparms** command. For more information, see "**mqsicvp** command" on page 3857.

Results

If you revert to a previous version of WebSphere Message Broker, you must reverse the changes that you make to the ODBC definitions. Update your ODBC files after you have run the **mqsimigratecomponents** command, but before you restart the broker at the earlier version.

Related tasks:

"Enabling ODBC connections to the databases" on page 668
Set up the resources and environment that the broker requires for Open Database Connectivity (ODBC) connections to user databases on distributed systems.

Migrating from SupportPac IA9Q

If you installed SupportPac IA9Q, which introduced the SRRetrieveITService and SRRetrieveEntity nodes, you must remove this SupportPac before you can upgrade to WebSphere Message Broker Version 7.0.

About this task

If you do not remove SupportPac IA9Q, you might encounter problems when you deploy or use the EndpointLookup and RegistryLookup nodes that replace the SRRetrieveITService and SRRetrieveEntity nodes.

Before you install WebSphere Message Broker Version 7.0, complete the following steps:

Procedure

1. Write down the properties of your SRRetrieveITService and SRRetrieveEntity nodes so that you can use the same values when you create the EndpointLookup and RegistryLookup nodes in WebSphere Message Broker Version 7.0.

2. Remove message flows that contain the SRRetrieveITService and SRRetrieveEntity nodes from your WebSphere Message Broker Version 6.0 brokers.
3. Remove the dynamic Cache Notification component (the Cache Synchronization WebSphere Message Broker BAR file), if you deployed it.
4. Edit the broker classpath in `bin/mqsiprofile.cmd` to remove the following files:
   - `sibc.jms.jar`
   - `sibc.jndi.jar`
   - `ibm-jaxrpc-client.jar`
   - Solaris `sibc.orb.jar` (on the Solaris platform only)

   When you have edited the broker classpath, delete the files from your system.
5. Remove the `ServiceRegistryMessageBrokerNodes_1.0.0.par` file.
6. Remove the following files from the shared classes directory *MQSI_working_path*`/shared-classes`:
   - `wsrr.properties`
   - `sdo-int.jar`
   - `ServiceRegistryClient.jar`
   - `WMBc4WSRR_1.0.0.jar`
7. Remove the WebSphere Message Broker Toolkit plugin directory and files from the toolkit. The directory was created when you unzipped SupportPac IA9Q; for example, `C:\IBM\MessageBrokersToolkit\6.0\evtoolkit\eclipse\plugins\com.ibm.sr.mb.nodes_1.0.1`

What to do next

Next: When you have removed SupportPac IA9Q, migrate the WebSphere Message Broker Toolkit.

Related tasks:

"Migrating from Version 6.0 products" on page 183
Migrate your components and resources to WebSphere Message Broker Version 7.0.

Related reference:

"Installation Guide" on page 233
Installation information for WebSphere Message Broker is provided in the *Installation Guide* that is supplied as a PDF file with your product package.

"EndpointLookup node" on page 4407
Use the EndpointLookup node to retrieve service endpoint information held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. Depending on the node configuration, the Web service URL destination used by the SOAP and HTTP request nodes can also be set. The input message is not modified.

"RegistryLookup node" on page 4646
Use the RegistryLookup node to retrieve any type of entity held in the WebSphere Service Registry and Repository (WSRR). The entities that match the specified search criteria are stored in the local environment. The input message is not modified.

Migrating the WebSphere Message Broker Toolkit development resources from Version 6.0 to Version 7.0

You cannot migrate the WebSphere Message Broker Toolkit component from WebSphere Message Broker Version 6.0, but you can install Version 7.0 to coexist with Version 6.0, and migrate the development resources that you have created in your workspace.

About this task

- You cannot deploy resources from the WebSphere Message Broker Toolkit Version 7.0 to brokers at a previous version that you have not migrated to Version 7.0.
- If any of the following actions have caused an error in the project:
  - Creating the metadata information for the user-defined node project
  - Correcting the plug-in identifier if it does not match the project name
  - Ensuring all the user-defined nodes are in the same category

  The WebSphere Message Broker Toolkit flags the error, and you can use a Quick Fix to rectify the error, see "Applying a Quick Fix to a task list error" on page 2862.However, if you have different user-defined nodes that depend on different resources that have identical names, the broker archive (BAR) file compiler produces an error indicating a naming conflict in the dependent resources. Quick Fix cannot be used to resolve BAR file compiler errors.
- You cannot migrate a deployable JAR file for a user-defined node that was created in Version 7.0, or before Version 7.0.

To migrate your WebSphere Message Broker Toolkit workspace to Version 7.0, complete the following steps:

Procedure

1. Install WebSphere Message Broker Toolkit Version 7.0 in a different location from WebSphere Message Broker Toolkit Version 6.1 or Version 6.0. For detailed instructions, see "Installing the WebSphere Message Broker Toolkit" on page 276, or refer to the "Installation Guide" on page 233.
2. When you start the WebSphere Message Broker Toolkit Version 7.0 for the first time, you are prompted to enter a workspace location. Enter the directory that contains the WebSphere Message Broker Toolkit Version 6.1 or Version 6.0 workspace that you want to migrate and click **OK**. The workspace and resources are now available in the WebSphere Message Broker Toolkit Version 7.0.
3. In the Broker Application Development perspective, select **Window** > **Reset Perspective** to ensure that all views and menus are updated for Version 7.0.
4. You must migrate any user-defined node source projects that were developed in Version 7.0, or before Version 7.0. An error is displayed on all projects that require migration. You can use a Quick Fix to clear these errors, see "Applying a Quick Fix to a task list error" on page 2862. After fixing the errors, you must package the user-defined node source projects and redistribute to the users, see "Packaging and distributing a user-defined node project" on page 3121.

Results

You can now view and modify existing resources, and create resources. You can deploy your workspace resources to Version 7.0 brokers.

What to do next

When you have migrated the resources associated with the WebSphere Message Broker Toolkit, you must migrate your brokers, see "Migrating a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0" on page 172.

When you have completed these tasks, for information about tasks that you might want to perform after migration, see "Post-migration tasks" on page 204.

Related concepts:

After you have migrated to Version 7.0, finish setting up your environment.

Migrating a broker from WebSphere Message Broker Version 6.0 to WebSphere Message Broker Version 7.0

Migrate one or more brokers to Version 7.0.

Before you begin

Before you start: Read "Preparing for migration from Version 6.0" on page 185.

About this task

To migrate a broker from WebSphere Message Broker Version 6.0 to WebSphere Message Broker Version 7.0, see the appropriate topic for your operating system:

- "Migrating a Version 6.0 broker to Version 7.0 on distributed operating systems" on page 194
- "Migrating a Version 6.0 broker to Version 7.0 on z/OS" on page 198

Results

You do not have to redeploy resources to a broker that you have migrated. When you start the broker, it starts all existing message flows.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Coexistence with previous versions and other products" on page 139
WebSphere Message Broker Version 7.0 supports restricted coexistence with previous versions and with other products.

Related tasks:

"Migrating from Version 6.0 products" on page 183
Migrate your components and resources to WebSphere Message Broker Version 7.0.

"Post-migration tasks" on page 204
After you have migrated to Version 7.0, finish setting up your environment.

"Supported migration paths" on page 3579
You can migrate to WebSphere Message Broker Version 7.0 from previous versions of the product.

Migrating a Version 6.0 broker to Version 7.0 on distributed operating systems

Migrate a broker to use the enhanced facilities available in Version 7.0.

Before you begin

Before you start:

- Back up your broker resources.
- For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- Install a supported version of WebSphere MQ and migrate your queue managers and other resources, following the instructions provided by WebSphere MQ.
- Optional: If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate the broker.
- Migrate the WebSphere Message Broker Toolkit from Version 6.0 to Version 7.0.
- Check that you have no aggregations in progress on this broker. When you migrate a broker to Version 7.0, all live data that is being stored for aggregations in progress is lost.
- If the broker runs in a locale that is not listed in "Locales" on page 3629, check that the code page is one of the supported code pages, and that the locale is set up correctly.

About this task

If you stop the broker, you can migrate it immediately to the new version on the same computer. If you prefer not to stop the broker to avoid problems for your business applications, or if you want to reproduce the broker function on another computer, you can associate the application logic on your Version 6.0 broker with a separate Version 7.0 broker.

Select the topic that is appropriate to your environment:

- "Migrating a Version 6.0 broker to Version 7.0"
- "Migrating application logic to a Version 7.0 broker" on page 196

Migrating a Version 6.0 broker to Version 7.0:
About this task

To migrate a Version 6.0 broker on a distributed operating system to Version 7.0, complete the following steps:

Procedure

1. Install WebSphere Message Broker Version 7.0 on the same computer as Version 6.0. Install at least the broker component; other components are optional. You must specify a new location for this installation.
2. Open a Version 6.0 command environment, and stop the Version 6.0 broker by using the **mqsistop** command.
3. Stop all channels that are connected to the Version 6.0 broker.
4. Optional: If your message flows access user databases by using ODBC connections, update the ODBC definitions to Version 7.0 format.
5. Set up the correct Version 7.0 command environment:
   - Linux UNIX On Linux and UNIX systems, open a new shell and run the environment profile **mqsiprofile** for this Version 7.0 installation.
   - Windows On Windows, click **Start**, and open the Command Console that is associated with this Version 7.0 installation.

     On Windows 7 and Windows Server 2008 systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.
6. Enter the **mqsimigratecomponents** command to migrate the broker. For example:

   ```
   mqsimigratecomponents Broker1
   ```

   All configuration data is retrieved from the Version 6.0 broker database. If you had set a default user ID and password for your Version 6.0 broker by using the **-u** and **-p** options on the **mqsicreatebroker** command, these values are migrated with the broker. You can change these values for your Version 7.0 broker by using the **mqsisetdbparms** command.
7. If the Version 7.0 support for your platform has changed from both 32 bit and 64-bit support to 64-bit support only, make the following changes to your environment:
8. On the AIX, Linux on x86-64, and Solaris on SPARC platforms, support has changed from both 32-bit and 64-bit support to 64-bit support only. 32-bit execution groups are converted to 64-bit. These platforms now require 64-bit libraries and 64-bit ODBC configurations for databases.
   a. Recompile C/C++ user-defined nodes, parsers, and exits to 64-bit, if the existing ones are 32-bit only.
   b. Configure the broker to point at these recompiled extensions by using the following command:

      ```
      mqsichangebroker -l userLilPath -x userExitPath
      ```

      where *userLilPath* defines one or more paths to your LIL files, and *userExitPath* defines one or more paths to your user exit programs.

   The following changes are made to environment variables, for all platforms:

Previous version	Version 7
MQSI_LILPATH64 and MQSI_LILPATH32	MQSI_LILPATH
MQSI_USER_EXIT_PATH64 and MQSI_USER_EXIT_PATH	MQSI_USER_EXIT_PATH
MQSI_SECURITY_PROVIDER_PATH64 and MQSI_SECURITY_PROVIDER_PATH32	MQSI_SECURITY_PROVIDER_PATH

Update all custom profiles that set these environment variables.

9. Copy all additional custom environment settings from your previous environment into your Version 7.0 environment; for example, MQSI_FILENODES_ROOT_DIRECTORY.
10. Start the Version 7.0 broker by using the **mqsistart** command.

Migrating application logic to a Version 7.0 broker:
About this task

To migrate application logic from a Version 6.0 broker on a distributed operating system to a different Version 7.0 broker on the same computer, or on a different computer, complete the following steps:

Procedure

1. Install WebSphere Message Broker Version 7.0 on the target computer. Install at least the broker component; other components are optional. If you are installing on the same computer, you must specify a different location.
2. Optional: If your message flows access user databases by using ODBC connections, update the ODBC definitions to Version 7.0 format.
3. Set up the correct Version 7.0 command environment:
   - Linux UNIX On Linux and UNIX systems, open a new shell and run the environment profile **mqsiprofile** for this Version 7.0 installation.
   - Windows On Windows, click **Start**, and open the Command Console that is associated with this Version 7.0 installation.

     On Windows 7 and Windows Server 2008 systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.
4. Create a Version 7.0 broker by using the **mqsicreatebroker** command; give it a name and a queue manager name that are different from the names of the Version 6.0 broker and queue manager. You can also create a local broker by using the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit, providing you have installed one or both of these components on this computer.
5. Start the Version 7.0 broker by using the **mqsistart** command. You can also start a local broker by using the WebSphere Message Broker Explorer or the WebSphere Message Broker Toolkit, providing you have installed one or both of these components on this computer.
6. Write a list of the execution groups that you have on the Version 6.0 broker, and create these same execution groups on the Version 7.0 broker. Use the WebSphere Message Broker Explorer, the Version 7.0 WebSphere Message Broker Toolkit, or the **mqsicreateexecutiongroup** command to complete this step. On the AIX, Linux on x86-64, and Solaris on SPARC platforms, you can create only 64-bit execution groups.
7. Deploy the message flows and message sets that are in use by the Version 6.0 broker to the Version 7.0 broker from the Version 7.0 WebSphere Message Broker Toolkit. You cannot complete this step unless you have already migrated the WebSphere Message Broker Toolkit.
8. Configure all other relevant properties of the Version 6.0 broker on the Version 7.0 broker.
9. When you are ready to delete your Version 6.0 broker:

a. In a Version 6.0 command environment, stop the Version 6.0 broker by using the **mqsistop** command.
b. Remove the Version 6.0 broker from the Version 6.0 WebSphere Message Broker Toolkit.
c. Redeploy the Version 6.0 topology from the Version 6.0 WebSphere Message Broker Toolkit to update the configuration data held by the Configuration Manager.
d. In a Version 6.0 command environment, delete the Version 6.0 broker by using the **mqsideletebroker** command.

What to do next

When you have completed these tasks, see the post-migration tasks for information about tasks that you might want to perform after migration.

Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Migrating a Version 6.0 broker to Version 7.0 on z/OS

Migrate a broker to use the enhanced facilities available in Version 7.0.

Before you begin

Before you start:

- Back up your broker resources.
- For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.
- Install WebSphere MQ and migrate your queue managers and other resources, following the instructions provided by WebSphere MQ.
- Optional: If your applications use publish/subscribe functions, and you have message flows that include one or more Publication nodes, you must migrate your subscriptions to WebSphere MQ before you migrate the broker.
- Ensure that you are familiar with the steps involved in creating a broker on z/OS.
- Ensure that you are familiar with the **mqsimigratecomponents** command which the JCL (Job Control Language) file uses to migrate a broker.
- Check that you have no aggregations in progress. When you migrate a broker to Version 7.0, any live data that is being stored for aggregations in progress is lost.
- If the broker runs in a locale that is not listed in "Locales" on page 3629, check that the code page is one of the supported code pages and that the locale is set up correctly.

About this task

To migrate a WebSphere Message Broker Version 6.0 broker to Version 7.0 on z/OS:

Procedure

1. Stop the Version 6.0 broker.
2. Create a new broker PDSE.
3. Copy all broker JCL files from the Version 7.0 installed SBIPPROC and SBIPSAMP PDSEs to the new broker PDSE and customize them all. See "Customizing the broker JCL" on page 625 for more information.

   You must take a backup copy of your Version 6.0 `ENVFILE` file before you submit the `BIPGEN` job from the Version 7.0 component data set. The `ENVFILE` file is stored in the directory referenced by the ++*HOME*++ JCL variable. Subsequently, if you want to migrate back to Version 6.0, restore the `ENVFILE` file, either from the backup file location, or by submitting the `BIPGEN` job from the Version 6.0 component data set, before you start the Version 6.0 broker.

a. Customize the BIPEDIT file by using the values that are defined in the Version 6.0 BIPEDIT file.
b. Copy all additional changes that you have made to the Version 6.1 version of the BIPBPROF and BIPDSNAO files to these files in the Version 7.0 component data set. Submit the BIPGEN job to create the environment file ENVFILE.
c. Customize and submit the BIPMGCMP (**mqsimigratecomponents**) job. This job migrates the registry, queues, and broker database. Connection to the database of the broker that you are migrating is required to run this command. After migration, all information is stored in an internal repository in Version 7.0; the Version 7.0 broker does not require a database.

4. Copy the renamed started task JCL BIPBRKP to the procedures library. When you copy the started task, keep a second copy of the original in a safe place for backup purposes.
5. The verification program runs when you start the Version 7.0 broker.

What to do next

Next: See the post-migration tasks for information about tasks that you might want to perform after migration.

The sample BIPEDIT file that is shipped with WebSphere Message Broker is

included here for your reference.

Migrating Configuration Manager ACLs

If you are migrating from WebSphere Message Broker , WebSphere Message Broker Version 6.0, or WebSphere Event Broker Version 6.0, you can use the Access Control Lists (ACLs) that you set up in the Configuration Manager as the basis for your security model in Version 7.0.

Before you begin

Before you start:

- Migrate your broker by following the instructions in "Migrating a broker from WebSphere Message Broker to WebSphere Message Broker Version 7.0" on page 172 or "Migrating a broker from WebSphere Message Broker Version 6.0 to WebSphere Message Broker Version 7.0" on page 193.
- Activate broker administration security by following the instructions in "Enabling broker administration security" on page 368.

Administration security for a broker in Version 7.0 is disabled by default. Because no security details are migrated, when you migrate a broker from a previous version security is disabled, even if you had set up security in the previous version.

About this task

The Configuration Manager has been removed as a result of the architectural and security model changes in Version 7.0, therefore the commands that controlled this component and its ACLs have been removed:

mqsichangeconfigmgr
mqsicreateconfigmgr
mqsideleteconfigmgr
mqsireportconfigmgr
mqsicreateaclentry
mqsideleteaclentry
mqsilistaclentry

Although you can use the ACLs that you set up in previous versions as the basis for your security model in Version 7.0, you might choose to reconsider your security model, and set up different levels of control that match the facilities available in this version.

If you choose to use your existing ACLs as a basis for your security model in Version 7.0, consider the following factors:

- You can obtain a list of existing ACLs maintained by your Configuration Manager by using the **mqsilistaclentry** command.
- You can migrate existing groups, users, or both, subject to the following factors:
  - You must define the user ID on the same computer as the queue manager associated with the Version 7.0 broker.
  - On Linux and UNIX systems, you can grant authority only to the primary group of a user. All users that you have defined with the same primary group automatically get the same level of security access. You must therefore consider the membership of all your groups to ensure that you give the required level of control to each user.

- You can grant only broker and execution level authorities for Version 7.0 brokers.
- If you grant read, write, and execute authority to a user ID for a Version 7.0 broker, this permission is equivalent to full control access in previous versions.
- If you grant read authority to a user ID for a Version 7.0 broker, this permission is equivalent to view access in previous versions.
- Check the authority that write and execute permissions grant for a Version 7.0 broker to determine the best match for edit and deploy access levels in previous versions.
- Although you can set up access for a particular computer or domain name in previous versions, you can use only user IDs and groups in Version 7.0. If you want to establish a more secure environment, consider the use of WebSphere MQ security exits and SSL.

To set up authorization for your Version 7.0 broker, complete the following steps.

Procedure

1. Review the authorizations that are required for specific tasks and commands. Details are provided in "Tasks and authorizations for broker administration security" on page 3645 and "Commands and authorizations for broker administration security" on page 3646.
2. Grant the authorities that your users require.
   - For details of this task on distributed systems, with examples, see "Granting and revoking authority on Linux, UNIX, and Windows systems" on page 374.
   - For details of this task on z/OS, with examples, see "Granting and revoking authority on z/OS systems" on page 376.

What to do next

Next: Start the broker in the WebSphere Message Broker Explorer, or run the **mqsistart** command.

Related concepts:

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

Related tasks:

"Enabling broker administration security" on page 368
Enable broker administration security on a broker to control which users can complete specific tasks against that broker and its resources.

"Authorizing users for broker administration" on page 371
Grant authority to one or more groups or users to authorize them to complete specific tasks against a broker and its resources.

"Enabling SSL on the WebSphere MQ Java Client" on page 540
The WebSphere MQ Java Client supports SSL-encrypted connections over the server-connection (SVRCONN) channel between an application and the queue manager. Configure SSL support for connections between applications that use the CMP API (including the WebSphere Message Broker Toolkit and the WebSphere Message Broker Explorer) and a broker.

WebSphere MQ Version 7 Information Center online

Migrating a WebSphere Message Broker that is configured by using Microsoft Cluster Services (MSCS)

You must complete a specific set of steps to migrate your Microsoft Cluster Services (MSCS) cluster to WebSphere Message Broker Version 7.0.

Before you begin

Read the topics within the section "Migrating from Version 6.0 products" on page 183, and the topic "Using a broker with an existing high availability manager" on page 843.

About this task

Use the following procedure to migrate a WebSphere Message Broker that is configured by using MSCS.

Migrating a WebSphere Message Broker Version 6.0 to WebSphere Message Broker Version 7.0

Procedure

1. Install WebSphere Message Broker Version 7.0 onto each node. You must specify a new location for this installation.
2. Stop all channels that are connected to the WebSphere Message Broker Version 6.0 broker.
3. In MSCS bring the broker resource offline, keeping the cluster disk and WebSphere MQ resource online on your primary node
4. In a WebSphere Message Broker Version 7.0 command console, run the following command:

   ```
   mqsimigratecomponents BROKER1 -m
   ```

   where BROKER1 is the name of your broker.
5. Move the broker cluster group to the secondary node. The broker resource must remain stopped.
6. In a WebSphere Message Broker Version 7.0 command console, run the following command:

   ```
   mqsimigratecomponents BROKER1 -m -1
   ```
7. Copy all additional custom environment settings from your previous environment into your WebSphere Message Broker Version 7.0 environment. For example: MQSI_FILENODES_ROOT_DIRECTORY.
8. Bring the cluster disk and WebSphere MQ resource offline.
9. Start the WebSphere Message Broker cluster group on its primary node.

What to do next

Migrating a WebSphere Message Broker Version 7.0 to WebSphere Message Broker Version 6.0

Due to changes in the file security model that are used in WebSphere Message Broker Version 7.0, you might be required to alter the file permissions of the shared resource.

If necessary, create a domain group, add the `userID` of your broker to this group, and give the group full access to the shared files.

1. In MSCS bring the broker resource offline, keeping the cluster disk and WebSphere MQ resource online on your primary node.
2. In a WebSphere Message Broker Version 6.0 command console, run the following command:

   ```
   mqsimigratecomponents BROKER1 -s 7.0 -t 6.0
   ```
3. In a WebSphere Message Broker Version 6.0 command console, run the following command:

   ```
   mqsistart BROKER1
   ```

   This command is required to update the Windows service to point at the WebSphere Message Broker Version 6.0 binary files.
4. In a WebSphere Message Broker Version 6.0 command console, run the following command:

   ```
   mqsistop BROKER1
   ```
5. Move the broker cluster group to the secondary node. The broker resource must remain stopped.
6. In a WebSphere Message Broker Version 7.0 command console, run the following command:

   ```
   mqsimigratecomponents MSCSV61BROKER -m -s 6.0 -t 7 -1
   ```
7. In a WebSphere Message Broker Version 7.0 command console, run the following command:

   ```
   mqsimigratecomponents MSCSV61BROKER -s 7.0 -t 6.0 -1
   ```
8. In a WebSphere Message Broker Version 6.0 command console, run the following command:

   ```
   mqsistart BROKER1
   ```

   This command is required to update the Windows service to point at the WebSphere Message Broker Version 6.0 binary files.
9. In a WebSphere Message Broker Version 6.0 command console, run the following command:

   ```
   mqsistop BROKER1
   ```
10. Bring the cluster disk and WebSphere MQ resource offline.
11. Start the broker cluster group on its primary node.

Related tasks:

"Migrating from Version 6.0 products" on page 183
Migrate your components and resources to WebSphere Message Broker Version 7.0.

"Using a broker with an existing high availability manager" on page 843
You can use WebSphere Message Broker Version 7.0 with an existing high availability manager, for example HACMP, HA/XD, VCS, or HP-UX Serviceguard.

Post-migration tasks

After you have migrated to Version 7.0, finish setting up your environment.

About this task

Test the WebSphere Message Broker Version 7.0 broker resources and components to verify that you experience no loss or unexpected change of functionality. Some changes in behavior might be caused by defects that have been fixed between versions.

The following topics describe further tasks that you can complete after migration:

Procedure

- "Reviewing technical changes in Version 7.0" on page 205
- "Setting up a command environment" on page 213
- "Migrating a flow containing HTTPRequest nodes" on page 214
- "Migrating a flow containing XMLTransformation nodes" on page 215
- "Migrating a flow containing data definitions" on page 217
- "Migrating CMP applications" on page 220
- "Updating error processing routines" on page 221

What to do next

Next: Complete the following tasks as required:

- Delete the Version 6.1 or Version 6.0 components (Configuration Manager, User Name Server, and brokers that you have replaced but not migrated).

  If the broker that you have migrated shares a queue manager with the Configuration Manager, the default server connection channel SYSTEM.BKR.CONFIG, which was created when you created the Configuration Manager, is deleted when you delete the Configuration Manager. The Version 7.0 broker requires this channel for connections from the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit, and CMP applications. You must re-create this channel on the broker queue manager after you have deleted the Configuration Manager.
- Remove the installed code for Version 6.1 or Version 6.0.
- Delete the broker database. You can also remove the installed database product, if you do not use it for other purposes.
- If you are migrating from Version 6.0, delete the configuration repository. You can also remove the installed database product, if you do not use it for other purposes.

Access the Version 6.1 or Version 6.0 information center for details of these tasks (or use the links provided).

Related concepts:

Reviewing technical changes in Version 7.0

Some minor changes in behavior are present in WebSphere Message Broker Version 7.0; for example, those changes caused by defects that have been fixed between versions.

If you are migrating from Version 6.0 or Version 6.1, read the following sections to understand the potential effects on your broker and message flows:

- "Changes to user ID and password requirements"
- "Changes to location of description properties" on page 206
- "Default Configuration wizard and database usage on Windows" on page 206
- "Default execution group when creating brokers" on page 206
- "Starting and stopping execution groups" on page 206
- "Using SOAPAsyncRequest, SOAPInput, and SOAPRequest nodes" on page 207
- "Using HTTPS with HTTPInput and HTTPReply nodes" on page 207
- "Monitoring message flows" on page 207
- "ESQL field references with an index of zero" on page 208
- "Using RegistryLookup nodes" on page 208
- "Interfaces in the WebSphere Message Broker Toolkit" on page 208

If you are migrating from Version 6.0, and you have created message sets, review the changes in behavior in "Message set migration" on page 209.

Changes to user ID and password requirements

User ID and password management in Version 7.0 has been updated:

- The requirement for a service user ID and password has been removed on all systems except Windows. These parameters (**-i, -a**) are no longer used when you migrate your brokers to Version 7.0.

  If you restore a Windows broker to an earlier version, the password value is restored with the broker. If you have changed the password by using the **mqsichangebroker** command, the updated value is set in the previous version.
- Because the Version 7.0 broker has no requirement for a database, the parameters to define and change database user IDs and passwords have been removed.

If you had set these values for the brokers that you are migrating, these parameters (**-u, -p**) are migrated with the broker, and are used as default values for data sources (user databases) for which you do not set explicit values. If you had not set **-u, -p**, that values for **-i, -a** are migrated. In Version 7.0, you can manage these user IDs and passwords for your user databases by using the **mqsisetdbparms** command.

- The requirement for the broker service user ID to be a member of the mqm group has been removed.
- If you change the database user ID and password by using the **mqsisetdbparms** command, you no longer need to restart the broker. You can instead restart the affected execution group by using the **mqsireload** command.

Changes to location of description properties

Long and short description properties of deployed Message Broker artifacts were not held in the deployed execution group repository, so they will not have been migrated to the Version 7.0 broker.

If the following fields have been used to hold keywords:

```
$MQSI name = value MQSI$
```

they will not be displayed in the migrated artefacts. To correct this behavior, redeploy the artefacts directly to the Version 7.0 broker.

For more information about defining keywords, see "Guidance for defining keywords" on page 4017.

Default Configuration wizard and database usage on Windows

Some of the sample programs use a database; for example, the Airline sample. If you had used the Default Configuration wizard to set up a default configuration on Windows, and deploy samples to the default broker, the samples that require a database use the Derby database that is embedded in the broker. Version 7.0 does not ship or support the Derby database. You must reconfigure your database samples by following the updated instructions in the samples documentation.

Default execution group when creating brokers

When you create a broker by using the **mqsicreatebroker** command, a default execution group is no longer created.

If you use either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer to create a broker, you can select an option to create a default execution group with the name `default` (unless you specify another name).

You can also create execution groups by using the **mqsicreateexecutiongroup** command.

Starting and stopping execution groups

Starting and stopping execution group behavior has been updated in Version 7.0. When you start or stop an execution group using the **mqsistartmsgflow** or **mqsistopmsgflow** commands without the **-m** parameter, the execution group process is stopped or started. When you stop the execution group in this way, or using the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer,

the run state of the message flows deployed to the execution group is remembered. When you next start the execution group only those message flows that were running when the execution group was stopped are restarted, unless you specifically request all flows to be started, or use the **-j** parameter on the command.

Using SOAPAsyncRequest, SOAPInput, and SOAPRequest nodes

The Failure action property of the SOAPAsyncRequest, SOAPInput, and SOAPRequest nodes has changed to be not configurable. If you have set this property, for example in a BAR file, the setting is ignored.

Using HTTPS with HTTPInput and HTTPReply nodes

The Version 7.0 broker checks for required SSL configuration when you run the **mqsistart** command.

If you have deployed a message flow that includes HTTPInput or HTTPReply nodes to a Version 6.1 or Version 6.0 broker, and you migrate the broker to Version 7.0 and start the broker again, you might see the following error message generated. (Message lines are continuous, but have been split to improve readability).

```
BIP3135S: An exception occurred while starting the servlet engine connector.
Exception text is HTTP Listener LifecycleException:
 Protocol handler start failed: java.io.FileNotFoundException: /home/leed/.keystore
 (No such file or directory)

 ExecutionGroup: de427601-2401-0000-0080-d525e90f1528
```

This error is generated because the Version 7.0 broker has detected that you have configured the HTTP nodes in the message flow to use HTTPS, but you have not set up the required SSL configuration; the broker does not load the message flow. In previous versions, this check was not performed and no error generated.

To resolve this error, configure your HTTP nodes to use SSL, and redeploy the message flow. For SSL configuration information, see “Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)” on page 535.

Monitoring message flows

The default behavior for publishing monitoring events has changed. In versions before Version 7.0, monitoring events are emitted out of sync point. Now, the default for all events except transaction rollback is that events are emitted only if the message flow commits its unit of work successfully. By default, transaction rollback events are emitted in a second unit of work, independent of the main unit of work.

These changes mean that you no longer see events that have been backed out because of a failed message flow; you see only the transaction start event and the transaction rollback event, if these events are defined. You also see all other events that are defined to be in an independent unit of work. See “Monitoring basics” on page 3320 for more information.

A sequence number has been added to the eventSequence element of the monitoring event. Because both the creation time and sequence number are always emitted in the monitoring event, the Sequence tab has been removed from the monitoring tab in the WebSphere Message Broker Toolkit.

ESQL field references with an index of zero

The validity of using a field reference index of zero has been corrected. If you have statements in your ESQL modules that include an index of zero, error BIP3226E is generated when you deploy the message flow.

For example, if you have code that contains the statement:

```
SET OutputRoot.XMLNSC.Top.A[0].B = 42;
```

You must update the code to contain the following content:

```
SET OutputRoot.XMLNSC.Top.A[1].B = 42;
```

Using RegistryLookup nodes

The default for the Depth Policy property of the RegistryLookup node has been changed from the value Return matched showing immediate relationships (For compatibility only) in Version 6.1 to the value Return matched only (Depth = 0) in Version 7.0.

If you do not explicitly set this property on a RegistryLookup node, it uses the default value Return matched only (Depth = 0) to determine the depth of the WSRR query and the contents of the entity data to be returned.

If you want to use the node in deprecated mode in Version 7.0, you must explicitly set the Depth Policy property to the value Return matched showing immediate relationships (For compatibility only), and rebuild the BAR file.

For more information about the RegistryLookup node and its properties, see “RegistryLookup node” on page 4646.

Interfaces in the WebSphere Message Broker Toolkit

The following changes are present in the WebSphere Message Broker Toolkit:

Problems view

In WebSphere Message Broker Toolkit Version 6.1, you can configure the list of problems shown in the Problems view by clicking either the icon on the Problems view pane bar, or the down arrow next to the icon, and selecting **Configure filter** from the list of options displayed. In WebSphere Message Broker Toolkit Version 7.0, the icon is no longer shown. Click the down arrow shown at the right end of the bar, and select **Configure contents**.

Broker Development view
In WebSphere Message Broker Toolkit Version 7.0, the Broker Development view shows pattern instance projects in a separate pane, in addition to other projects in your workspace.

Broker administration perspective
In WebSphere Message Broker Toolkit Version 6.1, you can connect, configure, and deploy to brokers by using the Broker administration perspective in the WebSphere Message Broker Toolkit. In Version 7.0, the Broker Administration perspective has been removed, and you can now connect, configure and deploy to brokers by using the Brokers view in the Broker Application Development perspective. For more advanced configuration tasks, you can use the WebSphere Message Broker Explorer.

Event Log viewer
In WebSphere Message Broker Toolkit Version 6.1, deployment responses and messages from the broker are displayed in the Event Log viewer. In Version 7.0, deployment messages from your instance of the WebSphere Message Broker Toolkit are displayed in the Deployment Log view, in the Broker Application Development perspective.

Command assistants
In WebSphere Message Broker Toolkit Version 6.1 and Version 6.0, you can use the command assistants to create, change, and delete components such as brokers on your local system. In Version 7.0, you can use the Brokers view to create and delete components. Alternatively, you can use the WebSphere Message Broker Explorer to create, change, and delete brokers on your local system.

XPath Expression Builder
In WebSphere Message Broker Toolkit Version 6.1, the Data Types Viewer shows two top-level categories, Data Types and Variables. In Version 7.0, you can find the variables under the single top-level category Data Types.

Message set migration

When you migrate a message flow that uses message sets, review the changes in behavior in WebSphere Message Broker Version 7.0.

Before you begin

Review this information about message set changes, and potential effects, if you are migrating from Version 6.0; no message set migration is required from Version 6.1.

You do not have to run migration commands; WebSphere Message Broker Toolkit Version 7.0 can read a Version 6.0 message set project and automatically convert it to Version 7.0 format when you modify and save it for the first time.

For guidance about changes to the behavior of parsers, and for general migration information, see the following sections:

- "Behavioral changes in the XMLNSC parser"
- "Behavioral changes in the MRM parser" on page 211
- "General migration information" on page 211

Behavioral changes in the XMLNSC parser:
About this task

The following changes are implemented in Version 7.0:

- In Version 6.0, the attributes of an XML element are displayed in the message tree that is created by the XMLNSC parser in the order in which they are displayed on the element in the XML document.

  In Version 7.0, the XMLNSC parser always displays namespace attributes ahead of other attributes when it creates the message tree. However, XML attributes are inherently unordered, therefore do not write message flow logic that assumes attribute position.
- In Version 6.0, the XMLNSC parser accepts the EBCDIC NEL as an XML line feed character on z/OS only.

  In Version 7.0, NEL is accepted on all platforms.
- In Version 6.0, the XMLNSC parser ignores a node's Validate property setting.

  In Version 7.0, the XMLNSC parser honors the Validate property setting. If you have set this property to Content or Content And Value, the parser validates the message against the message set defined by the Message Set property.

  Therefore, if you have accidentally set the Validate property in Version 6.0 to Content or Content And Value, the message flow throws an exception after migration to Version 7.0.

  To correct this situation, set the Validate property to None.
- In Version 6.0. the XMLNSC parser uses the default ESQL format "YYYY-MM-DD hh:mm:ss" when it writes a field of type TIMESTAMP or GMTTIMESTAMP. This format does not comply with the XML Schema 1.0 specification.

  In Version 7.0, the XMLNSC parser uses the format "YYYY-MM-DD'T'hh:mm:ss.sss", which complies with the XML Schema 1.0 specification. If you require another format to be written, you must cast the TIMESTAMP or GMTTIMESTAMP to a CHARACTER. (If the element was originally parsed by the XMLNSC parser and had a time zone indicator, the time zone indicator is also written to the output message field.)
- In Version 6.0, the XMLNSC parser uses the default ESQL strings "TRUE" and "FALSE" when it writes a field of type BOOLEAN. This use does not comply with the XML Schema 1.0 specification.

  In Version 7.0, the XMLNSC parser writes "true" and "false", which complies with the XML Schema 1.0 specification. If you require strings other than "true and "false" to be written, cast the BOOLEAN field to a CHARACTER.
- In Version 6.0, the XMLNSC parser does not validate XML documents against XML Schema generated from a message set.

  In Version 7.0, the XMLNSC parser offers this function. When you add a message set to a broker archive (BAR) file, if the Message Domain property of the message set is set to XMLNSC, an XML Schema is generated for each message definition file in the message set for potential use by the XMLNSC parser. These XML Schema are checked by the XMLNSC parser when the BAR file is deployed.

However, the checks are stricter than the checks that are carried out by the message definition file editor, and the deployment might fail. If the deployment fails, you must correct the message definition file to comply with XML Schema rules. If the message set contains one of the IBM supplied SOAP Envelope message definition files, reimport the message definition file by using the New Message Definition File From IBM supplied Message wizard.

Behavioral changes in the MRM parser:
About this task

The following changes are implemented in Version 7.0:

- In Version 6.0, the MRM parser TDS physical format Data Element Separations Tagged Fixed Length, Tagged Delimited, and Tagged Encoded Length write out any xsi:type attributes they encounter in the message tree, using a tag name of "type".

  In Version 7.0, the TDS physical format assumes that all xsi:type attributes are XML-specific, and does not write them out.
- In Version 6.0, the MRM TDS physical format Data Element Separations Fixed Length, Fixed Length AL3, and Tagged Fixed Length treat an element with a TDS Length of zero as fixed length when parsing, but as variable length when writing. Therefore, all data in the message tree for such an element is written to the bit stream without an exception being thrown.

  In Version 7.0, the element is treated as fixed length when parsing and writing. Therefore, all data in the message tree for such an element causes message BIP5436E to be generated, unless you have set the TDS property Truncate on output, in which case nothing is written.
- In Version 6.0, message BIP5374E is generated when a missing mandatory repeating element (minOccurs > 1) is detected during validation of an MRM message.

  In Version 7.0, two different conditions are detected during validation:
  - A mandatory element that is repeating but has no instances in the message tree. In this case, message BIP5378E is generated, which provides details of the elements that exist before and after the expected location of the missing element. Because of this change, you might have to change or enhance automated error processes that you have in place.
  - A mandatory element that is repeating and has the incorrect number of instances in the message tree. In this case, message BIP5374E is generated as before, giving details of the existing and the expected instances of the element.

General migration information:
About this task

The following changes are implemented in Version 7.0:

- A single message set can contain models for MRM or IDOC domains, and also for other domains such as XMLNSC. In Version 6.0, a `.dictionary` file for use by the MRM parser is always generated when the message set is added to a BAR file.

  In Version 7.0, a `.dictionary` file is generated only if you have either specified MRM or IDOC as the default message domain, or added MRM or IDOC to Supported message domains in the message set file. If a `.dictionary` file is no longer generated, add MRM or IDOC to Supported message domains.

- The XML parser is deprecated and might be withdrawn in a future release. Existing message flows that use the XML parser continue to operate in Version 7.0. Use the XMLNSC domain for most new message flows that need to parse or write XML documents. For more information, see "Which XML parser should you use?" on page 1080.
- The IDOC domain and parser are deprecated, and might be withdrawn in a future release. Existing message flows that use the IDOC parser continue to operate in Version 7.0. Use the MRM domain TDS physical format for new message flows that need to parse or write SAP ALE IDocs in text format that originate from the WebSphere MQ link for R3.
- The location and labeling of some MRM TDS properties have been updated; no behavioral changes are associated with these changes.
  - The Repeating Element Delimiter property has moved into a box labeled "Occurrences", to keep all repeating properties together.
  - The Virtual Decimal Point and Precision properties are moved below the "Sign" group of properties, to align them with CWF properties.
  - The Length Reference property was not used for local groups, group references, and complex elements, and is removed from their property sheets.
  - The local group property sheet now has two boxes labeled "Field Identification", to distinguish the Data Pattern property from the rest, because Data Pattern applies not to the group itself, but to its inclusion in its parent.
  - The message set Boolean representation properties are now displayed with prefix "Text" to distinguish them from new binary Boolean representation properties.
  - The Physical Type property enumeration value Character is renamed Text.
  - The Physical Type property enumeration value Messaging Standard Alternate is renamed TLOG Specific.
  - The Trim Fixed Len String property is renamed Trim On Input, and has moved into a new box labeled "Fixed length strings".
  - The Derive default length from logical type property has moved into a new box labeled "General settings".
- The location and labeling of some MRM CWF properties have been updated; no behavioral changes are associated with these changes.
  - The Format property has moved to be last in the "Physical representation" section, to align it with TDS properties.
  - The element property sheet now has a section labeled "Numeric representation" section which contains the Sign group of properties and Virtual Decimal Point, to align these properties with TDS properties.
  - The Length Count property is renamed Length, to align this property with TDS properties.
  - The String Justification property is renamed Justification, to align this property with TDS properties.
  - The Sign EBCDIC Custom property is renamed Sign EBCDIC Custom Overpunched, to align this property with TDS properties.
  - The Sign Orientation property enumeration values Leading and Trailing are renamed Leading Overpunched and Trailing Overpunched, to align these properties with TDS properties.
  - The message set byte order properties are now displayed with the prefix "Default" to align these properties with TDS properties.

Input message tree modification

You might see a change in behavior when you migrate message flows that modify input message trees.

When you migrate message flows from Version 6.0 of WebSphere Message Broker that have been incorrectly modifying input message trees in ESQL nodes or user-defined nodes, you might see a change in behavior because the changes are now reflected in a bit stream that is written from that tree.

Related concepts:

"Message tree structure" on page 1045
The message tree is a part of the logical message tree in which the broker stores its internal representation of the message body.

You can access message tree headers, the properties tree, the local environment tree, the environment tree and the exception list tree.

Setting up a command environment

After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

About this task

Also complete this task if you have migrated to WebSphere Message Broker Version 7.0 from an earlier version. A profile is provided to help you set up the environment.

If appropriate, you can extend the initialization performed by this profile; for example, for user databases, or for other products that you want to use within the broker.

Ensure that you use this environment each time you run an administrative command, or start a broker.

For information about setting up your command and runtime environment on a Windows system, see "Command environment: Windows systems" on page 306.

For information on setting up your command and runtime environment on Linux and UNIX systems, see "Command environment: Linux and UNIX systems" on page 310.

For information about setting up your command and runtime environment for execution groups on Linux and UNIX systems, see "Execution group-specific command environment: Linux and UNIX systems" on page 312.

For information about setting up your command and runtime environment for execution groups on Windows systems, see "Execution group-specific command environment: Windows systems" on page 309.

Migrating a flow containing HTTPRequest nodes

When you migrate a message flow that contains HTTPRequest nodes from Version 6.0, check how Version 7.0 validates messages in these nodes.

About this task

You must complete this task if you are migrating from Version 6.0; no migration is required from Version 6.1.

In WebSphere Message Broker Version 7.0, message validation for HTTPRequest nodes has changed. The validation options that you can specify on an HTTPRequest node apply only to the response message that is received by the node from the remote server when an HTTP request is made. In Version 6.0, these options were also applied to the message received by the In terminal of the node.

The message received at the In terminal is no longer validated; however, the outbound (request) message can still be validated. Set validation options on a preceding Compute node, or include a Validate node. The HTTPRequest node uses the validation options associated with the message that is received at the In terminal to validate that message when it is sent out.

Related tasks:

"Validate node" on page 4959
Use the Validate node to check that the message that arrives on its input terminal is as expected. You can use this node to check that the message has the expected message template properties, and to check that the content of the message is correct by selecting message validation.

Migrating a flow containing XMLTransformation nodes

When you migrate a message flow that contains XMLTransformation nodes, check how WebSphere Message Broker Version 7.0 uses the node properties and search priorities.

About this task

You must complete this task if you are migrating from Version 6.0; no migration is required from Version 6.1.

The XMLTransformation node in Version 6.0 is replaced by the XSLTransform node in Version 7.0. When you migrate a flow that contains one or more XMLTransformation nodes, consider the following enhancements:

Procedure

- You can no longer set the style sheet search and character set information search priorities in the node properties in the WebSphere Message Broker Toolkit. The following fixed search priorities are adopted. However, search priorities set on existing flows are still respected.
  - The node searches for the name of the style sheet to be used by interrogating each of the following items in turn:

1. The input message. The node searches the message XML data for stylesheet location information. For example, if the XML data contains this entry:

   ```
   <?xml-stylesheet type="text/xsl" href="aaa.xsl"?>
   ```

   the node uses "aaa.xsl" as the stylesheet name.
2. The local environment. If no stylesheet name is found in the input message, the node searches the local environment associated with the current message for stylesheet information that is stored in an element called XSL.StyleSheetName.

   In Version 6.0, element ComIbmXslXmltStylesheetname is used for the name of the style sheet, therefore the current node checks both elements. If both are present, the value in XSL.StyleSheetName takes precedence.
3. The properties of the node. If no stylesheet name is found in the input message or local environment, the node uses the `Stylesheet Name` and `Stylesheet Directory` properties to determine the correct values.

– The node searches for the character set to use for the output message by interrogating each of he following items in turn:

1. The local environment. The node searches the local environment associated with the current message for character set information that is stored in an element called XSL.OutputCharSet; for example, to encode the output of the transformation as UTF-16, enter the value `1200` as a string in this element.

   In Version 6.0, element ComIbmXslXmltOutputcharset is used for the output character set, therefore the current node checks both elements. If both are present, the value in XSL.OutputCharSet takes precedence.
2. The properties of the node. If no character set information is found in the local environment, the node uses the `Output Character Set` property to determine the correct value.

   If the node cannot determine the output character set from either of these two sources, either because no value is set or the selection priorities are set to zero, the default value of `1208` (UTF-8) is used.

- You can set additional node properties, or use additional local environment overrides, to specify the message domain, message set, message type, and message format of the output message. If you have included a ResetContentDescriptor node to set these values before passing the message to the XSLTransform node, you can now optimize the message flow by removing the ResetContentDescriptor node.

Use the FileRead node to read one record, or the entire contents of a file, from within a message flow.

Migrating a flow containing data definitions

When you migrate a message flow that uses data definitions from Version 6.0, Version 7.0 converts and replaces those definitions.

About this task

You must complete this task if you are migrating from Version 6.0; no migration is required from Version 6.1.

WebSphere Message Broker Version 7.0 manages data definitions in a data design project. A single file in the project (a `.dbm` file) represents the database. This file replaces the set of `.xmi` files that you created for each data definition in the Version 6.0 workbench.

- If you are migrating from Version 6.0, migration is performed only when you rebuild the message flow project in the WebSphere Message Broker Toolkit. Therefore, you must start a Version 7.0 WebSphere Message Broker Toolkit session to migrate the data definitions. See "Migrating data definitions in the workbench" on page 218.

Because the project files are changed by the migration process, and the old format files are deleted, back up your resources before you start to use existing resources in the Version 7.0 WebSphere Message Broker Toolkit.

When migration is complete, you can view data design projects in the Broker Application Development perspective, and you can view the contents of the `.dbm` files in the Data Project Explorer and Data Source Explorer views.

If a data definition is not migrated successfully, the database might no longer be supported. Check the version of the database that is referenced by the data

definition against the “Supported databases” on page 3591, and upgrade your database if necessary.

Migrating data definitions in the workbench

About this task

Complete the following steps:

Procedure

1. Start the Version 7.0 WebSphere Message Broker Toolkit.
2. Import the message flow that contains data definitions in `.xmi` files. You are asked to confirm that you want migration to be performed.
3. Select **Do not show this message again** if you want all projects to be migrated automatically when you import or rebuild them, and click **Yes** to continue with migration. The project is rebuilt, all data definitions are converted to the `.dbm` file format, and all database references from ESQL modules and mappings are replaced.

   To reset the option that suppresses the confirmation dialog, click **Windows** > **Preferences**, open **Broker Development**, and click **Database Definition**. Change the setting on this panel.
4. Clean all your projects after migration:
   a. Click **Project** > **Clean**.
   b. Select **Clean all projects**.
   c. Click **OK**.
5. Check the results of the migration. Errors and warnings are displayed in the Problems view.

Results

If you decide not to continue with migration, some errors might be generated in ESQL modules (`.esql` files) and in mappings (`.msgmap` files) that refer to databases. You must migrate the database resources in the project before you can deploy the project. You can start migration later in two ways:

- Rebuild the message flow project.
- Right-click the Database Connections folder and select **Database Definition Migration**. (The Database Connections folder appears in the toolkit only if you have not migrated all your database definitions, and it is removed when all migration has completed.)

How the migration works

About this task

Changes are made to the workspace resources as follows:

Procedure

- A new data design project is created if database definitions are found in the project. The first data design project name is set to the message flow project name, with `_DDP` appended; for example, `FlowProject1_DDP`.

  Each database definition is converted to Version 7.0 format. That is, the set of `.xmi` files is converted and stored as a single file called *`database_name`*`.dbm`. Multiple unique database definitions are converted and stored in a single data design project.

  You can rename the `.dbm` file, or the data design project.

- If you have created duplicate database definitions for the same database in the message flow project, another data design project is created for each definition.

  In Version 6.0, you can create multiple database definitions for the same database within a single message flow project. In Version 7.0 you can have only one definition, for each database, to ensure that mappings are unambiguous.

  You can create separate data definitions for the same database in separate data design projects, but you can refer to only one of these definitions from a single message flow project.

  The `.xmi` files are converted to a single `.dbm` file and each duplicate definition is stored in a separate data design project. The names of additional data design projects are also based on the name of the message flow project, and are appended with `_DDP2`, `_DDP3`, and so on.

  You might have to modify your message flow projects to ensure that all database references are to the same definition of the database.
- All old database definition files are deleted from the message flow project and from the file system.
- The first data design project that is created is added as a project reference to the message flow project.

  If data design projects have been created for duplicate database definitions, you cannot refer to these projects from the same message flow project.

  If you change the name of the data design project, you must modify the project reference in the message flow project.
- During conversion, information and errors are recorded in a log. Errors are also displayed in a dialog to indicate that migration has failed for a definition, and the cause of the failure. After migration, view the log file `migratedbdefinitions.log` in the `.metadata/.plugins/com.ibm.etools.mft.rdb` directory.

  The log contains details of the data design projects that have been created, the `.dbm` files that have been added to those projects, and the `.xmi` files that have been deleted.

  If you migrate these resources at a later date, for example when you import a different message flow project, the log records are appended to the existing content.

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Migrating a flow supporting ?wsdl queries

If you want WSDL and XML Schema information to be made available for existing SOAPInput-SOAPReply flows that implement web services, you must explicitly set the SOAPInput node property `Enable support for ?wsdl` and redeploy the flow.

About this task

In the unlikely event you have implemented an HTTPInput-HTTPReply flow to support `?wsdl` queries related to a SOAPInput-SOAPReply flow, you should now deprecate the HTTP flow. By sending `?wsdl` requests directly to the endpoint exposed by the SOAPInput node, this capability will continue to work even if the internal WSDL deployment details change in the future.

If you migrate your HTTP flow to use the embedded HTTP listener, the HTTPInput URL will clash with the SOAPInput URL, and a warning is written to the event log. In this case the `?wsdl` request is always serviced correctly, but web service requests could be sent to either the SOAPInput or the HTTPInput node.

Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

"HTTPInput node" on page 4474
Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

Migrating CMP applications

If you have written applications that use the CMP API, check that they access the correct resources.

Procedure

1. Update your CMP applications to use the file that is supplied by Version 7.0. You cannot use the `ConfigManagerProxy.jar` file from an earlier version to work with a Version 7.0 broker.

   You do not have to change the methods that the application uses; the Version 7.0 CMP API includes all deprecated classes and takes appropriate action.
2. Update the connection details that are used by your CMP applications to connect to the appropriate broker.

   If the application connects to a broker that is running on the same queue manager that was previously used by the Configuration Manager to which it connected, no change is required.

Updating error processing routines

Update your message processing to handle new or reused messages, and to delete obsolete messages.

About this task

WebSphere Message Broker Version 7.0 components generate new diagnostic messages (BIP messages), and no longer generates others that were reported in previous versions. The text of some messages have also been updated to reflect change in behavior and function in Version 7.0, although the meaning has been retained. One message, BIP8663, has been reused and has different content and meaning.

If you have applications that check for specific messages, you must update these routines. For example, you might have programs that automate error reporting, or identify the occurrence of specific error conditions.

For details of the content of all messages generated by Version 7.0, see Diagnostic messages.

Version 7.0 generates the following new messages:

- **Configuration:** messages in the range 1000 - 1999:

  ```
  BIP1014, BIP1054, BIP1060, BIP1115, BIP1117
  BIP1181 to BIP1191
  BIP1251 to BIP1269
  BIP1280 to BIP1295
  BIP1810
  ```

- **Broker:** messages in the range 2000 - 2999:

  ```
  BIP2082, BIP2289, BIP2319, BIP2358
  BIP2372, BIP2676, BIP2829, BIP2830
  BIP2850 to BIP2866
  BIP2870 to BIP2872
  BIP2880 to BIP2883
  BIP2890 to BIP2894
  ```

- **Built-in nodes:** messages in the range 3000 - 3999:

  BIP3226
  BIP3432 to BIP3439
  BIP3451 to BIP3463
  BIP3466 to BIP3471
  BIP3524 to BIP3526
  BIP3574, BIP3635, BIP3687
  BIP3747 to BIP3760
  BIP3769 to BIP3831
  BIP3915 to BIP3925

- **Built-in nodes:** messages in the range 4000 - 4999:

  BIP4015 to BIP4017
  BIP4071 to BIP4076
  BIP4251 to BIP4254
  BIP4359
  BIP4513 to BIP4516
  BIP4678
  BIP4821 to BIP4829
  BIP4833 to BIP4865

- **Parsers:** messages in the range 5000 - 5999:

  BIP5031, BIP5637

- **WebSphere MQ parsers:** messages in the range 6000 - 6999:

  BIP6069, BIP6265, BIP6266

- **Publish/subscribe:** messages in the range 7000 - 7999:

  BIP7036 to BIP7038
  BIP7042 to BIP7045
  BIP7099
  BIP7120 to BIP7123

- **Commands:** messages in the range 8000 - 8999:

  BIP8157, BIP8200
  BIP8231 to BIP8239
  BIP8769 to BIP8783
  BIP8919 to BIP8923
  BIP8934 to BIP8940
  BIP8990 to BIP8993

- **z/OS:** messages in the range 9000 - 9999:

  BIP9284
  BIP9286 to BIP9290

Version 7.0 reuses the message BIP8663.

Version 7.0 components no longer generate the following messages:

- **Configuration:** messages in the range 1000 - 1999:

  BIP1002 to BIP1013
  BIP1015 to BIP1016
  BIP1020 to BIP1023

```
BIP1029, BIP1032, BIP1037, BIP1040
BIP1042 to BIP1045
BIP1055 to BIP1057
BIP1059, BIP1070
BIP1072 to BIP1088
BIP1090, BIP1094
BIP1096 to BIP1107
BIP1109 to BIP1112
BIP1126, BIP1128, BIP1131, BIP1132, BIP1145, BIP1146
BIP1151 to BIP1165
BIP1170 to BIP1173
BIP1201 to BIP1211
BIP1213 to BIP1217
BIP1221 to BIP1230
BIP1301 to BIP1306
BIP1350 to BIP1353
BIP1355 to BIP1363
BIP1401 to BIP1415
BIP1449, BIP1450, BIP1461, BIP1462
BIP1502 to BIP1528
BIP1530 to BIP1552
BIP1557 to BIP1571
BIP1581 to BIP1589
BIP1702 to BIP1703
BIP1705 to BIP1708
BIP1711 to BIP1712
BIP1751 to BIP1760
BIP1762, BIP1764, BIP1765
BIP1767 to BIP1773
BIP1775 to BIP1781
BIP1806 to BIP1807
```

- **Broker:** messages in the range 2000 - 2999:

```
BIP2012, BIP2013
BIP2025 to BIP2028
BIP2032, BIP2035, BIP2036, BIP2040
BIP2048, BIP2049, BIP2053
BIP2072, BIP2073, BIP2090
BIP2092 to BIP2098
BIP2220, BIP2221, BIP2223, BIP2224, BIP2317
BIP2814 to BIP2816
```

- **Built-in nodes:** messages in the range 4000 - 4999:

```
BIP4046
```

- **Parsers:** messages in the range 5000 - 5999:

```
BIP5315
```

- **Publish/subscribe:** messages in the range 7000 - 7999:

```
BIP7003, BIP7007, BIP7011, BIP7012
BIP7028, BIP7029, BIP7060, BIP7090
```

- **Commands:** messages in the range 8000 - 8999:

```
BIP8058, BIP8060, BIP8061, BIP8066, BIP8077, BIP8078
BIP8088, BIP8089, BIP8090
```

```
BIP8102, BIP8103, BIP8106, BIP8107
BIP8109, BIP8110, BIP8112
BIP8118, BIP8119, BIP8148, BIP8180
BIP8201 to BIP8210, BIP8214,
BIP8250 to BIP8263, BIP8286
BIP8301 to BIP8311
BIP8380 to BIP8382
BIP8390 to BIP8394
BIP8617, BIP8618, BIP8620
BIP8664 to BIP8668
BIP8672, BIP8674, BIP8675, BIP8678, BIP8795, BIP8796
BIP8829 to BIP8832
BIP8834 to BIP8839
BIP8842 to BIP8845
BIP8925
BIP8930 to BIP8933
BIP8995
```

- **z/OS:** messages in the range 9000 - 9999:

```
BIP9144 to BIP9146
BIP9801 to BIP9842
```

Related tasks:

Chapter 3, “Migrating and upgrading,” on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Restoring migrated components to previous versions

You can restore migrated brokers to previous versions of WebSphere Message Broker.

About this task

You can only restore brokers to the state they were in before you migrated them; changes that you have made to them after migration, such as updated properties, are lost.

You might want to restore components if you encounter a problem after you have migrated your brokers to Version 7.0. For example, if a message flow does not work as expected in Version 7.0, restore that broker until you can resolve the problem.

You can restore brokers to a previous version only if they were migrated from that version originally. You cannot create a new Version 6.1 broker, then restore it to a previous level. Nor can you create a Version 6.0 broker, migrate it to Version 7.0, then restore it to Version 6.1.

The topics in this section explain how to restore brokers and resources that you have migrated from Version 6.1 or Version 6.0 products back to their original state:

- “Restoring components and resources to Version 6.1” on page 225
- “Restoring components and resources to Version 6.0” on page 227

Because you do not migrate Configuration Manager or User Name Server components, you do not have to restore these. If you have not deleted them, they

retain their existing configuration, and can be reused with brokers that you restore to a previous version.

Related tasks:

Chapter 3, "Migrating and upgrading," on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

"Uninstalling" on page 331
Remove the Broker component, the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer from your computer.

Restoring components and resources to Version 6.1

Restore components and resources that you have migrated from Version 6.1 products to their original state.

About this task

If you have migrated from WebSphere Message Broker Version 6.1 to Version 8.0, you can restore your installation to Version 6.1, subject to the following restrictions and procedures.

When you use the **mqsimigratecomponents** command, you must be logged in to a Version 8.0Version 7.0 command environment.

See the **mqsimigratecomponents** command description for usage information and details of parameters and the format to use when specifying version numbers.

Restrictions

Message flows that you have deployed to a broker after migration to Version 7.0 might no longer work when you restore that broker to Version 6.1; always check logs to search for errors or warnings about message flows that the broker cannot start.

Source files in the WebSphere Message Broker Toolkit Version 7.0 are maintained in a different format from that used in Version 6.1. The files are migrated to the new format when you save them in the WebSphere Message Broker Toolkit Version 7.0. After you have saved them, you can no longer use the resources with the WebSphere Message Broker Toolkit Version 6.1.

Changes that you made to brokers, the WebSphere Message Broker Toolkit, and development resources after migration to Version 7.0 are not retained when you restore your resources back to Version 6.1.

Migrating resources back to Version 6.1

The following sections describe how to restore the WebSphere Message Broker Toolkit and your brokers to Version 6.1. You can reuse your original Version 6.1 Configuration Manager and User Name Server components with the brokers that you restore to Version 6.1.

Restoring the WebSphere Message Broker Toolkit to Version 6.1

1. Close all WebSphere Message Broker Toolkit Version 7.0 sessions.
2. Restore the Version 6.1 workspace from the backup that you took before migration.

   Ensure that the workspace directories include the `.metadata` directory, which contains information that is specific to the release of Eclipse on which the toolkit is based.
3. Restart WebSphere Message Broker Toolkit Version 6.1.

Restoring brokers to Version 6.1

Use the **-s** and **-t** parameters of the **mqsimigratecomponents** command to migrate brokers from Version 7.0 to Version 6.1.

- Specify the installed level of Version 7.0 for the source version parameter (**-s**), for example `7.0.0.0` for the GA (general availability) level, or allow this to take the default value.
- Specify the appropriate level of Version 6.1 for the target version parameter (**-t**), for example `6.1.0.9` for Version 6.1, Fix Pack 9.

See the **mqsimigratecomponents** command for detailed information about these parameters and the format to use when specifying version numbers.

Restoring brokers on distributed systems

1. Stop the Version 7.0 broker by using the **mqsistop** command.
2. Restore the broker to Version 6.1 using the **mqsimigratecomponents** command, as shown in the following example:

   ```
   mqsimigratecomponents Broker -t 6.1.0.9
   ```
3. Reverse the changes that you made to the ODBC definitions when you migrated to Version 7.0; for more details, see "Updating your ODBC definitions when migrating" on page 188.
4. Start the Version 6.1 WebSphere Message Broker Toolkit, and add the broker to the configuration.
5. Open a Version 6.1 command window, and restart the broker by using the **mqsistart** command.

If you migrate to Version 7.0, deploy a message set to the Version 7.0 broker, and then migrate back to Version 6.1, Version 6.1 is unable to recognize the message set that was deployed by Version 7.0. In this case, all message sets that Version 6.1 is unable to use are deleted and the warning message BIP8688W is displayed for each message set, prompting you to redeploy it to Version 6.1 following successful migration.

Restoring brokers on z/OS

1. Stop the Version 7.0 broker by using one of the available options.
2. Submit the BIPMGCMP job to call the **mqsimigratecomponents** command, specifying the **-s** and **-t** parameters, as described for distributed systems.
3. Start the Version 6.1 WebSphere Message Broker Toolkit, and add the broker to the configuration.

4. Replace the started task JCL file in USER.PROCLIB with the Version 6.1 copy that you backed up.

"**mqsimigratecomponents** command" on page 3894
Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

Restoring components and resources to Version 6.0

Restore components and resources that you have migrated from Version 6.0 products to their original state.

About this task

If you have migrated from WebSphere Message Broker Version 6.0 to Version 7.0, you can restore your installation to Version 6.0, subject to the following restrictions and procedures.

When you use the **mqsimigratecomponents** command, you must be logged in to a Version 7.0 command environment.

See the **mqsimigratecomponents** command description for usage information and details of parameters and the format to use when specifying version numbers.

Restrictions

Message flows that you have deployed to a broker after migration to Version 7.0 might no longer work when you restore that broker to Version 6.0; always check logs to search for errors or warnings about message flows that the broker cannot start.

Source files in WebSphere Message Broker Toolkit Version 7.0 are maintained in a different format to that used in Version 6.0. The files are migrated to the new format when you save them in the WebSphere Message Broker Toolkit Version 7.0. After you have saved them, you can no longer use the resources in WebSphere Message Broker Toolkit Version 6.0. For detailed information, see "Conditions for using migrated resources with previous versions of the WebSphere Message Broker Toolkit" on page 229.

Changes that you made to brokers, the WebSphere Message Broker Toolkit, and development resources after migration to Version 7.0 are not retained.

Migrating resources back to Version 6.0

The following sections describe how to restore the WebSphere Message Broker Toolkit and your brokers to Version 6.0. You can reuse your original

Version 6.0 Configuration Manager and User Name Server components with the brokers that you restore to Version 6.0.

Restoring the WebSphere Message Broker Toolkit to Version 6.0

1. Close all WebSphere Message Broker Toolkit Version 7.0 sessions.
2. Restore the Version 6.0 workspace from the backup that you took before migration.

   Ensure that the workspace directories include the `.metadata` directory, which contains information that is specific to the release of Eclipse on which the toolkit is based.
3. Restart WebSphere Message Broker Toolkit Version 6.0.

Restoring brokers to Version 6.0

Use the **-s** and **-t** parameters of the **mqsimigratecomponents** command to migrate brokers from Version 7.0 to Version 6.0.

- Specify the installed level of Version 7.0 for the source version parameter (**-s**), for example `7.0.0.0` for the GA (general availability) level, or accept the default value.
- Specify the appropriate level of Version 6.0 for the target version parameter (**-t**), for example `6.0.0.9` for Version 6.0, Fix Pack 9.

See the **mqsimigratecomponents** command for detailed information about these parameters and the format to use when specifying version numbers.

Restoring brokers on distributed systems

1. Stop the Version 7.0 broker by using the **mqsistop** command.
2. Restore the broker to Version 6.0 by using the **mqsimigratecomponents** command, as shown in the following example:

   ```
   mqsimigratecomponents Broker -t 6.0.0.9
   ```
3. Reverse the changes that you made to the ODBC definitions when you migrated to Version 7.0.
4. Open a Version 6.0 command window, and restart the broker by using the **mqsistart** command.

If you migrate to Version 7.0, deploy a message set to the Version 7.0 broker, and then migrate back to Version 6.0, Version 6.0 is unable to recognize the message set that was deployed by Version 7.0. In this case, all message sets that Version 6.1 is unable to use are deleted and the warning message BIP8688W is displayed for each message set, prompting you to redeploy it to Version 6.1 following successful migration.

Restoring brokers on z/OS

1. Stop the Version 7.0 broker by using one of the available options.
2. Submit the BIPMGCMP job to call the **mqsimigratecomponents** command, specifying the **-s** and **-t** parameters as described previously.
3. Replace the started task JCL file in USER.PROCLIB with the Version 6.0 copy that you backed up.

Related concepts:

"Conditions for using migrated resources with previous versions of the WebSphere Message Broker Toolkit"
WebSphere Message Broker Version 7.0 can interoperate with components of previous versions. Conditions apply when you use migrated development and deployed resources with previous versions of the WebSphere Message Broker Toolkit.

Use the **mqsimigratecomponents** command to migrate a component from a previously installed version of the product to another version on the same computer.

Conditions for using migrated resources with previous versions of the WebSphere Message Broker Toolkit

WebSphere Message Broker Version 7.0 can interoperate with components of previous versions. Conditions apply when you use migrated development and deployed resources with previous versions of the WebSphere Message Broker Toolkit.

Version 6.1 and Version 6.0 resources

Import Version 6.1 and Version 6.0 resources into your Version 7.0 workspace to view and change them. After you have changed and saved resources, you can no longer use them in your Version 6.1 or Version 6.0 WebSphere Message Broker Toolkit.

You do not have to perform any explicit migration tasks on imported resources.

Restrictions after migration

After you have migrated WebSphere Message Broker Toolkit resources to Version 7.0, your use of these resources in the Version 6.1 and Version 6.0 WebSphere Message Broker Toolkit is restricted.

Development resources

Resources in Version 6.1 and Version 6.0 formats can coexist in the Version 7.0 workspace.

Resources remain in their original format until you save them in the Version 7.0 WebSphere Message Broker Toolkit. After saving, all resources are stored in the Version 7.0 format.

You can no longer use these saved resources in earlier versions of the WebSphere Message Broker Toolkit. Therefore you cannot share development resources between the Version 7.0 and previous versions of the WebSphere Message Broker Toolkit.

If you expect to continue development of these resources, you must retain a WebSphere Message Broker Toolkit at the version that you require.

Deployment resources

You can deploy broker archive (BAR) files that you edit or create in a Version 7.0 WebSphere Message Broker Toolkit only to Version 7.0 brokers.

You can import resources that you created in previous versions into your Version 7.0 workspace, but when you include these resources in a BAR file, you can deploy that BAR file only to Version 7.0 brokers.

The following table summarizes which of the files that you can include in a BAR file are deployable and accepted by the broker at each version. A broker rejects broker archive files that contain file types that are supported only by later brokers.

File type	Version 6.0	Version 6.1	Version 7.0
Compiled message flows (`.cmf`)	Yes	Yes	Yes
Message dictionaries (`.dictionary`)	Yes	Yes	Yes
XSL style sheets (`.xsl`, `.xslt`, `.xml`)	Yes	Yes	Yes
Java archives (`.jar`)	Yes	Yes	Yes
WebSphere TX maps (`.mar`)	No	Yes	Yes
XSD archives (`.xsdzip`)	No	Yes	Yes
Inbound adapter configuration (`.inadapter`)	No	Yes	Yes
Outbound adapter configuration (`.outadapter`)	No	Yes	Yes
Inbound SCA definitions	No	No	Yes
Outbound SCA definitions	No	No	Yes

The Version 7.0 WebSphere Message Broker Toolkit can coexist with the Version 6.1 and Version 6.0 WebSphere Message Broker Toolkit on the same computer. However, because you cannot share development resources between the Version 7.0 WebSphere Message Broker Toolkit and previous versions of the WebSphere Message Broker Toolkit, you might find that it is appropriate to create and maintain a different workspace for the Version 7.0 WebSphere Message Broker Toolkit.

Use the reference information in this section to understand installation requirements, installation options, and how they affect your computer.

Installing

Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

About this task

See "Finding the latest information" on page 232 for details about how to check that you have access to the most recent information available.

The "Installation Guide" on page 233 defines hardware and software requirements for WebSphere Message Broker and its corequisite and prerequisite products. It describes the tasks that you must complete to prepare for installation, to install WebSphere Message Broker, and to verify the installation. When you have completed installation, use this information center to create and configure your components and brokers.

If product fixes or updates are made available, refer to the following topics for information about how to apply these changes:

- "Applying service to the Broker component" on page 314
- "Applying service to the WebSphere Message Broker Toolkit" on page 325
- "Applying service to the WebSphere Message Broker Explorer" on page 329

You do not have to apply service to the runtime components and the WebSphere Message Broker Toolkit at the same time; all Version 7.0 fix pack levels are compatible with all other fix pack levels. However, if a fix pack delivers additional nodes, you must ensure that the WebSphere Message Broker Toolkit and the brokers to which you deploy the message flows that include these nodes are at the same fix pack level, and that you have set the correct function level of those brokers by using the **-f** flag on the **mqsichangebroker** command.

To install complementary products, see "Installing complementary products" on page 300.

Related tasks:

Chapter 7, "Configuring brokers for test and production environments," on page 579
Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

"Uninstalling" on page 331
Remove the Broker component, the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer from your computer.

"Resolving problems when installing" on page 3517
Work through the advice provided to help you to deal with problems that can arise when the product is installed.

"Finding the latest information"

Finding the latest information

Access the latest information for WebSphere Message Broker.

About this task

The following information is provided:

Requirements website
: For the latest details of hardware and software requirements on all supported platforms, visit the WebSphere Message Broker Requirements website.

readme.html
: The product readme file is frequently updated and includes information about last minute changes and known problems and workarounds. The latest version is always on the product readmes web page; always check to see that you have the latest copy. The version of file that is included on the product media, and which is installed when you install product components, contains a link to the latest version on the product readmes web page.

Installation Guide
The Installation Guide is provided as a PDF file with your product. See "Installation Guide" for details about how to access the guide online and where to find installation information in this information center.

Information center
The information center is installed with the WebSphere Message Broker Toolkit and the WebSphere Message Broker Explorer, and updates are typically included when you apply service to those components.

The information center is periodically updated independently of the code, and you can install the latest level from within the toolkit. For instructions about installing code and documentation updates, see "Applying service to the WebSphere Message Broker Toolkit" on page 325.

The information center is also available online at WebSphere Message Broker Library web page.

Support information
The WebSphere Message Broker support web page is regularly updated with the latest product support information. For example, if you are migrating from an earlier version, look under the heading "Solve a problem" for the document "Problems and solutions when migrating".

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

"Applying service to the Broker component" on page 314
Apply maintenance updates and program fixes to the Broker component.

"Applying service to the WebSphere Message Broker Toolkit" on page 325
Apply maintenance updates and program fixes to the WebSphere Message Broker Toolkit.

Related reference:

"Installation Guide"
Installation information for WebSphere Message Broker is provided in the *Installation Guide* that is supplied as a PDF file with your product package.

"Software requirements" on page 3588
View the operating system, database, and other software requirements.

"Hardware requirements" on page 3582
View the processor and related hardware requirements on all platforms.

Installation Guide

Installation information for WebSphere Message Broker is provided in the *Installation Guide* that is supplied as a PDF file with your product package.

The installation information provided by the *Installation Guide* is also contained in the information center:

See "Installation" on page 3581 for reference information about system requirements, including operating systems, hardware, and additional software and memory requirements.

The *Installation Guide* provides general preparation, planning, and security information for all platforms. It also provides installation instructions for distributed systems, common problems and solutions, and the names and locations of the installation log files. Verification programs on Linux on x86 and Windows are also provided.

If you are installing on z/OS, the equivalent installation instructions are provided in the Program Directory that is supplied in hardcopy with your product media.

The *Installation Guide* does not cover configuration or customization tasks on any operating system; it describes only how you install the product components onto your computers. When you have completed installation on distributed systems, you must initialize the local environment before you can create or configure resources. This task is described in "Setting up a command environment" on page 213. Environment initialization is not required on z/OS. For information about designing and configuring your broker environment on all systems, see Chapter 7, "Configuring brokers for test and production environments," on page 579.

The *Installation Guide* PDF file is provided as a convenience for printing and offline reading. You can find the *Installation Guide* PDF file in the following locations after a major release of the information center, such as Version 7.0:

- In English, on the WebSphere Message Broker customer FTP site. To access the PDF file on the customer FTP site, see WebSphere Message Broker Installation Guide.
- In English, from the WebSphere Message Broker Library web page.
- In English and supported languages, on the Quick Start CD.
- In English and supported languages, with your product package.

If significant changes are accumulated between major releases, the *Installation Guide* PDF file is refreshed and provided in English, on the customer FTP site, and the Library web page.

The PDF file content is the same as the content that is provided in the information center at the time of publish. However, the PDF file documentation is updated less frequently than the information center. For the latest information, see the "Installation" on page 3581 and "Installing" on page 231 sections in the online information center.

You can view, search, and print PDF files by using Adobe Reader. To download Adobe Reader, see the Adobe Systems Inc. website. For more information about printing the *Installation Guide* PDF file, see Printing information center topics and the Installation Guide PDF file.

Preparing for installation

Use the instructions in this tutorial for an overview of the installation tasks, and to prepare for installation of WebSphere Message Broker.

About this task

The tasks that you perform to complete installation are listed here; each task indicates whether it is required or optional. A summary of each task is provided, along with pointers to later chapters or sections which describe that task in more detail.

Procedure

1. Required: Make sure that you have acquired the product packages that you need for installation.

   Physical and electronic packages are available for WebSphere Message Broker Version 7.0.

   For more information about available packages and their contents, see “Installation packages” on page 3608. If you have ordered the product for electronic delivery from IBM Passport Advantage®, check that you have downloaded all the images that you need for all components and all platforms.

   Both DVDs and CDs are supplied in the physical package, where as only CD images are available from IBM Passport Advantage. The CD images that are available from IBM Passport Advantage contain the same content as the physical DVDs, but might be greater in number.

For example, a physical DVD might contain installation files for the Broker component, WebSphere Message Broker Toolkit, and WebSphere MQ, where as IBM Passport Advantage might provide a CD image for the Broker component, three images for the WebSphere Message Broker Toolkit, and another image for WebSphere MQ.

Find out how to access, download, and extract product images in "Accessing CDs and DVDs" on page 252.

For instructions about downloading and applying service updates, see "Applying service" on page 313.

2. Required: Make sure that you have access to the product documentation that you need for installation.
   - The product readme file `readme.html` contains the latest available information.
   - The information center describes planning and preparation on all platforms. The sections of the information center you need for installation are also available as a PDF file on the Quick Start CD.
   - This information center describes installation procedures for all components on all distributed platforms. The sections of the information center that you need for installation are also available as a PDF file on the Quick Start CD.
   - The *Program Directory for WebSphere Message Broker for z/OS* describes installation procedures for all components on z/OS.

   Find out how to get these documents in "Finding the latest information" on page 232.
3. Required: Decide which components you want to install on your computers.

   The following information provides a minimum level of detail about WebSphere Message Broker components; read "Choosing what to install" on page 260 to find out more about the components.
   - The WebSphere Message Broker Toolkit. You must install this component on at least one computer. You can install this component only on Windows 32-bit, Windows 64-bit, Linux on x86, and Linux on x86-64.

     Use the WebSphere Message Broker Toolkit to create, manage, deploy, and delete message flows and associated resources in a development environment.
   - The WebSphere Message Broker Explorer. You can install this component only on Windows 32-bit, Windows 64-bit, Linux on x86, and Linux on x86-64.

     Use the WebSphere Message Broker Explorer to administer your brokers in a production environment.
   - The Broker component. You must install this component on at least one computer.

     You can create multiple brokers on a single computer. Deploy your message flow resources to one or more brokers to process your application messages.
4. Required: Decide which platform you want to install your chosen components onto.

   The following table shows the components that you can install on the supported platforms.

Table 1. Summary of component and platform support

Component	Platform
WebSphere Message Broker Toolkit	• Linux on x86 • Linux on x86-64 • Windows 32-bit • Windows 64-bit
WebSphere Message Broker Explorer	• Linux on x86 • Linux on x86-64 • Windows 32-bit • Windows 64-bit
Broker component	All supported platforms

5. Required: Prepare each computer on which you are installing one or more components.
   a. Check that your target computers meet the initial hardware, storage, and software requirements.

      The requirements vary depending on what computers you want to install WebSphere Message Broker on, and what components you are installing; read the details in "Hardware requirements" on page 3582 and "Operating system requirements" on page 3590.

      The supported hardware and software environments are updated occasionally. To view the latest requirements, see the product requirements website:

      `www.ibm.com/software/integration/wbimessagebroker/requirements/`
   b. Complete the appropriate tasks for your computer to set up security and UNIX kernel configuration, and get ready to access the installation media.

      All these tasks are described in "Preparing the system" on page 245.
   c. Check that your user ID has the required authority to complete installation:
      - AIX systems: Use the user ID root for installation.
      - Linux and other UNIX systems: Use either the user ID root, or another ID and become root.
      - Windows systems: Your user ID must be a member of the group Administrators.
      - z/OS systems: Use a user ID that has suitable RACF privileges to perform installation.

      This information is a summary only; more details are provided in "Setting up security" on page 245.
6. Required: Check the programs that you use to perform component installation.

   The following table lists the programs that are available.

Table 2. Summary of available installation methods

Platform	Tools
Windows only	The Windows Launchpad. This program installs prerequisite products if they are not already installed, and identifies prerequisite products that are not at the supported level. See "Installing by using the Windows Launchpad" on page 262.

Table 2. Summary of available installation methods (continued)

Platform	Tools
Linux, UNIX, and Windows systems	Installation wizards on each supported platform have unique names, which are listed in "Installation wizard names" on page 3626. • To install the Broker component, see "Installing the Broker component" on page 267. • To install the WebSphere Message Broker Toolkit, see "Installing the WebSphere Message Broker Toolkit" on page 276. • To install the WebSphere Message Broker Explorer, see "Installing WebSphere Message Broker Explorer" on page 280.
z/OS only	SMP/E To install runtime components, see the *Program Directory for WebSphere Message Broker for z/OS*.

7. Required: Install additional products that are required by WebSphere Message Broker.

   WebSphere Message Broker requires other software products to work successfully. The order in which you install these products is not important. However, you must install all required products before you can configure and start WebSphere Message Broker components.

   The following table gives a summary of these requirements.

Table 3. Summary of prerequisite products

Component	Prerequisite products
WebSphere Message Broker Toolkit	• A web browser to view the information center.
WebSphere Message Broker Explorer	• Install WebSphere MQ Explorer. • A web browser to view the information center.
Broker component	• WebSphere MQ to communicate with other components. • A Java Runtime Environment (JRE).

   Full details of all these requirements are provided in "Additional software requirements" on page 3598:

   - For web browsers, see "Browsers" on page 3600.
   - For details of supported WebSphere MQ versions, see "WebSphere MQ" on page 3598.
   - For further information about JREs, see "JRE" on page 3599.

8. Optional: Configure a minimum broker domain and verify its operation.
   a. To create a minimum broker domain, install the WebSphere Message Broker Toolkit and the Broker component on a single computer. Because the WebSphere Message Broker Toolkit is required to complete this task, you must choose a Linux on x86, Linux on x86-64, or Windows computer.
   b. Use the Default Configuration wizard, which you can start from the WebSphere Message Broker Toolkit, to create the required components after installation.
   c. Use this broker domain to create message flow resources, verify your installation, investigate how the product works, and explore the product samples.

The verification process is described in "Verifying your WebSphere Message Broker installation" on page 290.

9. Optional: Change the broker operation mode.

   When you install WebSphere Message Broker and create brokers, they are configured with an operation mode set either to `trial` (if you have installed the Trial Edition) or `enterprise` (all other editions). You must configure your brokers to conform to the license that you have purchased. Therefore, if you have purchased the Starter Edition, Entry Edition, or the Remote Adapter Deployment, you must set the operation mode of all your brokers to the correct value.

   See "Checking the broker operation mode and function level" on page 298 for more details.

10. Optional: Change the broker function level.

    If new message flow nodes are delivered in a fix pack, they show in the WebSphere Message Broker Toolkit, but are not enabled in the runtime broker environment. If you deploy a BAR file that includes a message flow that uses a new node, the deployment fails.

    If you want to use and test the new nodes, you can enable them on an individual broker basis. See "Checking the broker operation mode and function level" on page 298 for more details.

Results

You have completed the tutorial.

WebSphere Message Broker Requirements

Coexistence and migration

WebSphere Message Broker Version 7.0 can coexist with previous versions.

You can install WebSphere Message Broker Version 7.0 on a computer on which you have installed previous versions, but each version must be installed into its own directory, referred to as *install_dir*. Different versions can coexist and can run independently, and you can migrate brokers from one version to another, if and when appropriate. For the Broker component and WebSphere Message Broker Toolkit, you can install multiple instances of the same version on the same computer, each in its own separate directory. For example, the Broker component can coexist with different fix pack levels, such as V7.0.0.0 with V7.0.0.1. You can install multiple instances of the same version of the Broker component and WebSphere Message Broker Toolkit on the same computer, however only one version of WebSphere Message Broker Explorer is allowed.

The following sections provide further details:
- "Coexistence"
- "Migration" on page 244

Coexistence

WebSphere Message Broker Version 7.0 can coexist with previous versions as follows:

- The Broker component can coexist with runtime components at Version 6.0, and Version 6.1.
- The WebSphere Message Broker Toolkit can coexist with the toolkit at Version 6.0, and Version 6.1.

The following sections describe how to achieve coexistence, and the restrictions that apply.

Broker component on distributed systems

When you install the Broker component on distributed systems, the default action taken by the installation wizard is to complete a `typical installation`, which installs the Broker component into a default directory. The default directory for a typical installation is fixed and you cannot change it.

If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

Linux `/opt/ibm/mqsi/v.r`

UNIX `/opt/IBM/mqsi/v.r`

Windows 32-bit
`C:\Program Files\IBM\MQSI\v.r`

Windows 64-bit
`C:\Program Files\IBM\MQSI\v.r` for the 64-bit version of WebSphere Message Broker

`C:\Program Files (x86)\IBM\MQSI\v.r` for the 32-bit version of WebSphere Message Broker

These locations define the default value of *install_dir* on each platform.

Each unique version and release of the product is therefore installed into a different default location.

The installation wizard differentiates only at version and release level; it does not differentiate between different modification levels and fix pack levels. The current modification level is 0 (Version 7.0.0). If a later modification level is made available, it installs into the same default location, and therefore upgrades the Version 7.0.0 to the higher modification level (for example, Version 7.0.1).

The installation wizard installs one fix pack over a previous fix pack, but prohibits you from installing a previous modification or fix pack over a more recent one.

You can install the product at the same version and release more than once; these installations can be at the same modification or fix pack level, or at different levels.

To achieve concurrent installations, you must select the `custom installation` option and specify a unique directory for each installation (one of which can be the default directory).

You can also use the custom installation to install into a non-default directory.

If you have never completed a typical installation of the product on the computer on which you have selected a custom installation, the directory is initially set to the default directory, but you can change this default value to your chosen value.

If you attempt to install the Broker component into a directory that already contains an installation of the Broker component at a previous version, you are prompted to confirm that you want to continue with the installation, because it overwrites the existing installation. Cancel the installation and select a different directory to preserve your existing configuration.

If you install the same version and release more than once, the native installer support cannot manage these installations in the normal way. For more information, see "How to uninstall multiple installations of the Broker component" on page 3620.

You can use multiple installations at different modification or fix pack levels to test out fixes or new functions, or to stage your adoption of a new fix pack level. For more information, see "Applying service" on page 313.

During and after installation, files are also stored in the working directory, which is associated with the user ID with which you are currently logged on. The location depends on the operating system:

Linux and UNIX
`/var/mqsi`

Windows
`%ALLUSERSPROFILE%\Application Data\IBM\MQSI`

The environment variable `%ALLUSERSPROFILE%` defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\MQSI`
- On **Windows** Vista and later operating systems: `C:\ProgramData\IBM\MQSI`

The actual location might be different on your computer.

If you have multiple installations on a single computer, you can review the contents of the file `install.properties`, which is stored in the root of the working directory. For each installation at Version 6.1 and above, the file is updated with the location and the level.

This example shows the contents of `install.properties` on a Windows 32-bit operating system on which a single installation has completed:

```
C\:\\Program\ Files\\IBM\\MQSI\\7.0=7.0.0.0
```

(The backslash character \ is interpreted as an escape character. It is inserted before each non-alphabetic and non-numeric character in the string to preserve the character. A colon, a space, and several backslash characters are escaped in this example.)

If you want to revert from your latest installation to a previous level for any reason, you must uninstall the current version and install the previous level of the product. Before you uninstall, back up any resources that you want to return to a previous state.

Because the version and release are included in the directory structure when you complete a typical installation, you can also install Version 7.0 and later releases on the computer on which you have already installed either Version 6.0, or Version 6.1. The Version 7.0 installation can coexist with the existing installation; you can operate the two configurations independently.

If you use custom installations for Version 7.0 and later releases, you can specify a unique installation directory for each release, and therefore achieve coexisting releases on a single computer.

The number of installations of Version 7.0, or later, is limited only by the availability of system resources.

Because different versions and releases can coexist, you can migrate to Version 7.0 from an earlier version in a controlled manner, and you do not have to migrate all brokers at the same time. For more information, see "Migration" on page 244.

Broker component on z/OS

On z/OS, you can install multiple copies of the Broker component on the same computer if you specify a different installation location for each copy. The installations can run independently of each other. The code can be at the same or different version and release levels; Version 6.0, Version 6.1, and Version 7.0. The number of installations is restricted only by the availability of system resources.

For more details about locations, libraries, and file system paths, see the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

Coexistence with components of the same version

Although you can install multiple versions of the Broker component on the same system, you should not install both an x86 and an x86-64 version, of the same version number, on the same system. Some data files used by the Broker component are specific to each version, and using files of the wrong version with a broker could cause unpredictable results. This warning applies for all versions of the product and for all platforms.

WebSphere Message Broker Toolkit on Linux on x86, Linux on x86-64, and Windows

Linux When you install the WebSphere Message Broker Toolkit, the default action taken by the installation wizard is to install Installation Manager files, shared files, and product-specific files into the following directories:

- Installation Manager installation directory:
  `/opt/IBM/InstallationManager`
- Shared resources directory:
  `/opt/IBM/SDPShared/`
- Package group directory:
  `/opt/IBM/WMBT700`

This location defines the default value of *install_dir* on this platform.

For a description of these directories, see "Installing the WebSphere Message Broker Toolkit" on page 276.

You can install multiple instances of the WebSphere Message Broker Toolkit Version 7.0 at the same modification or fix pack level, or at different levels, on a single computer. Each installation must be in a separate package group; package groups are described in more detail in "IBM Installation Manager" on page 3600.

Windows

When you install the WebSphere Message Broker Toolkit, the default action taken by the installation wizard is to install Installation Manager files, shared files, and product-specific files into the following directories:

- Installation Manager installation directory:
  `C:\Program Files\IBM\InstallationManager` for the 32-bit version of WebSphere Message Broker
  `C:\Program Files (x86)\IBM\InstallationManager` for the 64-bit version of WebSphere Message Broker
- Shared resources directory:
  `C:\Program Files\IBM\SDPShared\` for the 32-bit version of WebSphere Message Broker
  `C:\Program Files (x86)\IBM\SDPShared\v.r` for the 64-bit version of WebSphere Message Broker
- Package group directory:
  `C:\Program Files\IBM\WMBT700` for the 32-bit version of WebSphere Message Broker
  `C:\Program Files (x86)\IBM\WMBT700` for the 64-bit version of WebSphere Message Broker

  This location defines the default value of *install_dir* on this platform.

For a description of these directories, see "Installing the WebSphere Message Broker Toolkit" on page 276.

You can install multiple instances of the WebSphere Message Broker Toolkit Version 7.0 at the same modification or fix pack level, or at different levels, on a single computer. Each installation must be in a separate package group; package groups are described in more detail in "IBM Installation Manager" on page 3600.

If you install the WebSphere Message Broker Toolkit on Windows and you specify your own directory location, be aware of the file system limit of 256 characters imposed by Windows file systems. This limit can cause restrictions in path specification to resources (for example, message flows), and might cause access problems if the combination of path and resource name exceeds this limit. Keep installation locations and resource names short to avoid problems associated with this restriction.

The WebSphere Message Broker Toolkit Version 7.0 can coexist with the WebSphere Message Broker Toolkit Version 6.0 or Version 6.1. Only one instance of the WebSphere Message Broker Toolkit Version 6.0 can be installed on a single computer.

The WebSphere Message Broker Toolkit Version 7.0 can coexist with multiple installations of the Broker component, subject to the restrictions described for the Broker component.

Setting the environment for an installation

Because you can have more than one installation on a single computer, you must ensure that the commands that you issue on that computer are directed to the correct version of installed code.

- On Linux and UNIX systems, you must run the profile file **mqsiprofile** to set up the correct environment before you run other WebSphere Message Broker commands, such as **mqsicreatebroker**. The profile file is stored in *install_dir*/bin.

  If you add the profile file to your system logon profile, it is run automatically whenever you log on.
- On Windows systems, a command console is available for each installation. So you must run commands in the correct window for a particular installation.

  If you prefer, you can run the mqsiprofile.cmd file, which is stored in *install_dir*\bin.

If you have installed an earlier version of this product on the same computer, check that the earlier profile is not set for the current user ID. The two profiles are incompatible and might cause unpredictable results. Consider using a different user ID for each version and associate the correct profile with each user ID to avoid potential problems.

This requirement is not applicable on z/OS systems.

For more details about **mqsiprofile**, see "Setting up a command environment" on page 213.

WebSphere Message Broker Explorer

Only one copy of WebSphere Message Broker Explorer can be installed at any time on a single system, so you must ensure the latest level of WebSphere Message Broker Explorer is installed. For example, if you have WebSphere Message Broker V7.0.0.0 and WebSphere Message Broker V7.0.0.1 installed on the same system, you must ensure that WebSphere Message Broker Explorer is installed at the later V7.0.0.1 level. This only applies to Windows, Linux on x86, and Linux on x86-64 systems.

Migration

Because you can install WebSphere Message Broker Version 7.0 on the same computer as previous versions and other installations of Version 7.0, you are not required to complete any migration tasks before you install Version 7.0.

Because WebSphere Message Broker Version 7.0 requires a later version of WebSphere MQ, you must update any existing WebSphere Message Broker Version 6.0 and WebSphere Message Broker installations to use a supported version of WebSphere MQ before installing WebSphere Message Broker Version 7.0. For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

For details about migrating to WebSphere Message Broker Version 7.0, see Chapter 3, "Migrating and upgrading," on page 137.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

Chapter 3, "Migrating and upgrading," on page 137
To migrate a broker domain to WebSphere Message Broker Version 7.0, plan your migration strategy, perform pre-migration tasks, migrate your domain components, and then complete post-migration tasks.

Preparing the system

On some operating systems, you must complete several tasks before you install WebSphere Message Broker.

About this task

You might also want to complete other tasks, depending on your installation intentions.

Read the following sections before installing:

Procedure

1. "Setting up security."
2. "Configuring temporary space on distributed systems" on page 251.
3. If you are installing on a distributed system, see "Accessing CDs and DVDs on the local system" on page 253.
4. If you are installing on Linux or UNIX systems, see "Checking the kernel configuration on Linux and UNIX systems" on page 259.

What to do next

When you have completed these tasks, follow the installation instructions for distributed systems in the appropriate chapter:

- On distributed systems, choose which WebSphere Message Broker components to install. For more information, see "Choosing what to install" on page 260.
- On z/OS, refer to the *Program Directory for WebSphere Message Broker for z/OS* on the WebSphere Message Broker Library web page.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

Related information:

WebSphere Message Broker Requirements

Setting up security

Set up the required security before you install WebSphere Message Broker.

About this task

This section describes security requirements for installing the product and verifying your installation.

After installation, check the topics under the Security heading in the information center to review and implement the security requirements for additional users doing other tasks.

Security control of WebSphere Message Broker components, resources, and tasks depends on the definition of users and groups of users (principals) to the security subsystem of the operating system. Check that you have the correct authority, and that the required principals are in place, before you install WebSphere Message Broker.

User ID restrictions: some operating systems and other products impose restrictions on user IDs:

- On Windows systems, user IDs can be up to 12 characters long, but on Linux, UNIX, and z/OS systems, they are restricted to eight characters. Database products, for example DB2, might also restrict user IDs to eight characters. If you have a mixed environment, ensure that the user IDs that you use within the broker environment are limited to a maximum of eight characters.
- Ensure that the case (upper, lower, or mixed) of user IDs in your broker environment is consistent. In some environments, uppercase and lowercase user IDs are considered the same, but in other environments, user IDs of different case are considered unique. For example, on Windows the user IDs 'tester' and 'TESTER' are identical, but on Linux and UNIX systems they are recognized as different user IDs.
- Check the validity of spaces and special characters in user IDs to ensure that, if used, these characters are accepted by all relevant systems and products in your broker environment.

If your user ID does not conform to these restrictions, you might have problems with installation or verification. If so, use an alternative user ID, or create a new one, to complete installation and verification.

Set up the security appropriate to the operating systems that you are using:

- If you are installing on Linux or UNIX systems, go to “Security on Linux and UNIX systems” on page 247.
- If you are installing on Windows, go to “Security on Windows systems” on page 248.
- If you are installing on z/OS, go to “Security on z/OS systems” on page 251.

WebSphere Message Broker Requirements

Security on Linux and UNIX systems:

Set up the required security on Linux and UNIX systems before you install WebSphere Message Broker.

About this task

Use the security facilities provided by your operating system to complete these tasks; for example, the Systems Management Interface Tool (SMIT) on AIX, or the System Administration Manager on HP-Itanium.

Complete the following actions:

Procedure

1. Log into the system.

   On AIX, you must log in as root. On Linux and on other UNIX computers, your user ID must have root authority to complete installation. Follow your local security guidelines to acquire root authority; either log in as root, or log in as another user and become root.

   The use of a user ID other than root itself has some advantages; it provides an audit trail of the user ID that installs the product and it limits the scope of root authority to tasks performed in a single session. The use of a user ID other than root might also be mandatory if you are logging in from a remote system.

   If you are using a Linux on x86 or a Linux on x86-64 system and are not planning to install the Broker component, continue with step 6.
2. Create a security group called *mqbrkrs*.
3. Add your current logon ID to the group *mqbrkrs*.

   If you are installing on a system that runs as a production server (with the Broker component installed), create an additional new user ID for use only with product components and add it to the *mqbrkrs* group.

   On a Linux on x86 or a Linux on x86-64 system that you are running as a development or test system, you can use the ID that you logged in with to complete installation.
4. If you have already installed WebSphere MQ on this system, a group called *mqm* and a user called *mqm* are defined. If you have not yet installed WebSphere MQ, you must create this group and user.
5. Add to the group *mqm* the user ID that you logged in with, the new user ID (if you created one), and the user ID *mqm*.

   On some systems, you must log off and log on again for these new group definitions (*mqbrkrs* and *mqm*) to be recognized.
6. Verification procedures are provided for Linux on x86 and Linux on x86-64. To complete verification, you do not require root authority. If you do not want to complete verification with root authority, log off when you have completed installation. Log in with the same or a different user ID, but do not become root.

   If you log in with another user ID, and have not already added this ID to the groups *mqbrkrs* and *mqm*, do so before you open the WebSphere Message Broker Toolkit.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

Set up the required security before you install WebSphere Message Broker.

Related information:

WebSphere Message Broker Requirements

Security on Windows systems:

Set up the required security on Windows systems before you install WebSphere Message Broker.

About this task

Before you install the Broker component, the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer, log on with a user ID that has Administrator authority.

If you are installing the Broker component, the installation wizard calls the **mqsisetsecurity** command which completes the following tasks:

- Creates a new security group called *mqbrkrs*.
- Adds your current (logged on) user ID to the group *mqbrkrs*.
- Adds your current user ID to the group *mqm*, if that group exists.

  The *mqm* group exists if you have already installed WebSphere MQ on this system. If you have not, call the **mqsisetsecurity** command when you have completed WebSphere MQ installation. If you use the Windows Launchpad (described in "Installing by using the Windows Launchpad" on page 262), it completes WebSphere MQ installation first.

If you prefer to create principals before you install WebSphere Message Broker, use the security facilities provided by the Windows Control Panel.

If you are running Terminal Services on this computer, change user mode to ensure that actions taken during installation are completed correctly; for example, the creation of `.ini` files and other related files in the default system directory `C:\Windows`. If you do not change user mode, files might be written to other locations and, although the installation might complete successfully, the product might not work as expected.

- Before you install any product components, enter the following command to change user mode:

  ```
  change user /install
  ```

- When installation is complete, enter the following command to restore the original user mode:

  ```
  change user /execute
  ```

To complete verification, your user ID must have Administrator authority. If you log in with a different user ID from the ID with which you perform installation, you must add that user ID to the groups *mqbrkrs* and *mqm*. Use either the Windows security facilities or the **mqsisetsecurity** command (run this command after you have logged on with that different ID) to complete these additions.

"Security in a Windows domain environment"
Set up the required security configuration in a Windows domain environment.

Related information:

WebSphere Message Broker Requirements

Security in a Windows domain environment:

Set up the required security configuration in a Windows domain environment.

About this task

You can use Windows domain groups to organize different levels of authorization to selective WebSphere Message Broker resources across your domain. To design and implement this domain group topology, add each domain group to the relevant local security groups on the domain workstations. You can now manage authorities by adding domain user accounts to the appropriate domain groups. For information about the group membership required to administer WebSphere Message Broker resources, see "Security requirements for Windows systems" on page 3651.

Procedure

1. Design your authorization group categories, and define domain groups on the domain controller system that correspond to these authorization categories, by using Windows security. For example, suppose you have a single domain containing three distinct sets of systems, used in development, testing, and production. Within your organization, various user roles require different levels of authorization to WebSphere MQ and WebSphere Message Broker resources on those systems.

   Here is an example of how those authorization categories could map to domain groups:

Domain group	Description
ADM-MQprd	WebSphere MQ administrator authorities on production machines
ADM-MQuat	WebSphere MQ administrator authorities on test machines

Domain group	Description
ADM-MQdev	WebSphere MQ administrator authorities on development machines
ADM-MBprd	WebSphere Message Broker administrator authorities on production machines
ADM-MBuat	WebSphere Message Broker administrator authorities on test machines
ADM-MBdev	WebSphere Message Broker administrator authorities on development machines

2. Define and configure domain user accounts on the domain controller, by using Windows security. Add each user account to one or more domain groups to determine the authorizations granted that account. For example:

Table 4.

Domain user account	Role	Group membership
MQadmPRD	WebSphere MQ administrator for production systems	ADM-MQprd
MQadmUAT	WebSphere MQ administrator for test systems	ADM-MQuat
MQadmDEV	WebSphere MQ administrator for development systems	ADM-MQdev
MBadmPRD	WebSphere Message Broker administrator for production systems	ADM-MBprd
MBadmUAT	WebSphere Message Broker administrator for test systems	ADM-MBuat
MBadmDEV	WebSphere Message Broker administrator for development systems	ADM-MBdev
john.smith	WebSphere MQ and WebSphere Message Broker administrator for production environments	ADM-MQprd, ADM-MBprd

3. Install and configure WebSphere Message Broker on domain workstations.
   a. Install WebSphere Message Broker on the workstation.
   b. Add your domain groups to local groups *mqm* or *mqbrkrs* as appropriate. In our example, if a particular workstation is to serve as a development machine, add domain group *ADM-MQdev* to local group *mqm*, and domain group *ADM-MBdev* to local group *mqbrkrs*.

Security on z/OS systems:

User ID security required for z/OS system product installation.

About this task

The user ID that you use to install the product must be no more than eight characters in length. It must also have suitable RACF privileges to perform SMP/E installation in your environment. The user ID must have a valid OMVS segment, because the product installs into the file system paths specified during the SMP/E APPLY processing.

Configuring temporary space on distributed systems

Configure temporary directory space to enable WebSphere Message Broker Java components to operate correctly.

About this task

WebSphere Message Broker contains Java components. Some of these components require temporary directory space on the file system in order to extract class files from node packages (PAR files) and Java packages (JAR files).

The extracted files might not be visible to interactive users on the system, however, they consume space in the temporary directory.

The Java Runtime Environment also creates files in the temporary directory to support debug facilities.

To enable correct operation, allow at least 50 MB of space per execution group in the file system temporary directory for WebSphere Message Broker components. This space is required in addition to any space required for operation of user developed artifacts. Use of JavaCompute nodes, Java user-defined nodes, or additional plug-in nodes implemented in Java might require further temporary directory space.

On Linux, UNIX, and z/OS computers, the TMPDIR directory is typically `/tmp`; on Windows computers, it is `c:\temp`. If this directory is not large enough to hold the JAR files, the broker does not start.

To change the location of the temporary directory, use one of the following methods:

Procedure

- Use the environment variable `TMPDIR`.
- Set the system property `java.io.tmpdir`.

WebSphere Message Broker Requirements

Accessing CDs and DVDs

Accessing CDs and DVDs to install WebSphere Message Broker.

About this task

When you install or upgrade WebSphere Message Broker, you can access CDs or DVDs on the local system, or you can set up a shared drive and access the shared resource from multiple computers.

The information in the following sections is relevant to both CDs and DVDs. All references are to CDs; DVD behavior is identical. DVDs are available for Linux on x86, Linux on x86-64, Windows 32-bit, and Windows 64-bit only.

You can also install or upgrade from installation images that you have obtained from Passport Advantage, if you are registered with this scheme:

Procedure

1. Read the instructions that are provided with the packages.
2. Download the images that you require for the operating systems in your environment.
3. Extract the contents of the images. Specify a short path for the directory to which you are extracting; the depth of directory structure and the directory

names might cause problem if restrictions on some operating systems are reached. For example, the limit of 256 characters on Windows might be exceeded.

4. Set up local or remote access to these images in the same way that you do for a CD or DVD. For local installations, see "Accessing CDs and DVDs on the local system"; for remote installations, see "Accessing CDs and DVDs on a remote system" on page 256.

What to do next

If you are installing on Windows, you cannot enter a Universal Naming Convention (UNC) path (`\\server\drive`) to access the installation program; you must map the drive, otherwise the Java process times out. If you cannot map the drive, or choose not to map the drive, copy the contents of the DVD to a local drive and install from that drive.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

"Preparing the system" on page 245
On some operating systems, you must complete several tasks before you install WebSphere Message Broker.

Related information:

WebSphere Message Broker Requirements

Accessing CDs and DVDs on the local system:

If you want to install product components from a local CD or DVD, or a local downloaded image, complete this task.

About this task

Always consult your operating system documentation for exact details.

AIX

1. Log in as root. You cannot complete installation successfully if you have logged in as another ID and become root.
2. Complete the security setup described in "Security on Linux and UNIX systems" on page 247.
3. Create a CD mount point directory:
   ```
   mkdir /cdbroker
   ```
   where */cdbroker* is the mount point.
4. Insert the CD into the drive of the computer on to which you want to install product components.
5. Use SMIT to mount the CD, or use the following command:
   ```
   mount -r -v cdrfs /dev/cd0 /cdbroker
   ```
   where */dev/cd0* is the CD device and */cdbroker* is the mount point.

You are now ready to install the product that is supplied on this CD.

HP-Itanium

The HP-Itanium CDs have the format ISO 9660, with Rockridge extensions enabled. If volume management software is in use, the CD mounts automatically when you insert it into the CD drive. Alternatively, you can mount the CD as described in the following procedure.

If the CD is mounted incorrectly, some of the files cannot be read and the installation fails with a corrupted directory. You must mount the CD with Rockridge extensions enabled.

1. Log in and ensure that your user ID has root authority.
2. Complete the security setup described in "Security on Linux and UNIX systems" on page 247.
3. Create a CD mount point directory and grant read-only access to all users:

   ```
   mkdir /cdbroker
   chmod 775 /cdbroker
   ```

   where */cdbroker* is the mount point.
4. Insert the CD into the drive of the computer on to which you want to install product components.
5. Mount the CD by using the following command:

   ```
   mount -F cdfs /dev/dsk/device /cdbroker
   ```

   where */device* is the CD device, for example `/c0t0d0` and */cdbroker* is the mount point.

You are now ready to install the product that is supplied on this CD.

Linux on x86 and Linux on x86-64

1. Log in and ensure that your user ID has root authority.
2. Complete the security setup described in "Security on Linux and UNIX systems" on page 247.
3. Create a DVD mount point directory:

   ```
   mkdir /dvdbroker
   ```

   where */dvdbroker* is the mount point.
4. Insert the DVD into the drive of the computer on to which you want to install product components.
5. Run the following command:

   ```
   mount -o ro -t iso9660 /dev/dvdrom /dvdbroker
   ```

   where */dev/dvdrom* is the name of your DVD device (for example, `/dev/hdc`) and */dvdbroker* is the mount point.

You are now ready to install the product that is supplied on this DVD.

Linux, other than Linux on x86 and Linux on x86-64

1. Log in and ensure that your user ID has root authority.
2. Complete the security setup described in "Security on Linux and UNIX systems" on page 247.
3. Create a CD mount point directory:

   ```
   mkdir /cdbroker
   ```

   where */cdbroker* is the mount point.

4. Insert the CD into the drive of the computer on to which you want to install product components.
5. Run the following command:

   ```
   mount -o ro -t iso9660 /dev/cdrom /cdbroker
   ```

   where */dev/cdrom* is the name of your CD device (for example, `/dev/hdc`) and */cdbroker* is the mount point.

You are now ready to install the product that is supplied on this CD.

Solaris

1. Log in and ensure that your user ID has root authority.
2. Complete the security setup described in "Security on Linux and UNIX systems" on page 247.
3. Insert the CD into the drive of the computer on to which you want to install product components.
4. Enter the following command to check whether the Volume Manager is running on your system:

   ```
   /usr/bin/ps -ef | /bin/grep vold
   ```

   If the Volume Manager is running, the CD is mounted on `/cdrom/vol_label` automatically, where *vol_label* is the volume label of the current CD; for example, `wmb6_sol` for Runtime Disk 1.
5. If the Volume Manager is not started, run the following commands to mount the CD:

   ```
   mkdir -p /cdbroker
   mount -F hsfs -o ro /dev/dsk/cdrom /cdbroker
   ```

   where */dev/dsk/cdrom* is the CD location (for example, `c0t0d0`) and */cdbroker* is the mount point directory.

   Check where your CD is located by using the command `iostat -En`. Alternatively, use the **`volcheck`** command to mount a CD device automatically.

You are now ready to install the product that is supplied on this CD.

Windows

1. Log on with a user ID that has Administrator authority.
2. Complete the security setup described in "Security on Windows systems" on page 248.
3. Insert the DVD into the drive of the computer on to which you want to install product components. The Launchpad opens.

You are now ready to install the product that is supplied on this DVD.

WebSphere Message Broker Requirements

Accessing CDs and DVDs on a remote system:

If you want to install product components from a remote (server) CD or DVD, complete this task.

About this task

Always consult your operating system documentation for exact details of this task.

If you want to perform more than one installation of one or more components, you might find that a remote server setup provides some performance benefits, particularly for the WebSphere Message Broker Toolkit which is the largest component. You might also find this method more convenient if you want to run installations by using the silent interface.

If you want to install the WebSphere Message Broker Toolkit by using the silent interface, and you cannot install from DVD, you must copy the installation images onto a disk drive, as described here, to avoid the requirement to swap CDs during the process.

To enable a remote installation, you must complete tasks on both the server (the computer on which the CD, DVD, or shared drive is mounted) and each target system (on which you want to install the product). For details of the commands used in these examples, refer to the operating system documentation.

To set up a server, see "Setting up the server."

To set up a target system, see "Setting up the target system" on page 258.

WebSphere Message Broker Requirements

Setting up the server:

You can either share the CD drive on the server, or copy the installation images onto a disk and share the directory on that disk.

About this task

You can share a CD drive on Linux or UNIX with any other supported Linux or UNIX system, but not with Windows. You can share a Windows CD drive only with other Windows systems.

1. If you want to share a copy of the installation image, create the copy:
   a. Create a directory on the server to store the installation images:

      Linux and UNIX

      Enter the following command:

      ```
      mkdir /instbroker
      ```

      where *instbroker* is the directory into which you copy the product files.

      Windows

      Enter the following command:

      ```
      md m:\instbroker
      ```

      where *m* is the drive on which you want to store the installation images and *instbroker* is the directory on that drive.

      If you are creating directories for the WebSphere Message Broker Toolkit on Linux on x86, Linux on x86-64 or Windows, you must create all three disk subdirectories in the same directory, for example:

      ```
      /instbroker/disk1
      /instbroker/disk2
      /instbroker/disk3
      ```

      Where each subdirectory, for example `disk1`, is the root level of the corresponding CD image.

      This structure ensures that the installation program does not prompt for location, and does not fail because it cannot find the right images.

   b. Insert and mount the appropriate CD in the drive as described in "Accessing CDs and DVDs on the local system" on page 253. The installation programs for the runtime components and the WebSphere Message Broker Toolkit are on separate CDs; insert the correct CD for the components that you want to install from this server.

      If you have inserted a runtime or toolkit CD on Windows and autorun is enabled, the Launchpad is started. When the initial window opens, click **Cancel** to close it.

   c. Copy the complete contents of the CD to the new directory.

      Linux and UNIX

      Enter the following command:

      ```
      cp -rf /cdrom/. /instbroker
      ```

      Windows

      Enter the following command:

      ```
      xcopy f:\*.* m:\instbroker /e
      ```

      where *f* is the CD drive.

2. Grant users access to the drive that contains the product code. These instructions are the same for a disk drive on which you have copied the CD contents, and for the CD drive itself.

   AIX Either type **smit** and click **Communications Applications and Services** > **NFS** > **Network File System (NFS)** > **Add a Directory to Exports**

List, or enter the fast path command **smitty mknfsexp**. Complete the fields as appropriate and press Enter.

HP-UX and Linux

Use the **exportfs** command. The following example gives all users read-only access using NFS:

```
exportfs -i -o ro /instbroker
exportfs -a
```

where */instbroker* represents the CD drive or the directory that contains the CD copy.

Solaris

Use the **share** and **exportfs** commands. The following example gives all users read-only access using NFS:

```
share -F nfs -o ro -d "Broker LAN server" /instbroker
exportfs -a
```

where "*Broker LAN server*" is an optional description and */instbroker* represents the server CD drive or directory containing the CD copy.

Windows

Open Windows Explorer and right-click the drive that you want to share. Click **Sharing** and follow the instructions on the Properties dialog box.

WebSphere Message Broker Requirements

Setting up the target system:

Set up a target system to access CDs and DVDs from a server.

About this task

1. On Linux and UNIX systems, create a new directory on which to mount the shared directory. Enter the following command:

   ```
   mkdir /remotebroker
   ```

   where *remotebroker* is the name of the new directory.
2. Access the remote directory:

   Linux and UNIX

   Enter the following command:

   ```
   mount server name:instbroker /remotebroker
   ```

where *server name* is the name of the server on which you created the CD or DVD copy.

Windows

Connect to the appropriate drive and folder by using the **net use** command at a command prompt on the target system, for example:

```
net use x: \\server_name\instbroker
```

where *x*: is the required mapped drive on the target system.

If your shared installation directory name contains spaces (for example, Broker Image), enclose it in double quotation marks.

If your server is protected, you might need to specify a user ID and password on this command (see the Windows online help for more information about the **net use** command). Alternatively, use Windows Explorer or an alternative method to map the shared resource to a drive letter.

You cannot enter a UNC path (`\\server\drive`) to access the installation program; you must map the drive, as shown, otherwise the Java process times out. If you cannot map the drive, or choose not to map the drive, copy the contents of the DVD onto a local drive and install from that drive. In addition, you cannot enter a UNC path when the installation wizard requests a path as input; the wizard cannot interpret a UNC path.

3. Change to the remote image directory. You are now ready to run the Launchpad (on Windows only) or the installation wizard to install the product from the remote directory to your local system.

WebSphere Message Broker Requirements

Checking the kernel configuration on Linux and UNIX systems

Check the kernel configuration parameters on Linux and UNIX systems for prerequisite and corequisite products.

About this task

WebSphere Message Broker has no specific requirements for kernel configuration parameters; however, other products might require particular settings. If you do not tune your kernel parameters to suit the products that you have installed, you might see unexpected results or a deterioration in performance.

Follow these steps to configure your kernel parameters:

Procedure

1. Check the documented values for the following products:
   - WebSphere MQ
   - DB2 (if it is installed)
   - Other software that you have installed to work with WebSphere Message Broker, including other databases.

   You can access the relevant information for IBM products through the IBM product information centers web page.
2. Take the highest value for each parameter and compare it to the corresponding value in your kernel configuration.
3. If the current value is lower than the highest documented value, update the current setting by using the appropriate tooling that is supplied by the operating system provider. If the current value is higher, leave it unchanged.
4. On Solaris, increase the maximum number of concurrent open file descriptors on your system to at least 256.
5. If you have changed any kernel values, you might need to restart your system for these changes to take effect. Check the documentation for your operating system for further information about these parameters.

WebSphere Message Broker Requirements

Choosing what to install

Choose which components and products to install.

Before you begin

On some operating systems, you must complete several tasks before you install WebSphere Message Broker. For more information, see "Preparing the system" on page 245.

About this task

WebSphere Message Broker consists of three components; the Broker component, the WebSphere Message Broker Explorer, and the WebSphere Message Broker Toolkit. You can also install other products, such as the WebSphere Message Broker ODBC Database Extender:

- The Broker component
- The WebSphere Message Broker Explorer
- The WebSphere Message Broker Toolkit

- The WebSphere Message Broker ODBC Database Extender

You can install the Broker component on all supported operating systems. You can install the WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit on Windows 32-bit, Windows 64-bit, Linux on x86, and Linux on x86-64.

The Broker component

The Broker component is a set of execution processes that provides message processing facilities that interact with various application clients that use both point-to-point and publish/subscribe communications. The message flows that you create are hosted by the broker. A broker can host many message flows, in one or more execution groups, and can support many clients.

You define how messages are received, processed, and delivered to receiving applications or subscribers:

- You can customize some message processing nodes in a message flow with mappings, ESQL, Java, PHP, and XSL style sheets.
- You can create message models to define message structures determined by C and COBOL data structures, industry standards such as SWIFT or EDIFACT, and XML DTD or schema.
- You can develop user-defined extensions (nodes and parsers) to support message processing options that are not provided by the supplied nodes and parsers.
- You can debug message flows and step through processing to check paths and results.
- You can use message flow aggregation to manage multiple requests and responses that are generated by a single input message.

You can install more than one WebSphere Message Broker component on any system. For more details about how different installations can coexist, see “Coexistence and migration” on page 239.

For installation of the Broker component, you can choose between a typical installation and a custom installation. These installation options are explained in “Coexistence and migration” on page 239.

WebSphere Message Broker Explorer

The WebSphere Message Broker Explorer is a stand-alone administration environment that is based on the Eclipse platform which communicates with one or more brokers. Administrators use the WebSphere Message Broker Explorer to manage the resources associated with these brokers. Install the WebSphere Message Broker Explorer on computers on which you intend to perform only administrative tasks.

WebSphere Message Broker Toolkit

The WebSphere Message Broker Toolkit is an integrated development environment and graphical user interface that is based on the Eclipse platform and the Rational framework.

Application developers work in separate instances of the WebSphere Message Broker Toolkit to develop message flows, message sets, and user-defined nodes and parsers. You can access a shared repository (for example, CVS) to store resources and make them accessible in a secure manner to multiple users.

WebSphere Message Broker ODBC Database Extender

The WebSphere Message Broker ODBC Database Extender is required when using WebSphere Message Broker to interface with an ODBC data source that is not supported through the DataDirect ODBC drivers.

What to do next

Choose the interface you want to use to install WebSphere Message Broker. For more information, see "IBM Installation Manager" on page 3600

WebSphere Message Broker Requirements

Installing by using the Windows Launchpad

Use the Windows Launchpad to install the WebSphere Message Broker components and the prerequisite products.

Before you begin

Choose which WebSphere Message Broker components to install. For more information, see "Choosing what to install" on page 260.

About this task

On Windows only, use the Launchpad for additional help with installing:

- The WebSphere Message Broker Toolkit.
- The WebSphere Message Broker Explorer.
- The Broker component.
- Prerequisite products for the Broker component.

If you use the Launchpad, you can install everything that you need, and do not have to follow the procedures described in other chapters for installing the Broker component, the WebSphere Message Broker Toolkit, and the WebSphere Message Broker Explorer.

The Launchpad works with both physical media (the DVD) and with electronic images that you have downloaded from IBM Passport Advantage; however, the Launchpad depends on a file structure identical to that on the DVD, therefore you must not make any changes during or after download.

Multiple installations on a single computer

About this task

You can use the Launchpad to install only one instance of each component on a single computer. If you have selected and installed the broker or toolkit components, you cannot use the Launchpad to install these components again in a different location.

To install additional instances, run the appropriate installation wizard directly. For more information about completing these tasks, see “Installing the Broker component” on page 267, “Installing the WebSphere Message Broker Toolkit” on page 276, and “Installing WebSphere Message Broker Explorer” on page 280.

The Launchpad also manages only one installation of WebSphere MQ on a single computer. Refer to the relevant documentation for these products if you want to install multiple instances.

Installation summary

About this task

The following steps summarize the actions that you must take to complete the installation.

Procedure

1. Check the `readme.html` file for any updates to these installation instructions.
2. Check that you have enough memory and disk space; refer to “Memory and disk space requirements” on page 3584.
3. Decide whether you want to install from a server, or install locally on each system. These choices are described in “Accessing CDs and DVDs” on page 252.
4. Start the Windows Launchpad to install WebSphere Message Broker and its prerequisite product; WebSphere MQ. For more information about using the Launchpad, see “Starting the Windows Launchpad.”

WebSphere Message Broker Requirements

Starting the Windows Launchpad

Use the instructions to start the Windows Launchpad.

About this task

The Launchpad is available on every DVD and downloaded image from which product components or prerequisite products can be installed.

If you are using physical product media, the Launchpad starts automatically if autorun is enabled. If autorun is not enabled, or if you are installing from a downloaded image, navigate to root directory of the DVD or image, and double-click the file `mqsilaunchpad.exe` or type `mqsilaunchpad` in a command window and press **Enter**.

The **Installation** window displays. On the **Installation** window, you can install the set of products that are required for a default configuration of WebSphere Message Broker, including WebSphere MQ, if it is not already installed. For more information, see "Installing a default configuration by using the Installation window" on page 265.

Access further information from the left pane:

- Click **Installation Guide** to launch a PDF copy of the Installation Guide in Adobe Reader.
- Click **Readme** to view the readme file `readme.html` in a new web browser window.
- Click **Quick Tour** to take a tour around the product. See Chapter 2, "WebSphere Message Broker overview," on page 5 for further information.

The Launchpad might have to search for an installation wizard for some of your selections. If you are installing from DVD, all the required products are available, but if you are installing from a downloaded image, the program might be on another downloaded image, or might not be in the expected location. If necessary, the Launchpad prompts you to take the appropriate action to find the file. The following table shows, for each supplied product, the program names and their locations on the downloaded images.

Table 5. Installation wizard names and locations used by the Windows Launchpad

Product	Installation wizard name	Directory	Downloaded image
WebSphere Eclipse Platform V3.3[1]	`IBM WebSphere Eclipse Platform V3.3.msi`	`\WebSphere_MQ_V7.0.1\Prereqs\IES\MSI`	Runtime Disk 2
WebSphere MQ V7.0.1[1]	`IBM WebSphere MQ.msi`	`\WebSphere_MQ_V7.0.1\MSI`	Runtime Disk 2
Broker component	`setup.exe`	`\` (root directory)	Runtime Disk 1
WebSphere Message Broker Explorer	`install.exe`	`\MBExplorer`	Runtime Disk 1
WebSphere Message Broker Toolkit	`install.exe`	`\IBMInstallationManager`[2]	Toolkit Disk 1

Notes:

1. WebSphere Message Broker Trial Edition does not include this product. See "Installation packages" on page 3608 for further information.
2. The Launchpad starts Installation Manager, which installs itself (if required), and starts the WebSphere Message Broker Toolkit installation.

Related tasks:

WebSphere Message Broker Requirements

Installing a default configuration by using the Installation window:

Use the Windows Launchpad Installation window to install the set of products that are required for a default configuration of WebSphere Message Broker.

Before you begin

Read "Installing by using the Windows Launchpad" on page 262 for background information.

For the latest details of all supported levels of hardware and software, visit the WebSphere Message Broker Requirements website.

About this task

1. Start the Windows Launchpad. See "Starting the Windows Launchpad" on page 263 for more information.

   When the Launchpad starts, the Installation window opens and displays the following minimum set of products, along with version numbers, that are required for a default configuration of WebSphere Message Broker:

   - WebSphere MQ
   - WebSphere Message Broker
   - WebSphere Message Broker Toolkit
   - WebSphere Message Broker Explorer
2. Check the initial installation status that is shown for each listed product:
   - **Required** indicates that the product is not installed but is required for a minimum configuration, or you have cleared the associated check box to indicate that you do not intend to install the product, or the Launchpad cannot install it (and no check box is shown).
   - **Pending** indicates that the product is not installed but is required for a minimum configuration, or the check box is selected to show that this product is to be installed.
   - **Installed** indicates that the product is already installed at a level that is supported by WebSphere Message Broker. The installed version is shown and no check box is displayed.
   - **Partial Installation** indicates that the product is installed, but not all components required to ensure that the successful operation of a minimum configuration broker domain are present on the system. The associated check box is selected to show that additional components are installed.
3. Click the plus sign to the left of each listed product in turn. The Launchpad displays more information about the product, which you can use to decide if you want it installed. The additional information also provides an estimate of the time taken to complete each product installation, if appropriate.
4. Check the Installation has installed all the WebSphere MQ components that you require. WebSphere Message Broker requires only the server, WebSphere MQ Explorer, and the Java Messaging component, and only these components are installed.

   If you want additional components, use the WebSphere MQ installer.

5. WebSphere MQ Explorer requires the WebSphere Eclipse Platform to be installed; when you select WebSphere MQ, the Eclipse Platform is automatically installed.
6. If you do not want to install a listed product, clear the check box that is associated with the product. Its status is changed to **Required**, because you cannot configure and verify your installation without all the listed products. If the product you have cleared is a prerequisite for another product, that other product is also cleared. You can complete installation of any remaining products, and install the cleared products at a later time.

   If you are installing WebSphere Message Broker Trial Edition, you must install WebSphere MQ and the Eclipse platform before using the Launchpad. These products are not supplied with the Trial Edition. You must obtain prerequisite software from other sources to support the WebSphere Message Broker Trial Edition. See "Installation packages" on page 3608 for more information.
7. Click **Launch Installation for WebSphere Message Broker**.

   If you have cleared one or more of the required products, you are asked to confirm your choices.

   The Launchpad installs the products that you have selected in the order shown. You cannot change the Installation window after you have started the installation process. When the Launchpad starts each installation, it updates status from **Pending** to **In Progress**.

   If you have the incorrect WebSphere MQ level, for example V6.1, you might get the following warning:

   ```
   One or more of the selected installs will upgrade an existing version
   of the installed software. Please be aware that the old version may be
   removed with no further prompting.
   Click OK to continue.
   ```

   The Launchpad uninstalls the incorrect WebSphere MQ level, and then installs the correct level of WebSphere MQ.

   - If you have selected WebSphere MQ, the Launchpad starts the installation wizard silent interface for WebSphere Eclipse Platform V3.3; default values are used for all options. A progress bar is displayed. When the installation completes, the Launchpad starts the installation wizard silent interface for WebSphere MQ; default values are used for all options. A progress bar is displayed so that you can check on progress.
   - If you have selected WebSphere Message Broker (the Broker component), the Launchpad starts the installation wizard graphical interface. You must supply the input that is required by the installation wizard.

     The installation wizard guides you through a series of windows where you can make choices about where to install the component.

     You must also read and accept the Software License Agreement that is displayed.

     The license agreement covers your use of WebSphere MQ. Be aware it is only licensed for use with WebSphere Message Broker and must not be used for other purposes.

     You are asked if you want to open a command console when the wizard terminates; select **Yes** to open a console window that is initialized with the correct environment for command invocation. The command console is explained in "Command environment: Windows systems" on page 306. If you do not want to enter any commands at this time, select **No**.
   - If you have selected the WebSphere Message Broker Toolkit, the Launchpad starts the installation wizard graphical interface.

The process is controlled by Installation Manager, which installs itself if it is not already installed on this computer. For further information about Installation Manager, see "Additional software requirements" on page 3598.

The installation wizard guides you through a series of windows where you can make choices about where to install the component, which package group to install it in, and which language support you want to install. You must supply all input that is required by the installation wizard. You must also accept the Software License Agreement that is displayed.

If you want to launch the WebSphere Message Broker Toolkit when its installation wizard is complete, select **WebSphere Message Broker Toolkit** in the list of installed products that is displayed on the completion window. When you click **Finish**, the wizard ends and returns control to the Launchpad, and the WebSphere Message Broker Toolkit is started.

- If you have selected WebSphere Message Broker Explorer, the Launchpad starts the installation wizard graphical interface. You must supply the input that is required by the installation wizard.

  The installation wizard guides you through a series of windows where you can make choices about where to install the component.

  You must also read and accept the Software License Agreement that is displayed.

The status of each product changes to **Installed** when the Launchpad completes its installation.

When the Launchpad has installed all your selected products, it returns control to the Installation window.

8. Click **Refresh** to check the status of each product listed.
9. Click **Exit Launchpad** to end the program.

WebSphere Message Broker Requirements

Installing the Broker component

Use the installation wizard to install the Broker component.

Before you begin

Read the topic on "Preparing for installation" on page 235 and perform the tasks described in "Preparing the system" on page 245.

About this task

Complete the following tasks to install the Broker component on all supported operating systems.

If you are installing the Broker component on Windows, you can use the LaunchPad to complete this task. For more information, see "Installing by using the Windows Launchpad" on page 262. If you do not want to use the LaunchPad, complete the tasks in this topic instead.

The following list identifies the choices that you have for installing the Broker component, and the actions that you must take to complete your chosen task:

Procedure

1. Check the `readme.html` for any updates to these installation instructions. The readme file location is shown in "System requirements" on page 3581.
2. Check that you have enough memory and disk space; see "Memory and disk space requirements" on page 3584.
3. If you do not already have WebSphere MQ installed, install it before you install the Broker component.

   Although you can install WebSphere MQ after you have installed the Broker component, the installation wizard checks that you have the supported level of WebSphere MQ, or later, installed. If this check fails when you are using the graphical or console interface, the installation wizard displays a warning that lists potential problems. If you decide to continue, you must complete the installation of WebSphere MQ before you create or start any brokers.

   If you start the installer by using the silent interface and WebSphere MQ is not installed, or WebSphere MQ is installed but it is not at the prerequisite level, the check for WebSphere MQ fails. If you have not modified the default behavior by specifying a tailored response file, the wizard terminates without taking any further action. If you have modified the response file to ignore this check, the installation wizard continues.
4. Decide if you want to install from a remote server, or to install locally on each system. These choices are described in "Accessing CDs and DVDs" on page 252 for CDs, DVDs, and for installation images that you can download from Passport Advantage. The instructions here do not differentiate between CDs, DVDs, and downloaded images because the behavior is the same.
5. Decide whether to use the graphical installation, a console installation, or a silent installation. For more information about these interfaces, see "How to install and uninstall the Broker component" on page 3618.
   - To use the graphical installation, continue with these instructions.
   - To use a console installation, see "Installing the Broker component in console mode" on page 270.
   - To use a silent installation, see "Installing the Broker component in silent mode" on page 272.
6. Determine the installation wizard name for your operating system. For more information, see "Installation wizard names" on page 3626.
7. Start the installation wizard graphical interface locally or remotely.
   a. To install locally, load the product CD or DVD, then complete the following steps:

Linux and UNIX

Open a command prompt and navigate to the root directory of the CD or DVD. Type the installation wizard name with no options, and press **Enter**.

Windows

Take one of the following actions:

- If autorun is enabled, the Launchpad is started immediately. To use the Launchpad, see "Installing by using the Windows Launchpad" on page 262. To cancel the Launchpad, click **Exit Launchpad**.
- In Windows Explorer, navigate to the root directory of the CD or DVD. Locate the installation wizard and double-click the wizard to start it.
- Open a command prompt and navigate to the root directory of the CD or DVD. Type the installation wizard name with no options, and press **Enter**.

b. To install from a remote server, access the remote CD or DVD drive or network drive on which the product media is available. Find the installation wizard on the CD, DVD, or network drive and start it as previously described.

8. When the wizard starts, navigate through the windows and provide input when requested. You must also read and accept the Software License Agreement.

   If the directory that you specify for installation already contains a previous version of WebSphere Message Broker, for example Version 6.1.0.9, the installation wizard prevents you from installing Version 7.0 in this location. You must specify a different location. You can then migrate components to Version 7.0 from the previous version, when appropriate.

   Linux and UNIX only

   At the end of this installer, a panel asks if you would like to start the installation of the WebSphere Message Broker ODBC Database Extender (IE02) SupportPac. If selected, the IE02 SupportPac installer automatically launches in GUI mode. For more information, see the WebSphere Message Broker ODBC Database Extender (IE02) SupportPac installation instructions, which are located within the IE02 directory contained on the WebSphere Message Broker installation image.

9. When the summary window displays, check your choices and click **Next** to complete the installation. A progress bar displays so that you can check on progress.
10. If you want to install the WebSphere Message Broker ODBC Database Extender (IE02) package, select **Yes** when the window appears at the end of the installation process. See "Installing the WebSphere Message Broker ODBC Database Extender (IE02)" on page 273 for further details.
11. If you experience problems during installation, see "Resolving problems when installing" on page 3517.

What to do next

When you have completed installation, see the following topics:

- "Verifying your WebSphere Message Broker installation" on page 290

This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

- "Checking the broker operation mode and function level" on page 298

WebSphere Message Broker Requirements

Installing the Broker component in console mode

Install the Broker component by using the installation wizard in console mode.

Before you begin

On Linux and UNIX systems, ensure that you set up the required security before you install the Broker component. See "Security on Linux and UNIX systems" on page 247 for more information.

About this task

The following list identifies the choices that you have for installing the Broker component in console mode, and the actions that you must take to complete your chosen task:

Procedure

1. Determine the installation wizard name for your operating system. See "Installation wizard names" on page 3626.
2. Locate the installation wizard in the root directory of the local or remote CD or DVD, or the network drive.
3. If you are installing on HP-Itanium, `/usr/sbin/` must be included in the PATH statement.
4. Enter the following command at a command prompt for default invocation:

   `installer` `-console` (where *installer* is the installation wizard name).

   If you start the installation from a directory other than the one in which the wizard exists, include the absolute or relative path with the command name.

5. When the wizard starts, navigate through the windows and provide input when requested. You must also read and accept the Software License Agreement.

   The installation process specifies a default installation location that, if accepted, is version specific; for example: `C:\Program Files\IBM\MQSI\v.r`. The default directory includes the version and release of the product, in the format v.r (version.release). You do have the option of specifying a different directory location, but the installation process does not proceed if the location that you specify already contains a previous version of the Broker component. If the location that you specify already contains a previous version of the Broker component, you must specify a different location. You can then migrate components to Version 7.0 from the previous version, when appropriate.

   Linux and UNIX only

   At the end of this installer, a panel asks if you would like to start the installation of the WebSphere Message Broker ODBC Database Extender (IE02) SupportPac. If selected, the IE02 SupportPac installer automatically launches in console mode. For more information, see "Installing the WebSphere Message Broker ODBC Database Extender (IE02)" on page 273.
6. When the summary window is displayed, check your choices and enter 1 to complete installation.
7. If you experience problems during installation, see "Resolving problems when installing" on page 3517.

What to do next

When you have completed installation, see the following topics:

- "Verifying your WebSphere Message Broker installation" on page 290

  This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Related information:

Installing the Broker component in silent mode

Install the Broker component by using the installation wizard in silent mode.

About this task

The following list identifies the choices that you have for installing the Broker component in silent mode, and the actions that you must take to complete your chosen task.

Procedure

1. Determine the installation wizard name for your operating system. See "Installation wizard names" on page 3626.
2. Locate the installation wizard in the root directory of the local or remote CD or DVD, or the network drive.
3. If you are installing on HP-Itanium, `/usr/sbin/` must be included in the PATH statement.
4. Enter the following command at a command prompt for a typical installation with default settings.

   If you start the installation from a directory other than the one in which the installation wizard exists, include the absolute or relative path with the command name.

   Linux and UNIX

   `installer` `-silent -G licenseAccepted=true` (where *installer* is the installation wizard name).

   Windows

   Start the installation wizard within a **`start`** command with parameter `/w` to ensure that the installation completes before it returns to the command prompt:

   ```
   start /w setup.exe -silent -G licenseAccepted=true
   ```

   If you want to specify non-default settings, include a response file on the invocation. If you want to install the Broker component in a customized location, you must specify a response file. For more information about using response files, creating response files, and editing response files to define your requirements, see "Using response files with the Broker component" on page 3621.
5. The installation wizard completes without any user interaction.

   Linux and UNIX

   Note: The WebSphere Message Broker ODBC Database Extender (IE02) installer cannot be automatically started when running the install in silent mode. For more information, see "Installing the WebSphere Message Broker ODBC Database Extender (IE02)" on page 273.

   If you experience problems during installation, see "Resolving problems when installing" on page 3517.

What to do next

When you have completed installation, see the following topics:

- "Verifying your WebSphere Message Broker installation" on page 290

This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

- "Checking the broker operation mode and function level" on page 298
- "Start and main menu updates after installation" on page 3631

WebSphere Message Broker Requirements

Installing the WebSphere Message Broker ODBC Database Extender (IE02)

WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager, which is an implementation of the Open DataBase Connectivity interface for UNIX systems. This topic describes how you install WebSphere Message Broker ODBC Database Extender.

Before you begin

Before you start:

Read the information about the unixODBC Project and the IBM solidDB product family.

Install WebSphere Message Broker Version 7.0.0.1 or later.

About this task

WebSphere Message Broker ODBC Database Extender is required when using WebSphere Message Broker to interface with an ODBC data source that is not supported through the DataDirect ODBC drivers.

Procedure

1. To install the WebSphere Message Broker ODBC Database Extender, download the package for your platform to the directory of your choice, or select the option to install the WebSphere Message Broker ODBC Database Extender from the product disk.

To download the package externally, select WebSphere Message Broker on the WebSphere MQ SupportPacs web page and locate the package file.

The package file is called `install-ie02.bin` on all platforms.

This package must be run with the same privileges (typically root) that you used when installing WebSphere Message Broker. The default IE02 installation directory is `/opt/ibm/IE02/`.

2. Run the installer in one of the following modes:
   - Graphical
   - Console
   - Silent

   a. **Graphical**. From within the directory where you downloaded the package file, run the following command:

      ```
      ./install-ie02.bin
      ```

      The installer launches within a separate window and guides you through the installation process. However, if the installer cannot launch in Graphical mode, it launches in console mode.

   b. **Console**. From within the directory where you downloaded the package file, run the following command:

      ```
      ./install-ie02.bin –i console
      ```

      The installer launches, and guides you through the installation process from within the same console as the command was run.

   c. **Silent**. When specifying a silent installation, a response file is required to define the required responses to the options provided by the installer. See following example file:

      ```
      # This file was built by the Replay feature of InstallAnywhere.
      # It contains variables that were set by Panels, Consoles or Custom
      # Code.

      #Has the license been accepted
      #-----------------------------
      LICENSE_ACCEPTED=TRUE

      #Choose Install Folder
      #---------------------
      USER_INSTALL_DIR=/opt/ibm/IE02/
      ```

      Note the above example specifies that the license has been accepted. By using this example script you are accepting the terms of the license agreement.

      The response file must be named `installer.properties` and must be located in the same directory as the WebSphere Message Broker ODBC Database Extender installer.

      Run the following command from within the directory where you downloaded the WebSphere Message Broker ODBC Database Extender:
      `./install-ie02.bin –i silent`

      After the installation has completed, review the installation log that is located under the installation path specified during the installation. The file name of the log is:
      `WebSphere_Message_Broker_ODBC_Database_Extender_InstallLog.log`.

      If you are installing over a previous installation (within the same installation directory), the previous installation is silently uninstalled before the new version is installed.

What to do next

Next, Configure the WebSphere Message Broker Database Extender.

Related tasks:

"Configuring the WebSphere Message Broker ODBC Database Extender (IE02)"
WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager, which is an implementation of the Open DataBase Connectivity interface for UNIX systems, and this topic describes how you configure it.

How you use WebSphere Message Broker ODBC Database Extender (IE02) to load the correct data source driver.

Configuring the WebSphere Message Broker ODBC Database Extender (IE02):

WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager, which is an implementation of the Open DataBase Connectivity interface for UNIX systems, and this topic describes how you configure it.

Before you begin

Before you start:

Install the WebSphere Message Broker ODBC Database Extender.

About this task

To allow WebSphere Message Broker to take advantage of the additional database support, it needs to know where you have installed the SupportPac. The location of the SupportPac needs to be set by the value of the environment variable `IE02_PATH`.

This environment variable is automatically set within the WebSphere Message Broker profile during the installation of the SupportPac, by the creation of the script called `IE02.sh` which is placed within the directory `/var/mqsi/common/profiles`. See following example file:

```
#!/usr/bin/sh
# This file was created as part of the IBM WebSphere Message
Broker ODBC
# Database Extender SupportPac (IE02) install
export IE02_PATH=/opt/ibm/IE02/
```

Note: If you installed the SupportPac in silent mode, you must create a script in the directory `${MQSI_WORKPATH}/common/profiles` to set the environment variable `IE02_PATH`.

If you alter the location of your `$MQSI_WORKPATH` and, therefore, alter the location where WebSphere Message Broker dynamically runs additional scripts while

loading its profile, you must either copy the existing file, or create a new file containing the required contents within your new `${MQSI_WORKPATH}/common/profiles` directory.

You must not put the `lib` directory of the WebSphere Message Broker ODBC Database Extender into your library path (`LD_LIBRARY_PATH` or equivalent). If you do so, the WebSphere Message Broker ODBC Database Extender is not correctly loaded by WebSphere Message Broker and unpredictable results can occur.

What to do next

Configure the database that you are going to use; see "Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02)" on page 682

Related tasks:

How you use WebSphere Message Broker ODBC Database Extender (IE02) to load the correct data source driver.

Installing the WebSphere Message Broker Toolkit

Use the installation wizard graphical interface to install the WebSphere Message Broker Toolkit on Windows and Linux on x86.

About this task

If you are installing the WebSphere Message Broker Toolkit on Windows, you can use the LaunchPad. For more information about using the Windows Launchpad, see "Installing by using the Windows Launchpad" on page 262.

If you do not want to use the Windows LaunchPad, complete the following steps.

Procedure

1. Check the product readme file, `readme.html`, for updates to these installation instructions. The product readme file includes information pertinent to all components and platforms, and is maintained in US English on the product readmes web page. Translated readme files are available on the documentation FTP site.
2. Check that your computer has enough memory and disk space for your installation. Requirements for memory and disk space depend on the installation operating system, and on the WebSphere Message Broker components that you are installing. For more information, see "Memory and disk space requirements" on page 3584.
3. Before installing WebSphere Message Broker Toolkit on Linux, check that the default permissions are set correctly by running the following command under a user ID with root authority:

   ```
   umask
   ```

A value of *0022* should be returned, indicating the permissions are correctly set. If any other value is returned, set the correct permissions by running the following command:

```
umask 0022
```

4. Decide whether you want to install the WebSphere Message Broker Toolkit from a server or if you want to install the WebSphere Message Broker Toolkit locally. These choices are described in "Accessing CDs and DVDs" on page 252 for CDs, DVDs, and for installation images that you can download from Passport Advantage.
5. Decide whether you want to use the installation wizard graphical interface to install the WebSphere Message Broker Toolkit or if you want to complete a silent installation. For more information about these interfaces, see "How to install and uninstall the WebSphere Message Broker Toolkit" on page 3623. If you decide to use the installation wizard graphical interface, continue with these instructions. Alternatively, to use a silent installation, see "Installing the WebSphere Message Broker Toolkit in silent mode" on page 279.

   In either scenario, the installation of the WebSphere Message Broker Toolkit is controlled by the IBM Installation Manager. If the Installation Manager is not already installed, it is installed before the WebSphere Message Broker Toolkit is installed.
6. Start the installation wizard graphical interface by navigating to the `/Message_Broker_Toolkit_V7.0/disk1` directory and running the batch file `installToolkit.sh` as root on Linux, or `installToolkit.bat` on Windows. The installation wizard checks your system locale setting. If the locale setting listed in "Multicultural support" on page 3628 is supported, the wizard continues in this locale. If the current setting is not supported, the wizard continues in US English. This language is used for installation only, and does not affect other processes on your computer.

   The Installation Manager starts and the Install Packages window opens. The installation wizard is preconfigured to install both the Installation Manager and the WebSphere Message Broker Toolkit, therefore the WebSphere Message Broker Toolkit packages are already selected in this window. If the Installation Manager has not been installed on this computer, its packages are also selected and cannot be cleared.
7. Click **Next** to continue. The Software License Agreement window opens.
8. Read the license agreement, select **I accept the terms in the license agreements**, and click **Next**.

   If you do not accept the license, the installation wizard ends. If you have not installed the Installation Manager on this computer, or if you have installed the Installation Manager but have not yet installed any product that is managed by the Installation Manager, the Shared Directory window opens. Continue with step 9. Otherwise, because the shared resources directory has already been defined, the Package group directory window opens, so you can continue with step 10 on page 278.
9. If the WebSphere Message Broker Toolkit is not the first product that is installed by the Installation Manager, you might not be prompted to specify the shared resources directory. If you are prompted, specify the location of the shared resources directory that is used by all the products that are managed by the Installation Manager. The following directories show the default locations:
   - Linux on x86: `/opt/IBM/SDPShared/`.
   - Windows: `C:\Program Files\IBM\SDPShared\` for 32-bit editions, or `C:\Program Files (x86)\IBM\SDPShared\`*`v.r`* for 64-bit editions.

To specify a different location, type over the default location, or click **Browse**.

The shared resources directory must not contain another installation of WebSphere Message Broker Toolkit, or other files or products.

If the Installation Manager is not yet installed, you must also specify its installation directory. The following directories show the default locations:

- Linux on x86: `/opt/IBM/InstallationManager/`.
- Windows: `C:\Program Files\IBM\InstallationManager\` for 32-bit editions, or `C:\Program Files (x86)\IBM\InstallationManager\` for 64-bit editions.

To specify a different location, type over the default location, or click **Browse**.

Click **Next**. The Package group directory window opens. You can create a new package group for the WebSphere Message Broker Toolkit, which requires you to specify an installation directory, or you can choose an existing package group to share the resources.

For more information about installing the WebSphere Message Broker Toolkit into a package group, and for further reference information about Package groups, see "IBM Installation Manager" on page 3600.

10. If you want to use the WebSphere Message Broker Toolkit in a locale other than US English, select additional support from the list presented. English is always selected and installed; you cannot clear this selection. If you select one or more alternative locales, documentation and properties files for all supported languages are installed. Click **Next** to continue. The Summary window opens.
11. Check your choices and click **Back** if you want to make further changes to your responses on any of the previous windows. This window displays guidance information for the space required for the packages that you are about to install and indicates that your disk has sufficient space.

    Click **Next** to start installation. The Install Progress window opens.
12. The features that you are installing, their associated directories, and the locales that you have selected display for information. A progress bar displays, which you can use to check the status of the installation. When the installation has finished, the Completion window opens.
13. The wizard displays an indication of success or failure, and lists the products and options that have been installed. Click **View Log File** to check the results of the installation.

    On Windows, you can indicate that you want the WebSphere Message Broker Toolkit to launch when you click **Finish** to close the wizard. This option is not available on Linux on x86 because you might want to complete verification while logged on as a different user ID that does not have root authority.
14. If you experience problems during installation, see "Resolving problems when installing" on page 3517.

What to do next

When you have completed the installation, see "Verifying your WebSphere Message Broker installation" on page 290, "Checking the broker operation mode and function level" on page 298, and "Start and main menu updates after installation" on page 3631.

If you do not install optional locales at this time, you can install them later in the following way:

- On Linux on x86, navigate to the `/eclipse` directory within the Installation Manager installation directory, and start the Installation Manager program `IBMIM`.

(You cannot use the main menu entries unless you are already logged on as root; the menu item does not provide an option to become root, and root authority is required for all installation tasks.)

- On Windows, click **Start** > **Programs** > **IBM Installation Manager** > **IBM Installation Manager** to launch the Installation Manager, and click **Modify Packages** to change your installation.

  If you prefer to use the command line, navigate to the `\eclipse` directory within the Installation Manager installation directory, and start the Installation Manager program `IBMIM.exe`.

WebSphere Message Broker Requirements

Installing the WebSphere Message Broker Toolkit in silent mode

Install the WebSphere Message Broker Toolkit by using the installation wizard in silent mode.

About this task

To perform a silent installation, complete the following steps:

Procedure

1. Determine the installation wizard name for your operating system. See "Installation wizard names" on page 3626.
2. Locate the installation wizard in the `/Message_Broker_Toolkit_V7.0/disk1` directory of the local or remote DVD, or the network drive.
3. Enter the following command at a command prompt for an installation with all default settings:

   Linux on x86

   ```
   ./installToolkit-silent.sh
   ```

   Windows

   ```
   installToolkit-silent.bat
   ```

The `installToolkit-silent.sh` and `installToolkit-silent.bat` files use the `/Message_Broker_Toolkit_V7.0/disk1/IBMInstallationManager/mbtoolkit-silent.xml` response file that contains all the default settings for installation.

If you want to specify non-default settings, include a different response file on the invocation. To create a different response file, complete the first installation by using the graphical interface, specifying the `-record` option. The installation wizard records a response file that includes all your chosen selections. For more information about how to record and use response files, see "Using response files with the WebSphere Message Broker Toolkit" on page 3625.

4. The installation wizard completes without any user interaction. Check the log for success or failure of the installation process.
5. If you experience problems during installation, refer to "Resolving problems when installing" on page 3517.

What to do next

When you have completed installation, see "Verifying your WebSphere Message Broker installation" on page 290, "Checking the broker operation mode and function level" on page 298, and "Start and main menu updates after installation" on page 3631.

WebSphere Message Broker Requirements

Installing WebSphere Message Broker Explorer

To use WebSphere Message Broker Explorer only, without installing the complete WebSphere Message Broker Toolkit, use the WebSphere Message Broker Explorer installation wizard to install the WebSphere Message Broker Explorer.

Before you begin

Before you start:

- Alternatively, to install the complete WebSphere Message Broker Toolkit, see "Installing the WebSphere Message Broker Toolkit" on page 276.

- The WebSphere Message Broker Explorer installation searches the Windows registry for a version of WebSphere MQ Explorer. If registry access is disabled by a local security policy such as "Prevent access to registry editing tools", the installation cannot find WebSphere MQ Explorer. Before you install WebSphere Message Broker Explorer, remove this restriction temporarily and reinstate it after the installation.

About this task

To install WebSphere Message Broker Explorer on Windows or Linux on x86 and Linux on x86-64, complete the following tasks.

One version only of the WebSphere Message Broker Explorer can be active at any one time because one version only of the WebSphere MQ Explorer can be installed on any one system.

If you already have WebSphere Message Broker Explorer installed, and you decide to install a later version of WebSphere Message Broker Explorer, you must upgrade the existing version.

If you add another installation of WebSphere MQ after you install WebSphere Message Broker Explorer, you must install WebSphere Message Broker Explorer again to enable it in all WebSphere MQ installations.

To upgrade the existing version, complete the following steps.

1. Uninstall WebSphere Message Broker Explorer. For more information, see "Uninstalling the WebSphere Message Broker Explorer" on page 346. You can uninstall the WebSphere Message Broker Explorer only if you are the administration user (for example, root on Linux on x86 and Linux on x86-64, or Administrator on Windows).
2. Check that no files exist in the previous installation directory.
3. Install WebSphere Message Broker Explorer.

After you install the new version of the WebSphere Message Broker Explorer, if you are upgrading from an existing version of the WebSphere Message Broker Explorer, you must complete the following steps:

1. To initialize the new version of the WebSphere Message Broker Explorer, run the following command from a command line in which that **mqsiprofile** command has not run:

   ```
   strmqcfg -i
   ```

   To run this command, you must be the administration user.
2. Start WebSphere Message Broker Explorer either by using the WebSphere Message Broker Explorer Windows shortcut or by running the following command from a command line in which the **mqsiprofile** command has not run:

   ```
   strmqcfg -c -d
   ```

Windows On Windows, the **Add/Remove** program panels point to the new installation location. To remove the older version, navigate to the old location on the file system and run the uninstaller that is located there.

Windows If you are installing WebSphere Message Broker Explorer on Windows, you can use the Launchpad to complete this task. If you do not want to use the Launchpad, complete the tasks in this topic instead.

To use the installation wizard for the WebSphere Message Broker Explorer with a Java compatible screen reader for accessibility reasons, see "Installing the WebSphere Message Broker Explorer by using console mode with a screen reader" on page 285.

Linux To install WebSphere Message Broker Explorer on Linux on x86 and Linux on x86-64, you must have write access to the locations that you want to use for the installation and data (configuration) directories. If you use an installation directory in your home directory rather than the default installation directory, do not use a tilde character (~) as a path prefix. Specify the directory path name in full. An InstallAnywhere error occurs if you use a tilde character, which means the product is not installed and you must repeat the installation process. You can install to a private location if you do not have root access to the default installation location.

If you encounter problems during the installation process, you can view the installation log `MBExplorer_install.log`. The installation log is created in the installation directory, for example `C:\Program Files\IBM\MBExplorer\MBExplorer_install.log`.

Note: The installation log is not created until the installation wizard is complete and you click **Done** to exit the wizard.

If you previously installed the IS02: WebSphere Message Broker Explorer plug-in SupportPac, you must complete the following steps before you install WebSphere Message Broker Explorer:

1. Move or delete the location to which you extracted the IS02 SupportPac.
2. Delete the `BrokerExplorer.link` file, which you copied into the `links` directory. On Windows, the directory name is `C:\Program Files\IBM\WebSphere MQ\eclipseSDK33\eclipse\links\`. On Linux on x86 and Linux on x86-64, the directory name is `/opt/mqm/eclipseSDK33/eclipse/links`.
3. Start WebSphere Message Broker Explorer either by using the WebSphere Message Broker Explorer Windows shortcut or by running the following command from a command line in which the **mqsiprofile** command has not run:

   ```
   strmqcfg -c -d
   ```

4. Optional: If you want a new installation of your WebSphere Message Broker Explorer, complete one of the following steps:
   - Move or delete the WebSphere Message Broker Explorer `metadata` directory. On Windows, the directory name is `C:\Documents and Settings\<user>\Application Data\IBM\MQ Explorer\.metadata`. On Linux on x86 and Linux on x86-64, the directory name is `/home/user/.mqdata/.metadata`.
   - Alternatively, switch your Eclipse workspace.

   Moving or deleting the `metadata` directory, or switching your Eclipse workspace, resets your WebSphere Message Broker Explorer to its initial startup state. You must then reconnect to any remote queue managers. Any local queue manager is discovered automatically.

The following list identifies the choices that you have for installing the WebSphere Message Broker Explorer, and the actions that you must take to complete your chosen task.

Procedure

1. Check the `readme.html` for any updates to these installation instructions. The readme file location is shown in "System requirements" on page 3581.
2. Check that you have enough memory and disk space. For more information, see "Memory and disk space requirements" on page 3584.
3. If you do not already have WebSphere MQ installed, install it before you install the WebSphere Message Broker Explorer.
4. Decide whether you want to install from a server, or to install locally on each system. These choices are described in "Accessing CDs and DVDs" on page 252 for both CDs and DVDs, and for images that you downloaded from Passport Advantage (if you are registered with the scheme). The instructions here do not differentiate between CDs, DVDs, and downloaded images; their behavior is the same.
5. Decide whether to use the graphical installation, a console installation, or a silent installation.
   - To use the graphical installation, continue with these instructions.
   - To use the installation wizard with a screen reader, see "Installing the WebSphere Message Broker Explorer by using console mode with a screen reader" on page 285.
   - Windows To use a console installation on Windows, see "Installing the WebSphere Message Broker Explorer in console mode on Windows" on page 285.
   - Linux To use a console installation on Linux, see "Installing the WebSphere Message Broker Explorer in console mode on Linux" on page 287.
   - To use a silent installation, see "Installing the WebSphere Message Broker Explorer in silent mode" on page 288.
6. Open the installation wizard by using the executable file or binary file. On Windows, this file is `install.exe`. On Linux on x86 and Linux on x86-64, this file is `install.bin`. These files are in the `\MBExplorer` directory on the DVD.
7. When you open the wizard, continue with the installation process by working through each of the following panels. The installation wizard itself contains help information about selected panels.
8. Select the language to use for the installation process, then click **OK**.
9. On the Introduction panel, click **Next**.
10. Read the software license agreement, select the option to accept the terms of the license, then click **Next**.
11. Enter (or browse for) a product installation directory for the WebSphere Message Broker Explorer, or accept the default location. On Windows, the default installation directory for WebSphere Message Broker Explorer is `C:\Program Files\IBM\MBExplorer`. On Linux on x86 and Linux on x86-64, the default installation directory is `/opt/IBM/MBExplorer`.

    If the product installation directory exists because you previously installed WebSphere Message Broker Explorer, either click **Refresh** to refresh the existing installation or click **Select** to select a new product directory.
12. Click **Next**.
13. Read the summary panel. If necessary, click **Previous** to go back and modify earlier panels.
14. Click **Install** and wait while the files are installed.
15. On the Install complete panel, click **Done**.

Results

You can now use the WebSphere Message Broker Explorer. To start the WebSphere Message Broker Explorer, complete one of the following steps:

- On Windows:

  Click **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **IBM WebSphere Message Broker Explorer**.
- On Linux on x86 and Linux on x86-64:

  Open a command shell in which the **mqsiprofile** command has not run and enter the `strmqcfg` command, or run `/usr/bin/strmqcfg`.

What to do next

When you complete installation, see "Verifying your WebSphere Message Broker installation" on page 290.

Installing the WebSphere Message Broker Explorer in console mode on Windows

You can install WebSphere Message Broker Explorer using the installation wizard in console mode on Windows and Linux.

About this task

Use the following steps to install the WebSphere Message Broker Explorer using the console mode on Windows. If you encounter any problems during the installation process, you can view the install log `MBExplorer_install.log`.

Procedure

1. Type the following command on a command line to run a console install:
   `<dvd_rom>/MBExplorer/install.exe -i console`
2. Select the language that you want to use for the installation process by typing the number next to the language and press **Enter**. The installer uses the term "locale" rather than "language". Alternatively, press **Enter** to accept the default language.
3. Read the console install instructions, and press **Enter** to continue.

4. Read the software license agreement and type 1 to accept the terms of the license. Press **Enter**.
5. Type the name of the product installation directory for the WebSphere Message Broker Explorer and press **Enter**. Alternatively, press **Enter** to accept the default location. The default installation directory for the WebSphere Message Broker Explorer on Windows is `C:\Program Files\IBM\MBExplorer`.
6. Read the Pre-Installation Summary information and press **Enter** to install the WebSphere Message Broker Explorer. Wait while the files are installed.
7. On the Installation Complete panel, press **Enter** to exit the console installer.

Results

You can now use the WebSphere Message Broker Explorer. To use the WebSphere Message Broker Explorer you must start the WebSphere MQ Explorer. To start the WebSphere MQ Explorer, click **Start** > **All Programs** > **IBM WebSphere MQ** > **WebSphere MQ Explorer**, or open a command line in which the **mqsiprofile** command has not been run and enter the `strmqcfg` command.

What to do next

When you have completed installation, see "Verifying your WebSphere Message Broker installation" on page 290.

Related tasks:

Installing the WebSphere Message Broker Explorer in console mode on Linux

You can install WebSphere Message Broker Explorer using the installation wizard in console mode on Windows and Linux.

About this task

Use the following steps to install the WebSphere Message Broker Explorer using the console mode on Linux. If you encounter any problems during the installation process, you can view the install log `MBExplorer_install.log`.

Procedure

1. Type the following command on a command line to run a console install:
   `<cd_rom>/MBExplorer/install.bin -i console`
2. Select the language that you want to use for the installation process by typing the number next to the language and press **Enter**. The installer uses the term "locale" rather than "language". Alternatively, press **Enter** to accept the default language.
3. Read the software license agreement and type 1 to accept the terms of the license. Press **Enter**.
4. Type the name of the product installation directory for the WebSphere Message Broker Explorer and press **Enter**. Alternatively, press **Enter** to accept the default location. The default installation directory for the WebSphere Message Broker Explorer on Linux systems is `/opt/IBM/MBExplorer`. If the product installation directory already exists because you have previously installed the WebSphere Message Broker Explorer, you can either refresh the existing installation or select a new product directory.
5. Confirm that the install location is correct, and press **Enter** to continue.
6. Read the Pre-Installation Summary information and press **Enter** to install the WebSphere Message Broker Explorer. Wait while the files are installed.
7. On the Installation Complete panel, press **Enter** to exit the console installer.

Results

You can now use the WebSphere Message Broker Explorer. To use the WebSphere Message Broker Explorer you must start the WebSphere MQ Explorer. To start the WebSphere MQ Explorer, open a command shell in which the **`mqsiprofile`** command has not been run and enter the `strmqcfg` command, or run `/usr/bin/strmqcfg`.

What to do next

When you have completed installation, see "Verifying your WebSphere Message Broker installation" on page 290.

Access the latest information for WebSphere Message Broker.

Installing the WebSphere Message Broker Explorer in silent mode

You can install WebSphere Message Broker Explorer by using the installation wizard in silent mode.

About this task

Before you can run the installation wizard in silent mode, you must create a response file that contains the installation options. You can create a response file during an installation using the graphical installation wizard, or you can use a sample response file supplied in the `samples-scripts` directory in the root directory of the installation media. To install silently, you specify the path to the response file as an argument to the installation command.

Use the following steps to create the response file and run the installation wizard in silent mode:

Procedure

1. Create a response file using the graphical installation wizard or by manually editing a response file:
   - Create a response file during an installation using the graphical installation wizard. You must provide a full path for the response file, or the response file is not created by the installation wizard.

     Enter the following commands into a command prompt:

– On Windows:

```
install.exe -r <filepath>
```

– On Linux:

```
install.bin -r <filepath>
```

This command starts the GUI installation as normal, except that it also records all your answers and saves them in the file you specified, for example, `c:\temp\mbx-response.properties`. You can then use this response file with the silent installer for subsequent installations of WebSphere Message Broker Explorer.

- Alternatively, use the supplied template in the `samples-scripts` directory in the root directory of the local or remote CD or DVD, or the network drive. Or use the following template to create a response file manually:

```
# Thu Jul 09 16:44:28 BST 2009
# Replay feature output
# ---------------------
# This file was built by the Replay feature of InstallAnywhere.
# It contains variables that were set by Panels, Consoles or Custom Code.

#Has the license been accepted
#-----------------------------
LICENSE_ACCEPTED=TRUE

#Choose Install Folder
#---------------------
USER_INSTALL_DIR=C:\\Program Files\\IBM\\MBExplorer
```

2. To run the installation wizard in silent mode with the response file, run the following command:
   - On Windows:

     ```
     install.exe -i silent -f <filename>
     ```

   - On Linux:

     ```
     install.bin -i silent -f <filename>
     ```

   where *<filename>* is the path to the response file, for example: `d:\messagebroker_runtime1\sample-scripts\mbx-response.properties`.

Results

You can now use the WebSphere Message Broker Explorer. To use the WebSphere Message Broker Explorer you must start the WebSphere MQ Explorer. To start the WebSphere MQ Explorer, complete one of the following steps:

- On Windows:

  Click **Start** > **All Programs** > **IBM WebSphere MQ** > **WebSphere MQ Explorer**, or, on a command line in which the **mqsiprofile** command has not been run, enter the `strmqcfg` command.

- On Linux:

  Open a command shell in which the **mqsiprofile** command has not been run and enter the `strmqcfg` command, or run `/usr/bin/strmqcfg`.

What to do next

When you have completed installation, see "Verifying your WebSphere Message Broker installation" on page 290.

Verifying your WebSphere Message Broker installation

You can verify your installation of WebSphere Message Broker by using the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

About this task

This section describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

- "Verifying your installation by using the WebSphere Message Broker Toolkit" on page 291
- "Verifying your installation using the WebSphere Message Broker Explorer" on page 295

After verification, you can keep all the components to carry out further development and unit test. Development and test environments are restricted to Linux on x86, Linux on x86-64, and Windows computers on which one copy of each component is installed on each computer. You can also create additional components and resources on your test computers to investigate the ways in which your business requirements can be met by this product.

If you have purchased WebSphere Message Broker Remote Adapter Deployment, Starter Edition, or Entry Edition, you must modify the operation mode of the broker after you have completed the procedures in this chapter (unless you are

running a test environment). The broker operation mode is always set to the default `enterprise` when you install the Broker component from the full product packages. If you intend to keep and use the default broker that you create in this chapter, you are required to modify its mode to conform to the terms of your license. See "Checking the broker operation mode and function level" on page 298 for details of this task.

Verifying your installation by using the WebSphere Message Broker Toolkit

Use the instructions in this tutorial to verify your installation of WebSphere Message Broker and learn how to run samples with the WebSphere Message Broker Toolkit.

Before you begin

You must have installed the WebSphere Message Broker Toolkit to run this tutorial.

About this task

To verify your installation by using the WebSphere Message Broker Toolkit, complete the following tasks:

- Create a Default Configuration.
- Run the Pager samples.
- (Optional) Start the Samples Preparation wizard.
- Remove the samples.

Before you can run sample programs, you must use the Default Configuration wizard to create a broker, which has a fixed name and properties that the samples depend on.

The Default Configuration wizard requires that the following conditions are met:

- You have installed the Broker component and the WebSphere Message Broker Toolkit.
- None of the Default Configuration wizard resources exist (the resources are listed in the table that is included later in this section).
- This configuration is required for test and evaluation purposes only.
- Your current user ID has the following characteristics on Windows only:
  - It is a member of groups mqbrkrs and mqm.
  - It has Administrator authority.
  - It is a local ID, not a domain ID.

  For more information about these security requirements, see "Broker component security" on page 497.

You cannot complete the configuration and verification described here if the previously described conditions are not met.

Use the following instructions to complete these tasks:

Procedure

1. Start the WebSphere Message Broker Toolkit:
   - On Windows:

On Windows, you cannot complete verification unless you have Administrator authority; carry out verification with the same user ID that you used to complete installation.

If you did not launch the WebSphere Message Broker Toolkit from the installation wizard, launch it from the **Start** menu, or run the script file provided. On a command line, navigate to the root directory of the package group and enter the following command:

```
mb.exe
```

The script file runs the following command; if you prefer you can use this command yourself:

```
eclipse.exe -product com.ibm.etools.msgbroker.tooling.ide
```

- On Linux:

  On Linux on x86 and Linux on x86-64, you do not need root authority to complete verification. You cannot launch the WebSphere Message Broker Toolkit from the installation wizard because you might experience problems during operation if you were to create resources such as brokers when you are logged in as root, and this option is therefore unavailable.

  Log off from the user ID with which you have installed the product. Log in as the same ID (if ID is not root), or log in as another ID, but do not become root.

  Launch the WebSphere Message Broker Toolkit from the main menu or run the script file provided. On a command line, navigate to the root directory of the package group and enter the following command:

  ```
  ./launcher
  ```

  If you prefer, you can also run the application directly:

  ```
  ./eclipse -product com.ibm.etools.msgbroker.tooling.ide
  ```

  However, you must set the *LD_LIBRARY_PATH* before running the application. For details about how to set *LD_LIBRARY_PATH*, see the launcher script.

When you first launch the WebSphere Message Broker Toolkit, you are asked to specify the location of your workspace. This directory exists on your local drive, and is where the WebSphere Message Broker Toolkit stores all the resources that you create. You can accept the default directory shown, or you can specify your own choice either by typing it in, or by clicking **Browse** to specify the location. Select **Use this as the default and do not ask again** to inhibit the display of the workspace dialog next time you launch the WebSphere Message Broker Toolkit.

The WebSphere Message Broker Toolkit opens and the Welcome page is displayed.

2. Click the **Get Started** icon  to begin the configuration and verification process.

   The Get Started page opens, from which you can start the Quick Tour or create a default configuration that is used by a sample program to verify that your installation is successful.

3. Create the Default Configuration:

   a. On the Get Started page, click the link to **Create the Default Configuration**.

       The "Creating the Default Configuration" page opens.

   b. Click **Start the Default Configuration wizard**.

Follow the guidance provided by the wizard to navigate through its pages.

The wizard creates a default broker that can be used by a sample program to verify that your installation is successful.

The wizard displays a progress bar that shows which task it is currently performing. It also reports on all the actions that it takes by writing progress information into a scrollable text window from which you can copy and paste some or all of the information displayed.

The information in the text window is also written to a log file in your workspace directory structure. The default workspace directory is shown in the example, but you can choose another location when you start the WebSphere Message Broker Toolkit.

Linux on x86 and Linux on x86-64

```
user_home_dir/IBM/wmbt70/workspace/.metadata/
DefaultConfigurationWizard.log
```

Windows

```
user_home_dir\IBM\wmbt70\workspace\.metadata\
DefaultConfigurationWizard.log
```

If the wizard encounters an error in processing, it informs you of what has happened and returns any error information, for example a return code from a command. If you know why the error has occurred from the error text, and can correct the situation, you can do so now. Return to the error message display and click **Yes** to continue the wizard.

If you do not understand the error, and do not know how to fix it, click **No**. If the wizard can, it rolls back all the actions that it has taken so far, so that when it completes, your system is in the same state as it was before you started the wizard. The text window shows you exactly what the wizard has, and has not, done.

Click **Open Log File** to access the log from the summary page of the wizard; this option is available whether the wizard has succeeded or failed.

The wizard creates the resources shown in the following table.

Table 6. Resources created by the Default Configuration wizard

Name	Type
MB7BROKER	Broker
MB7QMGR	WebSphere MQ queue manager that hosts the broker. The queue manager has a listener at the first available port greater than or equal to 2414.

It also starts the broker so that it is ready to process a sample.

c. On the final page, ignore the option to start the Samples Preparation wizard; you start this wizard later in these instructions.

d. Click **Finish** to close the wizard. When the wizard completes, it opens the Broker Application Development perspective and displays the resources that the wizard has created.

4. To verify your installation, click **Help** > **Samples and Tutorials** > **WebSphere Message Broker Toolkit - Message Broker** to open the Samples and Tutorials panel. The Samples and Tutorials panel can also be opened from the Welcome page.

   a. Expand **Application Samples**, and click **Pager Samples** to open the Pager samples page. The following options are displayed:

      - **Import and deploy the Pager samples**

This option starts the Samples Preparation wizard, which helps you to import the samples into your workspace, and to deploy the samples and associated resources (for example, message flows) to the default broker.

- **Run the Pager samples**

  This option opens the help page that contains a description of each of three sample programs, and icons that you can click to start each one.

- **Find out what the Pager samples do**

  This option opens a page that describes in detail what the Pager samples do and how they work. You can examine the message flows that implement the sample function, and the messages that are handled by those flows.

b. Click **Import and deploy the Pager samples**. The Samples Preparation wizard starts and displays its first page. The option to import and deploy to the default broker is preselected.

c. Click **Next** and follow the guidance provided by the wizard to navigate through its pages.

   The wizard displays a progress bar that shows which task it is currently performing. It also reports on all the actions that it takes by writing progress information into a scrollable text window.

   You can copy and paste some or all of the information that is reported in this text window. This information is also written to the following log file:

   Linux on x86 and Linux on x86-64

   ```
   user_home_dir/IBM/wmbt70/workspace/.metadata/
   samplePreparationWizard.log
   ```

   Windows

   ```
   user_home_dir\eclipse\workspace\.metadata\
   samplePreparationWizard.log
   ```

   If the wizard encounters an error in processing, it informs you of what has happened and returns any error information, for example a return code from a command. If you know why the error has occurred from the error text, and can correct the situation, you can do so now. Return to the error message display and click **Yes** to continue the wizard.

   If you do not understand the error, and do not know how to fix it, click **No**. If the wizard can, it rolls back all the actions that it has taken so far, so that when it completes, your system is in the same state as it was in before you started the wizard. The text window shows you exactly what the wizard has, and has not, done.

   The wizard displays information messages to show that the Pager samples and associated resources are deployed and ready to run.

d. Click **Next** when you have read the messages about the actions that have been completed by the wizard. The confirmation page is displayed.

e. Click **Finish** to close the wizard. The "Pager samples" page (from which you launched the wizard) is redisplayed.

f. Click **Run the Pager samples**. On the page that opens, click **How to use the applications** to read about the Text Messenger and Surf report publisher applications. When you understand what the applications do, and how to use them, click the icon that represents the application that you want to run.

   If you want more detailed information about the contents of these applications, and how the message flows work, click **Find out what the Pager samples do**.

g. When you have sent and received messages successfully, you have verified that your installation is complete. You can now close your Pager applications and the Samples Gallery.

5. (Optional) You can start the Samples Preparation wizard to create the resources and start other supplied sample programs. Click **File** > **New** > **Other** > **Message Broker - Default Configuration and Samples** in the WebSphere Message Broker Toolkit, and select **Prepare the Samples**. The Samples Preparation wizard opens, and lists other samples that are available.

   You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

6. To remove the sample or samples when you have finished with them, run the Samples Preparation wizard again and remove the samples that you have added. This action removes the samples from the broker, and removes the sample resources from your workspace.

   When you have completed your verification tests, run the Default Configuration wizard to remove all the default resources. Use the same workspace and the same user ID that you used to create the resources. To start the wizard from the WebSphere Message Broker Toolkit, click **File** > **New** > **Other** and expand Message Broker - Default Configuration and Samples. Select **Create the Default Configuration** and click **Next**.

Results

You have completed the tutorial.

Verifying your installation using the WebSphere Message Broker Explorer

Use the instructions in this tutorial to verify your installation of WebSphere Message Broker and learn how to deploy broker archive files with the WebSphere Message Broker Explorer.

Before you begin

You must have installed the WebSphere Message Broker Explorer to run this tutorial. If you are using the WebSphere Message Broker Toolkit you can verify your installation using one of the samples. For a list of samples, see "Samples" on page 98.

About this task

To verify your installation using the WebSphere Message Broker Explorer you can complete the following tasks:

- Create a Default Configuration
- Deploy a broker archive file
- Check the results of a deployment

- Test the message flow

Use the following instructions to complete these tasks:

Procedure

1. To use the WebSphere Message Broker Explorer you must start the WebSphere MQ Explorer. To start the WebSphere MQ Explorer, complete one of the following steps:
   - On Windows:

     Click **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **IBM WebSphere Message Broker Explorer**, or open a command line in which the **mqsiprofile** command has not been run and enter the `strmqcfg` command.
   - On Linux:

     Enter the `strmqcfg` command on a command line in which the **mqsiprofile** command has not been run, or run `/usr/bin/strmqcfg`.
2. Create the Default Configuration:
   - Start the Create the Default Configuration wizard using the following link:

     Start the Default Configuration wizard

     You can use this link only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.
   - Alternatively, you can use the following instructions to start the Create the Default Configuration wizard:
     a. In the **WebSphere MQ Explorer - Navigator** view, click the **Brokers** folder.
     b. In the **WebSphere MQ Explorer - Content** view, click the **Create the Default Configuration** button. The Create the Default Configuration wizard is displayed.

   a. You can click **Cancel** at any time to cancel the creation of the default configuration.
   b. The Default Configuration Summary page lists the resources created. Click **Next** to continue.
   c. Click **Finish**.

   The default broker is created and started. The broker is also added to the **WebSphere MQ Explorer - Navigator** view.
3. Deploy the broker archive file to the broker:
   a. Expand the **Broker Archive Files** folder.
   b. Expand the **Getting Started** folder.
   c. Right-click the `pager.bar` file, and click **Deploy File**.
   d. Select the MB7BROKER broker, and click **Finish**. The broker archive file is deployed to the broker.
4. Check the results of the deployment:
   a. In the **WebSphere MQ Explorer - Navigator** view, expand the **Brokers**.
   b. Click MB7BROKER to select the broker.
   c. View messages from the broker in the Administration Log view. If the deployment was successful, message BIP2881I is displayed in the Administration Log view. You can also see the TextMessenger message flow and the PagerMessageSets message set deployed to the Default execution group under the MB7BROKER broker.

5. Test the message flow:
   a. In the **WebSphere MQ Explorer - Navigator** view, expand MB7QMGR in the **Queue Managers** folder.
   b. Right-click the **Queues** folder, and click **New** > **Local Queue**.
   c. Enter TEXTMESSENGER as the name for the queue, and click **Finish**. This queue is the input queue for the Pager message flow.
   d. Click **OK**.
   e. Right-click the **Queues** folder, and click **New** > **Local Queue**.
   f. Enter TEXTMESSENGER_FAIL as the name for the queue, and click **Finish**. This queue is the failure queue for the Pager message flow.
   g. Click **OK**.
   h. Right-click the **Queues** folder, and click **New** > **Local Queue**.
   i. Enter PAGER as the name for the queue, and click **Finish**. This queue is the output queue for the Pager message flow.
   j. Click **OK**.
   k. In the **WebSphere MQ Explorer - Content** view right-click the TEXTMESSENGER queue, and click **Put Test Message**. The Put test message dialog is displayed.
   l. Enter the following message in the message data field, and click **Put message** to put the test message to the input queue for the Pager message flow:

      ```
      <Pager><text>This is my message to the pager.</text></Pager>
      ```

      The test message is passed through the message flow, transformed, and the output message is put to the Pager queue.
   m. Click **Close** to close the Put test message dialog.
   n. Right-click the Pager queue, and click **Browse Messages**. The Message browser dialog opens and displays any messages on the queue. If the test is successful, the queue shows a message like the following:

      ```
      <?xml version="1.0"?><!DOCTYPE Pager>
      <!--MRM Generated XML Output on :Sat Jun 20 10:38:56 2009-->
      <Pager><Text> Powered by IBM.</Text></Pager>
      ```
6. Click **Close** to close the Message browser dialog.

Results

You have completed the tutorial.

Checking the broker operation mode and function level

You must ensure that your production brokers conform to the terms of your license. You can also change the function level to enable the use of nodes that are supplied in the latest fix pack.

About this task

The following tasks are described in this topic:

- Configure your brokers to conform to your license
- Change the function levels of your brokers

For a full description of the broker operation mode, and behavior associated with each mode, see "Operation modes" on page 48.

Configuring your brokers to conform to your license

Procedure

- **Upgrading from the Trial Edition**

  If you installed WebSphere Message Broker Trial Edition, and have now purchased the product, you can keep the components and all the associated resources that you have already created and configured. You do not have to uninstall the Trial Edition and reinstall the purchased packages. However, if you do not reinstall, the operation mode of your existing brokers, and the default operation mode of all new brokers that you create, has the value `trial`. To change the value, complete the following steps.

  – If you intend to keep the brokers that you created for your trial domain for further development and unit test by your developers, change the operation mode of each broker to `enterprise`, as described in "Changing the operation mode of your broker" on page 655.

    After this change, your brokers are no longer restricted by the trial period, but check the license agreement file to ensure that your configuration conforms to any restrictions for development and unit test. Development and unit test conditions are described in "License requirements" on page 3606.

  – If you intend to use the brokers that you created for your trial domain for production purposes, change the operation mode to conform to the license that you have purchased:

    - If you have purchased Remote Adapter Deployment, change the operation mode to `adapter`.
    - If you have purchased Starter Edition, change the operation mode to `starter`.
    - If you have purchased the full (unrestricted) license, change the operation mode to `enterprise`.
    - If you have purchased Entry Edition, change the operation mode to `entry`.

  If you do reinstall the Broker component with the new physical or electronic packages for your purchased product, the default operation mode of all new brokers that you create has the value `enterprise`. If you have purchased Starter Edition, Remote Adapter Deployment, or Entry Edition, you must always change the mode to conform to the license that you have purchased.

  If you also installed a trial version of WebSphere MQ, you are now entitled to install the restricted license version that is supplied as part of WebSphere Message Broker. If the supplied products meet your requirements and you intend to use them only with WebSphere Message Broker, you do not need to make further purchases.

To upgrade your trial version of WebSphere MQ, complete the following steps.

1. Uninstall the trial version.
2. Install a licensed version of WebSphere MQ:
   - A version of WebSphere MQ is included with WebSphere Message Broker for use only with WebSphere Message Broker. Use either the supplied media or the images that you have downloaded to install this version. If you are installing on Windows, you can use the Launchpad to install this product.
   - To use WebSphere MQ for applications that are not related to your use of WebSphere Message Broker, you must purchase a separate license.

     To use additions or enhancements that are included in WebSphere MQ, you can also purchase a separate license.

- **Remote Adapter Deployment, Starter Edition, or Entry Edition**

  If you have purchased WebSphere Message Broker Remote Adapter Deployment, WebSphere Message Broker Starter Edition, or WebSphere Message Broker Entry Edition and installed components from the full runtime package, read the following information.

  - All brokers that you have created (for example, by completing the verification procedures) have an operation mode set to `enterprise`, which is the default setting for this installation. You can keep these brokers for further development and unit test, subject to any restrictions that apply for unit test environments, as indicated in your license. Development and unit test conditions are described in "License requirements" on page 3606.
  - If you intend to use these brokers for production purposes, follow the instructions in "Changing the operation mode of your broker" on page 655, to conform to the license that you have purchased.
    - If you have purchased Remote Adapter Deployment, change the operation mode to `adapter`.
    - If you have purchased Starter Edition, change the operation mode to `starter`.
    - If you have purchased Entry Edition, change the operation mode to `entry`.
  - When you create new brokers, you must set the operation mode to conform to the license that you have purchased, because by default the operation mode is set to the value `enterprise`. You can use the **-o** parameter on the **mqsicreatebroker** command to override this default value by specifying an alternative value of `adapter`, `starter`, or `entry`. Alternatively, you can change the mode by using the **mqsimode** command for the created broker.

- **Full (unrestricted) license for WebSphere Message Broker**

  If you have purchased a full (unrestricted) license and installed components from the full runtime package, all brokers that you create have an operation mode set to the default value of `enterprise`, which is the correct setting for your license.

  Whenever you create a new broker, on existing installations or on different installations or computers, the operation mode is set to `enterprise`, and you do not need to change this value.

  You can continue to work with all the components and associated resources that you have already created. For example, after you have completed verification, you might keep the resources that you have created for further development and unit test (subject to any restrictions that apply for unit test environments, as indicated in your license). Development and unit test conditions are described in "License requirements" on page 3606.

Changing the function levels of your brokers

About this task

Note: Version 7.0.0.1 can be installed as a full generally available version, or as a fix pack. Version 7.0.0.1 has the function enabled for Version 7.0.0.1 regardless of the installation route chosen. Subsequent Version 7.0 fix packs use the following procedure.

When a fix pack is delivered, it might include new nodes that you can add to your message flows to provide specific functions.

The default function level of the broker is not set to a specific value; the default value is equivalent to the value `7.0.0.0`, which represents the level for Version 7.0. At this level, nodes that might be added by later fix packs are not supported by the broker.

Nodes that are added in later fix packs are available in the WebSphere Message Broker Toolkit, and you can include these nodes in a message flow. You can deploy the message flow to a broker only if you have set the function level of that broker to the value that represents the fix pack in which the nodes are first delivered.

Because you can control the function level of each broker, you can try out new nodes on test brokers without affecting the operation of your production brokers. When you are satisfied that the nodes provide the function that you require, and work as you expect, you can set the function level of other brokers in your domain, when appropriate.

To change the function level of a broker, use the **mqsichangebroker** command, specifying the **-f** flag with the appropriate value.

For more information about nodes added in fix packs, and the use of the **mqsichangebroker** command, see "**mqsichangebroker** command" on page 3723.

Installing complementary products

WebSphere Message Broker works with several other products to provide complementary services.

About this task

If you want to use these optional services in your WebSphere Message Broker environment, refer to the following installation information:

- IBM Tivoli License Manager
- Eclipse plug-ins from another vendor
- "Publishing in a Citrix XenApp environment" on page 302

Related tasks:

"Installation and uninstallation interfaces" on page 3617
You can use different interfaces for installation and uninstallation of the Broker component and the WebSphere Message Broker Toolkit.

Installing Tivoli License Manager

IBM Tivoli License Manager (ITLM) enables you to monitor the use of IBM (and other) software products. WebSphere Message Broker includes support for ITLM Version 2.1.

About this task

Use ITLM to perform the following software auditing functions:

- Monitor the licenses used by different machines.
- Help keep unnecessary licenses to a minimum.
- Guard against software license compliance problems.

Ensure that you choose the correct ITLM license for the WebSphere Message Broker edition that you have purchased. See "Operation modes" on page 48.

If you are using one or more of the WebSphere Adapters with WebSphere Message Broker, you must activate ITLM to include those adapters, for example in monitoring activities. If you require this support, follow the instructions in "Activating IBM Tivoli License Manager for WebSphere Adapters" on page 2036.

To find out more about using ITLM to monitor usage of WebSphere Message Broker and other IBM products, or to purchase ITLM, see the IBM Tivoli License Manager website.

For information about installing this product, see the IBM Tivoli License Manager Information Center.

Installing plug-ins using Eclipse Update Manager

Use Eclipse Update Manager to install and update plug-ins provided by partners and other software vendors.

About this task

Do not use the Eclipse Update Manager to update or install plug-ins that are managed by IBM Installation Manager. Always use Installation Manager to work with products that are installed with Installation Manager. For other products, use Eclipse Update Manager, but follow the restrictions and guidance provided:

- Do not delete the `platform.xml` file to prompt Eclipse to regenerate the file. The regenerated contents will be incomplete and therefore invalid.
- Always save a backup copy of your `platform.xml` file before you make any changes to your configuration, for example by using Eclipse Update Manager to install or update plug-ins that are provided by another software vendor.
- When you use Eclipse Update Manager (graphical interface or command line), always specify the package group directory as the destination; never specify the shared resource directory. The shared resource directory is managed by Installation Manager and is reserved for its use.
- Do not use Eclipse Update Manager to search for updates for features that you have installed using Installation Manager.
- Do not select **Clean up all configuration errors** in the Eclipse Update Manager interface; this option might lose information that is maintained by Installation Manager.

Publishing in a Citrix XenApp environment

Supply application location and user details to Citrix to publish a WebSphere Message Broker command console or WebSphere Message Broker Toolkit.

About this task

Read the Citrix documentation for general information about publishing applications. Publishing does not involve any tasks within WebSphere Message Broker; you complete the following tasks in the Citrix Presentation Server console.

"Publishing a WebSphere Message Broker command console"

"Publishing a WebSphere Message Broker Toolkit"

"Publishing applications using the CMP API"

Publishing a WebSphere Message Broker command console:
About this task

The following steps show how to set the Application Location and User information to publish a WebSphere Message Broker command console.

Procedure

1. Set the **Application Type** to `Application`.
2. Set the **Command Line** to the following value: This example assumes that you have installed a 32-bit operating system.

   ```
   C:\WINDOWS\system32\cmd.exe /k title IBM WebSphere Message Brokers 7.0
        &&"install_dir\MQSI\7.0\bin\mqsiprofile.cmd"
   ```

   On Windows, you can install the Broker component in multiple locations. Each one can have a different level of service (fix pack) applied and can support a certain set of brokers. Each installation has its own command console executable. To publish command consoles corresponding to different runtime environments, modify the path to `mqsiprofile.cmd` appropriately.
3. Set the **Working Directory** to *install_dir*`\MQSI\7.0`.
4. Define the users who are authorized to use the WebSphere Message Broker command console. This must be a subset of users or groups who are authorized to use the command console locally, on the server.

   Attention: Users who have access to the WebSphere Message Broker command console through Citrix can use the console to run other commands that are unrelated to the broker.

Publishing a WebSphere Message Broker Toolkit:
About this task

To publish a WebSphere Message Broker Toolkit, set the Application Location and User information as follows:

Procedure

1. Set the **Application Type** to `Application`.
2. Set the **Command Line** to the package group directory for WebSphere Message Broker Toolkit that your system uses, for example:

   ```
   E:\WMBT700\eclipse.exe
   ```
3. Set the **Working Directory** to the appropriate workspace, for example:

   ```
   E:\workspace\wmbt70\workspace1
   ```

   When the WebSphere Message Broker Toolkit is run from Citrix, a window inviting the user to select a workspace is displayed. This is the same window that you see when you run the WebSphere Message Broker Toolkit locally. At this stage you can specify a different workspace, for which you have the necessary Windows read and write file permissions on the server.
4. Define the users who are authorized to use the WebSphere Message Broker command console. This must be a subset of users or groups who are authorized to use the command console locally, on the server.

Publishing applications using the CMP API:

About this task

You can publish a Java application that uses the CMP API programming interface. The steps are similar to publishing a WebSphere Message Broker Toolkit or command console.

Example

For example, to publish the CMP API Exerciser sample, publish this file:

install_dir\sample\ConfigManagerProxy\StartConfigManagerProxyExerciser.bat

Related concepts:

"Users and Citrix"
Review the categories of user that might want to use with Citrix, and how to configure for concurrent multi-users.

Related tasks:

"Developing applications that use the Administration API" on page 956
Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

Related reference:

"System requirements for Citrix XenApp" on page 3605
This topic gives information about licensing issues, and the software and hardware that you need to use WebSphere Message Broker in a Citrix XenApp environment.

Users and Citrix:

Review the categories of user that might want to use with Citrix, and how to configure for concurrent multi-users.

Categories of user

The following categories of user exist:

Application developers
: These users do not need to run mqsi commands, but must be placed in an access control list (ACL) before they can use a broker. Put these users only in the user list for publishing WebSphere Message Broker Toolkit.

Administrators
: If you use Citrix to publish the WebSphere Message Broker Toolkit and the WebSphere Message Broker command console, put all administrators in the users lists for both applications. For information about the permissions that administrators need, see "Security requirements for administrative tasks" on page 3644.

You can create Windows groups that correspond to the application developer and administrator categories, put the groups in the appropriate user lists, then allocate users to the relevant Windows group. Alternatively, you can give appropriate permissions directly to the user.

Make all users members of the Remote Desktop Users group, so that they can use Terminal Server.

Attention: Users who have access to the WebSphere Message Broker command console through Citrix can use the console to run other commands that are unrelated to the broker.

For information about the rights of groups such as mqm, mqbrkrs, and Administrators, see "Security requirements for Windows systems" on page 3651.

Concurrent multi-users

Allowing multiple concurrent users to access WebSphere Message Broker by Citrix on a Windows server requires the same planning as allowing multiple concurrent users to access the WebSphere Message Broker on a Linux or UNIX server. For example:

- All application developers should have their own execution group, so that they can deploy message flows and start and stop execution groups without conflicting with each other during development and testing. However, an exection group might be administered by more than one administrator. In these cases, administrators should coordinate their activities so that they do not conflict with each other. For example, when one administrator is starting an execution group, no one else should be trying to stop it.
- All users should have their own workspace. The Windows system administrator should give each user the appropriate read and write permissions for the directory that corresponds to their workspace.
- The WebSphere Message Broker Toolkit user can create the default configuration from the Samples; the product samples are deployed to the default configuration. Because you can create only one default configuration, only one user should use it at one time.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Security requirements depend on the administrative task that you want to perform.

Setting up a command environment

After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

About this task

Also complete this task if you have migrated to WebSphere Message Broker Version 7.0 from an earlier version. A profile is provided to help you set up the environment.

If appropriate, you can extend the initialization performed by this profile; for example, for user databases, or for other products that you want to use within the broker.

Ensure that you use this environment each time you run an administrative command, or start a broker.

For information about setting up your command and runtime environment on a Windows system, see "Command environment: Windows systems."

For information on setting up your command and runtime environment on Linux and UNIX systems, see "Command environment: Linux and UNIX systems" on page 310.

For information about setting up your command and runtime environment for execution groups on Linux and UNIX systems, see "Execution group-specific command environment: Linux and UNIX systems" on page 312.

For information about setting up your command and runtime environment for execution groups on Windows systems, see "Execution group-specific command environment: Windows systems" on page 309.

The topics in this section describe the WebSphere Message Broker runtime commands.

Command environment: Windows systems

Set up the Windows environment to run WebSphere Message Broker commands.

About this task

On Windows systems, the components run as services, therefore they do not inherit the environment that is set for the command prompt from which you start them. The components run the **mqsiprofile** command when they start, which completes the environment initialization.

The **mqsiprofile** command is located in the directory *install_dir*\bin.

You must not change the location of the **mqsiprofile** command, or make user modifications to the command, because it might be replaced if you install service, or an update, to the product.

If you need to run your own settings, add one or more command files called *your_file_name*.cmd to the directory *work_path*\common\profiles, where *work_path* identifies the broker's working directory.

The default working directory is %ALLUSERSPROFILE%\Application Data\IBM\MQSI where %ALLUSERSPROFILE% is the environment variable that defines the system working directory. The default directory depends on the operating system:

- On Windows XP and Windows Server 2003: C:\Documents and Settings\All Users\Application Data\IBM\MQSI
- On Windows Vista and Windows Server 2008: C:\ProgramData\IBM\MQSI

The actual value might be different on your computer.

If you are unsure of the broker's work path, enter the following command in a command console:

```
echo %MQSI_WORKPATH%
```

When **mqsiprofile** runs, it automatically calls any additional user-written scripts in this directory.

A typical reason for adding scripts is "Running database setup scripts" on page 308.

When you have configured any additional setup, you can use one of the following methods to initialize the runtime environment for components and commands:

Procedure

1. If you have only one installation of the runtime product, open a command console by clicking **Start** > **All Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console**. The **mqsiprofile** command initializes the environment and invokes any additional scripts in the common\profiles directory.
2. If you have one or more installations of the runtime product, open a command prompt window. Locate and run the mqsiprofile.cmd script in the directory in which you installed the appropriate product. The **mqsiprofile** command initializes the environment and invokes any additional scripts in the common\profiles directory.

What to do next

Check whether the following conditions apply to your environment:

- If you have a previous version of the product on this system, ensure that you run the correct profile before using Version 7.0. The **mqsiprofile** command places the Version 7.0 commands and libraries at the front of your search path, and invokes any user profiles that you have supplied which can override any combination of PATH, CLASSPATH, or library PATH.
- If you use the same user ID, and you run multiple profiles (from multiple different installations or versions), you might get unexpected results. Log off and log on again before you run the specific profile that you require.

Running database setup scripts:
About this task

A broker might require access to user databases from deployed message flows.

When you install a database product on Windows, the relevant settings are typically made to the system environment. However, some database managers provide a profile to perform this setup, or provide details of actions that you must take in their documentation. Always check the database product documentation for environment setup details; the information provided here is for general guidance only.

If a profile is provided for the database that you are using, complete the following steps:

Procedure

1. If you can update the profile to provide permanent values for the details that are required (for example, the database server name or the installation directory):
   a. Complete the changes to the database profile.
   b. Copy the profile file to the directory *work_path*\common\profiles.
2. If you cannot update the profile permanently, but need to make changes each time, you must run it independently of the **mqsiprofile** command before you start the component.

What to do next

When your environment has been set up, see "Working with databases" on page 2109 for information about setting up your databases for use with the broker.

Related tasks:

"Working with databases" on page 2109
Create and configure databases to use with your message flow applications.

"Setting up a command environment" on page 213
After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

"Changing the location of the work path" on page 1011
The work path directory is the location where a component stores internal data, such as installation logs, component details, and trace output. The shared-classes directory is also located in the work path directory and is used for deployed Java code. If the work path directory does not have enough capacity, redirect the directory to another file system that has enough capacity.

"Command environment: Linux and UNIX systems" on page 310
Set up the Linux or UNIX environment to run WebSphere Message Broker commands.

Related reference:

"Additional software requirements" on page 3598
WebSphere Message Broker requires additional software products to run successfully.

"Runtime commands" on page 3715
The topics in this section describe the WebSphere Message Broker runtime commands.

Execution group-specific command environment: Windows systems

Extend or change the Windows environment that is used when running a specific WebSphere Message Broker.

About this task

To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

To run your own additional environment settings for a broker, add a script (or scripts) in the *%MQSI_WORKPATH%\config\<my_broker_name>\<my_eg_label>\profiles* directory.

Ensure that the broker name, and any execution groups that you create, contain only characters that are valid on your file system. You might also have to create the required directory structure.

All files placed into the *%MQSI_WORKPATH%\config\<my_broker_name>\<my_eg_label>\profiles* directory that have a `.cmd` extension, are processed when the execution group *<my_eg_label>* on broker *<my_broker_name>* starts.

Scripts in the *%MQSI_WORKPATH%\config\<my_broker_name>\<my_eg_label>\profiles* directory are run after the **mqsiprofile** script, and any scripts placed in the *common\profiles* directory have been run.

To diagnose any problems, a log file is written that lists the profile scripts that have been read, and the environment used by this broker. The log file location is under the work path of the broker and is located at *%MQSI_WORKPATH%\common\log\<my_broker_name>.<my_eg_label>.profilelog*

Execution group profile scripts are not removed automatically when an execution group is deleted. If you no longer need the profile files that you have created, delete them manually.

Related tasks:

"Setting up a command environment" on page 213
After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

"Command environment: Windows systems" on page 306
Set up the Windows environment to run WebSphere Message Broker commands.

"Controlling the functional level of WebSphere Message Broker" on page 51
You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

Command environment: Linux and UNIX systems

Set up the Linux or UNIX environment to run WebSphere Message Broker commands.

About this task

When you start a runtime component on Linux and UNIX systems, it inherits the environment from where you issue the **mqsistart** command.

You must therefore initialize the environment before you start a component; the command **mqsiprofile** located in the directory *install_dir*/bin, performs this initialization. If you are starting a broker, you might also need to initialize the environment for any databases that are accessed by the broker.

You must not change the location of the **mqsiprofile** command, or make user modifications to the command, because it might be replaced if you install service, or an update, to the product.

If you want to run your own additional environment settings, add a script called *your_file_name*.sh to the brokers *work_path* directory which contains the:

```
/common/profiles
```

subdirectory.

When you run **mqsiprofile** again, the command automatically calls the additional user-written scripts in this location.

You must log out and log back in, to pick up the new files in the /common/profiles directory, before you run **mqsiprofile** again

The newly added script is not picked up if you run a **mqsistart** command from an existing initialized command shell.

work_path identifies the working directory defined for the broker; if you are unsure of the work path, enter the following command:

```
echo $MQSI_WORKPATH
```

A typical reason for adding scripts is "Running database setup scripts" on page 311.

When you have configured any additional setup, you can initialize the runtime environment for components and commands:

Procedure

1. Issue the **mqsiprofile** command:

   ```
   . install_dir/bin/mqsiprofile
   ```

   You must include the period and space preceding the location for this invocation to work correctly. Add this command to your login profile if you want it to be run at the start of every session.

   This command accesses additional scripts that you have copied to the common/profiles directory, therefore the environment is initialized for runtime components and other resources such as databases.
2. Start the components that you want to run on this system by means of the **mqsistart** command.

What to do next

Check if the following conditions apply to your environment:

- If you have a previous version of the product on the system, ensure that you run the correct profile before using WebSphere Message Broker Version 7.0. The **mqsiprofile** command places the Version 7.0 commands and libraries at the front of your search path, and calls any user profiles that you have supplied that can override any combination of PATH, CLASSPATH, or library PATH.
- If you use the same user ID, and you run multiple profiles (from multiple different installations or versions), you might get unexpected results. Log off and log on again before you run the specific profile that you require.
- ODBC settings on Linux and UNIX systems are found in a text file defined by the ODBCUOINI environment variable. Set ODBCUOINI to point to a copy of the sample file install_dir/ODBC/V6.0/odbc.ini .

  You can check that your ODBC environment is configured correctly by running the **mqsicvp** command. This command also validates the connection to all data sources that are listed in the odbc.ini file that have been associated with a broker by using the **mqsisetdbparms** command. For more information, see "**mqsicvp** command" on page 3857.

Running database setup scripts:
About this task

A broker might require access to user databases from deployed message flows.

When you install a database product on Linux and UNIX systems, some database managers provide a profile to perform the environment setup that the database requires, or provide details of actions that you must take in their documentation. Always check the database product documentation for environment setup details; the information provided here is for general guidance only and might not be complete.

Procedure

1. If you can update the profile to provide permanent values for the details that are required (for example, the database server name or the installation directory):
   a. Complete the changes to the profile.
   b. Copy the profile file to the directory *work_path*\common\profiles.
2. If you cannot update the profile permanently, but have to change it each time, you must run it independently of the **mqsiprofile** command:
   a. Run the appropriate profiles to initialize the environment for the database:
      - For DB2, issue the following command for the relevant DB2 instance:

        . *db2_instance_directory*/sqllib/db2profile
      - For Oracle, export ORACLE_HOME and ORACLE_SID, then issue the following command:

        . ${ORACLE_HOME}/bin/oraenv
      - For Sybase, issue the following command, specifying your installation directory:

        . *Sybase_installation_directory*/SYBASE.sh
      - For Informix, check the documentation for the client on your broker system for details of the actions that you must take. For example, you might have to specify the following environment variables:

```
export INFORMIXDIR=/installation_directory_of_informix_client_software
export PATH=${INFORMIXDIR}/bin:${PATH}
export INFORMIXSERVER=server_name
export INFORMIXSQLHOSTS=${INFORMIXDIR}/etc/sqlhosts
export TERMCAP=${INFORMIXDIR}/etc/termcap
export TERM=vt100
export LIBPATH=${INFORMIXDIR}/lib:${INFORMIXDIR}/lib/esql:
               ${INFORMIXDIR}/lib/cli:$LIBPATH
```

where *server_name* is defined in the file `sqlhosts` (the required value is typically the machine name), and the location of the file `sqlhosts` is set up as part of the installation process.

To configure your system to run this setup at the start of every session, add these statements to the login profile of the user that is going to run the broker.

What to do next

When your environment has been set up, see "Working with databases" on page 2109 for information about setting up your databases for use with the broker.

Set up the Windows environment to run WebSphere Message Broker commands.

Related reference:

"Additional software requirements" on page 3598
WebSphere Message Broker requires additional software products to run successfully.

"Runtime commands" on page 3715
The topics in this section describe the WebSphere Message Broker runtime commands.

Execution group-specific command environment: Linux and UNIX systems

Extend or change the Linux or UNIX environment used when running a specific execution group.

About this task

To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

If you want to run your own additional environment settings, add a script (or scripts) in the *$MQSI_WORKPATH/config/<my_broker_name>/<my_eg_label>/profiles* directory.

Ensure that the broker name, and any execution groups that you create, contain only characters that are valid on your file system. You might also have to create the required directory structure.

All files placed into the *$MQSI_WORKPATH/config/<my_broker_name>/<my_eg_label>/profiles* directory that have a `.sh` extension, are processed when the execution group *<my_eg_label>* on broker *<my_broker_name>* starts.

Scripts in the *$MQSI_WORKPATH/config/<my_broker_name>/<my_eg_label>/profiles* directory are run after the **mqsiprofile** script, and any scripts placed in the *common/profiles* directory have been run.

To diagnose any problems, a log file is written that lists the profile scripts that have been read, and the environment used by this execution group. The log file location is under the work path of the broker and is located at:

```
$MQSI_WORKPATH/common/log/<my_broker_name>.<my_eg_uuid>.profilelog
```

Execution group profile scripts are not removed automatically when an execution group is deleted. If you no longer need the profile files that you have created, deleted them manually.

You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

Applying service

Apply service to the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, and the Broker component.

Service updates and other fixes are delivered occasionally in the form of Program Temporary Fixes (PTFs) or fix packs. You can download these fixes from the web and update your existing installations. Check regularly for updates and recommended fixes on the WebSphere Message Broker support web page.

For information on obtaining the function level that your enterprise is using, see the **mqsichangebroker** command.

For information about installation directories for fix packs, and installing more than one fix pack at the same or different levels on a single computer, see "Coexistence and migration" on page 239.

Applying service to the Broker component

Apply maintenance updates and program fixes to the Broker component.

Before you begin

Before you apply service, check that you have backed up all associated resources. You might also choose to back up installation and work path directories. For details of this task, see “Backing up resources” on page 1013.

About this task

You can download maintenance updates for all components of WebSphere Message Broker from a website, in the form of a Program Temporary Fix (PTF), also known as a fix pack. Fix packs are cumulative; therefore, if multiple fix packs are available, you do not have to install a previous fix pack before you install the latest available. However, you must first install the GA (general availability) code to ensure that you comply with your license agreement. You can find the latest information about current fixes by following the link **Recommended fixes** in the Download section of the WebSphere Message Broker support web page.

In some circumstances, fix packs are also provided as a media refresh; CDs and DVDs are re-created, and electronic images on IBM Passport Advantage are replaced. Check with your IBM representative if you want a media refresh.

If you have installed the Trial Edition, you can apply service to this installation, if you are within your 90 day trial period.

Fix packs for WebSphere Message Broker are installed by using the same technology as the GA release. Therefore product files are consistently tracked and updated appropriately. For information about the default directories for a typical installation, see “Coexistence and migration” on page 239.

If you have applied one or more interim fixes to your existing installation, contact your IBM Service representative for instructions and possible updated interim fixes for the fix pack level that you are installing.

Because you can install more than one copy of the Broker component on a single computer, you can choose how to apply service:

1. Apply service to an existing installation.

   When you apply the fix pack, the new level of the product overwrites the existing level. The installer prohibits you from installing a previous modification or fix pack over a more recent one. You must stop all brokers before you apply service. All the brokers and resources that you have defined are retained. When the fix pack is successfully installed, restart the brokers.
2. Install the fix pack level of the product at a new location.

   Fix packs are supplied as complete installations. You can install the product in a new location on your computer by using the fix pack packages. You can install only within the terms of your license:

   - You must have installed a GA level of the product on this computer.
   - You must conform to the license restrictions for the number of installations on a single computer; your license might permit you to install more than one copy of the product, but allow you to run only one installation at a time.

   This option provides several advantages:

   - You do not have to stop brokers to complete the installation.
   - You can choose which broker runs at which service level by running the appropriate **mqsiprofile** before you start the component.
   - You can back out a broker to the previous service level by using the **mqsiprofile** from the older code level, and restarting the broker.

   If you already have more than one installation on the computer, read the additional information in "Applying service on computers with multiple installations" on page 316.

Service is not affected by the operation mode in which you broker is working.

What to do next

If you want to remove service that you have applied, see "Uninstalling service for the Broker component" on page 338.

Downloading a fix pack:
About this task

Download the latest fix pack from the WebSphere Message Broker support web page:

Procedure

1. Click **Downloads** to open the page of available download packages.
2. Click **Recommended fixes**, then click the appropriate product and version. Available fixes are displayed.
3. Click the fix that you want to download. Details about the fix, and instructions for download and installation, are displayed.
4. Click **Problems Fixed** to find out what PMRs, APARs, and defects have been fixed in the fix pack.
5. Select your chosen operating system and click **FC** in the **Download package** section to start the download process.
6. If you haven't already signed in, sign in with your IBM ID and password and click Submit. If you do not have an ID, you can register on this page.
7. Select the fixes you want to download.
8. Select the download method to be used to download fixes.

9. Accept the download terms and conditions.
10. Click **Download now**.
11. When the download completes, follow the instructions to apply the maintenance updates for this fix.
    a. If you are applying service to an existing installation, the installation wizard uses this current installation directory as the default directory for typical installations in graphical, console, and silent modes.

       This location might therefore be different from the default directory that is set for an initial typical installation on a computer on which the product has not been installed. The default installation directories are described in "Coexistence and migration" on page 239, "Uninstalling the Broker component by using the silent interface" on page 336, or "Uninstalling the Broker component by using the graphical interface" on page 333. If you have previously installed components into non-default locations, check carefully that you are installing the fix pack into the required location.
       - Windows
       - Linux and UNIX
       - z/OS

    b. If you are applying service by installing an additional copy of the product, follow the instructions provided in the "Installation Guide" on page 233, specifying a new installation location.

Applying service on computers with multiple installations:
About this task

If you have installed the Broker component more than once on a single computer, you can choose to apply service to one or more of these installations in any order. You might therefore choose to install a service level on one instance initially, and complete some tests, before you apply the fixes to additional installations.

You must ensure that you comply with the terms of your license at all circumstances.

Distributed systems

You specify which installation you want a broker to work with by running the **mqsiprofile** command that is associated with that installation. Any resources that you have defined are associated with the installation for which you have run **mqsiprofile**. When the **mqsiprofile** command has completed, restart the broker.

If you decide to return to a previous level, stop the broker, run the **mqsiprofile** command that is associated with the installation at the previous service level, and restart the broker.

For further details about working with multiple installations, see "Command environment: Windows systems" on page 306 and "Command environment: Linux and UNIX systems" on page 310.

z/OS systems

You can create component profiles to work with one of multiple installations. Details are provided in "Installing service on z/OS" on page 322.

For further information about components, see "z/OS customization overview" on page 592.

If you have a single installation on a computer, and you want to apply service, you must stop all brokers, apply service, and restart the brokers. The service is applied to the product code, and you can start the brokers immediately to run against the new service level.

Installing service on Windows:

Apply maintenance updates and program fixes to the broker component.

Before you begin

Before you start:

- Download the required update package for the WebSphere Message Broker component, as described in "Applying service to the Broker component" on page 314.
- Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.

About this task

Fix packs are supplied as self-extracting executable programs. Complete the following steps to install the updates that you have downloaded:

Procedure

1. Check that your user ID has the correct authority to install service for the broker component. The requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. Ensure that all WebSphere Message Broker function is stopped:

a. Stop all brokers on this computer by using the "**mqsistop** command" on page 3972, or by stopping the Windows services for these components from **Start** > **Settings** > **Control Panel** > **Administrative Tools** > **Services**.
b. Close all instances of the WebSphere Message Broker Explorer.
c. Close all instances of the WebSphere Message Broker Toolkit.
d. Check that all files associated with WebSphere Message Broker are closed.

3. Close all Windows programs before applying maintenance to the WebSphere Message Broker component to ensure that data is not lost.
4. Run the fix pack self-extracting program from either Windows Explorer or the command line.

   The program is referred to as *FixPackLauncher* and its name is in the form *V.R.M-prod-platform-fixpack*.exe. Where *V.R.M-prod* represents the version, release, and modification level of the product, *-platform* identifies the platform, and *-fixpack* identifies the fix pack. For example, the file name 7.0.0-WS-MB-WINIA32-FP0001.exe identifies the file for Fix Pack 1 on Version 7.0.0 of WebSphere Message Broker on Windows.

   - If you start this program from Windows Explorer, or you start it from the command line with no options, the *FixPackLauncher* runs with default options. It extracts the updates from the fix pack file, and starts the graphical interface of the WebSphere Message Broker installation wizard.
   - If you run the wizard from the command line with options, you can choose the interface that you want to use, and how the WebSphere Message Broker installation wizard runs.

     For further details about how you can install, and other options that you can specify, see "Installation and uninstallation interfaces" on page 3617 and "How to install and uninstall the Broker component" on page 3618.

     If you start this wizard from a directory other than the one in which the file is saved, you must include the fully qualified path of the file and its name.

     Graphical interface

     Use the following command format:

     ```
     FixPackLauncher -a -gui
     ```

     -gui specifies that you want to use the graphical interface of the installation program. The graphical interface is used by default if you specify only *FixPackLauncher*.

     For example, you can use either of the following commands:

     ```
     7.0.0-WS-MB-WINIA32-FP0001.exe
     7.0.0-WS-MB-WINIA32-FP0001.exe -a -gui
     ```

     Console interface

     Use the following command format:

     ```
     FixPackLauncher -a -console
     ```

     -console specifies that you want to use the console interface of the installation program. You must specify this option if you want the installation to use this interface.

     For example:

     ```
     7.0.0-WS-MB-WINIA32-FP0001.exe -a -console
     ```

     Silent interface

     Use the following command format:

```
FixPackLauncher -s -a -options "path" -silent
```

`-s` specifies that you want the extraction to use its silent interface. You must specify this option if you want the extraction to be completed without interaction.

`-a` specifies that you want to pass options to the installation program.

`-options "path"` specifies the path to the silent installation response file.

`-silent` specifies that you want to use the silent interface of the installation program. You must specify this option if you want the installation to use this interface.

If you do not specify a response file, the default options are used from the supplied response file. If you want to tailor the options to suit your installation requirements, create your own response file and specify its location on the command.

For example, to run both the extractor program and the WebSphere Message Broker installation program silently with a response file, enter the following command:

```
FixPackLauncher -s -a -options "C:\response1.txt" -silent
```

5. If you use the graphical or console interface of the WebSphere Message Broker installation program, follow the prompts given and provide any input that is required to complete the installation.
6. If you run the fix pack installation program or the WebSphere Message Broker installation program silently, check the installation log to ensure that the process was successful. File `mqsi7_install.log` is stored in your installation directory.

   If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

   Linux `/opt/ibm/mqsi/v.r`

   UNIX `/opt/IBM/mqsi/v.r`

   Windows 32-bit
   `C:\Program Files\IBM\MQSI\v.r`

   Windows 64-bit
   `C:\Program Files\IBM\MQSI\v.r` for the 64-bit version of WebSphere Message Broker

   `C:\Program Files (x86)\IBM\MQSI\v.r` for the 32-bit version of WebSphere Message Broker

   These locations define the default value of *install_dir* on each platform.
7. When installation has successfully completed, review the release notes that are supplied in the directory `readmes`, and complete any manual post-installation tasks that are required.
8. When you have completed any required ODBC changes, restart the components by using the **mqsistart** command.

Installing service on Linux and UNIX:

Apply maintenance updates and program fixes to the Broker component.

Before you begin

Before you start:

- Download the required update package for the Broker component, as described in "Applying service to the Broker component" on page 314.
- Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.

About this task

To install the updates that you have downloaded:

Procedure

1. Check that your user ID has the correct authority to uninstall the Broker component. The requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. Log in to the system. On AIX, you must log in as root. On Linux and on other UNIX computers, your user ID must have root authority to complete installation. Follow your local security guidelines to acquire root authority; either log in as root, or log in as another user and become root.
3. Stop all brokers that are running on this computer by using the **mqsistop** command. If you are applying service on a computer that is running Linux on x86, close all instances of the WebSphere Message Broker Toolkit and the WebSphere Message Broker Explorer.

Check that all files associated with WebSphere Message Broker are closed.

4. Change to the directory where you downloaded the fix pack file. The file name is in the form *V.R.M-prod-platform-fixpack*.tar.z, where *V.R.M-prod* represents the version, release, and modification level of the product, *-platform* identifies the platform, and *-fixpack* identifies the fix pack. For example, the file name 7.0.0-WS-MB-AIXPPC64-FP0001.tar.z identifies the file for Fix Pack 1 on Version 7.0.0 of WebSphere Message Broker on AIX.

   Note: When using AIX, if you selected HTTP for the download instead of the Download Director, the file name extension is .tar.tgz instead of .tar.z.

5. Replace the .z file with a .tar file, by entering the following command:

   uncompress -fv *V.R.M-prod-platform-fixpack*.tar.z

6. Untar the image and extract all the directories, subdirectories, and files required to apply the update, by entering the following command:

   tar -xvf *V.R.M-prod-platform-fixpack*.tar

7. Decide which interface you want to use for the installation; -graphical (the default option if none is specified), -console, or -silent. For further details of how you can run and installation, and other options that you can specify, see "Installation and uninstallation interfaces" on page 3617 and "How to install and uninstall the Broker component" on page 3618.

8. Depending on the choice you have selected, run one of the following commands. Where *installer* is the appropriate installation program for your platform, as listed in the following table.

   - To use the installation wizard graphical interface, type the *installer* name with no options at a command prompt, and press Enter. Include the absolute or relative path names if you start installation from a directory other than the one in which the wizard exists. When you start the installation wizard, it guides you through a series of panels where you can make choices about where to install the components, and which components you want to install.
   - To use the installation wizard console interface, enter *installer* -console. Include the absolute or relative path names if you start installation from a directory other than the one in which the wizard exists. When you start the installation wizard, it prompts you to enter input for all options, including where to install the components, and which components you want to install.
   - To use the installation wizard silent interface, enter *installer* -silent. Include the absolute or relative path names if you start installation from a directory other than the one in which the wizard exists. If you want to specify non-default settings, include a response file on the command. For more details of how to specify a response file, and how to create and edit a response file to define your requirements, see "Using response files with the Broker component" on page 3621.

Platform	Installation program
AIX	setupaix
HP-Itanium	setuphpia64
Linux on POWER	setuplinuxppc
Linux on x86	setuplinuxia32
Linux on x86-64	setuplinuxx64
Linux on IBM z Systems	setuplinux390

Platform	Installation program
Solaris on SPARC	`setupsolaris`
Solaris on x86-64	`setupsolarisx64`

The installer extracts the update files and runs according to the arguments supplied.

9. Follow the instructions presented by the installation program and provide all input that is required to complete the installation.

   When installation has successfully completed, review the release notes that are supplied in the directory `readmes`, and complete all manual post-installation tasks that are required.

10. If you have defined ODBC connections for brokers on this computer, you must update the `odbc.ini` files before you restart your brokers.
11. When you have completed any required ODBC changes, restart the brokers by using the **mqsistart** command.

Installing service on z/OS:

Apply maintenance updates to the broker.

Before you begin

Before you start:

- Download the required update package for WebSphere Message Broker, as described in "Applying service to the Broker component" on page 314.
- Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.

About this task

Use this three stage process to install service on z/OS:

1. Store the updates on your target system.
2. Install and test the fix pack. If testing is not satisfactory, you can remove this fix pack at this stage.
3. After testing, confirm the fix pack as your current base level of installation.

Follow these instructions to complete the process:

Procedure

1. Receive the updates. Use SMP/E RECEIVE to transfer the contents of the fix pack from the tape or the downloaded package to your system at the specified location.
2. Apply the updates. Use SMP/E APPLY to install the fix pack which completes the link edit steps and generates a runtime environment in your chosen location.

   The installation process completes updates to USS and to four product data sets (SBIPSAMP, SBIPINST, SBIPPROC, and SBIPAUTH).

   If your SMP/E target system is not on the same file system as your production system, copy the data sets (including the data set that represents your USS mount point) to the system where they are to be used, overwriting the current content. When you complete this action, all runtime components use the updated data sets when they next restart.

   If you do not want all your brokers to use the updated installation, copy the data sets to a different location and start selected brokers against that copy. Further details are provided in "Multiple concurrent installations at different levels."

   You can specify the same destination for receiving the fix pack contents (the SMP/E target system) and for installing (the production system). If you specify a different location, you must copy the product data sets to the appropriate location.

   When you have installed the fix pack, test it to ensure that it is working correctly in your environment. If you find problems at this stage, you can remove the fix pack by using SMP/E RESTORE. The command restores your installation to the level that you last accepted (SMP/E ACCEPT).
3. Confirm the update. Use SMP/E ACCEPT to commit the changes and to establish this fix pack as the current level. When you have completed this step, you cannot restore your system to a previous service level. If you want to use an earlier service level, you must reinstall that level.

Multiple concurrent installations at different levels:
About this task

If you want to install a later fix pack level, and retain your existing installation so that you can use both service levels, install the second level in a different location. You can then set up additional customization so that one or more of your existing brokers can use the second service level. By retaining the product files in the first location, you can switch a broker back to the first level, if required.

The following steps are a summary of the tasks that you must complete to run a broker at one service level concurrently with a broker at another service level. These steps are identical to those you take for setting up an initial installation, except where indicated.

For a full description of installation and customization for brokers, see "Creating a broker on z/OS" on page 620.

Procedure

1. To install a second service or fix pack level:
   a. Install the second level of the broker by using the instructions provided with that level.
   b. Copy all the template data sets and the main files from the HFS file system to a unique location.
2. To prepare a broker for use with the second installation:
   a. Create and customize a new broker component data set. Complete the steps described in "Customizing the broker component data set" on page 624.
   b. Copy the template JCL from the second location to the new dataset.
   c. Customize the JCL to work with the second location. For more details about this step, see "Customizing the broker JCL" on page 625.
3. To change a broker to work with the second installation:
   a. Submit the `BIPGEN` job to update the environment file `ENVFILE` for the broker. This task is described in "Creating the environment file" on page 626.
   b. Copy the customized started task from the new data set into the procedures library, for example `USER.PROCLIB`.
   c. Start the broker; the broker is now associated with the second location.
4. To roll back to the previous version:
   a. Open the original broker component data set, that is associated with the first location.
   b. Resubmit the `BIPGEN` job from that data set.
   c. Copy the original `PROC` into the procedures library `USER.PROCLIB`.
   d. Stop and restart the broker.

Applying service to the WebSphere Message Broker Toolkit

Apply maintenance updates and program fixes to the WebSphere Message Broker Toolkit.

Before you begin

Before you apply a fix pack or other service pack to the WebSphere Message Broker Toolkit, you might want to preserve the resources that you have created or imported into Version 7.0. For details of this task, see "Backing up the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit workspace" on page 1016.

Check that your user ID has the correct authority to complete this task; see "Installation and uninstallation authorization" on page 3628 for details.

About this task

The WebSphere Message Broker Toolkit uses IBM Installation Manager to install service updates. Occasionally, an update is also required to Installation Manager; if an update is required, it is downloaded automatically and you are prompted to apply service to Installation Manager before you can apply service to the WebSphere Message Broker Toolkit.

Occasionally, updates to the information center are also made available. These updates are integrated with component updates when they are made available, and are therefore automatically included when you apply any updates using these instructions.

If you have installed the Trial Edition, you can apply service to this installation, if you are within your 90 day trial period.

You can install multiple versions of the WebSphere Message Broker Toolkit at the same modification or fix pack level, or at different levels, on a single computer. Each installation must be in a separate package group; package groups are described in more detail in "IBM Installation Manager" on page 3600.

For information about current fixes, follow the link **Recommended fixes** in the Download section of the WebSphere Message Broker support web page. Click the link for Version 7.0, and select the updates you want to apply. Service release notes, the list of problems fixed in a fix pack or other maintenance release, and the instructions you must follow to complete the service upgrade are available. The instructions provide full details of how to apply each service fix, and include information about fixes to Installation Manager, if required. Always use those instructions in preference to the information in this topic, because they are maintained regularly and provide the latest information.

If you want Installation Manager to retrieve updates from a different location, see "Changing the update repositories for Installation Manager" on page 327. If you use FTP or HTTP proxies to allow applications to access the Internet, see "Setting FTP and HTTP proxies for Installation Manager" on page 329.

Use Installation Manager for all service updates, including those updates to Installation Manager itself. In most cases, the following instructions are sufficient; occasionally, further steps are necessary, therefore you must always check with the instructions provided with each fix on the support website.

Procedure

1. Start Installation Manager by using one of the following two methods:
   - From the Linux main menu or the Windows Start menu:
     - Linux On Linux: You can use this option only if you are logged in as root. If you have logged in as another user, you cannot use the main menu links, even if you become root.
       - On Red Hat: Click **System** > **IBM Installation Manager**.
       - On SUSE: Click **System Tools** > **IBM Installation Manager**.
     - Windows On Windows: Click **Start** > **Programs** > **IBM Installation Manager** > **IBM Installation Manager**.
   - From the command line:

     Navigate to the `eclipse` subdirectory in the directory in which Installation Manager is installed and run the following command:
     - Linux `IBMIM`
     - Windows `IBMIM.exe`

   Installation Manager opens and displays its initial panel.
2. Click **Update Packages**, then select the package group in which you have installed the WebSphere Message Broker Toolkit.
3. Click **Next**. Installation Manager searches the selected update site or sites, and displays a list of available updates for the products and features that you have installed.

   Initially **Show recommended** (below the list) is selected, and the latest updates only are shown. To include earlier updates as well, select **Show all**.

   For information about how you can change the locations that are searched, see "Changing the update repositories for Installation Manager" on page 327.
4. Select the updates that you want to apply and click **Update**. The updates are applied.
5. To return to the Installation Manager initial panel, click **OK**.
6. To close Installation Manager, click **File** > **Exit**. Verify that the changes have worked; see "Verifying your installation by using the WebSphere Message Broker Toolkit" on page 291.

Results

If you want to remove service that you have applied, see "Uninstalling service from the WebSphere Message Broker Toolkit" on page 344.

Changing the update repositories for Installation Manager:

If you have a large number of WebSphere Message Broker Toolkit users, or your users do not have regular access to the Internet, you might find it more convenient to download updates to a local site or server, and modify Installation Manager to access the updates at that alternative site.

About this task

For example, if you want to limit Internet access to a restricted set of computers, or if you want to reduce download times, or both, you can set up local repositories that your users can access to apply updates.

To set up alternative repositories:

Procedure

1. Start Installation Manager from the Start menu (on Windows) or main menu (on Linux on x86), or from the command line. Installation Manager opens and displays its initial panel.
2. Click **File** > **Preferences**. The Preferences dialog is displayed.
3. Click **Repositories** in the left pane. The Repositories page is displayed.
4. Click **Add Repository**. If you know the name and location of the update repositories that Installation Manager is to search, enter the URL or fully qualified location of the update file, including the repository name; for example, `repository.config`.

To search for repositories, which can be on a local or a remote computer, click **Browse** and navigate to the correct location. The field **File of type** lists the values `repository.config`, `diskTag.inf`, `.jar`, and `.zip`, and repositories with these names and types are searched for by default. The identity of an update depends on what type of update it is (for example, disk images are named `diskTag.inf`),

If you are not sure what updates you might want, leave the contents of field **File of type** unchanged; all available updates are shown. Click the required repository to select it, then click **Open**. The repository is added to the displayed list of repositories. If the repository is not connected, a red cross is displayed in the **Connection** column. You might need to check your network connections, or try again at a later time.

When it is added to the list, the repository is initially shown as selected, to indicate that its contents will be included when you run Installation Manager to update packages.

Repeat this step to add additional repositories if appropriate from the same or another location. You can have one or more locations selected at any time; Installation Manager searches all selected repositories listed on the Repositories page.

5. If you want Installation Manager to search only the repositories that you have added, clear **Search service repositories during installation and update**. The service repositories are those locations on the product support Web sites that host updates. If you clear this option, the default service repositories are not searched. The service repositories location is fixed and predefined; you cannot change it.
6. Click **OK** on the Browse panel if you opened it, and click **OK** on the Repositories page.
7. Click **Apply** to confirm the update, then click **OK** to close the Preferences dialog box.

What to do next

To remove a repository from the selected list, clear its selection. If you want to delete a repository in the list, select the repository and click **Remove Repository**. To clear selection of all listed repositories, click **Clear Credentials**.

Setting FTP and HTTP proxies for Installation Manager:

If your environment has a firewall, or uses proxies to control access to the Internet, you can change the Installation Manager settings to enhance your access security.

About this task

You do not have to complete this task if you have changed the Installation Manager repository location to a local site.

Complete the following steps:

Procedure

1. Start Installation Manager from the Start menu (on Windows) or main menu (on Linux on x86), or from the command line. Installation Manager opens and displays its initial panel.
2. Click **File** > **Preferences**. The Preferences dialog is displayed.
3. Expand the **Internet** tree in the left pane, and select **FTP Proxy** or **HTTP Proxy**.
4. Select **Enable proxy server** and enter the details in the entry fields that are required for the protocol that you selected.
5. Click **Apply** to confirm the updates, then click **OK** to close the Preferences dialog box.

Related tasks:

Applying service to the WebSphere Message Broker Explorer

You can apply maintenance or fixes to the WebSphere Message Broker Explorer.

About this task

Download the latest fix pack from the WebSphere Message Broker support web page:

Procedure

1. Click **Recommended fixes** in the Download section of the support page.
2. Click your WebSphere Message Broker product. Available fixes are displayed.
3. Click the fix that you want to download. Details about the fix, and instructions for download and installation, are displayed.
4. Click **Problems fixed** to find out what PMRs, APARs, and defects have been fixed in the fix pack.
5. Click **Release notes** to read more detail about the fix pack contents.
6. Click **FC** in the **Download package** section to start the download process. Accept the download terms and conditions and sign in to the download site with your IBM ID. If you do not have an ID, you can register on this page. When the download completes, extract the executable file or binary file.
7. Decide whether to use the graphical installation, a console installation, or a silent installation.
   - To use the graphical installation, see Installing the WebSphere Message Broker Explorer.
   - To use the installation wizard with a screen reader, see Installing the WebSphere Message Broker Explorer by using console mode with a screen reader.
   - To use a console installation on Windows, see Installing the WebSphere Message Broker Explorer in console mode on Windows.
   - To use a console installation on Linux, see Installing the WebSphere Message Broker Explorer in console mode on Linux.
   - To use a silent installation, see Installing the WebSphere Message Broker Explorer in silent mode.

   To apply service to any Broker component on Windows using the *fixpacklauncher* see Installing service on Windows.
8. Launch the installation wizard by running the executable file or binary file.

   The name of this file is in the form `V.R.M-prod-platform-fixpack.exe` on Windows and `V.R.M-prod-platform-fixpack.bin` on Linux platforms. Where *V.R.M* represents the version, release, and modification level of the product, *prod* identifies the product, *platform* identifies the platform, and *fixpack* identifies the fix pack. For example, the file name `7.0.0-WS-MBX-WINIA32-FP0004.exe` identifies the file for Fix Pack 4 on Version 7.0.0 of WebSphere Message Broker Explorer on Windows.

   On Linux, you must make this file executable by using the **chmod** command. For example, use the following command: `chmod u+x 7.0.0-WS-MBX-LINUXIA32-FP0004.bin`
9. When you have launched the wizard, continue with the installation process by working through each of the panels. The installation wizard itself contains help information about selected panels. You can apply service to a new location on your system.

Uninstalling

Remove the Broker component, the WebSphere Message Broker Toolkit, or the WebSphere Message Broker Explorer from your computer.

Before you begin

Before you start:

Check that your user ID has the correct authority to complete this task. The requirements for each platform are defined in "Installation and uninstallation authorization" on page 3628.

About this task

Follow the appropriate link for the task that you want to complete:

- "Uninstalling the Broker component" on page 332
- "Uninstalling the WebSphere Message Broker Toolkit" on page 340
- "Uninstalling the WebSphere Message Broker Explorer" on page 346
- "Uninstalling the WebSphere Message Broker ODBC Database Extender (IE02)" on page 339

What to do next

You might also want to uninstall complementary products. See the documentation provided by those products to complete this task:

- IBM DB2: Access the appropriate information for your installation:
  - DB2 V9.1 Information Center (distributed systems)
  - DB2 V9.5 Information Center (distributed systems)
  - DB2 Information Center (z/OS) (Versions 8 and 9)
- IBM Tivoli License Manager: access the IBM Tivoli License Manager Information Center.

Related tasks:

"Installing" on page 231
Installation information for WebSphere Message Broker is provided in the WebSphere Message Broker Installation Guide, which is available in the WebSphere Message Broker Version 7.0 information center, on the WebSphere Message Broker Version 7.0 Library web page, and in the WebSphere Message Broker Version 7.0 Quick Start Guide.

"Finding the latest information" on page 232
Access the latest information for WebSphere Message Broker.

Uninstalling the Broker component

You can uninstall the Broker component on distributed systems in a number of ways.

About this task

This section describes this task for the following systems:
- AIX
- HP-UX
- Linux
- Solaris
- Windows

If you are uninstalling on Linux or UNIX systems, make sure that the directory `/var` is not full; the uninstallation wizard requires space in this directory while it is running.

Procedure

1. Check that your user ID has the correct authority to uninstall the Broker component, or to uninstall service that you have applied. The requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. Decide which mode of uninstallation you want to use. The choices are explained in "How to install and uninstall the Broker component" on page 3618.
3. If you have multiple installations of the Broker component on your system, see "How to uninstall multiple installations of the Broker component" on page 3620.
4. Follow the uninstallation instructions provided in the appropriate topic:
   - "Uninstalling the Broker component by using the graphical interface" on page 333
   - "Uninstalling the Broker component by using the console interface" on page 335
   - "Uninstalling the Broker component by using the silent interface" on page 336
   - "Uninstalling service for the Broker component" on page 338

Results

If, in exceptional circumstances, the uninstallation wizard fails to remove the product successfully, you can remove the product manually. Contact your IBM Service Center for assistance if a failure occurs.

For information about removing service updates, see "Uninstalling service for the Broker component" on page 338.

Related tasks:

Check the authorization requirements for the user ID that you use to install or uninstall the Broker component and the WebSphere Message Broker Toolkit.

Uninstalling the Broker component by using the graphical interface

Remove the Broker component by using the graphical interface.

Before you begin

Always use the WebSphere Message Broker uninstallation wizard to remove the Broker component, unless otherwise stated. Do not use the uninstallation program that is provided by the operating system; for example, **geninstall** on AIX, or **swremove** on HP-UX.

On HP-UX Version 11.23, and on Linux on POWER, a known restriction prevents the creation of the wizard. If this situation occurs, use the alternative command that is specified in these instructions. Also, check the `readme.html` file to ensure that no additional operating systems are affected by this restriction.

About this task

For information about the graphical interface and alternative interfaces available, see "How to install and uninstall the Broker component" on page 3618.

To start the graphical interface of the uninstaller, complete the following steps:

Procedure

1. Stop all running processes that are associated with brokers before you uninstall. Use the "**mqsilist** command" on page 3882 to check which brokers are running. Use the "**mqsistop** command" on page 3972 to stop each broker.
2. On Windows, Linux on x86, and Linux on x86-64, end all active sessions of the WebSphere Message Broker Toolkit.
3. If you do not plan to reinstall brokers on this computer, delete all the brokers that are associated with this installation by using the "**mqsideletebroker** command" on page 3863. When you delete a broker, all its associated data and resources are deleted.
4. Run the following command from outside the installation directory, specifying the full path. This method of invocation ensures that the full directory structure is removed during uninstallation. Where *install_dir* is the home directory of your WebSphere Message Broker installation:
   - On HP-UX systems running Version 11.23 only, and on Linux on POWER systems:

```
/install_dir/_uninst_runtime_jvm/bin/java -jar
/install_dir/_uninst_runtime/uninstall.jar
```

   - On all other operating systems:

     install_dir/_uninst_runtime/*uninstaller*

   If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

   Linux /opt/ibm/mqsi/*v.r*

   UNIX /opt/IBM/mqsi/*v.r*

   Windows 32-bit
   C:\Program Files\IBM\MQSI*v.r*

   Windows 64-bit
   C:\Program Files\IBM\MQSI*v.r* for the 64-bit version of WebSphere Message Broker

   C:\Program Files (x86)\IBM\MQSI*v.r* for the 32-bit version of WebSphere Message Broker

   These locations define the default value of *install_dir* on each platform.

   Alternatively, if you have a single installation of the Broker component on Windows, you can navigate to **Start** > **Settings** > **Control Panel** > **Add/Remove Programs**. Select WebSphere Message Broker and click **Change/Remove**. The uninstaller graphical interface opens.
5. Follow the prompts to complete uninstallation.

Related tasks:

"**mqsilist** command" on page 3882
Use the **mqsilist** command to list installed brokers and their associated resources.

"**mqsistop** command" on page 3972
Use the **mqsistop** command to stop the specified component.

Uninstalling the Broker component by using the console interface

Remove the Broker component by using the console interface.

Before you begin

Always use the WebSphere Message Broker uninstallation wizard to remove the Broker component, unless otherwise stated. Do not use the uninstallation program that is provided by the operating system; for example, **geninstall** on AIX, or **swremove** on HP-UX.

On HP-UX Version 11.23, and on Linux on POWER, a known restriction prevents the creation of the wizard. If this situation occurs, use the alternative command specified in these instructions. Also check the `readme.html` file to ensure that no additional operating systems are affected by this restriction.

About this task

For information about the console interface and alternative interfaces available, see "How to install and uninstall the Broker component" on page 3618.

To start the console interface of the uninstaller, complete the following steps:

Procedure

1. Stop all running processes that are associated with brokers before you uninstall. Use the "**mqsilist** command" on page 3882 to check which brokers are running. Use the "**mqsistop** command" on page 3972 to stop each broker.
2. On Windows, Linux on x86, and Linux on x86-64, end any active sessions of the WebSphere Message Broker Toolkit.
3. If you do not plan to reinstall brokers on this computer, delete all the brokers that are associated with this installation by using the "**mqsideletebroker** command" on page 3863. When you delete a broker, all its associated data and resources are deleted.
4. Run the uninstallation program from outside the installation directory, specifying the full path to ensure that the folders are removed during uninstallation, where *install_dir* is the home directory of your WebSphere Message Broker installation:
   - On some HP-UX systems that are running Version 11.23:

```
/install_dir/_uninst_runtime_jvm/bin/java -jar
/install_dir/_uninst_runtime/uninstall.jar -console
```

   - On some Linux on POWER systems:

```
/install_dir/_uninst_runtime_jvm/jre/bin/java -jar
/install_dir/_uninst_runtime/uninstall.jar -console
```

   - On all other operating systems:

```
install_dir/_uninst_runtime/uninstaller -console
```

If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

Linux `/opt/ibm/mqsi/v.r`

UNIX `/opt/IBM/mqsi/v.r`

Windows 32-bit
`C:\Program Files\IBM\MQSI\v.r`

Windows 64-bit
`C:\Program Files\IBM\MQSI\v.r` for the 64-bit version of WebSphere Message Broker

`C:\Program Files (x86)\IBM\MQSI\v.r` for the 32-bit version of WebSphere Message Broker

These locations define the default value of *install_dir* on each platform.

5. When started, the uninstaller presents text-based screens on the console. Navigate between these screens using the following options:
   - 1 next
   - 2 previous
   - 3 cancel
   - 4 redisplay

   The uninstaller asks you to confirm that you want to uninstall the product and that the location it is uninstalling from is correct. When you have responded to these questions, the uninstallation starts.

Use the **mqsistop** command to stop the specified component.

Uninstalling the Broker component by using the silent interface

Remove the Broker component without user interaction by using the silent interface.

Before you begin

Always use the WebSphere Message Broker uninstallation wizard to remove the Broker component, unless otherwise stated. Do not use the uninstallation program that is provided by the operating system; for example, **geninstall** on AIX, or **swremove** on HP-UX.

On HP-UX Version 11.23, and on Linux on POWER, a known restriction prevents the creation of the wizard. If this situation occurs, use the alternative command specified in these instructions. Also check the `readme.html` file to ensure that no additional operating systems are affected by this restriction.

If you use the silent interface to uninstall the Broker component, the wizard always uninstalls the Broker component from the last known Version 7.0 installation location (that is, the most recent installation), regardless of the location of the uninstallation wizard that you start. If you want to remove the Broker component from an earlier Version 7.0 installation, use the console or graphical interface.

About this task

You can remove the Broker component without user interaction. This process is called unattended (or silent) removal. This topic describes how to run the uninstallation program silently without a response file; the program assumes all the default values.

If you want to complete a silent uninstallation, but have non-default requirements, you can use a response file. A response file is a text file that contains values for the options that you select when you uninstall WebSphere Message Broker. For more details of how to create, edit, and employ a response file to specify your requirements, see Using response files.

For information about the silent interface and alternative interfaces available, see "How to install and uninstall the Broker component" on page 3618.

To start the silent interface of the uninstaller, complete the following steps:

Procedure

1. Stop all running processes that are associated with brokers before you uninstall. Use the "**mqsilist** command" on page 3882 to check which brokers are running. Use the "**mqsistop** command" on page 3972 to stop each broker.
2. On Windows, Linux on x86, and Linux on x86-64, end any active sessions of the WebSphere Message Broker Toolkit.
3. If you do not plan to reinstall brokers on this computer, delete all the brokers that are associated with this installation by using the "**mqsideletebroker** command" on page 3863. When you delete a broker, all its associated data and resources are deleted.
4. Run the following command from outside the installation directory, specifying the full path (this method of invocation ensures that the full directory structure is removed during uninstallation), where *install_dir* is the home directory of your WebSphere Message Broker installation:
   - On some HP-UX systems that are running Version 11.23 only:

```
/install_dir/_uninst_runtime_jvm/bin/java -jar
/install_dir/_uninst_runtime/uninstall.jar -silent
```

   - On some Linux on POWER systems:

```
/install_dir/_uninst_runtime_jvm/jre/bin/java -jar
/install_dir/_uninst_runtime/uninstall.jar -silent
```

- On all other operating systems:

  install_dir/_uninst_runtime/*uninstaller -silent*

If you accepted the default location during installation, this directory is as follows. The default directory includes the version and release of the product that you are installing in the format v.r (version.release):

Linux /opt/ibm/mqsi/*v.r*

UNIX /opt/IBM/mqsi/*v.r*

Windows 32-bit
C:\Program Files\IBM\MQSI*v.r*

Windows 64-bit
C:\Program Files\IBM\MQSI*v.r* for the 64-bit version of WebSphere Message Broker

C:\Program Files (x86)\IBM\MQSI*v.r* for the 32-bit version of WebSphere Message Broker

These locations define the default value of *install_dir* on each platform. The uninstallation program runs without interaction.

Uninstalling service for the Broker component

On some platforms, you can remove fixes that you have applied.

About this task

Distributed systems

You cannot remove individual fixes that you have applied to the Broker component on distributed systems. If you want to restore a system to a previous service level, you must uninstall the product before you reinstall the required level of service.

If you have a single installation on your computer, create and retain a backup image, or keep previous GA or fix pack images or media, in case you experience problems after you have installed service. If you have multiple installations, each one can be at a different service level and you

can transfer the broker to work with an alternative installation at a newer or older level of service. This option is described in "Applying service to the Broker component" on page 314.

When you uninstall the product, the components that you have created are not lost, and you can continue to use these components and associated resources with the reinstalled product. However, you might want to take a backup of the installation and work path directories before you start this procedure.

To restore a system on which you have a single installation to a previous service level:

1. Uninstall the entire product.
2. Reinstall the GA level of the product. This step is required to ensure that you comply with your license agreement.
3. Install the required level of fix pack.

z/OS On z/OS systems, you can uninstall service levels under some circumstances during the installation phase; for further information, see "Installing service on z/OS" on page 322.

Uninstalling the WebSphere Message Broker ODBC Database Extender (IE02)

How you uninstall the WebSphere Message Broker ODBC Database Extender.

Procedure

To uninstall the WebSphere Message Broker ODBC Database Extender, change your directory to `Uninstall_IE02` within the installation path `IE02 ($IE02_PATH)`, and run the following command:

```
./Uninstall_IE02
```

This command launches the uninstaller in the same mode that it was previously installed. For example, in Graphical, Console, or Silent mode.
The uninstaller does not delete the `/var/mqsi/common/profiles/IE02.sh` file. You can remove this file manually after you have removed the SupportPac, although no problems are caused if the file is not removed.

Related tasks:

WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager, which is an implementation of the Open DataBase Connectivity

interface for UNIX systems, and this topic describes how you configure it.

"Installing the WebSphere Message Broker ODBC Database Extender (IE02)" on page 273
WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager, which is an implementation of the Open DataBase Connectivity interface for UNIX systems. This topic describes how you install WebSphere Message Broker ODBC Database Extender.

Uninstalling the WebSphere Message Broker Toolkit

Choose the method that you want to use to uninstall the WebSphere Message Broker Toolkit and follow the instructions to remove the component.

About this task

Complete the following steps to uninstall the WebSphere Message Broker Toolkit:

Procedure

1. Check that your user ID has the correct authority to uninstall the WebSphere Message Broker Toolkit or to uninstall service that you have applied. The requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. If you are uninstalling the WebSphere Message Broker Toolkit component, decide which mode of uninstallation you want to use. The choices are explained in "How to install and uninstall the WebSphere Message Broker Toolkit" on page 3623.
3. Follow the instructions provided in the appropriate topic:
   - "Uninstalling the WebSphere Message Broker Toolkit in graphical mode" on page 341
   - "Uninstalling the WebSphere Message Broker Toolkit in silent mode" on page 343
   - "Uninstalling service from the WebSphere Message Broker Toolkit" on page 344

Results

When you uninstall the WebSphere Message Broker Toolkit component, entries are removed from the system menus:

Linux If you have installed the WebSphere Message Broker Toolkit more than once on Linux on x86, the main menu shows a single entry, regardless of the number of installations that you have completed; the entry always accesses the last installation that you completed. When you uninstall this component, the single entry is removed, and you cannot access remaining installations using the main menu. Navigate to the correct package group installation directory and start the WebSphere Message Broker Toolkit from the command line.

Windows Entries in the Windows Start menu are grouped by package group. When you uninstall this component, the entry within the appropriate package group is correctly removed.

Uninstalling the WebSphere Message Broker Toolkit in graphical mode

The graphical interface guides you through the process of uninstalling the WebSphere Message Broker Toolkit.

About this task

For information about the modes that are available, see "How to install and uninstall the WebSphere Message Broker Toolkit" on page 3623.

Complete the following steps:

Procedure

1. Log on to the computer on which WebSphere Message Broker Toolkit is installed with a user ID that has the correct authority. The authority requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. Start the IBM Installation Manager.
   - Linux Choose one of the following options:
     - The main menu. You can use this option only if you are logged in as root. If you logged in as another user, you cannot use the main menu links, even if you become root.
       - On Red Hat, click **System** > **IBM Installation Manager**.
       - On SUSE, click **System Tools** > **IBM Installation Manager**.
     - Navigate to the `eclipse` subdirectory in the directory in which Installation Manager is installed and run the command `IBMIM`.
     - On the command line, start the WebSphere Message Broker Toolkit uninstallation wizard (where *package_group_dir* is the directory in which you installed the package group):

       ```
       package_group_dir/uninstall/uninstall.sh
       ```

       For example:

       ```
       /opt/IBM/WMBT700/uninstall/uninstall.sh
       ```
   - Windows Choose one of the following options:
     - Click **Start** > **Programs** > **IBM Installation Manager** > **IBM Installation Manager**.

- Click **Start** > **Settings** > **Control Panel** > **Add/Remove Programs**. Open the package group and select the package group in which you installed WebSphere Message Broker Toolkit, for example **IBM Software Development Platform_1**.
- Navigate to the `eclipse` subdirectory in the directory in which Installation Manager is installed and run the command `IBMIM.exe`.
- On the command line, start the WebSphere Message Broker Toolkit uninstallation wizard (where *package_group_dir* is the directory in which you installed the package group):

  package_group_dir`\uninstall\uninstall.bat`

  For example, on Windows XP:

  `C:\Program Files\IBM\WMBT700\uninstall\uninstall.bat`

3. If you started Installation Manager from the Start or main menu, or by running `IBMIM` or `IBMIM.exe`, click **Uninstall Packages**. The Uninstall Package window displays.
4. Select the WebSphere Message Broker Toolkit, then click **Next**. The Uninstall Summary window is displayed.
5. Check the list of items. Click **Back** to change items, or click **Uninstall** to continue. The uninstallation process starts.
6. Follow the guidance through the series of windows, providing input and responses as required.
7. When the process completes, check the log file for errors. The file `YYYYMMDD_TIME.xml` is written to the following directory:
   - Linux `/var/ibm/InstallationManager/logs`
   - Windows `%ALLUSERSPROFILE%\Application Data\IBM\Installation Manager\logs`, where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:
     - On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs`.
     - On Windows Vista and later operating systems: `C:\ProgramData\IBM\Installation Manager\logs`.

   The actual value might be different on your computer.
8. Restart your computer to complete the uninstallation of the WebSphere Message Broker Toolkit.

Related tasks:

Uninstalling the WebSphere Message Broker Toolkit in silent mode

Uninstall the WebSphere Message Broker Toolkit without user interaction.

About this task

For information about alternative modes that are available, see "How to install and uninstall the WebSphere Message Broker Toolkit" on page 3623.

Complete the following steps:

Procedure

1. Log on to the computer on which WebSphere Message Broker Toolkit is installed with a user ID that has the correct authority. The authority requirements are defined in "Installation and uninstallation authorization" on page 3628.
2. To silently uninstall the WebSphere Message Broker Toolkit, start IBM Installation Manager by using the supplied script files.
   a. Navigate to the uninstallation directory and open the script file in a text editor:
      - Linux *package_group_dir*/uninstall/uninstall.sh

        For example:

        /opt/IBM/WMBT700/uninstall/uninstall.sh
      - Windows *package_group_dir*\uninstall\uninstall.bat

        For example, on Windows XP:

        C:\Program Files\IBM\WMBT700\uninstall\uninstall.bat
   b. Modify the invocation of the IBMIM executable file as follows:
      - Linux If you plan to run the script file from the command line in the uninstallation directory:

        IM_dir/IBMIM -nosplash -input uninstall.xml -silent

        Otherwise:

        IM_dir/IBMIM -nosplash -input *package_group_dir*/uninstall/uninstall.xml -silent
      - Windows If you plan to run the script file from the command line in the uninstallation directory:

        IM_dir\IBMIMc -nosplash -input uninstall.xml -silent

        Otherwise:

        IM_dir\IBMIMc -nosplash -input *package_group_dir*\uninstall\uninstall.xml -silent

      Replace *IM_dir/*, or *IM_dir*\, depending on your platform, with the full path for Installation Manager on your operating system. If you have installed Installation Manager in the default location, the full path is:
      - Linux /opt/IBM/InstallationManager/eclipse/
      - Windows On Windows 32-bit editions: C:\Program Files\IBM\InstallationManager\eclipse\
      - Windows On Windows 64-bit editions: C:\Program Files(x86)\IBM\InstallationManager\eclipse\

        Note, that on Windows you must enclose the full path name in double quotation marks. For example:

```
"C:\Program Files(x86)\IBM\InstallationManager\eclipse\IBMIMc"
 -nosplash -input package_group_dir\uninstall\uninstall.xml
 -silent
```

3. Run the file that you just edited. The product is uninstalled silently; control is returned to the command line when uninstallation is finished.
4. When the process completes, check the log file for errors. The file `YYYYMMDD_TIME.xml` is written to the following directory:
   - Linux `/var/ibm/InstallationManager/logs`.
   - Windows `%ALLUSERSPROFILE%\Application Data\IBM\Installation Manager\logs` where `%ALLUSERSPROFILE%` is the environment variable that defines the system working directory. The default directory depends on the operating system:
     – On Windows XP and Windows Server 2003: `C:\Documents and Settings\All Users\Application Data\IBM\Installation Manager\logs`.
     – On Windows Vista and later operating systems: `C:\ProgramData\IBM\Installation Manager\logs`.

   The actual value might be different on your computer.
5. Restart your computer to complete the uninstallation of the WebSphere Message Broker Toolkit.
6. Delete the uninstallation directory if it still exists.

Uninstalling service from the WebSphere Message Broker Toolkit

Remove maintenance or fixes from the WebSphere Message Broker Toolkit.

Before you begin

Linux To remove service from the WebSphere Message Broker Toolkit on Linux on x86 and Linux on x86-64, your user ID must have root authority. Follow your local security guidelines to acquire root authority; either log in as root, or log in as another user and become root.

Windows To remove service from the WebSphere Message Broker Toolkit on Windows, your user ID must have Administrator authority.

About this task

You can remove WebSphere Message Broker interim fix and service updates from the toolkit using IBM Installation Manager.

To uninstall service:

Procedure

1. Close all sessions of the WebSphere Message Broker Toolkit on this computer.
2. Start Installation Manager in one of the following ways:
   - From the Linux on x86 and Linux on x86-64 main menu, or the Windows Start menu:
     - On Linux, you can use this option only if you are logged in as root. If you have logged in as another user, you cannot use the main menu links, even if you become root.
       - On Red Hat, click **System** > **IBM Installation Manager**.
       - On SUSE, click **System Tools** > **IBM Installation Manager**.
     - On Windows, click **Start** > **Programs** > **IBM Installation Manager** > **IBM Installation Manager** .
   - Navigate to the `eclipse` subdirectory in the directory in which Installation Manager is installed and run the following command:
     - Linux `IBMIM`
     - Windows `IBMIM.exe`

   Installation Manager starts and displays its initial panel.
3. Click **Roll Back Packages**, then select the package group in which you have installed the WebSphere Message Broker Toolkit.
4. Click **Next**. The Roll Back Packages panel displays the products that you have installed in the selected group. The service updates that you have applied to any item in the list are displayed under the item to which they apply.
5. If updates are installed, select the updates that you want to remove from each particular installation. A summary of the selected updates is displayed. Click **more details...** to open the readme file associated with the fix.
6. Click **Next** to continue. Installation Manager checks that no WebSphere Message Broker Toolkit sessions are running. If the check fails, an error message is displayed and you cannot continue with the operation. Close all active sessions, then return to this step and click **Next** again.

   Installation Manager displays the exact identification of the fixes that you selected; check that what is listed is correct. If you want to change your choices, click **Back** to view the list of fixes again.
7. Click **Roll Back**. Installation Manager starts to remove the selected fixes. A progress bar is displayed so that you can monitor the request. A completion message is displayed; click **View log** to read the report that is generated by the removal.
8. If the fix has been removed successfully, click **Finish** to return to the initial panel. If the removal failed, examine the contents of the log file to determine the cause of the error.
9. Click **File** > **Exit** to close Installation Manager. Verify that the changes have worked; see “Verifying your installation by using the WebSphere Message Broker Toolkit” on page 291.

Uninstalling the WebSphere Message Broker Explorer on Linux

You can uninstall the WebSphere Message Broker Explorer by using the graphical installation wizard.

About this task

Complete the following steps to uninstall the WebSphere Message Broker Explorer by using the graphical installation wizard on Linux. To uninstall successfully on Linux systems, you must have write permissions to the installation directory. You might also need root administrator privileges to complete this task.

Procedure

1. Navigate to the uninstall directory. The default location on Linux is `/opt/IBM/MBExplorer/Uninstall_Message_Broker_Explorer`. You can use your native file explorer to run the file in this directory.
2. Run the `./Uninstall_Message_Broker_Explorer` file. The uninstaller launches.
3. Click **Uninstall** to uninstall the WebSphere Message Broker Explorer. The uninstaller lists any items that cannot be uninstalled. You can delete these items manually.

4. When the uninstall process is completed, click **Done** to close the uninstaller.

Related concepts:

Uninstalling the WebSphere Message Broker Explorer in console mode

You can uninstall the WebSphere Message Broker Explorer using the console mode of the installation wizard.

About this task

Use the following steps to uninstall the WebSphere Message Broker Explorer using the console mode of the installation wizard on Windows and Linux. To uninstall successfully on Linux systems, you need write permissions to the installation directory. You are likely to require root administrator privileges for this task.

Procedure

1. Navigate to the Uninstall directory:
   - The default location on Windows is `C:\Program Files\IBM\MBExplorer\Uninstall_Message_Broker_Explorer`
   - The default location on Linux is `/opt/IBM/MBExplorer/Uninstall_Message_Broker_Explorer`. You can also use your native file explorer to run this file.
2. Run the following command: A new uninstaller command window launches:
   - On Windows, the command to uninstall the product from the console is: `Uninstall_Message_Broker_Explorer.exe -i console`.
   - On Linux, the command to to uninstall the product from the console is: `./Uninstall_Message_Broker_Explorer -i console`.

   The uninstaller launches.
3. Press Enter to uninstall the WebSphere Message Broker Explorer. The uninstaller lists any items that could not be uninstalled. You can delete these items manually.
4. When the uninstallation has ended, press **Enter** to exit the uninstaller.

Related concepts:

Uninstalling the WebSphere Message Broker Explorer in silent mode

You can uninstall the WebSphere Message Broker Explorer using the installation wizard in silent mode.

About this task

Use the following steps to uninstall the WebSphere Message Broker Explorer using the silent mode on Windows and Linux.

Procedure

1. On a command line, navigate to the uninstallation directory for WebSphere Message Broker Explorer in the file system. The default uninstallation directory for the WebSphere Message Broker Explorer on Windows is `C:\Program Files\IBM\MBExplorer\Uninstall_Message_Broker_Explorer`. The default uninstallation directory for the WebSphere Message Broker Explorer on Linux systems is `/opt/IBM/MBExplorer/Uninstall_Message_Broker_Explorer`.
2. Enter the following command on a command line to start the uninstaller in silent mode: `Uninstall_Message_Broker_Explorer.exe -i silent` If you run the silent uninstallation command directly from a command line, the command prompt returns immediately, and the installation wizard completes the uninstallation as a background task. If you run the silent uninstallation command as part of a batch file or script, control is returned to the batch file or script after the uninstallation has completed.

Results

The WebSphere Message Broker Explorer files have been removed from your system.

Uninstalling service from the WebSphere Message Broker Explorer

You must reinstall the WebSphere Message Broker Explorer to revert to a previous service level.

About this task

You cannot remove individual fixes that you have applied to the WebSphere Message Broker Explorer. If you want to restore a system to a previous service level, you must reinstall the desired level of service. If you have a single installation on your computer, create and retain a backup image, or keep previous GA or fix pack images or media, in case of problems after you have installed service. To restore a Windows or Linux system on which you have an installation of the WebSphere Message Broker Explorer to a previous service level, you have two options:

- Uninstall the current level, then reinstall the previous service level of the WebSphere Message Broker Explorer.
- Install the previous service level of the WebSphere Message Broker Explorer to a new location on your system.

To uninstall the current level of service from the WebSphere Message Broker Explorer, and return to a previous level use the following instructions:

Procedure

1. Uninstall the WebSphere Message Broker Explorer.
2. Reinstall the GA level of the WebSphere Message Broker Explorer.
3. Install the desired level of fix pack.

Chapter 5. Security

Security is an important consideration for both developers of WebSphere Message Broker applications, and for system administrators configuring WebSphere Message Broker authorities.

When you are designing a WebSphere Message Broker application, it is important to consider the security measures that are needed to protect the information in the system.

The "Security overview" introduces the concepts that you need to understand before you set up security for WebSphere Message Broker.

The following topics explain the different aspects of security that you need to consider when you are designing your applications:
- "Broker administration security" on page 361
- "Message flow security" on page 382
- "Broker component security" on page 497
- "Setting up z/OS security" on page 556
- "Activating broker administration security for WebSphere MQ Version 7.1, or later" on page 381

Related concepts:

"What's new in Version 7.0?" on page 7
Learn about the main new functions in IBM WebSphere Message Broker Version 7.0.

"WS-Security" on page 765
Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

Security overview

When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

An important aspect of securing an enterprise system is the ability to protect the information that is passed from third parties. This capability includes restricting access to WebSphere MQ and JMS queues. For information about the steps involved, refer to the documentation supplied by your transport provider. If you are using HTTPS, you need to set specific properties in the HTTP nodes. For information about this option, see "HTTPInput node" on page 4474, "HTTPRequest node" on page 4488, and "HTTPReply node" on page 4484.

In addition to securing the transport, you can secure individual messages based on their identity. For more information about securing messages in a message flow, see “Message flow security” on page 382.

Some security configuration is required to enable WebSphere Message Broker to work correctly and to protect the information in the system. For example, you can secure the messaging transport with SSL connections, restrict access to queues, apply WS-Security to Web services, and secure access to message flows.

In addition, system administrators need WebSphere Message Broker authorities that allow them to perform customization and configuration tasks, run utilities, perform problem determination, and collect diagnostic materials.

The following topics introduce the concepts that you need to understand before you set up security for WebSphere Message Broker:

- “Planning for security when you install WebSphere Message Broker” on page 353
- “Broker administration security overview” on page 362
- “Message flow security overview” on page 383
- “WS-Security” on page 765
- “Authorization for configuration tasks” on page 353
- “Security exits” on page 354
- “Public key cryptography” on page 354
- “Digital certificates” on page 356
- “Digital signatures” on page 360

Additionally, if WebSphere MQ Version 7.1, or later, has been selected for the queue manager and channel auth security is required to be enabled, see “Activating broker administration security for WebSphere MQ Version 7.1, or later” on page 381.

Planning for security when you install WebSphere Message Broker

The Installation Guide describes the security tasks that you must complete before, during, and after installation.

About this task

On Linux and UNIX systems, you must complete security tasks before you install WebSphere Message Broker; these tasks are described in the Installation Guide. On Windows systems, security tasks are completed during and after installation.

Always refer to the Installation Guide for the latest information about installation tasks.

After installation, refer to "Creating user IDs" on page 498 for further security considerations.

For an introduction to various aspects of security, see "Security overview" on page 351.

Related reference:

"Installation Guide" on page 233
Installation information for WebSphere Message Broker is provided in the *Installation Guide* that is supplied as a PDF file with your product package.

Authorization for configuration tasks

Authorization is the process of granting or denying access to a system resource.

For WebSphere Message Broker, authorization is concerned with controlling who has permission to access WebSphere Message Broker resources, and ensuring that users who attempt to work with those resources have the necessary authorization to do so.

Examples of tasks that require authorization are:

- Configuring a broker using, for example, the "**mqsicreatebroker** command" on page 3831.
- Accessing queues, for example, putting a message to the input queue of a message flow.
- Taking actions within the WebSphere Message Broker Toolkit, for example, deploying a message flow to an execution group.

Related tasks:

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

Security exits

Use security exit programs to verify that the partner at the other end of a connection is genuine.

When you connect from the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer to a broker on another computer, a security exit is not started by default to monitor the connection. If you want to protect access to the broker from client programs, you can use the WebSphere MQ security exit facility.

You can enable a security exit at each end of the connection between your client session and the broker:

- Set up a security exit on the channel at the broker end. This security exit has no special requirements; you can provide a standard security exit.
- Set up a security exit in the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer. Identify the security exit properties when you connect to the broker. The security exit is a standard WebSphere MQ security exit, written in Java.

For an overview of security exits and details of their implementation, see "Channel security exit programs" in the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

Public key cryptography

All encryption systems rely on the concept of a key. A key is the basis for a transformation, usually mathematical, of an ordinary message into an unreadable message. For centuries, most encryption systems have relied on private key encryption. Public key encryption is the only challenge to private key encryption that has appeared in the last 30 years.

Private key encryption

Private key encryption systems use a single key that is shared between the sender and the receiver. Both must have the key; the sender encrypts the message by using the key, and the receiver decrypts the message with the same key. Both the sender and receiver must keep the key private to keep their communication private. This kind of encryption has characteristics that make it unsuitable for widespread general use:

- Private key encryption requires a key for every pair of individuals who need to communicate privately. The necessary number of keys rises dramatically as the number of participants increases.
- Keys must be shared between pairs of communicators, therefore the keys must be distributed to the participants. The need to transmit secret keys makes them vulnerable to theft.
- Participants can communicate only by prior arrangement. You cannot send a usable encrypted message to someone spontaneously. You and the other participant must make arrangements to communicate by sharing keys.

Private key encryption is also called symmetric encryption because the same key is used to encrypt and decrypt the message.

Public key encryption

Public key encryption uses a pair of mathematically-related keys. A message that is encrypted with the first key must be decrypted with the second key, and a message that is encrypted with the second key must be decrypted with the first key.

Each participant in a public key system has a pair of keys. One key is nominated as the private key and is kept secret. The other key is distributed to anyone who wants it; this key is the public key.

Anyone can encrypt a message by using your public key, but only you can read it. When you receive the message, you decrypt it by using your private key.

Similarly, you can encrypt a message for anyone else by using their public key, and they decrypt it by using their private key. You can then send the message safely over an unsecured connection.

This kind of encryption has characteristics that make it very suitable for general use:

- Public key encryption requires only two keys per participant.
- The need for secrecy is more easily met: only the private key needs to be kept secret, and because it does not need to be shared, it is less vulnerable to theft in transmission than the shared key in a symmetric key system.
- Public keys can be published, which eliminates the need for prior sharing of a secret key before communication. Anyone who knows your public key can use it to send you a message that only you can read.

Public key encryption is also called asymmetric encryption, because the same key cannot be used to encrypt and decrypt the message. Instead, one key of a pair is used to undo the work of the other.

With symmetric key encryption, beware of stolen or intercepted keys. In public key encryption, where anyone can create a key pair and publish the public key, the challenge is in verifying the identity of the owner of the public key. Nothing prevents a user from creating a key pair and publishing the public key under a false name. The listed owner of the public key cannot read messages that are encrypted with that key because the owner does not have the corresponding private key. If the creator of the false public key can intercept these messages, that person can decrypt and read messages that are intended for someone else. To counteract the potential for forged keys, public key systems provide mechanisms for validating public keys and other information with digital certificates and digital signatures.

Public Key Infrastructure (PKI)

PKI is an infrastructure that uses public key technology to allow applications to interact securely. PKI uses public key encryption to provide privacy. In practice, only a small amount of data is encrypted in this way. Typically, a *session key* is used with a symmetric algorithm to transmit the bulk of the data efficiently.

In business transactions, trust is even more important than privacy. PKI uses the private key to allow an application to sign a document. For the recipient to authenticate the sender, it needs a reliable way to obtain the public key for the sender. This public key is provided in the form of a digital certificate, which is mediated by a trusted third party certificate authority (CA).

Related concepts:

"Digital certificates"
Certificates provide a way of authenticating users. Instead of requiring each participant in an application to authenticate every user, third-party authentication relies on the use of digital certificates.

WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

Digital certificates

Certificates provide a way of authenticating users. Instead of requiring each participant in an application to authenticate every user, third-party authentication relies on the use of digital certificates.

A digital certificate is equivalent to an electronic ID card. The certificate serves two purposes:

- Establishes the identity of the owner of the certificate

- Distributes the owner's public key

Certificates are issued by trusted third parties, called certificate authorities (CAs). These authorities can be commercial ventures or local entities, depending on the requirements of your application. The CA is trusted to adequately authenticate users before issuing certificates. A CA issues certificates with digital signatures. When a user presents a certificate, the recipient of the certificate validates it by using the digital signature. If the digital signature validates the certificate, the certificate is recognized as intact and authentic. Participants in an application need to validate certificates only; they do not need to authenticate users. The fact that a user can present a valid certificate proves that the CA has authenticated the user. The designation, "trusted third parties", indicates that the system relies on the trustworthiness of the CAs.

The certificates and private keys are stored in files called *keystores* and *truststores*.

- A keystore holds the private keys and public key certificates for an application.
- A truststore contains the CA certificates required to authenticate certificates that are presented by another application.

Contents of a digital certificate

A certificate contains several pieces of information, including information about the owner of the certificate and the issuing CA. Specifically, a certificate includes:

- The distinguished name (DN) of the owner. A DN is a unique identifier, a fully qualified name including not only the common name (CN) of the owner but also the owner's organization and other distinguishing information.
- The public key of the owner.
- The date on which the certificate is issued.
- The date on which the certificate expires.
- The distinguished name of the issuing CA.
- The digital signature of the issuing CA. The message-digest function creates a signature based upon all the previously listed fields.

The idea of a certificate is that a CA takes the public key of the owner, signs the public key with its own private key, and returns the information to the owner as a certificate. When the owner distributes the certificate to another party, it signs the certificate with its private key. The receiver can extract the certificate that contains the CA signature with the public key of the owner. By using the CA public key and the CA signature on the extracted certificate, the receiver can validate the CA signature. If valid, the public key that is used to extract the certificate is considered good. The owner signature is validated, and if the validation succeeds, the owner is successfully authenticated to the receiver.

The additional information in a certificate helps an application to determine whether to honor the certificate. With the expiration date, the application can determine if the certificate is still valid. With the name of the issuing CA, the application can check that the CA is considered trustworthy by the site.

An application that needs to authenticate itself must provide its personal certificate, the one containing its public key, and the certificate of the CA that signed its certificate, called a signer certificate. In cases where chains of trust are established, several signer certificates can be involved.

Requesting certificates

To get a certificate, send a certificate request to the CA. The certificate request includes:

- The distinguished name of the owner or the user for whom the certificate is requested
- The public key of the owner
- The digital signature of the owner

The message digest function creates a signature based on all the previously listed fields.

The CA verifies the signature with the public key in the request to ensure that the request is intact and authentic. The CA then authenticates the owner. Exactly what the authentication consists of depends on a prior agreement between the CA and the requesting organization. If the owner in the request is authenticated successfully, the CA issues a certificate for that owner.

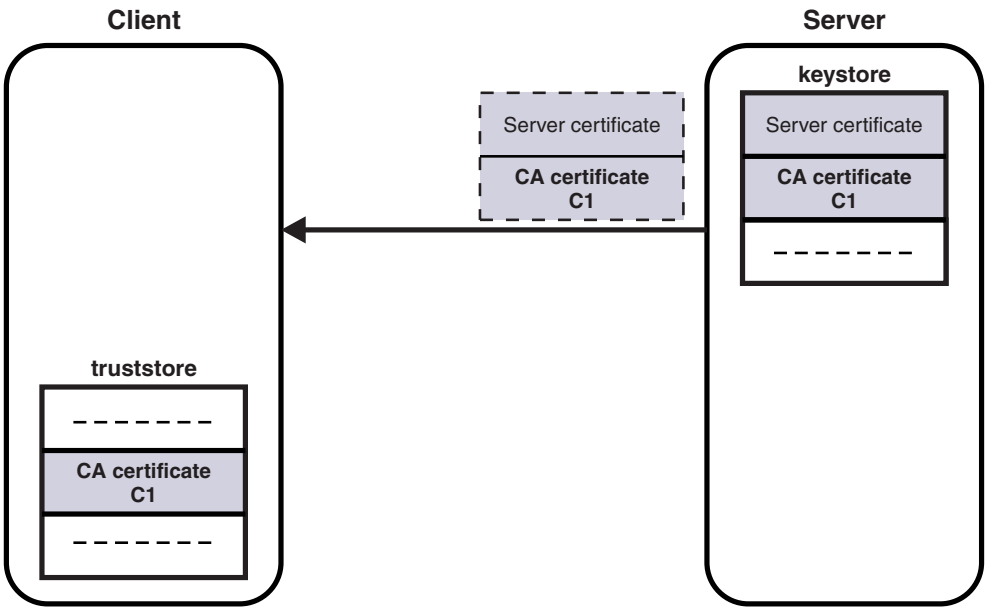
Using certificates: Chain of trust and self-signed certificate

To verify the digital signature on a certificate, you must have the public key of the issuing CA. Public keys are distributed in certificates, therefore you must have a certificate for the issuing CA that is signed by the issuer. One CA can certify other CAs, so a chain of CAs can issue certificates for other CAs, all of whose public keys you need. Eventually, you reach a root CA that issues itself a self-signed certificate. To validate a user certificate, you need certificates for all of the intervening participants back to the root CA. You then have the public keys that you need to validate each certificate, including the user certificate.

A self-signed certificate contains the public key of the issuer and is signed with the private key. The digital signature is validated like any other, and if the certificate is valid, the public key it contains is used to check the validity of other certificates issued by the CA. However, anyone can generate a self-signed certificate. In fact, you can probably generate self-signed certificates for testing purposes before installing production certificates. The fact that a self-signed certificate contains a valid public key does not mean that the issuer is a trusted certificate authority. To ensure that self-signed certificates are generated by trusted CAs, such certificates must be distributed by secure means; for example, hand-delivered on floppy disks, downloaded from secure sites, and so on.

Applications that use certificates store these certificates in a keystore file. This file typically contains the necessary personal certificates, its signing certificates, and its private key. The private key is used by the application to create digital signatures. Servers always have personal certificates in their keystore files. A client requires a personal certificate only if the client must authenticate to the server when mutual authentication is enabled.

To allow a client to authenticate a server, a server keystore file contains the private key and the certificate of the server and the certificates of its CA. A client truststore file must contain the signer certificates of the CAs of each server, which the client must authenticate. The following diagram illustrates how a client authenticates a server.



If mutual authentication is needed, the client keystore file must contain the client private key and certificate. The server truststore file requires a copy of the certificate of the client CA. The following diagram illustrates mutual authentication.

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

Digital signatures

A digital signature is a number that is attached to a document. For example, in an authentication system that uses public-key encryption, digital signatures are used to sign certificates.

This signature establishes the following information:

- The integrity of the message: Is the message intact? That is, has the message been modified between the time it was digitally signed and now?
- The identity of the signer of the message: Is the message authentic? That is, was the message signed by the user who claims to have signed it?

A digital signature is created in two steps. The first step distills the document into a large number. This number is the digest code or fingerprint. The digest code is then encrypted, which results in the digital signature. The digital signature is appended to the document from which the digest code is generated.

Several options are available for generating the digest code. This process is not encryption, but a sophisticated checksum. The message cannot regenerate from the resulting digest code. The crucial aspect of distilling the document to a number is that if the message changes, even in a trivial way, a different digest code results. When the recipient gets a message and verifies the digest code by recomputing it, any changes in the document result in a mismatch between the stated and the computed digest codes.

To stop someone from intercepting a message, changing it, recomputing the digest code, and retransmitting the modified message and code, you need a way to verify the digest code as well. To verify the digest code, reverse the use of the public and private keys. For private communication, it makes no sense to encrypt messages with your private key; these keys can be decrypted by anyone with your public key. However, this technique can be useful for proving that a message came from you. No one can create it because no-one else has your private key. If some meaningful message results from decrypting a document by using someone's public key, the decryption process verifies that the holder of the corresponding private key did encrypt the message.

The second step in creating a digital signature takes advantage of this reverse application of public and private keys. After a digest code is computed for a

document, the digest code is encrypted with the sender's private key. The result is the digital signature, which is attached to the end of the message.

When the message is received, the recipient follows these steps to verify the signature:

1. Recomputes the digest code for the message.
2. Decrypts the signature by using the sender's public key. This decryption yields the original digest code for the message.
3. Compares the original and recomputed digest codes. If these codes match, the message is both intact and authentic. If not, something has changed and the message is not to be trusted.

"WS-Security" on page 765
Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

Related tasks:

"Setting up z/OS security" on page 556
On z/OS, you must complete several security configuration tasks before WebSphere Message Broker can work correctly.

Broker administration security overview

Broker administration security controls the rights of users to complete administrative tasks for a broker and its resources.

Broker administration security is an optional feature of the broker. When you create a broker, the default setting is that broker administration security is not enabled. You can specify an additional parameter to enable security when you create the broker. You can also change the status of the broker administration security after you have created the broker, and can therefore enable or disable it when appropriate.

When you have enabled broker administration security, set up security control by registering WebSphere MQ permissions for specific user IDs. Permissions are recorded on the following authorization queues that are defined on the broker queue manager:

- SYSTEM.BROKER.AUTH. This queue represents the broker and its properties. Only one queue exists of this name for each broker. This queue is defined as a local queue.
- One SYSTEM.BROKER.AUTH.*EG* for each execution group that you define on the broker, where *EG* is the name of the execution group. These queues are defined as alias queues.

When you create a broker, the queue SYSTEM.BROKER.AUTH is created. Read, write, and execute authorities are automatically granted to the user group mqbrkrs on this queue. This queue is created even if you do not enable security at this time.

If you enable security, the broker checks the authorizations that you have set up on this queue when it receives a request that views or changes its properties or resources. If the user ID associated with the request is not authorized, the broker refuses the request.

When you create an execution group on a broker for which you have enabled security, the execution group authorization queue SYSTEM.BROKER.AUTH.*EG* is created, where *EG* is the name of the execution group. Read, write, and execute authorities are automatically granted to the user group mqbrkrs on this queue.

If you are migrating from Version 6.1 or Version 6.0, and you use Access Control Lists (ACLs) that you define to the Configuration Manager, you cannot migrate your ACLs directly to Version 7.0. Review the guidance provided in "Migrating

Configuration Manager ACLs" on page 179 to understand how to set up security by using the ACLs as a basis for security in your Version 7.0 environment.

See the following topics for more information about permissions and queues:

- "Broker permissions and equivalent WebSphere MQ permissions" on page 365
- "Authorization queues for broker administration security" on page 366

Authorization on z/OS

On z/OS, WebSphere MQ uses the System Authorization Facility (SAF) to route requests for authority checks to an external security manager (ESM) such as the z/OS Security Server Resource Access Control Facility (RACF). WebSphere MQ does no authority checks of its own. All information about broker administration security on z/OS assumes that you are using RACF as your ESM. If you are using a different ESM, you might need to interpret the information provided for RACF in a way that is relevant to your ESM.

If you are activating security on the WebSphere MQ queue manager on z/OS for the first time, you must set up the profiles or other resources that are required by your ESM to access queues. You must also check that the queue manager is configured to access the security profiles in the correct class; MQQUEUE for uppercase queue names and MXQUEUE for mixed case queue names.

For further information about queue manager security and security profiles, see the *z/OS System Administration Guide* and *z/OS System Setup Guide* sections of the WebSphere MQ Version 7 Information Center online.

Authority checking

If you have activated broker administration security, all actions performed by users of the following interfaces are subject to authority checking:

- A WebSphere Message Broker Toolkit session
- A WebSphere Message Broker Explorer session
- A Java program that uses the CMP API to perform operations on the broker
- All the following commands:
  - **mqsichangeresourcestats**
  - **mqsicreateexecutiongroup**
  - **mqsideleteexecutiongroup**
  - **mqsideploy**
  - **mqsilist**
  - **mqsimode**
  - **mqsireloadsecurity**
  - **mqsireportresourcestats**
  - **mqsistartmsgflow**
  - **mqsistopmsgflow**

  For additional authorization required for these commands, see "Commands and authorizations for broker administration security" on page 3646.

  You can run all commands that are not stated here only on the computer on which the broker is running. Either your user ID, or the ID under which the broker is running, must be a member of the security group mqbrkrs when you run the unlisted commands. Each command topic describes the authority that is required.

Users of the WebSphere Message Broker Explorer and WebSphere Message Broker Toolkit who do not have read, write, and execute authority for the broker or execution groups, have only restricted access to those resources. An icon is

displayed against each resource to indicate that user authority is restricted. The actions that the user can request against a resource are determined by the restricted authority that is in place for that user.

Authority persistence

If a user ID is granted authority to access a broker, the access is retained at least until the current connection or session is ended by one of the following events:

- The user closes the WebSphere Message Broker Explorer or WebSphere Message Broker Toolkit session
- The CMP API application disconnects from the `BrokerProxy` object

Even if you update or remove the authority for this user ID, the authorization does not change while the connection is active.

However, authorization is always checked for operations against execution groups and message flows; if you change or remove the authorization for a user ID to an execution group, subsequent requests in the current connection might fail.

Additional administration security

In your environment, a check on the user ID making a request might not provide a sufficient level of security. If you require a more secure solution, one or both of the following options are available:

- You can enable SSL on a WebSphere MQ client connection between the source of the request (for example, the WebSphere Message Broker Explorer) and the target queue manager on which the broker is running.
- You can configure your WebSphere MQ network so that certain types of users can be directed through a specific server connection (SVRCONN) channel, provided they comply with the CHLAUTH rules. For details of channel security, see the *System Administration Guide* section in the WebSphere MQ Version 7 Information Center online.

WebSphere MQ Version 7 Information Center online

Broker permissions and equivalent WebSphere MQ permissions

If you have enabled broker administration security, you can give different permissions to user IDs to allow them to complete various actions against a broker or its resources.

When a user requests an action against a broker or an execution group, the broker accesses the appropriate authorization queues to check that the user ID has the correct authority for that action against the target resource.

Permission to perform a broker administration task is mapped to a WebSphere MQ authority associated with the relevant authorization queue, and is created and maintained by the broker administrator. The mapping from broker permission to WebSphere MQ permission is shown in the following table.

Broker permission	WebSphere MQ permission
Read	Inquire
Write	Put
Execute	Set

For information about the authorizations that are required for specific tasks, see "Tasks and authorizations for broker administration security" on page 3645.

WebSphere MQ specific and generic profiles

WebSphere MQ supports both specific and generic profiles to manage WebSphere MQ permissions. When you enable broker administration security, you can create specific profiles to define WebSphere MQ permissions on SYSTEM.BROKER.AUTH and on one or more SYSTEM.BROKER.AUTH.*EG* queues (where *EG* is the name of a specific execution group).

You might want to grant a user, or group of users, authority to a number of execution groups, or perhaps all execution groups. You can use a WebSphere MQ generic profile to grant authority in this way. A generic profile defines authority to an existing set of execution groups, and all additional groups, that match the profile. A generic profile is one that uses special characters (wildcard characters) in the profile name, such as asterisks (*).

For example, if you want to create a generic profile to authorize access to all execution groups defined on the broker, you can specify SYSTEM.BROKER.AUTH.**. If you want a profile for a set of execution groups with names that all start with the same character string, you can specify SYSTEM.BROKER.AUTH.TEST**.

For more information about WebSphere MQ generic profile wildcard characters, see “Using wildcard characters”, and for information about WebSphere MQ generic profile priorities, see “Profile priorities”. You can find both topics in the *System Administration Guide* section of the WebSphere MQ Version 7 Information Center online.

Authorization queues for broker administration security

If you have enabled broker administration security, the broker examines specific queues to determine if a user has the authority to complete a particular task against a broker or its resources.

When you create a broker, the queue SYSTEM.BROKER.AUTH is created. Read, write, and execute authorities are automatically granted to the user group mqbrkrs on this queue. This queue is created even if you do not enable security at this time.

The SYSTEM.BROKER.AUTH queue is created as a local queue, and is used to define which users are authorized to perform actions on the broker and the broker properties.

When you create an execution group on a broker for which you have enabled security, the execution group authorization queue SYSTEM.BROKER.AUTH.*EG* is created. where *EG* is the name of the execution group. Read, write, and execute authorities are automatically granted to the user group mqbrkrs on this queue. The dedicated execution group queues are created as aliases to the queue SYSTEM.BROKER.AUTH.

If you create a broker without administration security, you can change it later. If you have defined one or more execution groups on that broker when you change its security setting, the required execution group authorization queues are defined.

A queue can be created only by a user ID that is a member of the WebSphere MQ security group mqm. Therefore the user ID who creates a broker, changes a broker, and the ID under which the broker is running when an execution group is created, must be a member of that security group. If the user ID does not have this authority, a message is returned to the command (for the **mqsichangebroker** command only), or written to the system log, with the error and the name of the queue. You must create the queue yourself, or ask your WebSphere MQ administrator to create it for you.

WebSphere MQ restricts the length of a queue name to 48 characters. Queue name characters must be in the En_US ASCII character set, and contain only uppercase and lowercase letters, digits, and the following special characters; period (.), forward slash (/), underscore (_), and percent (%). If the name of your execution group includes a character that is not valid, that character is replaced in the WebSphere MQ queue name by an underscore character. For example, if you create an execution group with the name `test@environment`, the authorization queue is created with the name SYSTEM.BROKER.AUTH.test_environment.

If you are running a secure environment, limit the names of your execution groups to 29 characters. This limit ensures that the authorization queue names generated, which include the prefix SYSTEM.BROKER.AUTH, do not exceed the WebSphere MQ limit of 48 characters.

If your execution group names do not all conform to the length and character requirements, execution groups with similar names might result in a shared authorization queue. If this situation occurs, a warning message is returned to the user that issued the command, or is written to the system log, when the second execution group is created to state that the queue is shared.

When you delete an execution group, its associated authorization queue is retained. The queue is deleted if you specify the appropriate parameter when you delete the broker. The queue can be reused if you re-create the execution group, but you must check the authorities that you have defined on the queue to ensure that they are still valid.

If you rename an execution group, you must first create an authorization queue with the appropriate name. You must also re-create the WebSphere MQ permissions associated with the original authorization queue on this queue before you rename the execution group; the broker does not perform this task on your behalf. The broker rejects the rename request if the authorization queue does not exist, to ensure that security is not affected by the renaming. If you do not re-create these permissions, no user IDs are authorized to perform a task against the renamed execution group.

When you delete a broker, you can specify that all its authorization queues are also deleted; they are not deleted by default. If you specify that the queue manager is deleted at this time, all queues are deleted.

Setting up broker administration security

Control the actions that users can request against a broker and its resources.

About this task

You can activate administrative control for an individual broker when you create it. If appropriate, you can enable the security after creation by changing broker properties. When you have activated broker administration security, grant users or groups authority to complete their expected tasks.

- "Enabling broker administration security"
- "Authorizing users for broker administration" on page 371
- "Disabling broker administration security" on page 380

On z/OS, WebSphere MQ uses the System Authorization Facility (SAF) to route requests for authority checks to an external security manager (ESM) such as the z/OS Security Server Resource Access Control Facility (RACF). WebSphere MQ does no authority checks of its own. All information about broker administration security on z/OS assumes that you are using RACF as your ESM. If you are using a different ESM, you might need to interpret the information provided for RACF in a way that is relevant to your ESM.

Enabling broker administration security

Enable broker administration security on a broker to control which users can complete specific tasks against that broker and its resources.

About this task

You can optionally enable administration security for a broker when you create it. If you decide to enable administrative security after you have created the broker, you can change the appropriate broker property.

When you create or change a broker, your user ID must be a member of the WebSphere MQ control group mqm.

Procedure

1. To enable broker administration security when you create the broker, select the security option in the "Create broker" wizard in WebSphere Message Broker Explorer, or specify the parameter **-s active** on the **mqsicreatebroker** command. For example, to create a broker called MB7BROKER with security enabled on AIX, enter the following command:

   ```
   mqsicreatebroker MB7BROKER -q MB7QMGR -s active
   ```

   The broker creates the authorization queue SYSTEM.BROKER.AUTH. This queue is used to define which users are authorized to perform an action on the broker.

   The broker also assigns default permissions of inquire, put, and set authority to this queue. These permissions grant read, write, and execute authority on the broker to all members of the mqbrkrs group. Therefore, you must ensure that at least one member of your broker administration team is a member of this group. You must also manage the membership of this group with care, and ensure that this level of authorization is granted only to users who require it.

   On z/OS, these permissions are implemented as levels of authority in the external security manager (ESM) that you are using with WebSphere MQ. If you are using RACF as your ESM, the levels are hierarchical: for example, ALTER access implies READ and WRITE access. You must therefore check the documentation for your ESM to understand the authorization levels that it supports. On distributed platforms, no equivalent hierarchy exists, and the three permissions are independent.
2. To enable broker administration security on an existing broker:
   a. Stop the broker in the WebSphere Message Broker Explorer, or run the **mqsistop** command.
   b. Select the security option for this broker in the WebSphere Message Broker Explorer, or run the **mqsichangebroker** command, specifying the parameter **-s active**. For example, to enable security for the broker MB7BROKER, enter the following command:

      ```
      mqsichangebroker MB7BROKER -s active
      ```

      The broker creates a queue for each defined execution group, with a name that conforms to the format SYSTEM.BROKER.AUTH.*EG*, where *EG* is the name of the execution group. It assigns default permissions of inquire, put, and set authority to the queue, which grants read, write, and execute access to the execution group and its properties, for the mqbrkrs group. These queues, and the broker authorization queue SYSTEM.BROKER.AUTH, are now ready for use.

      The names of queues that are generated for your execution groups might not match exactly the name of the execution groups, because WebSphere MQ enforces some restrictions on the authorization queue names. For details of these restrictions, and the possible effects, see "Authorization queues for broker administration security" on page 366.

c. Start the broker in the WebSphere Message Broker Explorer, or run the **mqsistart** command.

3. Check that the user ID under which your broker is running is a member of the WebSphere MQ security group mqm. Without this authority, the broker cannot create or delete the authorization queues for execution groups at run time.

   Because mqm authority grants full access control to all WebSphere MQ resources, you might not want your broker running with this level of authority. If you do not want the broker to run with mqm authority, you must work with your WebSphere MQ administrator to ensure that the required queues are created (and deleted) at the appropriate time.

   If you want to give your broker mqm authority:

   - On Linux and UNIX systems, add to mqm the user ID that started the broker.
   - On Windows, add to mqm the user ID that you specified as the service user ID. When you add this user ID, the same level of authority is granted to all user IDs defined in the same primary group. You must therefore control carefully your group memberships to ensure that access is not granted to user IDs that do not require it.
   - On z/OS, grant equivalent permissions to the started task user ID.

4. Check also that the user ID associated with the broker, defined in the previous step, has WebSphere MQ altuser authority. This authority is required by the broker to request WebSphere MQ to check authorities.

   Display registry entries for a broker by using **mqsireportbroker** *brokerName*.

What to do next

Next: Grant authority to users to reflect what tasks you want them to be able to complete, by populating the queues with the appropriate details. This task is described in "Authorizing users for broker administration" on page 371.

Authorizing users for broker administration

Grant authority to one or more groups or users to authorize them to complete specific tasks against a broker and its resources.

About this task

You must activate broker administration security before you can grant or revoke permissions for specific user IDs. When you first activate security, you must set up initial control for each user to authorize them to perform certain operations. You can then grant additional authority, revoke permissions, as required.

You can grant authorities to individual principals (user IDs), to groups of users, or both, on all platforms:

- If you grant a group or a user ID authority at the broker level (on queue SYSTEM.BROKER.AUTH), it does not inherit authority for execution groups. You must explicitly grant authority to all, or to individual, execution groups.
- On Linux and UNIX, you can authorize both principals and groups, but if you specify a principal, you must grant authority to the primary group to which that principal belongs.
- If a user ID is a member of the WebSphere MQ security group mqm, it automatically has authority to all WebSphere MQ objects.
- On Windows, if a user ID is a member of the security group Administrators, it automatically has authority to all WebSphere MQ objects.

When you change authorizations on a queue, the broker accesses the updated values the next time that a request is processed. You do not have to stop and restart the broker.

If you update user ID or group membership by using the operating system facilities on the platform on which the broker queue manager is running, you must ensure that the queue manager is aware of these changes. Select the option **Refresh Authorization Service** in the WebSphere MQ Explorer to notify the queue manager of the updated status.

The authority that is required depends on the requirements of the user:

- "Required authority for administrators" on page 372
- "Required authority for users who connect to the broker" on page 372
- "Required authority for developers" on page 373

The way in which you set up the required authorities differs by platform:

- "Granting and revoking authority on Linux, UNIX, and Windows systems" on page 374
- "Granting and revoking authority on z/OS systems" on page 376

These platform-specific topics also give examples of command usage for viewing what authorizations are in place by using the WebSphere MQ **dspmqaut** command, and for dumping this information by using the **dmpmqaut** command.

Required authority for administrators:
About this task

When you activate administration security, the WebSphere MQ permissions for inquire, put, and set are granted for the group mqbrkrs for the queue SYSTEM.BROKER.AUTH. These permissions grant read, write, and execute authority on the broker and its properties to all user IDs that are members of mqbrkrs.

If you want additional user IDs to have administrator authorization, either add those IDs to the group mqbrkrs, or add WebSphere MQ permissions for inquire, put, and set for those user IDs to this queue.

The following table summarizes the WebSphere MQ permissions that are required:

Object	Name	Permissions
Queue manager	The queue manager associated with the broker; for example, MB7QMGR	Connect Inquire
Queue	SYSTEM.BROKER.DEPLOY.QUEUE	Put
Queue	SYSTEM.BROKER.DEPLOY.REPLY	Get Put
Queue	SYSTEM.BROKER.AUTH	Inquire Put Set
Queue	SYSTEM.BROKER.AUTH.*EG*	Inquire Put Set

For more information about permissions on authorization queues, see "Broker permissions and equivalent WebSphere MQ permissions" on page 365 and "Tasks and authorizations for broker administration security" on page 3645.

Required authority for users who connect to the broker:
About this task

If a user or application wants to connect to a broker, you must grant them the appropriate permissions. All applications written to the CMP API, and users of the WebSphere Message Broker Explorer and the WebSphere Message Broker Toolkit, require permissions based on their expected actions. The following table shows the WebSphere MQ permissions that are required:

Object	Name	Permissions
Queue manager	The queue manager associated with the broker; for example, MB7QMGR	Connect Inquire
Queue	SYSTEM.BROKER.DEPLOY.QUEUE	Put
Queue	SYSTEM.BROKER.DEPLOY.REPLY	Get Put
Queue	SYSTEM.BROKER.AUTH	Inquire[1]
Queue	SYSTEM.BROKER.AUTH.*EG*	Inquire[1]

Notes:

1. Users and applications can connect to the broker without this level of authority, but are unable to request actions against the broker, including viewing properties.

Required authority for developers:
About this task

If your users are working with existing execution groups, and development resources such as BAR files, add the WebSphere MQ permissions inquire, put, and set for those users to one or more SYSTEM.BROKER.AUTH.*EG* queues (where *EG* is the name of the execution group).

When you run a broker with administration security enabled, you might need to restrict the names and the length of the names that you give to your execution groups, because WebSphere MQ enforces some restrictions on the authorization queue names. For details of these restrictions, and the possible effects, see "Authorization queues for broker administration security" on page 366.

Granting and revoking authority on Linux, UNIX, and Windows systems:

Grant or revoke authority to one or more groups or users to complete specific tasks against a broker running on Linux, UNIX, or Windows.

Before you begin

Before you start:

Activate broker administration security for the broker before you grant and revoke authority for requests sent to that broker.

About this task

Use WebSphere MQ commands to set up and manage your required security levels. If you prefer, you can make authorization changes to the security queues by using the WebSphere MQ Explorer.

For security reasons, it is important that authorities are set correctly. The **setmqaut** command grants and revokes authorities cumulatively. Therefore, to avoid retaining unwanted pre-existing authorities, it is helpful to set authorities explicitly on each **setmqaut** command, rather than granting and revoking individual authorities. Granting and revoking is achieved by specifying "`-all`" (to remove all authorities) followed by the required authorities.

The following command grants execute authority and retains any pre-existing authorities:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 +set
```

The following command grants execute authority only and does not retain pre-existing authorities:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set
```

Multiple authorities can also be set in this manner. For example, the following command grants execute and write authorities only (and not retain pre-existing authorities):

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set +put
```

It is also helpful to use the **dspmqaut** command after each **setmqaut** command, to check that authorities have been correctly set.

For further information about the commands shown in the following examples, and for details of the parameters, see the WebSphere MQ Version 7 Information Center online.

Examples

All the examples shown here are for a broker that is associated with the queue manager `test`.

Grant only execute authority to the broker to the user IDs that are defined in the group group1:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1 -all +set
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group1
```

Grant only execute and write authority to the broker to the user IDs that are defined in the group group2:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2 -all +set +put
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2
```

Revoke execute authority from the user IDs that are defined in the group group2:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2 -set
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH -g group2
```

Using a generic WebSphere MQ profile on a UNIX system, grant only write authority for all execution groups for the user IDs that are defined in the group group3:

```
setmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3 -all +put
dspmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3
```

Note: You enclose generic profile names in quotes on UNIX and Linux systems. For more information see the WebSphere MQ Version 7 Information Center online and search for the "Using OAM generic profiles on UNIX systems and Windows" topic.

Using a generic WebSphere MQ revoke write authority on a UNIX system for all execution groups for the user IDs that are defined in the group group3:

```
setmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3 -all –put
dspmqaut -m test -t queue -n "SYSTEM.BROKER.AUTH.**" -g group3
```

Grant only read authority for a specific execution group called `default` for group group4:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group4 -all +inq
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group4
```

Revoke execute and write authority for a specific execution group called `default` for group group5:

```
setmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group5 -set -put
dspmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.default -g group5
```

Using a generic WebSphere MQ on a non-UNIX system, dump all WebSphere MQ authorities for all execution groups:

```
dmpmqaut -m test -t queue -n SYSTEM.BROKER.AUTH.**
```

Granting and revoking authority on z/OS systems:

Grant or revoke authority to one or more groups or users to complete specific tasks against a broker running on z/OS.

Before you begin

Before you start:

Activate broker administration security for the broker before you grant and revoke authority for requests sent to that broker.

About this task

Configure the external security manager (ESM) that you are using with WebSphere MQ to grant the required permissions on z/OS systems. For example, if you are using RACF, set up profiles to hold the information required for WebSphere MQ security checking. The examples in this topic assume that you are using RACF.

Complete the following steps:

Procedure

1. Activate security on the queue manager that is associated with the broker.
2. Activate queue security on the same queue manager:
   - If you use uppercase profiles, you must define profiles in `MQQUEUE (Member Class)` or `GMQQUEUE (Group Class)`.
   - If you use mixed case profiles, you must define profiles in `MXQUEUE (Member Class)` or `GMXQUEUE (Group Class)`.

   For example:
   - Define the broker profile for queue manager `MQ01`:
     ```
     RDEFINE MQQUEUE MQ01.SYSTEM.BROKER.AUTH UACC(NONE)
     ```
   - Define the profile for all execution groups on queue manager `MQ01`:
     ```
     RDEFINE MXQUEUE MQ01.SYSTEM.BROKER.AUTH.** UACC(NONE)
     ```
   - Define a profile for the specific execution group called `default` for queue manager `MQ01`:
     ```
     RDEFINE MXQUEUE MQ01.SYSTEM.BROKER.AUTH.default UACC(NONE)
     ```
3. Activate the WebSphere MQ class so that security checks can be made by the broker. For example, activate the class `MQQUEUE`:
   ```
   SETROPTS CLASSACT(MQQUEUE)
   ```

4. Define WebSphere MQ permissions. The mapping between broker permissions, associated WebSphere MQ permissions, and associated RACF access levels is shown in the following table.

Broker permission	WebSphere MQ permission	RACF access level
Read	Inquire	READ
Write	Put	UPDATE
Execute	Set	ALTER

Examples

All the examples shown here are for a broker that is associated with the queue manager `MQ01`.

Add execute permission for group GROUP1 to the broker:

```
PERMIT MQ01.SYSTEM.BROKER.AUTH CLASS(MQQUEUE) ID(GROUP1) ACCESS(ALTER)
```

Remove broker execute permission to the broker for group GROUP2:

```
PERMIT MQ01.SYSTEM.BROKER.AUTH CLASS(MQQUEUE) ID(GROUP2) ACCESS(ALTER) DEL
```

Add write permission to all execution groups for group GROUP3:

```
PERMIT MQ01.SYSTEM.BROKER.AUTH.** CLASS(MXQUEUE) ID(GROUP3) ACCESS(UPDATE)
```

Remove write permission to all execution groups for group GROUP4:

```
PERMIT MQ01.SYSTEM.BROKER.AUTH.** CLASS(MXQUEUE) ID(GROUP4) DEL
```

Add read permission to a specific execution group called `default` for group GROUP5:

```
PERMIT MQ01.SYSTEM.BROKER.AUTH.default CLASS(MXQUEUE) ID(GROUP5) ACCESS(READ)
```

The following JCL file shows one way in which you can check the RACF permissions that you have set for the broker `MQTEST`:

```
//RACFDUMP JOB ,MQTEST,USER=MQTEST,TIME=1,MSGCLASS=H
//STEP1 EXEC PGM=IKJEFT01,REGION=64M,DYNAMNBR=99
//SYSTSPRT DD SYSOUT=*
//SYSTSIN  DD *
 /* LIST ALL EXISTING PROFILES IN THE MQADMIN CLASS */

Disabling broker administration security

Disable broker administration security to remove control over a broker and its resources.

About this task

You can disable administrative security for a broker by updating the relevant broker property.

Procedure

1. Stop the broker in the WebSphere Message Broker Explorer, or run the **mqsistop** command.

2. Clear the security option for this broker in the WebSphere Message Broker Explorer, or run the **mqsichangebroker** command, specifying the parameter **-s inactive**. For example, to disable security for the broker MB7BROKER, enter the following command:

   ```
   mqsichangebroker MB7BROKER -s inactive
   ```

3. Start the broker in the WebSphere Message Broker Explorer, or run the **mqsistart** command.

Results

When this command completes, all users are able to complete tasks against the broker; for example, they can run the **mqsichangeproperties** command to change broker properties. They can also complete all tasks against all execution groups that have been defined, and are defined in the future, on this broker.

When you disable broker administration security, the authorization queues that are associated with this broker are retained. If you enable security again, these queues are reused, therefore you must ensure that the authorizations defined by these queues are correct.

Activating broker administration security for WebSphere MQ Version 7.1, or later

Describes how to enable channel authentication security and the effect of this on a broker queue manager.

About this task

When you create a broker, if the WebSphere MQ queue manager does not exist, the queue manager is automatically created. If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel authentication security will be automatically disabled.

If more precise control over the access granted to connecting systems is required at a channel level, channel authentication security can be enabled. For more details, see WebSphere MQ Version 7.1 Channel authentication records

To enable channel authentication security in order to start using channel authentication records you must run this MQSC command:

```
ALTER QMGR CHLAUTH(ENABLED
```

Once enabled, there will be consequences for any channel based communication with a broker. However, this should not affect any privileged or non-privileged user from accessing local brokers. See following table for a definition of privileged users who have full administrative authorities:

Table 7. . Privileged users by platform.

Platform	Privileged users
Windows systems	• SYSTEM • Members of the mqm group • Members of the Administrators group
UNIX and Linux systems	• Members of the mqm group

Privileged or non-privileged users wanting to remotely administer a broker by means of `CMP/API/MBX/Toolkit` must run the following commands in order to grant their user access:

Procedure

1. Enable remote administration on Queue Manager
2. `setmqaut -m` *`QMNAME`* `-n SYSTEM.MQEXPLORER.REPLY.MODEL -t queue -p` *`username`* `+dsp +inq +put +get`
3. `SET CHLAUTH('SYSTEM.BKR.CONFIG')TYPE(ADDRESSMAP)ADDRESS('address-of-machine-who-is-allowed')MCAUSER('NonPrivilegedUser')ACTION(ADD)`

   Where 'NonPrivilegedUser' is a user defined on the remote machine.

What to do next

The rule would need to be set up for any ip-address wanting to administer the broker remotely.

Control the actions that users can request against a broker and its resources.

"Setting up z/OS security" on page 556
On z/OS, you must complete several security configuration tasks before WebSphere Message Broker can work correctly.

Message flow security overview

WebSphere Message Broker provides a security manager, which enables you to control access to individual messages in a message flow, using the identity of the message.

You can configure the broker to perform end-to-end processing of an identity carried in a message through a message flow. This capability enables you to configure security for a message flow, allowing you to control access based on the identity associated with the message and providing a security mechanism that is independent of both transport type and message format.

If you do not enable message flow security, the default security facilities in WebSphere Message Broker are based on the facilities provided by the transport mechanism. In this case, the broker processes all messages that are delivered to it, using the broker service identity as a proxy identity for all message instances. Any identity that is present in the incoming message is ignored.

Instead of delegating this authority to the transport mechanism, the security manager enables the broker to:

- Extract the identity from an inbound message
- Authenticate the identity (using an external security provider)
- Map the identity to an alternative identity (using an external security provider)
- Check that either the alternative identity or the original identity is authorized to access the message flow (using an external security provider)
- Propagate either the alternative identity or the original identity with an outbound message.

The security functions that are associated with a message flow are controlled by using "Security profiles" on page 387, which are created by the broker administrator and accessed by the security manager at run time. The following external security providers (also known as Policy Decision Points or PDPs) are supported:

- WS-Trust V1.3 compliant security token servers (including TFIM V6.2) for authentication, mapping, and authorization
- Tivoli Federated Identity Manager (TFIM) V6.1 for authentication, mapping, and authorization
- Lightweight Directory Access Protocol (LDAP) for authentication and authorization

You can invoke message flow security by configuring either a security enabled input node or a SecurityPEP node. The SecurityPEP node enables you to invoke the message flow security manager at any point in the message flow between an input node and an output (or request) node.

For an overview of the sequence of events that occur when the message flow security manager is invoked using either a security enabled input node or a SecurityPEP node, see the following topics:

- "Invoking message flow security using a security enabled input node" on page 406
- "Invoking message flow security using a SecurityPEP node" on page 411

The input nodes that support message flow security are:

- MQInput
- HTTPInput
- SCAInput
- SCAAsyncResponse
- SOAPInput

However, the support for treating security exceptions as normal exceptions is provided by only the MQInput, HTTPInput, SCAInput, and SCAAsyncResponse nodes; it is not available in the SOAPInput node.

The output nodes that support identity propagation are:

- MQOutput
- HTTPRequest
- SCARequest
- SCAAsyncRequest
- SOAPRequest
- SOAPAsyncRequest

If the message flow is a Web Service that is implemented by using the "SOAP nodes" on page 1609, the identity can be taken from the "WS-Security" on page 765 header tokens that are defined through appropriate "Policy sets" on page 774 and bindings.

To improve performance, the authentication, authorization, and mapping information from the configured providers is cached for reuse. You can use the

mqsireloadsecurity command to reload the security cache, and you can use the **mqsichangeproperties** command to set the expiry and sweep intervals for the security cache.

For a SOAPRequest and SOAPAsyncRequest node, an appropriate policy set and bindings can be defined to specify how the token is placed in the WS-Security header (rather than the underlying transport headers). For more information, see "Policy sets" on page 774.

The following topics in this section provide more detailed information about message flow security:

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

"MQOutput node" on page 4612
Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

Security profiles

A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

Security profiles are configured by the broker administrator before deploying a message flow, and are accessed by the security manager at run time.

A security profile allows a broker administrator to specify whether identity and security token propagation, authentication, authorization, and mapping are performed on the identity or security tokens associated with messages in the message flow, and if so, which external security provider (also known as a Policy Decision Point or PDP) is used. IBM Tivoli Federated Identity Manager (TFIM) V6.1, and WS-Trust v1.3 compliant security token servers (including TFIM V6.2), are supported for authentication, authorization, and mapping. Lightweight Directory Access Protocol (LDAP) is supported for authentication and authorization.

Security profiles apply to the SecurityPEP node and to security enabled input, output, and request nodes, and are configured by the administrator at deployment time in the Broker Archive editor. These nodes have a **Security Profile** property (in the Broker Archive editor), which can be left blank, set to *No Security*, or set to a specific security profile name. Set *No Security* to explicitly turn off security for the node. If you leave the **Security Profile** property blank, the node inherits the **Security Profile** property that is set at the message flow level. If you leave the **Security Profile** property blank at both levels, security is turned off for the node. When this property is set to the name of a specific security profile, that profile determines what message flow security is configured. If the named security profile does not exist in the run time, the message flow fails to deploy. If the specified external security provider does not support the type of token configured on the node for the security operation, an error is reported and the message flow fails to deploy.

The security profile also specifies whether propagation is required. A pre-configured profile that specifies propagation is provided for use by output and request nodes. This profile is the *Default Propagation* security profile. This profile can also be used on an input node to extract tokens and put them into the message tree ready for propagation or processing in a SecurityPEP node.

Security profiles contain values for the following properties:

authentication
Defines the type of authentication that is performed on the source identity.

This property applies only to SecurityPEP nodes and input nodes. For more information, see “Authentication and validation” on page 398.

authenticationConfig
Defines the information that the broker needs to connect to the provider, and the information needed to look up the identity tokens. It is a provider-specific configuration string. This property applies only to SecurityPEP nodes and input nodes.

mapping
Defines the type of mapping that is performed on the source identity. This property applies only to SecurityPEP nodes and input nodes. For more information, see “Identity mapping” on page 403.

mappingConfig
Defines how the broker connects to the provider, and contains additional information required to look up the mapping routine. It is a provider-specific configuration string. This property applies only to SecurityPEP nodes and input nodes.

authorization
Defines the types of authorization checks that are performed on the mapped or source identity. This property applies only to SecurityPEP nodes and input nodes. For more information, see “Authorization” on page 401.

authorizationConfig
Defines how the broker connects to the provider, and contains additional information that can be used to check access (for example, a group that can be checked for membership). It is a provider-specific configuration string. This property applies only to SecurityPEP nodes and input nodes.

passwordValue
Defines how passwords are treated when they enter a message flow. If *PLAIN* is selected, the password appears in the Properties folder in plain text. If *OBFUSCATE* is selected, the password appears in the Properties folder in base64 encoding. If *MASK* is selected, the password appears in the Properties folder as four asterisks (****). This property applies only to SecurityPEP nodes and input nodes.

Propagation
Enables or disables identity propagation on output and request nodes. On the security enabled input nodes, you can choose to select only identity propagation, without specifying any other security operations, to make the extracted incoming identity or security token available for use in the other nodes in the message flow, such as output or request nodes. For more information, see “Identity and security token propagation” on page 426.

For information on configuring a security profile for LDAP, TFIM, or a WS-Trust v1.3 compliant security token server (STS), see “Creating a security profile” on page 433.

Related concepts:

“Identity” on page 390
In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

“Authentication and validation” on page 398
Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. Applying authentication to a SAML security token involves validating the assertions that it carries and confirming that it is

being processed within its validity period.

"Identity mapping" on page 403
Identity mapping is the transformation of a security token from one format to another format, or the federation of an identity from one realm to an equivalent identity in another realm.

"Authorization" on page 401
Authorization is the process of verifying that an identity token has permission to access a message flow.

"Identity and security token propagation" on page 426
Identity and security token propagation enables the identity and security tokens (associated with each message) to be propagated throughout a message flow, and on to target applications through output or request nodes.

Related tasks:

"Configuring the extraction of an identity or security token" on page 447
You can configure the SecurityPEP node or security enabled input nodes to extract the identity or security token from a message and store it in the properties tree identity fields, enabling it to be processed throughout the message flow and propagated at output or request nodes.

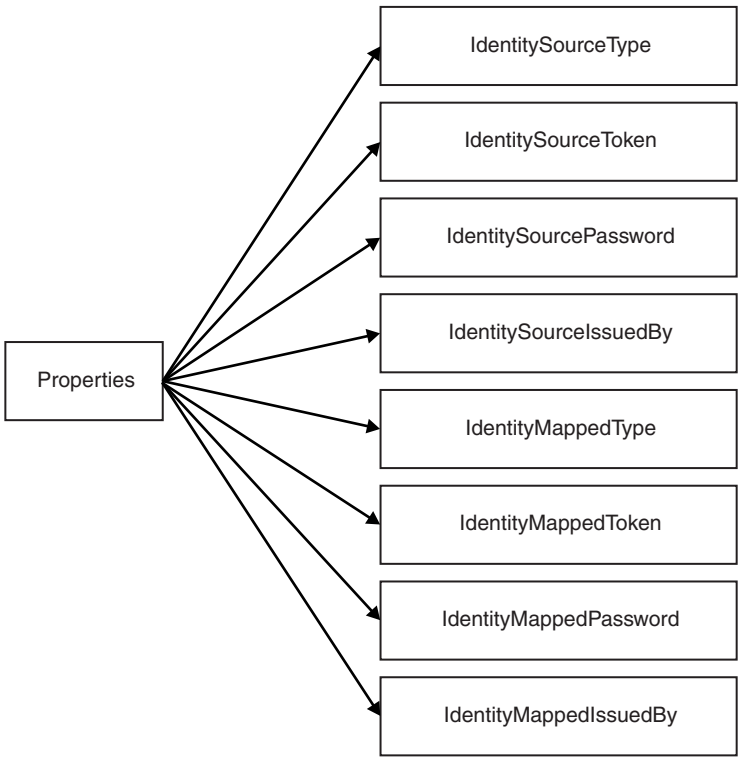
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

Identity

In WebSphere Message Broker, an identity is a security token that uniquely identifies an individual, or that provides a set of assertions that can be validated.

When a SecurityPEP node or a supported input node is configured with a security profile, the extracted identity is held in the broker as eight properties in the Properties folder of the message tree structure. These properties define two identities in the broker: source and mapped. For both the source and mapped identities, values are held for **Type**, **Token**, **Password**, and **IssuedBy** properties:



The **Identity token type** property on the security-enabled input nodes can be set to a value of *Transport Default*, which causes the token type to be created from the default identity header or fields of the transport. For WebSphere MQ, *Transport Default* provides an identity type of *Username*. For HTTP, *Transport Default* provides an identity type of *Username and Password*. The Identity token type property on the SecurityPEP node can be set to *Current Token*, which enables it to use the identity in the Properties folder fields instead of extracting a new identity from the message.

The following table shows the support that is provided (by the message flow security manager and external security providers) for the extraction of different types of security token. For information about the token types that are supported for identity propagation, see “Identity and security token propagation” on page 426.

Table 8. Support for security token types - token extraction

Token type (format)	Broker security manager support for token extraction	External security provider support
Username	Username tokens are supported for extraction by the following nodes: • HTTPInput • MQInput • SCAInput • SCAAsyncResponse • SecurityPEP • SOAPInput The token is obtained from one of the following transport headers: • MQ – From MQMD user ID • HTTP – From HTTP BasicAuth header containing only a username part • SOAP – From a WS-Security UsernameToken header. The policy set and binding (associated with the SOAP node) must define a username profile, and the wsse:UsernameToken must contain only a `wsse:Username` element. – From the Kerberos subject in a WS-Security header. The policy set and binding (associated with the SOAP node) must define a Kerberos profile. – From the HTTP BasicAuth header containing only a username part if no policy set is defined on the SOAP node. Alternatively, the token can be taken from any part of the message tree when the token location is specified (on the node) using an XPath expression or ESQL field path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *username*.	LDAP: Authorization

Table 8. Support for security token types - token extraction (continued)

Token type (format)	Broker security manager support for token extraction	External security provider support
Username and password or Username and RACF PassTicket	Username and password tokens are supported for extraction by the following nodes: • HTTPInput • MQInput • SCAInput • SecurityPEP • SCAAsyncResponse • SOAPInput The token is obtained from one of the following transport headers: • HTTP – From HTTP BasicAuth header containing both a username and password part • SOAP – From a WS-Security UsernameToken header. The policy set and binding (associated with the SOAP node) must define a username profile and the wsse:UsernameToken must contain both `wsse:Username` and `wsse:Password` elements. – From the HTTP BasicAuth header containing only a username part if no policy set is defined on the SOAP node Alternatively, the token can be obtained from any part of the message tree when the token location is specified (on the node) using an XPath expression or ESQL path. The password token can carry either a clear text password or a RACF PassTicket. If you are using a WS-Trust V1.3 STS (such as TFIM V6.2), you can use it to map (issue) or validate RACF PassTickets, by specifying the token type as *Username and password*. This support is available with security enabled input nodes and SecurityPEP nodes. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or	LDAP: • Authentication • Authorization TFIM V6.1: • Authentication • Mapping • Authorization WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization

Table 8. Support for security token types - token extraction (continued)

Token type (format)	Broker security manager support for token extraction	External security provider support
SAML assertion	SAML tokens are supported for extraction by the following nodes: • SecurityPEP • MQInput • HTTPInput • SCAInput • SCAAsyncResponse • SOAPInput The token is obtained from one of the following places: • SOAP – From a WS-Security header. The policy set and binding (associated with the SOAP node) must define a SAML profile. • Any part of the message tree when the token location is specified using an XPath expression or ESQL path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *SAML*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization

Table 8. Support for security token types - token extraction (continued)

Token type (format)	Broker security manager support for token extraction	External security provider support
Kerberos GSS v5 AP_REQ	Kerberos tickets are supported for processing by the message flow security manager from the SecurityPEP node. A WS-Security Kerberos token profile is supported by the following SOAP nodes, but in this case, the Kerberos Key Distribution Center is communicated with directly, and the properties folder is populated with a Username token representing the Kerberos subject: • SOAPInput The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *kerberosTicket*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization
LTPA v2 token	LTPA tokens are supported for extraction by the following nodes: • SecurityPEP • SOAPInput The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *LTPA*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization

Table 8. Support for security token types - token extraction (continued)

Token type (format)	Broker security manager support for token extraction	External security provider support
X.509 Certificate	X.509 tokens are supported for extraction by the following nodes: • SecurityPEP • MQInput • HTTPInput • SCAInput • SCAAsyncResponse • SOAPInput The token is obtained from one of the following places: • SOAP – From a WS-Security header. The policy set and binding (associated with the SOAP node) must define an X.509 profile. • Any part of the message tree when the token location is specified using an XPath expression or ESQL path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *X.509*.	TFIM V6.1: • Authentication • Mapping • Authorization. WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization.
Universal WSSE token	Universal WSSE tokens are supported for extraction by the SecurityPEP node only. The token is obtained from any part of the message tree at a SecurityPEP node, if the token location is specified using an XPath expression or ESQL path. The literal string value used by the broker (and which you can use to specify the token type in an ESQL or Java program) is *UniversalWsse*.	WS-Trust V1.3 STS (including TFIM V6.2): • Authentication • Mapping • Authorization.

The source identity is set by the SecurityPEP or input node only if a security profile is associated with the node. The information to complete these fields is typically found in the headers of a message but can also be located in the body (provided that the node has been configured with an ESQL Path or XPath reference for the various properties). If multiple identities are available (for example, if you are using message aggregation), the first identity is used. The token extraction is transport specific and can be performed only using transports that support the

flow of identities. These transports are: Websphere MQ, HTTP(S), and SOAP. See "MQInput node" on page 4594 and "HTTPInput node" on page 4474 for more information.

You can modify the values in the properties (for example, from ESQL), but do not write to the *IdentitySource** values. For example, you can create a custom identity mapping routine in ESQL or Java by using the *IdentitySource** values to create custom *IdentityMapped** values.

SAML and Universal WSSE tokens are stored in the Properties tree IdentitySourceToken or IdentityMappedToken field as a character bit stream. To access this data as a message tree, parse it into a suitable parser, such as XMLNSC:

```
-- Parse the mapped SAML2.0 token in the properties folder and set it in the message body
   CREATE LASTCHILD OF OutputRoot DOMAIN('XMLNSC') PARSE(InputRoot.Properties.IdentityMappedToken,
   InputProperties.Encoding, InputProperties.CodedCharSetId);
```

To set either SAML or Universal WSSE tokens into the properties fields, you must obtain the bit stream of a tree; for example, by using the ESQL `ASBITSTREAM` function.

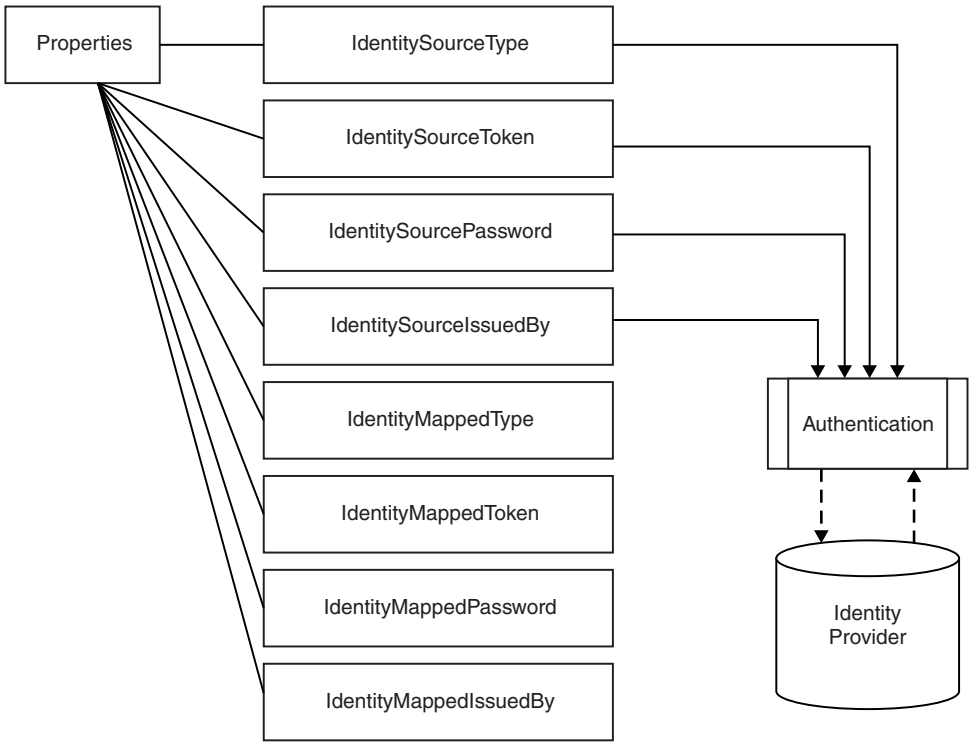
Authentication and validation

Authentication is the process of establishing the identity of a user or system and verifying that the identity is valid. Applying authentication to a SAML security token involves validating the assertions that it carries and confirming that it is being processed within its validity period.

In WebSphere Message Broker message flow security, authentication involves the security manager passing the identity type and token to an external security provider. For more information about security tokens, see "Identity" on page 390.



The following external security providers (also known as Policy Decision Points) are supported for authentication:

- Lightweight Directory Access Protocol (LDAP)
- Tivoli Federated Identity Manager (TFIM) V6.1
- WS-Trust V1.3 security token servers (STS), including TFIM V6.2

The external security provider checks the identities and returns a value to confirm whether the identity is authentic. If the identity is not authentic, a security exception is raised.

Some identity providers support only a single type of authentication token. If a token of another type is passed into the message flow, an exception is raised. For example, LDAP supports only a *Username and password* token.

You can use an LDAP provider for the authentication of an incoming identity token. The LDAP server must be LDAP Version 3 compliant.

Alternatively, you can use a WS-Trust v1.3 STS provider (for example, TFIM Version 6.2) for the authentication of an incoming identity or security token. The security manager invokes the WS-Trust v1.3 provider once, even if it is set for additional security operations (such as mapping or authorization). As a result, when you are using TFIM, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

For more information about using TFIM V6.2 for authentication, see "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

TFIM V6.1 is also supported, for compatibility with previous versions of WebSphere Message Broker. For more information about using TFIM V6.1 for authentication, see "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 416.

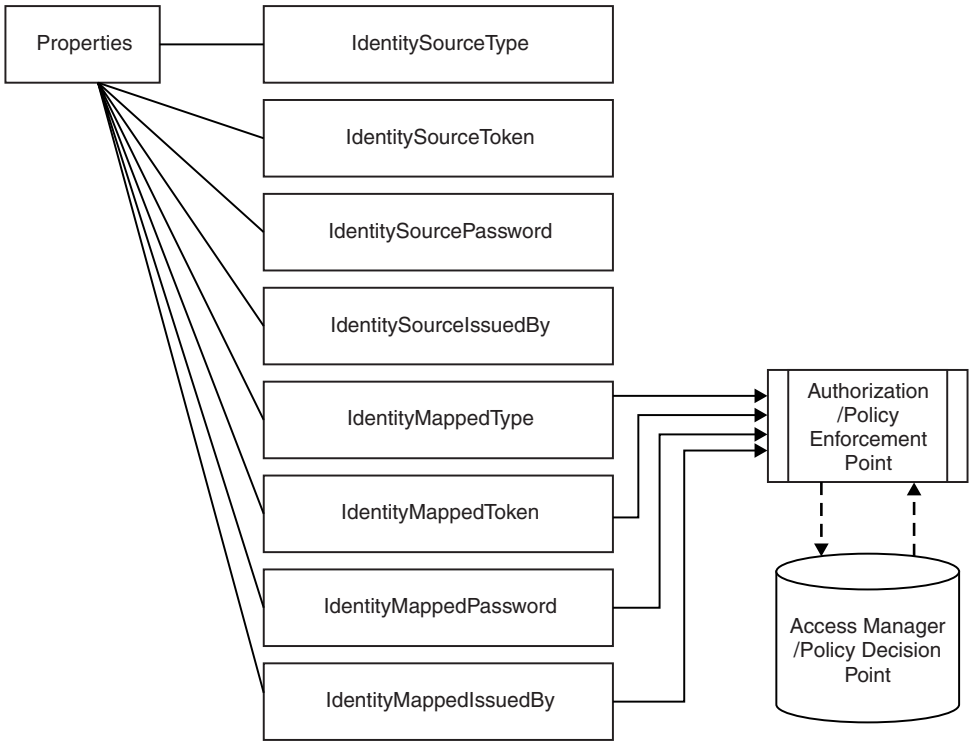
"SecurityPEP node" on page 4729
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

Authorization

Authorization is the process of verifying that an identity token has permission to access a message flow.

If authentication and mapping are configured, they are used to verify the identity before it is authorized.



If a mapped identity exists, authorization is applied to the mapped identity. If a mapped identity does not exist, the source identity is used.

If you specify LDAP as the provider for authorization, the security manager queries the configured LDAP server (which must be LDAP Version 3 compliant), to validate that the identity is a member of the LDAP group that is configured in the security profile.

If you specify *WS-Trust v1.3 STS* as the provider for authorization, the security manager invokes the security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to validate that the identity token provided has permission to access the message flow. If you are using TFIM V6.1 rather than TFIM V6.2, you can specify *TFIM* as the provider for authorization.

For more information about using TFIM V6.2 for authorization, see "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

For information about using TFIM V6.1 for authorization, see “Authentication, mapping, and authorization with TFIM V6.1 and TAM” on page 416.

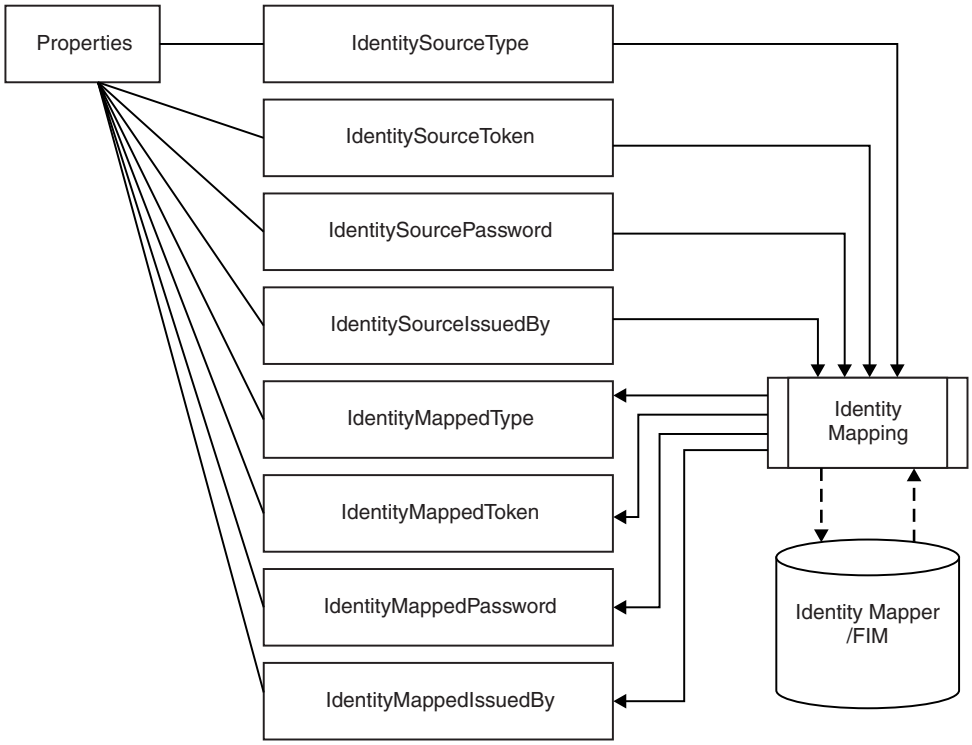
Identity mapping

Identity mapping is the transformation of a security token from one format to another format, or the federation of an identity from one realm to an equivalent identity in another realm.



WebSphere Message Broker provides support for identity mapping (also known as identity federation) and token issuance and exchange. Identity mapping is the process of mapping an identity in one realm to another identity in a different realm. For example, you might map *User001* from the eSellers realm to *eSellerUser01* in the eShipping realm. Token issuance and exchange involves the mapping of a token of one type to a token of a different type. For example, an incoming Username and Password token from a client over MQ might be mapped into an equivalent SAML assertion, to be propagated to a Web Services call. Alternatively, you might exchange a SAML 1.1 assertion from a client application for an equivalent SAML 2.0 assertion for an updated backend server.

Mapping using a WS-Trust provider

The WebSphere Message Broker security manager supports mapping operations through WS-Trust V1.3 compliant security token servers (STS), such as IBM Tivoli Federated Identity Manager (TFIM) V6.2. Mapping is performed for SecurityPEP nodes and input nodes that have an associated security profile that includes a mapping operation configured with a WS-Trust V1.3 STS.

WS-Trust V1.3 (TFIM V6.2) can also be selected for authentication and authorization in the profile. However, if more than one security operation is associated with the security profile, only one WS-Trust request is issued to the STS. As a result, the STS must be configured to perform all the required operations. For example, if a TFIM V 6.2 server is specified, the TFIM module chain that is invoked must include the appropriate validate, authorize, and issue modules. If you require each operation to be performed through a separate WS-Trust call, you must use a series of SecurityPEP nodes, each associated with a different security profile that is configured for only one security operation (authentication, authorization, or mapping).

If the security profile specifies only mapping with WS-Trust v1.3 STS, the request is sent with a request type of *Issue*, whereas a mixed set of security operations sends a request type of *Validate*. When mapping is included, the STS must return a token in its response, even if it is the original token; otherwise, an error occurs.

To provide compatibility with previous versions of WebSphere Message Broker, support is also provided for TFIM V6.1.

In the broker, identity mapping is performed at the input node or SecurityPEP node, after authentication but before authorization. The source identity is passed to an identity mapper for processing. If both mapping and authorization are configured, the authorization operation uses the mapped output token rather than the source token, which means that the authorization is performed on the federated identity.

Mapping is not performed in output nodes, even if the node has been configured with a security profile.

WebSphere Message Broker supports mapping between any type of security token that is supported by the configured security provider. For more information about the support provided, see “Identity” on page 390.

When mapping from an X.509 certificate, TFIM can validate the certificate but cannot verify the identity of the original sender. However, if it is required, this verification integrity check can be performed by the SOAPInput node. For more information, see “WS-Security mechanisms” on page 768.

For more information about using TFIM V6.2 for mapping, see “Authentication, mapping, and authorization with TFIM V6.2 and TAM” on page 419.

For information about using TFIM V6.1, see “Authentication, mapping, and authorization with TFIM V6.1 and TAM” on page 416.

User-defined mapping

When you develop a message flow, you can implement a custom token mapping to be used for identity propagation. For example, you can implement a custom token

mapping using a compute node (which can be a Compute, JavaCompute, or PHPCompute node) following the input node. In the compute node, you can read the source identity values from the Properties folder, process them, then write the new identity values to the mapped identity fields. If there is no identity provided in the message, you can still use a compute node to insert some identity credentials into the mapped identity fields. The mapped identity fields are then used in place of the source identity fields by subsequent nodes. Any security operations that are configured on the input node are performed using the source identity, before you can create a new identity in the mapped identity fields (by using the compute node). However, you can include a SecurityPEP node after your compute node has created a new mapped identity.

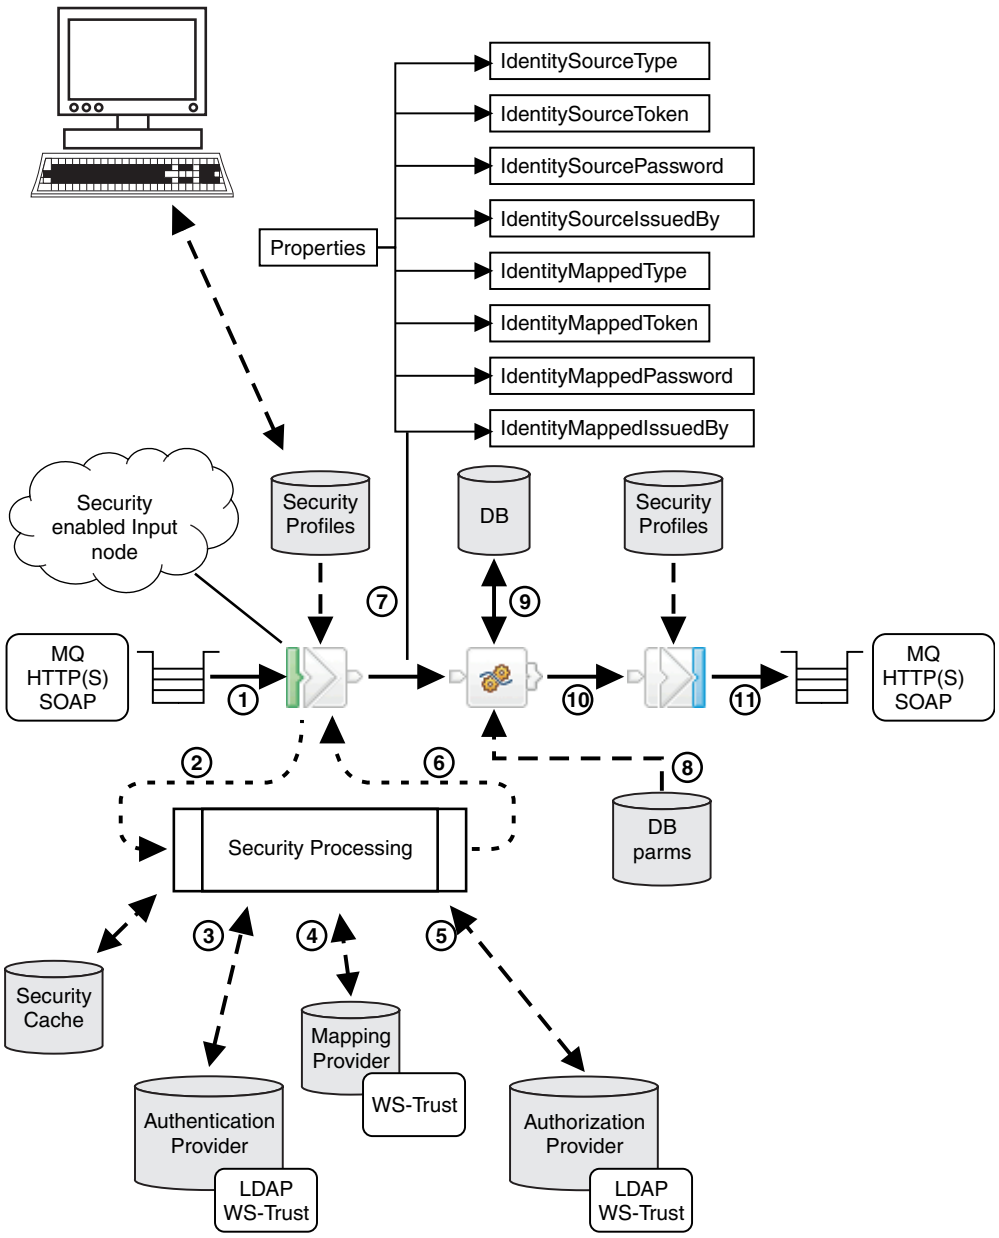
Invoking message flow security using a security enabled input node

You can invoke the message flow security manager by configuring a security enabled input node.

The following diagram shows an example message flow and gives an overview of the sequence of events that occur when an input message is received by a security enabled input node in the message flow:



The following steps explain the sequence of events that occur when a message arrives at a security enabled input node in the message flow. The numbers correspond to those in the preceding diagram:

1. When a message arrives at a security enabled input node (MQ, HTTP, SCA, or SOAP), the presence of a security profile associated with the node indicates whether message flow security is configured. SOAP nodes can implement some WS-Security capabilities without using the broker's security manager; for more information, see “Implementing WS-Security” on page 769. The broker's security manager is called to read the profile, which specifies the combination of propagation, authentication, authorization, and mapping to be performed with the identity of the message. It also specifies the external security provider (also known as the Policy Decision Point or PDP) to be used.

   You can create security profiles by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer. You then use the Broker Archive editor to configure

the security profile on either an individual node or the whole message flow. If you associate the security profile with the message flow, the security profile applies to all security enabled input and output nodes and SecurityPEP nodes in the message flow. However, a security profile that is associated with an individual node takes precedence over a security profile that is associated with the message flow. A predefined security profile, called *Default propagation*, is provided for setting identity propagation. To explicitly set no security on a node, set the security profile to *No security*.

2. If a security profile is associated with the node or message flow, the security enabled input node extracts the identity information from the input message (based on the configuration on the node's **Security** properties page) and sets the Source Identity elements in the Properties folder. If the security tokens cannot be successfully extracted, a security exception is raised.

   If you require a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity), you must also define and specify an appropriate policy set and bindings for the relevant token profile. For more information, see "Policy sets" on page 774.

   For MQ, HTTP, or SCA input nodes, the **Security** properties page is used to configure the extraction of the identity. This defaults to *Transport Default*. For example, an HTTPInput node extracts a username and password from the HTTP BasicAuth header. The **Security** properties page allows the Identity token type and its location to be explicitly configured to control the extraction. This source identity information can be in a message header, the message body, or both.

   For information about the tokens that are supported by each node, see "Identity" on page 390.

3. If authentication is specified in the security profile, the security manager calls the configured security provider to authenticate the identity. A failure results in a security exception being returned to the node. The security providers that are supported by Message Broker for authentication are LDAP, WS-Trust v1.3 compliant security token servers (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the authentication result, which enables subsequent messages (with the same credentials) arriving at the message flow to be completed with the cached result, provided that it has not expired.

4. If identity mapping is specified in the security profile, the security manager calls the configured security provider to map the identity to an alternative identity. A failure results in a security exception being returned to the node. Otherwise, the mapped identity information is set in the Mapped Identity elements in the Properties folder.

   The security providers that are supported by Message Broker for identity mapping are WS-Trust V1.3 compliant security token servers (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the result of the identity mapping.

   Alternatively, you can use a SecurityPEP node at any point in the message flow to map the identity that was authenticated at the security enabled input node. For more information, see "Invoking message flow security using a SecurityPEP node" on page 411.

5. If authorization is specified in the security profile, the security manager calls the configured security provider to authorize that the identity (either mapped or source) has access to this message flow. A failure results in a security exception being returned to the node.

The security providers that are supported by Message Broker for authorization are LDAP, WS-Trust V1.3 compliant security token servers (such as TFIM V6.2) and TFIM V6.1.

A security cache is provided for the authorization result.

Alternatively, you can use a SecurityPEP node at any point in the message flow to authorize the identity that was authenticated at the security enabled input node. For more information, see "Invoking message flow security using a SecurityPEP node" on page 411.

6. When all security processing is complete, or when a security exception is raised by the message flow security manager, control returns to the input node.

   When a security exception is returned to the security enabled input node, it performs the appropriate transport handling and ends the message flow transaction. For example, an HTTPInput node returns an HTTP header with a 401 HTTP response code, without propagating to an output terminal. A SOAPInput node returns a SOAP Fault, reporting the security exception. Alternatively, if the `Treat security exceptions as normal` property is set on the security enabled input node, a security exception is propagated to the node's Failure terminal. The security enabled input node propagates to its Out terminal only if all the configured operations in the associated security profile complete successfully.
7. The message, including the Properties folder and its source and mapped identity information, is propagated down the message flow.
8. At subsequent nodes in the message flow an identity might be required to access a resource such as a database. The identity used to access such a resource is a proxy identity, either the broker's identity or an identity configured for the specific resource by using the **mqsisetdbparms** command.
9. When you are developing a message flow you can use the identity fields in the Properties folder for application processing (for example, identity-based routing or content building based on identity). Also, as an alternative to invoking mapping through a WS-Trust V1.3 enabled STS (such as TFIM V6.2) or TFIM V6.1, you can set the mapped identity fields in a compute node, such as a Compute, JavaCompute, PHPCompute, or Mapping node.
10. When the message reaches a security enabled output or request node (MQOutput, HTTPRequest, SOAPRequest, or SOAPAsyncRequest), a security profile (with propagation enabled) associated with the node indicates that the current identity token is to be propagated when the message is sent.

    If the security profile indicates that propagation is required, the mapped identity is used. If the mapped identity is not set, or if it has a token type that is not supported by the node, the source identity is used. If no identity is set, or if neither the mapped nor source identity has a token type that is supported by the node, a security exception is returned to the node.

    SOAP nodes also require the appropriate policy set and bindings for the token profile to be associated with the node.

    If you want to include a security token in the message that is issued at an output node, and if the output node is not able to propagate that type of token, you can use a compute node (before the output node) to put the token from the properties tree into the relevant message location.

    For information about the tokens that are supported by each node, see "Identity and security token propagation" on page 426.
11. The propagated identity is included in the appropriate message header when it is sent.

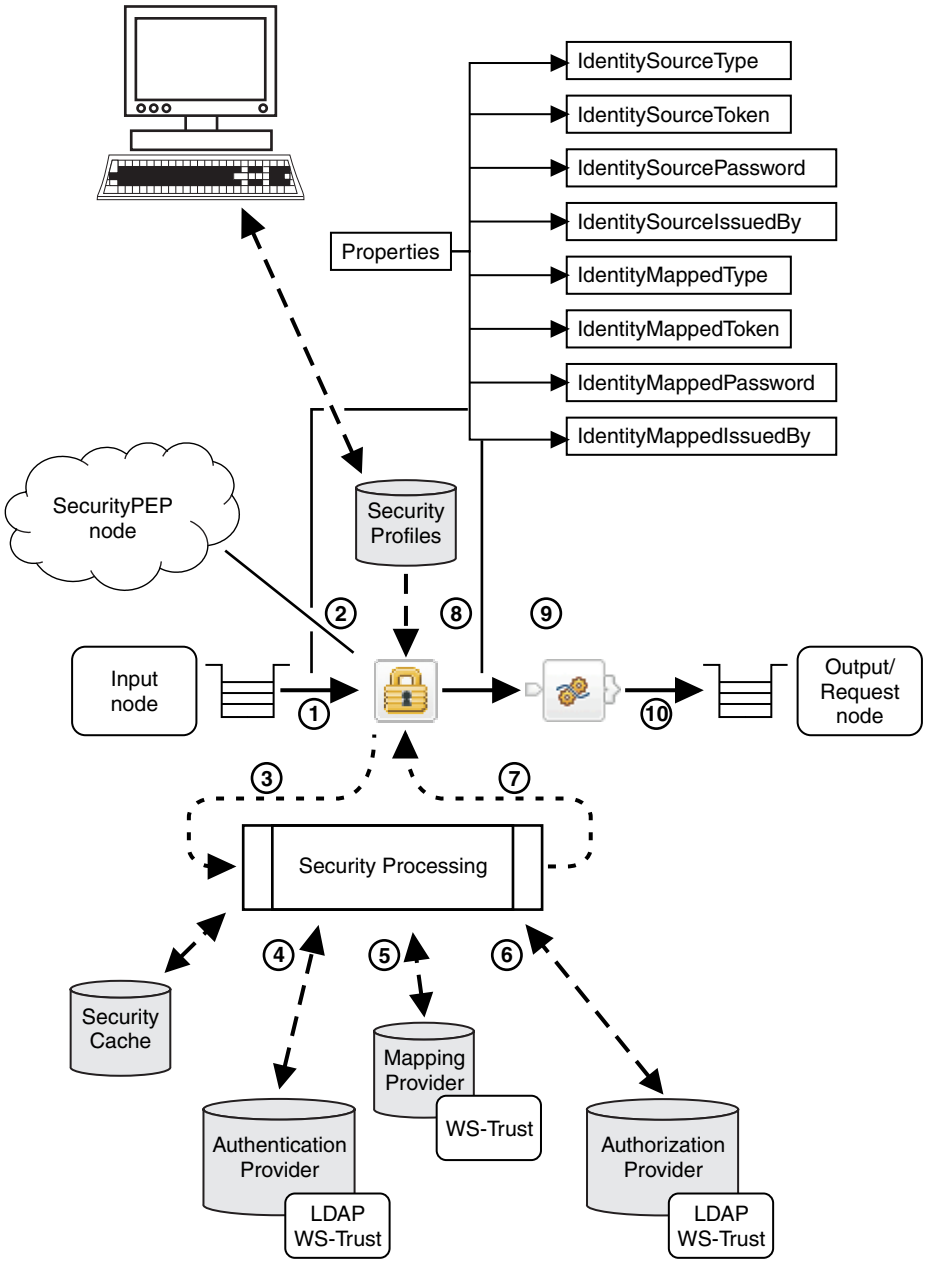
Invoking message flow security using a SecurityPEP node

You can invoke the message flow security manager at any point in a message flow, between an input node and an output or request node, by using a SecurityPEP node.

The following diagram shows an example message flow and gives an overview of the sequence of events that occur when an input message is received by an input node that is not security enabled (or that has no associated security profile) and is later processed by a SecurityPEP node in the message flow:



The following steps explain the sequence of events that occur when a message arrives at an input node that is not security enabled (or that has no associated security profile). The numbers correspond to those in the preceding diagram:

1. You can use a SecurityPEP node at any point in a message flow between an input and an output or request node. The SecurityPEP node enables security to be applied in a message flow in the following situations:
   - When the message flow input node is not security enabled (for example, FileInput, TCPIPClientInput, SAPInput, and JMSInput nodes).
   - When the message flow input node is security enabled and might be configured to perform authentication operations, but the message flow is required to perform some routing or filtering before the business function being invoked is known; as a result, authorization needs to be performed later in the message flow logic.

- When the message flow includes multiple output or request nodes, which require a specific identity mapping to be performed before each node, to obtain the appropriate security tokens for propagation.

The message tree that is propagated into the SecurityPEP node includes the properties tree identity fields. These fields are empty, unless a security enabled input node (or a prior SecurityPEP node) has already extracted identity tokens, and possibly performed some security operations.

2. When a message arrives at a SecurityPEP, the presence of a security profile associated with the node indicates whether message flow security is configured. The broker's security manager is called to read the profile, which specifies the combination of propagation, authentication, authorization, and mapping to be performed with the identity of the message. It also specifies the external security provider (also known as the Policy Decision Point or PDP) to be used.

   You can create security profiles by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer. You then use the Broker Archive editor to configure the security profile on either an individual node or the whole message flow. If you associate the security profile with the message flow, the security profile applies to all security enabled input and output and SecurityPEP nodes in the message flow. However, a security profile that is associated with an individual node takes precedence over a security profile that is associate with the message flow. Predefined security profiles are provided for setting identity propagation and for explicitly setting no security on a node.

3. If a security profile is associated with the SecurityPEP node or message flow, the node extracts the identity information from the message tree based on the node configuration and sets the Source Identity elements in the Properties folder. If the node sets a token type of *Current token*, the existing identity tokens in the Mapped Identity properties fields are used (if they exists); if there are no identity tokens in the Mapped Identity properties fields, the tokens in the Source Identity properties fields are used. If the security tokens cannot be successfully extracted, a security exception is raised and propagated to the failure terminal (if wired).

4. If authentication is specified in the security profile, the security manager calls the configured security provider to authenticate the identity. A failure results in a security exception being returned to the node. The security providers that are supported by Message Broker for authentication are LDAP, WS-Trust v1.3 compliant security token servers (such as TFIM V6.2), and TFIM V6.1.

   A security cache is provided for the authentication result, which enables subsequent messages (with the same credentials) arriving at the message flow to be completed with the cached result, provided that it has not expired.

5. If identity mapping is specified in the security profile, the security manager calls the configured security provider to map the identity to an alternative identity. A failure results in a security exception being returned to the node. Otherwise, the mapped identity information is set in the Mapped Identity elements in the Properties folder.

   The security providers that are supported by Message Broker for identity mapping are WS-Trust V1.3 compliant security token servers (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the result of the identity mapping.

6. If authorization is specified in the security profile, the security manager calls the configured security provider to authorize that the identity (either mapped or source) has access to this message flow. A failure results in a security exception being returned to the node.

   The security providers that are supported by Message Broker for authorization are LDAP, WS-Trust V1.3 compliant security token servers (such as TFIM V6.2) and TFIM V6.1.

   A security cache is provided for the authorization result.
7. When all security processing is complete, or when a security exception is raised by the message flow security manager, control returns to the SecurityPEP node.

   When a security exception is returned to the SecurityPEP node, the exception is either propagated to the failure terminal if it is connected, or returned to the preceding node as a recoverable exception. The SecurityPEP node propagates to its Out terminal only if all the configured operations in the associated security profile complete successfully.
8. The message, including the populated Properties folder and its source and mapped identity information, is propagated down the message flow.
9. When you are developing a message flow, you can use the identity fields in the Properties folder for application processing (for example, identity-based routing or content building based on identity). If the identity is to be propagated in an outbound message from an output or request node that does not support propagation of the token, you can use a compute node (including a Compute, JavaCompute, PHPCompute, or Mapping node), to move the identity token into the required transport header or message body location.
10. When the message reaches an output node, a security profile associated with the node can indicate whether an identity is to be taken from the Properties folder and propagated when the message is sent. Only specific transport nodes can propagate tokens that are the default for the transport; any other token type must be handled by a compute node, as described above.

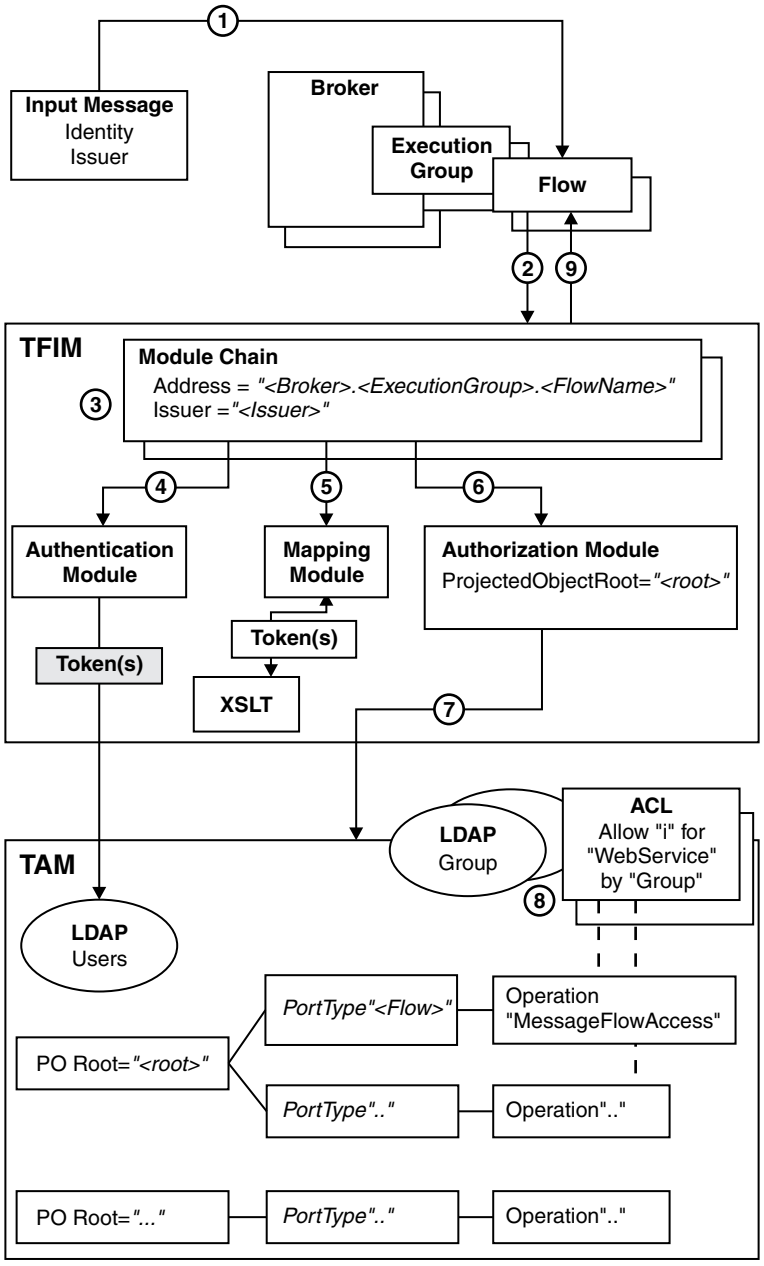
Authentication, mapping, and authorization with TFIM V6.1 and TAM

Use WebSphere Message Broker, Tivoli Federated Identity Manager (TFIM) V6.1, and Tivoli Access Manager (TAM) to control authentication, mapping, and authorization.

Note: Support for TFIM V6.1 is included for compatibility with previous versions of WebSphere Message Broker. If possible, upgrade to TFIM V6.2 and refer to the information in "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

WebSphere Message Broker makes a single TFIM WS-Trust call for an input node that is configured with a TFIM security profile, which means that a single module chain must be configured to perform all the required authentication, mapping, and authorization operations.

The following diagram shows the configuration of WebSphere Message Broker, TFIM, and TAM to enable authentication, mapping, and authorization of an identity in a message flow:



The numbers in the preceding diagram correspond to the following sequence of events:

1. A message enters a message flow.
2. A WS-Trust request is issued by the broker, with these properties:
   - RequestType = Validate
   - Identity = Token(s) from input message
   - Issuer = Issuer from input message
   - AppliesTo Address = *"Broker.ExecutionGroup.FlowName"*
   - PortType = *"FlowName"*
   - Operation = "MessageFlowAccess"

3. TFIM selects a module chain to process the WS-Trust request, based on the AppliesTo Address and Issuer properties of the request.
4. A module chain can perform authentication if it includes a module (such as a UsernameTokenSTSModule or X509STSModule) in `validate` mode.
5. A module chain can perform mapping by using an XSLTransformationModule in `mapping` mode to manipulate the identity information.
6. A module chain can perform authorization by using an AuthorizationSTSModule in `other` mode. The module chain must be configured with a *Protected Object Root* value.
7. The AuthorizationSTSModule performs the authorization check by making a request to TAM with these properties:
   - Action = "i" (invoke)
   - Action Group = "WebService"
   - Protected Object = *"ProtectedObjectRoot.FlowName.MessageFlowAccess"*

   where *"i"* and *"WebService"* are default values used by an AuthorizationSTSModule; and *FlowName* and *MessageFlowAccess* are the WS-Trust request PortType and Operation values.
8. TAM processes the authorization request by:
   a. Finding the Access Control Lists (ACLs) associated with protected object *"<ProtectedObjectRoot>.<FlowName>.MessageFlowAccess"*.
   b. Checking whether or not the ACLs grant action "i" on action group "WebService" to the user (with the user either named directly, or by membership of a named group).
9. The WS-Trust reply is returned to the broker. If this action is the result of a mapping request, the WS-Trust reply contains the mapped identity token.

For further information about how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

For information about how to configure TAM, see the IBM Tivoli Access Manager Information Center.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

Authentication, mapping, and authorization with TFIM V6.2 and TAM

You can use WebSphere Message Broker, Tivoli Federated Identity Manager (TFIM) V6.2, and Tivoli Access Manager (TAM) to control authentication, mapping, and authorization.

WebSphere Message Broker makes a single TFIM WS-Trust call for an input node or SecurityPEP node that is configured with a WS-Trust V1.3 STS security profile. As a result, a single module chain must be configured to perform all the required authentication, mapping, and authorization operations.

When you use a WS-Trust v1.3 STS for authentication, authorization, or mapping, a request is made to the trust service with the following parameters, which control the STS processing. If you are using TFIM V6.2, these parameters are used in the selection of the TFIM module chain:

Parameter	Value
RequestType	The type of request issued to the trust service. Valid values are: **`Issue`** This value can be specified when mapping is the only operation that is set to `WS-Trust V1.3 STS` in the security profile. It is not valid if `WS-Trust V1.3 STS` is specified for authentication or authorization. The namespace qualified value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue`, which shows in TFIM V6.2 as *Issue Oasis URI*. **`Validate`** This value must be set when the security profile also includes authentication or authorization (in addition to mapping) for the same `WS-Trust V1.3 STS` provider. The namespace qualified value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Validate`, which shows in TFIM V6.2 as *Validate Oasis URI*.
Issuer	This value is determined by the effective setting of the `IssuedBy` property on the **Basic** tab of the SecurityPEP node or the **Security** tab of the input node.

Parameter	Value

AppliesTo	This value is determined by the type of node:
	MQInput or SCAInput node with MQ binding:
	The WebSphere MQ IRI of the node's input queue; for example:
	`wmq://msg/queue/queue_name@queue_manager_name`
	HTTPInput, SOAPInput, or SOAPAsyncResponse node with HTTP binding:
	The endpoint URL; for example:
	`http://myflow/myInputNodePath`
	SecurityPEP node with a default (blank) WS-Trust AppliesTo address:
	The URN for the message flow that contains the node; for example:
	`urn:/broker_name.execution_group_name.flow_name`
	SecurityPEP node with WS-Trust AppliesTo address set on the Advanced tab of the node:
	The URI value configured in the property. This value is typically the URL of the target service that is used when you invoke a mapping operation to obtain the required token for the following request node; for example:
	`http://remotehost.ibm.com:9080/targetservice`
	You can also set the `AppliesTo service name` and `AppliesTo port type` properties on the **Advanced** tab of the node. The WS-Trust request includes these optional elements only when they are configured. These values are typically valid QNames; for example:
	`http://myservice.mycom.com:myservicename`
	When you set these properties in the SecurityPEP node, you must configure them in the TFIM module chain:
	• In the service name and port type TFIM properties, the information to the left of the colon must match the namespace URI of the WS-Addressing namespace that is used for the PortType and ServiceName elements in the WS-Trust request set by the broker, which is:
	`http://www.w3.org/2005/08/addressing`
	• The information to the right of the colon in the service name and port type TFIM properties must match the value configured on the SecurityPEP node. You can also configure a regular expression in TFIM to specify a match

This section describes an authorization configuration that you can use to perform the authorization operation with TFIM V6.2 and TAM.

In the security profile, set the TFIM V6.2 endpoint for the authorization operation. When you create a module chain to be used by a security enabled input node or SecurityPEP node, and resolved by *AppliesTo* information, you must include the TFIM TAMAuthorizationSTModule to invoke TAM authorization.

The TAMAuthorizationSTSModule requires the following TFIM STS universal user context attributes:

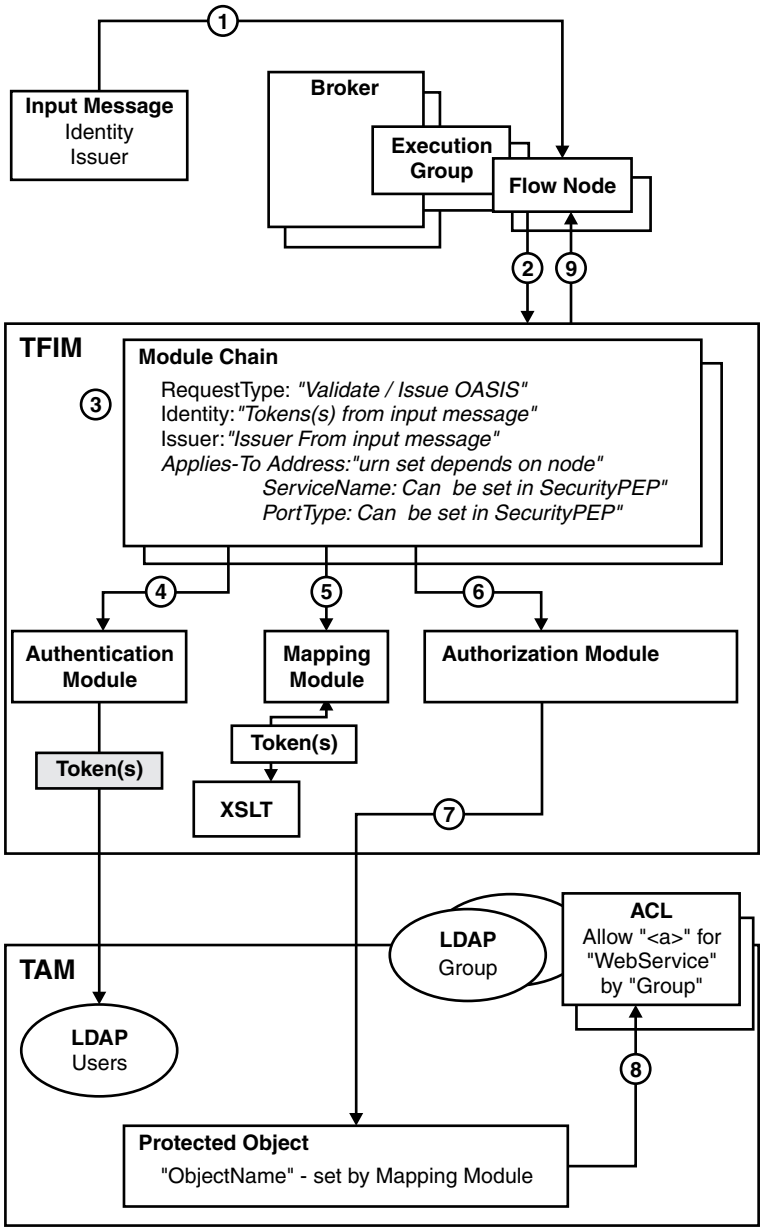
PrincipalName
The username to be authorized. This username must exist in your TAM user repository.

ObjectName
The TAM object name of the resource on which an authorization check is to be made. Typically this is derived from the *AppliesTo* information that is passed by the message flow security manager from the security enabled input node or SecurityPEP node.

Action
The TAM action to be authorized; for example, *x* (eXecute).

The TAM Access Control List (ACL), which determines the authorization decision, is located in the TAM protected object space using the path that is set on the *ObjectName* attribute of the TFIM STS universal user context input to the TAMAuthorizationSTSModule module.

The following diagram shows the configuration of WebSphere Message Broker, TFIM V6.2, and TAM to enable authentication, mapping, and authorization of an identity in a message flow:



The numbers in the preceding diagram correspond to the following sequence of events:

1. A message enters a message flow.
2. A WS-Trust request is issued by the broker, with the *RequestType*, *Issuer*, and *AppliesTo* properties set.
3. TFIM selects a module chain to process the WS-Trust request, based on the *RequestType*, *Issuer*, and *AppliesTo* properties of the request.
4. A module chain can perform authentication if it includes a module in *Validate* mode that is appropriate to the token type that is being passed in the request from the message flow input message. For example, a Username and Password token can be authenticated using a UsernameTokenSTSModule .

5. The module chain must perform some mapping by using an XSLTransformationModule in mapping mode to manipulate the identity information and to provide the required context attributes in the TFIM stsuser object for use by subsequent modules.
6. A module chain can perform authorization in TAM by using the TAMAuthorizationSTSModule.
7. The TAMAuthorizationSTSModule performs the authorization check by making a request to TAM with these properties:
   - Action = *a* (where *a* is the stsuser context action attribute). For example, *x* for eXecute could be set using the following code:

     ```
     <stsuuser:ContextAttributes>
         <!-- Action -->
         <stsuuser:Attribute name="Action" type="urn:ibm:names:ITFIM:stsmodule:tamazn">
           <stsuuser:Value>x</stsuuser:Value>
         </stsuuser:Attribute>
       </stsuuser:ContextAttributes>
     ```

   - Action Group = *WebService*
   - Protected Object = *ProtectedObjectName* (where *ProtectedObjectName* is the stsuser context action attribute). For example, *x* for eXecute could be set using the following code:

     ```
     <stsuuser:ContextAttributes>
         <!-- ObjectName -->
         <stsuuser:Attribute name="ObjectName" type="urn:ibm:names:ITFIM:stsmodule:tamazn">
           <stsuuser:Value>ProtectedObjectName</stsuuser:Value>
         </stsuuser:Attribute>
       </stsuuser:ContextAttributes>
     ```

     Typically, *ProtectedObjectName* is set conditionally from the *AppliesTo* information in the request.
8. TAM processes the authorization request by:
   a. Finding the Access Control Lists (ACLs) associated with protected object *ProtectedObjectName*
   b. Checking whether the ACLs grant action *a* on action group *WebService* to the user (the user is named either directly or indirectly, through membership of a named group).
9. The WS-Trust reply is returned to the broker. If this action is the result of a mapping request, the WS-Trust reply contains the mapped identity token.

For further information about how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

For information about how to configure TAM, see the IBM Tivoli Access Manager Information Center.

Identity and security token propagation

Identity and security token propagation enables the identity and security tokens (associated with each message) to be propagated throughout a message flow, and on to target applications through output or request nodes.

In an enterprise system, you can use different physical identities or security tokens (such as user names, certificates, and SAML assertions) to represent a single logical identity through different parts of the enterprise. The propagation of an identity or security token ensures that the logical identity is kept throughout the system by mapping between the various physical forms as necessary. For example, a message might enter the system using a certificate, but a user name token might be required for server processing of the message. Identity mapping is used to convert from the certificate to the username token, and identity propagation ensures that the mapped identity is placed in the correct place for the outbound transport.

When an output or request node propagates an identity, the mapped identity is used. If the mapped identity is not set, or if it has a token type that is not supported by the node, the source identity is used. If no identity is set, or if neither the mapped nor source identity has a token type that is supported by the node, a security exception is thrown by the node.

The output nodes that support identity propagation are:

- CICSRequest
- HTTPRequest
- IMSRequest
- MQOutput
- SAPRequest
- SCAAsyncRequest
- SCARequest
- SOAPAsyncRequest
- SOAPRequest

The following table shows the support that is provided by the message flow security manager for the propagation of the different types of security token. For more information about these security tokens, see “Identity” on page 390.

Table 9. Support for security token types - token propagation

Token type (format)	Broker security manager support	Token propagated in	
Username	Username tokens are supported for propagation by the following nodes: • CICSRequest • HTTPRequest • IMSRequest • MQOutput • SCAAsyncRequest • SCARequest	**CICS**	The request security credentials
		HTTP	BasicAuth header
		IMS	The request security credentials
		MQ	MQMD.UserIdentifier transport header

Table 9. Support for security token types - token propagation (continued)

Token type (format)	Broker security manager support	Token propagated in
Username and password	Username and password tokens are supported for propagation by the following nodes: • CICSRequest • HTTPRequest • IMSRequest • MQOutput • SAPRequest • SCAAsyncRequest • SCARequest • SOAPAsyncRequest • SOAPRequest	**CICS** The request security credentials **HTTP** BasicAuth header **IMS** The request security credentials **MQ** MQMD.UserIdentifier transport header **SAP** The request security credentials **SOAP** • BasicAuth header, if there is no policy set and binding • SOAP header, if a policy set and binding sets the Username token profile • Kerberos client credentials, if a policy set and binding sets the Kerberos token profile
SAML assertion	SAML tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the SAML token profile
X.509 certificate	X.509 tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the X.509 binary token profile
LTPA v2 token	LTPA v2 tokens are supported for propagation by the following nodes: • SOAPRequest • SOAPAsyncRequest	SOAP header when a policy set and binding sets the LTPA token profile
Universal WSSE token	Universal WSSE tokens are not supported for propagation by any node.	

For information about how to configure a message flow to propagate a message identity, see “Configuring for identity propagation” on page 492. For more information about how one physical identity is converted to another, see “Identity mapping” on page 403.

"CICSRequest node" on page 4321
Use the CICSRequest node to call CICS Transaction Server for z/OS programs over TCP/IP-based IP InterCommunications (IPIC) protocol.

"HTTPInput node" on page 4474
Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

"MQInput node" on page 4594
Use the MQInput node to receive messages from clients that connect to the broker by using the WebSphere MQ Enterprise Transport, and that use the MQI and AMI application programming interfaces.

"SOAPInput node" on page 4795
Use the SOAPInput node to process client SOAP messages, so that the broker operates as a SOAP Web Services provider.

"SecurityPEP node" on page 4729
Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

"SCAInput node" on page 4707
Use the SCAInput node with the SCAReply node to process messages from WebSphere Process Server.

"SCARequest node" on page 4719
Use the SCARequest node to send a request to WebSphere Process Server. The node is a synchronous request and response node, and blocks after sending the request until the response is received. The node can also send one-way requests.

"SAPRequest node" on page 4685
Use the SAPRequest node to send requests to an SAP application.

"IMSRequest node" on page 4504
Use the IMSRequest node to send a request to run a transaction on a local or remote IMS system, and wait for a response. IMS Connect must be configured and running on the IMS system.

Security exception processing

A security exception is raised when a message flow security failure occurs during security processing in an input node or SecurityPEP node.

Security exceptions are processed in a different way from other errors on the input node. An error is typically caught on the input node and routed down the Failure terminal for error processing, but security exceptions are not processed in the same way. By default, the broker does not allow security exceptions to be caught within the message flow, but backs the message out or returns an error (as in the case of HTTP). Security exceptions in input nodes are managed in this way to prevent a security denial of service attack filling the logs and destabilizing the system.

However, security exceptions in SecurityPEP nodes are managed in a different way. If a security operation fails in a SecurityPEP node, a security exception is raised, wrapped in a normal recoverable exception, which invokes the error handling that is provided by the message flow.

If you have designed the message flow to be in a secure area and you want to explicitly perform processing of security exceptions, you can select the **Treat Security Exceptions as normal exceptions** property on the MQInput or HTTPInput nodes. This property causes security exceptions to be processed in the same way as other exceptions in the message flow.

If you associate the Default Propagation security profile with an output or request node, the token type of the mapped or source security token must be the same as the transport default for that node; otherwise, a security exception occurs. For example, for an MQOutput node, the token type must be *Username*, for an HTTPRequest node, the token type must be *Username + Password*, and for a SOAPRequest node, the token type must be the type that is defined in either the policy set and binding or the transport binding.

For information on how to diagnose the causes of security exceptions, see "Diagnosing security problems" on page 496.

Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

Setting up message flow security

Set up security on a message flow to control access based on the identity of a message passing through the message flow.

About this task

You can configure the broker to perform end-to-end processing of an identity carried in a message through a message flow. Administrators can configure security at message flow level, controlling access based on the identity flowed in a message. This security mechanism is independent of both the transport and the message format.

To set up security for a message flow, perform the tasks described in the following topics:

Procedure

1. "Creating a security profile" on page 433
2. "Configuring the extraction of an identity or security token" on page 447
3. "Configuring identity authentication and security token validation" on page 450
4. "Configuring identity mapping" on page 463
5. "Configuring authorization" on page 470
6. "Configuring for identity propagation" on page 492
7. "Database security" on page 495
8. "Diagnosing security problems" on page 496

What to do next

If the message flow is a Web service implemented by using the "SOAP nodes" on page 1609, and the identity is to be taken from the "WS-Security" on page 765 header tokens, you must also create appropriate "Policy sets" on page 774 and bindings, then configure them on the relevant SOAP nodes (in addition to the security profile). See "Associating policy sets and bindings with message flows and nodes" on page 785.

To work with an identity, you must configure the policy sets and bindings for the relevant capabilities:

- To work with a Username and Password identity, configure the policy sets and bindings for "Username token capabilities" on page 791.
- To work with an X.509 Certificate identity, configure the policy sets and bindings for "X.509 certificate token capabilities" on page 795.

  In the policy set binding, the `Certificates` mode of the X.509 certificate authentication token must be set as `Trust Any` (rather than `Trust Store`), so that

the certificate is passed to the security provider defined by the security profile. Setting *Trust Store* causes the certificate to be validated in the local broker trust store.

- To work with a SAML assertion, configure the policy sets and bindings for "SAML token capabilities" on page 804.
- To work with an LTPA token, configure the policy sets and bindings for "LTPA token capabilities" on page 813.
- To work with a Kerberos ticket, configure the policy sets and bindings for "Kerberos token capabilities" on page 809.

For more information, see "Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854.

"Security profiles" on page 387
A security profile defines the security operations that are to be performed in a message flow at SecurityPEP nodes and security enabled input and output nodes.

"Message flow security overview" on page 383
WebSphere Message Broker provides a security manager, which enables you to control access to individual messages in a message flow, using the identity of the message.

Related tasks:

"Configuring the extraction of an identity or security token" on page 447
You can configure the SecurityPEP node or security enabled input nodes to extract the identity or security token from a message and store it in the properties tree identity fields, enabling it to be processed throughout the message flow and propagated at output or request nodes.

"Creating a security profile" on page 433
You can create a security profile for use with Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2. Support is also provided for TFIM V6.1, for compatibility with previous versions of WebSphere Message Broker. You can create the security profile by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer.

"Creating a security profile for LDAP" on page 435
Create a security profile for use with Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS), by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer.

"Configuring identity authentication and security token validation" on page 450
You can configure a message flow to perform identity authentication or security token validation using Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token sever (STS) such as Tivoli Federated Identity Manager (TFIM) Version 6.2. Support for TFIM V6.1 is also provided, for compatibility with previous versions of WebSphere Message Broker.

"Configuring identity mapping" on page 463
Configure a security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to map the incoming security token and, if required, to authenticate and authorize it.

"Configuring authorization" on page 470
Configure the broker to use an external security provider to authorize an identity in a message flow. You can use either Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token server (STS) such as Tivoli Federated Identity Manager (TFIM) V6.2. Support for TFIM V6.1 is also provided for compatibility with previous versions of WebSphere Message Broker.

"Configuring for identity propagation" on page 492
To enable a message flow to perform identity propagation, the input nodes must extract the identity and the output node must propagate it.

Creating a security profile

You can create a security profile for use with Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2. Support is also provided for TFIM V6.1, for compatibility with previous versions of WebSphere Message Broker. You can create the security profile by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer.

About this task

Before you can enable security on a node or a message flow, you need to create a security profile that defines the security operations that you want to perform.

You can create a security profile for use with external security providers to provide the required security enforcement and mapping. You can configure the security profile to use different security providers for different security functions; for example, you might use LDAP for authentication and WS-Trust V1.3 STS for mapping and authorization.

If you want to extract and propagate an identity without security enforcement or mapping, you can use the supplied security profile called Default Propagation. The Default Propagation profile is a predefined profile that requests only identity propagation.

To create a security profile, see:

- "Creating a security profile for LDAP" on page 435
- "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440
- "Creating a security profile for TFIM V6.1" on page 444

Use the **mqsicreateconfigurableservice** command to create an object name for a broker external resource.

Creating a security profile for LDAP:

Create a security profile for use with Lightweight Directory Access Protocol (LDAP) or Secure LDAP (LDAPS), by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer.

Before you begin

Before you start:

Ensure that you have an LDAP server that is LDAP Version 3 compliant, for example:

- IBM Tivoli Directory Server
- Microsoft Active Directory
- OpenLDAP.

About this task

If your LDAP directory does not permit login by unrecognized user IDs, and does not grant search access rights on the subtree, you must also set up a separate authorized login ID that the broker can use for the search. For information on how to do this, see "Configuring authorization with LDAP" on page 472 or "Configuring authentication with LDAP" on page 453.

Creating a security profile using mqsicreateconfigurableservice:
About this task

You can use the **mqsicreateconfigurableservice** command to create a security profile that uses LDAP for authentication, authorization, or both. The security profile ensures that each message has an authenticated ID and is authorized for the message flow.

Procedure

1. Open a command window that is configured for your environment.
2. Enter the **mqsicreateconfigurableservice** command on the command line. For example:

   ```
   mqsicreateconfigurableservice WBRK_BROKER -c SecurityProfiles -o LDAP
   -n authentication,authenticationConfig,authorization,authorizationConfig,propagation,rejectBla
   -v "LDAP,\"ldap://ldap.acme.com:389/ou=sales,o=acme.com\",LDAP,
   \"ldap://ldap.acme.com:389/cn=All Sales,ou=acmegroups,o=acme.com\",TRUE,TRUE
   ```

   You must enclose the LDAP URL (which contains commas) with escaped double quotation marks (\" and \") so that the URL commas are not confused with the comma separator of the value parameter of **mqsicreateconfigurableservice**.

   If the LDAP URL includes an element name with a space, in this case `cn=All Sales`, the set of values after the -v flag must be enclosed by double quotation marks, (")

For more information about the structure of the command, refer to the "**mqsicreateconfigurableservice** command" on page 3849.

You can define the security-specific parts of the command in the following way:

a. Set the **authentication** to *LDAP*. This ensures that the incoming identity is validated.

b. Set the **authenticationConfig** using the following syntax:

ldap[s]**://***server***[:***port***]/***baseDN***[?[***uid_attr***][?[base|sub]]]**

For example:

```
ldap://ldap.acme.com:389/ou=sales,o=acme.com
ldaps://localhost:636/ou=sales,o=acme?cn?base
```

ldap: (Required) Fixed protocol string.

s: (Optional) Specifies whether SSL should be used. Default is not to use SSL.

server: (Required) The name or IP address of the LDAP server to contact.

port: (Optional) The port to connect to. Default is 389 (non-SSL). For LDAP servers with SSL enabled, the port is typically 636.

baseDN
(Required) String defining the base distinguished name (DN) of all users in the directory. If users exist in different subtrees, specify a common subtree under which a search on the username uniquely resolves to the required user entry, and set the *sub* attribute.

uid_attr:
(Optional) String defining the attribute to which the incoming username maps, typically uid, CN, or email address. Default is *uid*.

base|sub:
(Optional) Defines whether to perform a base or subtree search. If `base` is defined, the authentication is faster because the DN of the user can be constructed from the *uid_att*, *username*, and *baseDN* values. If *sub* is selected, a search must be performed before the DN can be resolved. Default is *sub*.

c. Set the **authorization** to *LDAP*. This ensures that the incoming identity is checked for group membership in LDAP.

d. Set the **authorizationConfig** using the following syntax:

```
ldap[s]://server[:port]/groupDN[?[member_attr]
[?[base|sub][?[x-userBaseDN=baseDN,
x-uid_attr=uid_attr]]]]
```

For example:

```
ldap://ldap.acme.com:389/cn=All Sales,ou=acmegroups,
o=acme.com?uniquemember?sub?x-userBaseDN=ou=sales%2co=ibm.com,
x-uid_attr=emailaddress
```

ldap: (Required) Fixed protocol string

s: (Optional) Specifies whether SSL is used. Default is not to use SSL.

server: (Required) The name or IP address of the LDAP server to contact.

port: (Optional) The port to connect to. Default is 389 (non-SSL). For LDAP servers with SSL enabled, the port is typically 636.

groupDN
(Required) Fully defined distinguished name of the group in which users must be members to be granted access.

member_attr:
(Optional) The attribute of the group used to filter the search. Default is to look for both **member** and **uniquemember** attributes.

The following options are required only if authentication has not preceded the authorization, and if the authentication configuration string has not been specified. If the authentication configuration string has been specified, the following parameters are ignored and those provided by the **baseDN**, **uid_attr**, and **[base|sub]** for authentication are used instead:

base|sub:
(Optional) Defines whether to perform a base or subtree search. If `base` is defined, the authentication is faster because the DN of the user can be constructed from uid_att + username + baseDN. If `sub` is selected, a search must be performed before the DN can be resolved. Default is `sub`.

baseDN
(Optional) String defining the base distinguished name of all users in the directory. Must be preceded by the string `x-userBaseDN`. Any commas in the BaseDN must be rendered as `%2c`.

x-uid_attr:
(Optional) String defining the attribute to which the incoming username should map, typically uid, CN, or email address. Default is uid. Must be preceded by the string `x-uid_attr`.

When you submit the command from a batch (.bat) file or command (.cmd) file, if the LDAP URL includes an extension with LDAP URL "percent hex hex" escaped characters (for example, a comma replaced by `%2c`, or a space replaced by `%20`), the percent signs must be escaped from the batch interpreter with an extra percent sign (`%%`). For example:

```
mqsicreateconfigurableservice WBRK_BROKER -c SecurityProfiles -o LDAP_URI_FUN
-n authentication,authenticationConfig,authorization,authorizationConfig -v
"LDAP,\"ldap://ldap.acme.com:389/ou=sales,o=acme.com?emailaddress?sub\",
LDAP,\"ldap://ldap.acme.com:389/cn=All Sales,ou=acmegroups,
o=acme.com?report?base?x-BaseDN=ou=sales%%2co=acme.com,
x-uid_attr=emailaddress\""
```

The selected group must be defined on the LDAP server, and all of the required users must be members of the group.

3. If you need to reconfigure the security profile after it has been created, use the **mqsichangeproperties** command.

Creating a security profile using the WebSphere Message Broker Explorer:
About this task

You can use the WebSphere Message Broker Explorer to create a security profile for LDAP.

Procedure

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Security Profiles**. The Security Profiles window is displayed, containing a list of existing security profiles for the broker on the left, and a pane in which you can configure the profile on the right.
3. Click **Add** to create a new profile and add it to the list. You can edit the name of the security profile by highlighting it in the list and pressing **F2**.

4. Configure the security profile using the entry fields on the right side of the pane:
   a. Select the type of **Authentication** required. This can be `LDAP`, `TFIM`, or `NONE`.
   b. If you have selected LDAP for authentication, edit the following fields in the **LDAP Parameters** section:
      - LDAP Host
      - LDAP baseDN
      - LDAP uid attr
      - LDAP search Scope

      The values that you enter in the **LDAP Parameters** fields create a configuration string, which is displayed in the **Authentication Config** field. For information about the valid values for the parameters, see "Creating a security profile using mqsicreateconfigurableservice" on page 435.
   c. Select the type of **Mapping** required. This can be either `TFIM` or `NONE`.
   d. If you have selected TFIM for mapping, type the URL of the TFIM server in the **TFIM Configuration** field of the **TFIM Parameters** section.

      The value that you specify in the **TFIM Configuration** field creates a configuration string, which is displayed in the **Mapping Config** field.
   e. Select the type of **Authorization** required. This can be `LDAP`, `TFIM`, or `NONE`.
   f. If you have selected LDAP for authorization, edit the following fields in the **LDAP Parameters** section:
      - LDAP Host
      - LDAP baseDN
      - LDAP uid attr
      - LDAP search Scope
      - LDAP group baseDN
      - LDAP group member.

      The values that you enter in the **LDAP Parameters** fields create a configuration string, which is displayed in the **Authorization Config** field. For information about the valid values for the parameters, see "Creating a security profile using mqsicreateconfigurableservice" on page 435.
   g. In the **Propagation** field, specify whether you require the identity to be propagated. The default is `False`.
   h. In the **Reject Empty Password** field, specify whether you want the security manager to reject a username that has an empty password token, without passing it to LDAP. The default is `False`, which means that a username is passed to LDAP even if it has an empty password token.
   i. In the **Password Value** field, select the way in which the password is displayed in the properties folder. The options are:

      PLAIN The password appears in the Properties folder as plain text.

      OBFUSCATE
      The password appears in the Properties folder as base64 encoding.

      MASK The password appears in the Properties folder as four asterisks (****).
5. Click **Finish** to deploy the security profile to the broker.

Results

To delete an existing security profile, select the profile in the list and then click **Delete**.

Creating a security profile for WS-Trust V1.3 (TFIM V6.2):

You can create a security profile for a WS-Trust V1.3 compliant Security Token Server (STS), for example, Tivoli Federated Identity Manager (TFIM) V6.2, for any combination of the following security operations: authentication, authorization, and mapping.

About this task

You can use either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer to create the security profile:

- "Creating a profile using mqsicreateconfigurableservice"
- "Creating a profile using the WebSphere Message Broker Explorer" on page 442

Creating a profile using mqsicreateconfigurableservice:
About this task

To create a security profile that uses a WS-Trust V1.3 compliant Security Token Server (STS), you can use the **mqsicreateconfigurableservice** command by setting the configuration parameter to the full URL of the STS. The URL must consist of the transport scheme, host name, port, and path. For TFIM V6.2 WS-Trust V1.3 endpoint, the path is `/TrustServerWST13/services/RequestSecurityToken`. For example:

```
http://stsserver.mycompany.com:9080/TrustServerWST13/services/RequestSecurityToken
```

Procedure

To create a security profile that uses WS-Trust v1.3 for mapping, enter the following command:

```
mqsicreateconfigurableservice brokername -c SecurityProfiles
-o profilename -n mapping,mappingConfig
-v "WS-Trust v1.3 STS",http://stsserver.mycompany.com:9080/TrustServerWST13/services/RequestSecuri
```

If the URL specifies an address beginning with `https://`, an SSL secured connection is used for requests to the WS-Trust v1.3 server. For example, to create a security profile that uses an HTTPS connection to WS-Trust v1.3 for mapping, enter the following command:

```
mqsicreateconfigurableservice brokername -c SecurityProfiles
-o profilename -n mapping,mappingConfig
-v "WS-Trust v1.3 STS",https://stsserver.mycompany.com:9080/TrustServerWST13/services/RequestSecur
```

In addition to specifying the security profile URL as an address beginning with `https://`, you can configure the following advanced parameters, by setting broker environment variables:

MQSI_STS_SSL_PROTOCOL
The version of the SSL protocol to be used. Valid values are:
- SSL
- SSLv3
- TLS

The initial value is `SSLv3`.

MQSI_STS_SSL_ALLOWED_CIPHERS
A space-separated list of the encryption ciphers that can be used. For a list of all the cipher suites that are supported by WebSphere Message Broker, see the Java product information for your operating system. For operating systems that use IBM Java, see Appendix A of the IBM JSSE2 Guide: http://www.ibm.com/developerworks/java/jdk/security/60/secguides/jsse2Docs/JSSE2RefGuide.html

MQSI_STS_REQUEST_TIMEOUT
The STS request timeout, specified in seconds. The initial value is `100`. For information about providing environment variables to the broker, see "Setting up a command environment" on page 213.

If WS-Trust v1.3 STS is selected for more than one operation (for example, for authentication and mapping), the WS-Trust v1.3 server URL must be identical for all the operations, and is therefore specified only once.
The following example creates a security profile that uses TFIM V6.2 for authentication, mapping, and authorization:

```
mqsicreateconfigurableservice MYBROKER -c SecurityProfiles -o MyWSTrustProfile
-n authentication,mapping,authorization,propagation,mappingConfig
-v "WS-Trust v1.3 STS","WS-Trust v1.3 STS","WS-Trust v1.3 STS",TRUE,http://stsserver.mycompany.com:90
```

Creating a profile using the WebSphere Message Broker Explorer:
About this task

You can use the WebSphere Message Broker Explorer to create a security profile for using WS-Trust v1.3.

Procedure

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Security Profiles**. The Security Profiles window is displayed, containing a list of existing security profiles for the broker on the left and, on the right, a pane in which you can configure the profile.
3. Click **Add** to create a new profile and add it to the list. You can edit the name of the security profile by highlighting it in the list and pressing **F2**. The security profile name must not include spaces.
4. Configure the security profile using the entry fields on the right side of the pane:
   a. Select the security provider that you require for `Authentication`, `Mapping`, and `Authorization`. When you select `WS-Trust v1.3 STS` for any of these options, the **STS URI** field in the **Security Token Service (STS) Parameters** group is enabled.
   b. Type the URL of the WS-Trust v1.3 STS into the **STS URL** field. The STS URL must contain the following URL parts:
      - Transport scheme (http or https)
      - Host name (a fully qualified domain name)
      - Port
      - Path (for example, for TFIM V6.2: `/TrustServerWST13/services/RequestSecurityToken`)

      For example:

      ```
      http://stsserver.mycompany.com:9080/TrustServerWST13/services/RequestSecurityToken
      ```

      The URL that you enter forms a configuration string, which is displayed in one or more of the configuration fields (**Authentication Config**, **Mapping Config**, and **Authorization Config**), depending on the security operations that are configured to use `WS-Trust v1.3 STS`.

      For more information about the valid values for the configuration parameter, see “Creating a profile using mqsicreateconfigurableservice” on page 441.
   c. In the **Propagation** field, specify whether you require the identity to be propagated. The default is `False`.

d. In the **Password Value** field, select the way in which the password is displayed in the properties folder. The password is optional, and is required only when the token type is `Username + Password`. The options are:

   PLAIN The password is shown in the Properties folder as plain text.

   OBFUSCATE
   The password is shown in the Properties folder as base64 encoding.

   MASK The password is shown in the Properties folder as four asterisks (****).

5. Click **Finish** to deploy the security profile to the broker.

Creating a security profile for TFIM V6.1:

You can create a security profile for Tivoli Federated Identity Manager (TFIM) V6.1 for any combination of the following functions: authentication, authorization, and mapping. You can use either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer to create the security profile.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of WebSphere Message Broker. If possible, upgrade to TFIM V6.2 and follow the instructions in "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

Creating a profile using mqsicreateconfigurableservice:
About this task

To create a security profile that uses TFIM V6.1, you can use the **mqsicreateconfigurableservice** command by setting the configuration parameter to the URL of the TFIM server. For example: `http://tfimserver.mycompany.com:9080`

Procedure

To create a security profile that uses TFIM V6.1 for mapping, enter the following command:

```
mqsicreateconfigurableservice brokername -c SecurityProfiles -o profilename
-n mapping,mappingConfig -v TFIM,http://tfimserver.mycompany.com:9080
```

If the URL specifies an address beginning with `https://`, an SSL secured connection is used for requests to the TFIM server. For example, to create a security profile that uses an HTTPS connection to TFIM for mapping, enter the following command:

```
mqsicreateconfigurableservice brokername -c SecurityProfiles -o profilename
-n mapping,mappingConfig -v TFIM,https://tfimserver.mycompany.com:9443
```

where `https://tfimserver.mycompany.com:9443` is the address of the TFIM server. If TFIM is selected for more than one operation (for example, for authentication and mapping), the TFIM server URL must be identical for all the operations, and is therefore specified only once.
The following example creates a security profile that uses TFIM for authentication, mapping, and authorization:

```
mqsicreateconfigurableservice MYBROKER -c SecurityProfiles -o TFIM
-n authentication,mapping,authorization,propagation,mappingConfig
-v TFIM,TFIM,TFIM,TRUE,http://tfimhost1.ibm.com:9080
```

Creating a profile for TFIM V6.1 using the WebSphere Message Broker Explorer:
About this task

You can use the WebSphere Message Broker Explorer to create a security profile for using TFIM V6.1.

Procedure

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Security Profiles**. The Security Profiles window is displayed, containing a list of existing security profiles for the broker on the left and, on the right, a pane in which you can configure the profile.
3. Click **Add** to create a new profile and add it to the list. You can edit the name of the security profile by highlighting it in the list and pressing **F2**.
4. Configure the security profile using the entry fields on the right side of the pane:
   a. Select the type of **Authentication**, **Mapping**, and **Authorization** required. If you select `TFIM V6.1` for any of these options, the **TFIM Configuration** field at the bottom of the pane is enabled.
   b. If you have selected TFIM V6.1 for authentication, mapping or authorization, type the URL of the TFIM server into the **TFIM Configuration** field. The URL that you enter forms a configuration string, which is displayed in one or more of the configuration fields (**Authentication Config**, **Mapping Config**, and **Authorization Config**) depending on the entry fields that have TFIM selected.

      For more information about the valid values for the configuration parameter, see "Creating a profile using mqsicreateconfigurableservice" on page 444.
   c. In the **Propagation** field, specify whether you require the identity to be propagated. The default is `False`.
   d. In the **Password Value** field, select the way in which the password is displayed in the properties folder. The options are:

      PLAIN The password is shown in the Properties folder as plain text.

      OBFUSCATE
      The password is shown in the Properties folder as base64 encoding.

MASK The password is shown in the Properties folder as four asterisks (****).

5. Click **Finish** to deploy the security profile to the broker.

Configuring the extraction of an identity or security token

You can configure the SecurityPEP node or security enabled input nodes to extract the identity or security token from a message and store it in the properties tree identity fields, enabling it to be processed throughout the message flow and propagated at output or request nodes.

Before you begin

Before you start:

Check that an appropriate security profile exists or create a new security profile. See "Creating a security profile" on page 433.

About this task

If an input node or SecurityPEP node is associated with a profile that specifies a security operation (authentication, mapping, or authorization), or specifies propagation as enabled, the node can retrieve an identity or security token from the message bit stream.

- An MQInput node, with the `Identity token type` security property set to `Transport default`, retrieves the UserIdentifier element from the message descriptor (MQMD) and puts it into the Identity Source Token element of the Properties folder. At the same time, it sets the Identity Source Type element to `username` and the Identity Source Issued By element to `MQMD.PutApplName` (the put application name).
- An HTTPInput node, with the `Identity token type` security property set to `Transport default`, retrieves the BasicAuth header from the HTTP request, decodes it, and puts it into the Identity Source Token and Password elements in the Properties folder. At the same time, it sets the Identity Source Type element to `username + Password` and the Identity Source Issued By element to the HTTP header `UserAgent` property.
- A SOAPInput node retrieves the appropriate tokens as defined by the configured WS-Security policy sets and bindings, or (if they are not set), the transport binding determines the token type; for example, HTTP transport is BasicAuth. The SOAPInput node then populates the identity source fields in the Properties

folder with the retrieved tokens. With a Kerberos policy set and bindings, the token type is a Username containing the Service Principal Name (SPN) from the Kerberos ticket.

- A SecurityPEP node, with the `Identity token type` property set to `Current token`, can use the token that has been extracted by an upstream input or SecurityPEP node and stored in the Properties folder.

In some cases, the information extracted from the transport headers is not set or is insufficient to perform authentication or authorization. For example, for authentication to occur, a Username + Password type token is required; however, with WebSphere MQ, only a username is available, which means that the incoming identity has to be trusted. However, you can increase security by applying transport-level security using WebSphere MQ Extended Security Edition.

If the transport header cannot provide the required identity credentials, the information must be provided as part of the body of the incoming message. To enable the identity information to be taken from the body of the message, you must specify the location of the information by using either the **Security** tab on the HTTP, MQ, and SCA input nodes or the **Basic** tab on the SecurityPEP node, or by configuring the required policy set and bindings WS-Security profile on the SOAP node. A SOAP node with a Kerberos policy set and bindings extracts a Username token containing the Service Principal Name (SPN) of the Kerberos ticket.

Procedure

1. In **Identity Token Type**, specify the type of identity token that is in the message. The type can have one of the following values:
   - `Transport Default` (on the security enabled input nodes)
   - `Current token` (on the SecurityPEP node)
   - `Username`
   - `Username and password`
   - `X.509 Certificate`
   - `SAML assertion`
   - `Kerberos GSS v5 AP_REQ` (on the SecurityPEP node)
   - `LTPA v2 token` (on the SecurityPEP node)
   - `Universal WSSE token` (on the SecurityPEP node)

   On the security enabled input nodes, the default value is *Transport Default*. On the SecurityPEP node, the default value is *Current token*, which means that the token type that exists in the identity mapped or source field in the Properties folder is used.
2. In **Identity Token Location**, specify the location in the message where the identity is specified. This string is in the form of an ESQL field reference, XPath expression, or string literal, and must resolve to a token with the type `Username`, `Username and password`, `SAML assertion`, `Kerberos GSS v5 AP_REQ`, `LTPA v2 token`, or `X.509 Certificate`. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.).
3. In **Identity Password Location**, enter the location in the message where the password is specified. This string is in the form of an ESQL field reference, XPath expression, or string literal, and must resolve to a string containing a password. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.). This option can be set only if the **Identity Token Type** is set to `Username and password`.

4. In **Identity IssuedBy Location**, specify a string or path expression to show where (in the message) information about the issuer of the identity is held. This string is in the form of an ESQL field reference, XPath expression, or string literal, defining where the identity was defined. If you use a string literal, it must be enclosed in single quotes and must not contain a period (.).

   If you leave this property blank on the security enabled input nodes, the transport header value is used (if there is one). For example, for MQ the MQMD.PutApplName value is used. If you leave this property blank on the SecurityPEP node, the WS-Trust request is sent to the STS without the optional Issuer element in the WS-Trust message.
5. (Optional) Ensure that all input nodes share the same information by promoting the properties to the message flow.

What to do next

To enable the extraction of an identity in a security enabled input node or SecurityPEP node, select a security profile that has at least one security operation configured (authentication, mapping, or authorization) or propagation enabled:

1. In the Message Broker Toolkit, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, select a security profile.
5. Save the BAR file.

Set up security on a message flow to control access based on the identity of a message passing through the message flow.

Configuring authentication with HTTP basic authentication:

Use a security profile to configure HTTP basic authentication in the HTTPRequest or SOAPInput nodes.

About this task

Basic authentication is a common extension in the HTTP protocol that allows a client to provide identity information to a remote web server in the form of a username and password sent in the HTTP header data. Security profiles in WebSphere Message Broker provide a way for message flow designers to provide these credentials without building the HTTP headers in a Compute node.

If identity propagation is enabled for the selected security profile, the HTTPRequest and SOAPRequest nodes automatically pick up username and password credentials, if present, from the Properties tree. See “Configuring for identity propagation” on page 492. The predefined security profile Default Propagation has this setting enabled.

To enable basic authentication, select an appropriate security profile for the output node or the message flow in the Broker Archive editor. The credentials are picked up from the following Properties tree locations if set:

```
Properties.IdentityMappedType
Properties.IdentityMappedToken
Properties.IdentityMappedPassword
```

If the mapped identity fields are not set, the credentials are picked up from the following Properties tree locations:

```
Properties.IdentitySourceType
Properties.IdentitySourceToken
Properties.IdentitySourcePassword
```

For basic authentication both a username and password are required, therefore the appropriate Type field must be set to the string `usernameAndPassword`. For example:

```
SET OutputRoot.Properties.IdentitySourceType='usernameAndPassword';
SET OutputRoot.Properties.IdentitySourceToken = 'myUser';
SET OutputRoot.Properties.IdentitySourcePassword = 'myPassw0rd';
```

These fields are interpreted by a subsequent HTTPRequest or SOAPRequest node and converted into a basic authentication HTTP header.

You can also propagate credentials from an input message by setting a security profile which includes propagation on an input node, and then using the input node properties `Identity token type`, `Identity Token location` and `Identity password location`. These three properties take an XPath expression that specifies the location in the input message to retrieve the appropriate token or password from. When configured correctly, these properties place the identity information in the `Properties.IdentitySourceType`, `Properties.IdentitySourceToken` and `Properties.IdentitySourcePassword` fields. HTTPRequest or SOAPRequest nodes then use these values directly, with an appropriate security policy.

You can override the configuration of the security profile by selecting the build option **Override configurable property values** in the Broker Archive editor.

Configuring authentication with LDAP:

This topic describes how to configure a message flow to perform identity authentication using Lightweight Directory Access Protocol (LDAP).

Before you begin

Before you start:

Before you can configure a message flow to perform identity authentication using LDAP, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for LDAP" on page 435.

About this task

To authenticate the identity of a user or system, the broker attempts to connect to the LDAP server using the username and password associated with the identity. To do this, the broker needs the following information:

- To resolve the username to an LDAP entry, the broker needs to know the base distinguished name (base DN) of the accepted login IDs. This is required to enable the broker to differentiate between different entries with the same name.
- If the identities do not all have a common base DN, but can be uniquely resolved from a subtree, the DN can be specified in the broker configuration. When a subtree search has been specified, the broker must first connect to the

LDAP server and search for the given username in order to obtain the full username distinguished name (DN) to be used for authentication. If your LDAP directory does not permit login of unrecognized IDs, and does not grant search access rights on the subtree, you must set up a separate authorized login ID that the broker can use for the search. Use the **mqsisetdbparms** command to specify a username and password. For example:

```
mqsisetdbparms -n ldap::LDAP -u username -p password
```

or

```
mqsisetdbparms -n ldap::<servername> -u username -p password
```

where <*servername*> is your base LDAP server name, for example, `ldap.mydomain.com`.

If you specify `ldap::LDAP`, it creates a default setting for the broker, which the broker attempts to use if you have not explicitly used the **mqsisetdbparms** command to create a login ID for a specific <*servername*>. All servers that do not have an explicit `ldap::servername` entry then start using the credentials in the `ldap::LDAP` entry. This means that any servers that were previously using anonymous bind by default will start using the details in `ldap::LDAP`.

The username that you specify in the **-u** parameter must be recognized by the LDAP server as a complete user name. In most cases this means that you need to specify the full DN of the user. Alternatively, by specifying a username to be anonymous, you can force the broker to bind anonymously to this LDAP server. This might be useful if you have specified a non-anonymous bind as your default (ldap::LDAP). For example:

```
mqsisetdbparms -n ldap::<servername> -u anonymous -p password
```

In this case, the value specified for *password* is ignored.

Steps for enabling LDAP authentication:

Procedure

To enable an existing message flow to perform identity authentication, use the Broker Archive editor to select a security profile that uses LDAP for authentication. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the BAR file and then click **Open with** > **Broker Archive Editor**.
3. Click the **Manage and Configure** tab.
4. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
5. In the **Security Profile Name** field, select a security profile that uses LDAP for authentication.
6. Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see “Policy sets” on page 774.

If the message identity does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from WebSphere MQ with only a username, the password information must be taken from the message body. For more information, see "Configuring the extraction of an identity or security token" on page 447.

Configuring authentication or security token validation with a WS-Trust v1.3 STS (TFIM V6.2):

You can configure supported message flow input nodes or SecurityPEP nodes to perform identity authentication or security token validation using a WS-Trust v1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2.

Before you begin

Before you start:

Before you can configure identity authentication or token validation, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

About this task

When the security profile is configured to use WS-Trust V1.3 STS for authentication, the broker security manager issues trust requests and processes trust responses according to the WS-Trust V1.3 standard.

When you use a WS-Trust v1.3 STS for authentication, a request is made to the trust service with the following parameters, which control the STS processing. If you are using TFIM V6.2, the following parameters are used in the selection of the TFIM module chain:

- RequestType
- Issuer
- AppliesTo

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

The WS-Trust v1.3 specification, published by OASIS, is available at:
`http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html`

.

Steps for enabling WS-Trust v1.3 authentication:

Procedure

To enable an existing message flow to perform authentication or token validation, use the Broker Archive editor to select a security profile that uses a WS-Trust v1.3 STS for authentication and to associate it with the node or message flow. If a security profile is specified on either a message flow or a node, the profile must be available when the message flow is deployed; otherwise, a deployment error occurs.

1. In the Message Broker Toolkit, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

4. In the **Security Profile Name** field, select a security profile that configures WS-Trust v1.3 STS for authentication.
5. Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 774.

If the message identity (or security token) does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from WebSphere MQ with only a username, the password information must be taken from the message body. For more information, see "Configuring the extraction of an identity or security token" on page 447.

Use the SecurityPEP node in a message flow to invoke the message flow security manager at any point in the message flow.

Configuring authentication with TFIM V6.1:

You can configure a message flow to perform identity authentication by using Tivoli Federated Identity Manager (TFIM) V6.1.

Before you begin

Before you start:

Before you can configure a message flow to perform identity authentication, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for TFIM V6.1" on page 444.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of WebSphere Message Broker. If possible, upgrade to TFIM V6.2 and follow the instructions in "Configuring authentication or security token validation with a WS-Trust v1.3 STS (TFIM V6.2)" on page 457.

When you use TFIM V6.1 for authentication, a request is made to the TFIM trust service with the following three parameters, which select the module chain:

- Issuer = Properties.IdentitySourceIssuedBy
- Applies To = The Fully Qualified Name of the Flow: <*Brokername*>.<*Execution Group Name*>.<*Message Flow Name*>
- Token = Properties.IdentitySourceToken

For more information about these parameters, see "Authentication, mapping, and authorization with TFIM V6.1 and TAM" on page 416.

For further information about how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

Steps for enabling TFIM authentication:

Procedure

To enable an existing message flow to perform identity authentication, use the Broker Archive editor to select a security profile that uses TFIM for authentication. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
3. Click the **Manage and Configure** tab.
4. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
5. In the **Security Profile Name** field, select a security profile that uses TFIM for authentication.
6. Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 774.

If the message identity does not contain enough information for authentication, the information must be taken from the message body. For example, if a password is required for authentication but the message came from WebSphere MQ with only a username, the password information must be taken from the message body. Use the MQOutput node to send messages to clients that connect to the broker using the WebSphere MQ Enterprise Transport and that use the MQI and AMI application programming interfaces.

Configuring identity mapping

Configure a security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you start:

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile. For information about security profiles, see "Creating a security profile" on page 433.

About this task

WebSphere Message Broker provides support for identity mapping (also known as identity federation) and token issuance and exchange. Identity mapping is the process of mapping an identity in one realm to another identity in a different realm. For example, you might map *User001* from the eSellers realm to *eSellerUser01* in the eShipping realm. Token issuance and exchange involves the mapping of a token of one type to a token of a different type. For example, an incoming Username and Password token from a client over MQ might be mapped into an equivalent SAML assertion, to be propagated to a Web Services call. Alternatively, you might exchange a SAML 1.1 assertion from a client application for an equivalent SAML 2.0 assertion for an updated backend server.

For information about configuring identity mapping with either a WS-Trust V1.3 STS (for example, TFIM V6.2) or with TFIM V6.1, see:

- "Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2)" on page 465
- "Configuring identity mapping with TFIM V6.1" on page 467

Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2):

Configure a WS-Trust V1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2, to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you start:

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile. For information about security profiles, see "Creating a security profile" on page 433.

About this task

To configure TFIM V6.2 to map an incoming security token, you must create a custom module chain in TFIM, which performs the security operations. The TFIM configuration controls the token type that is returned from the mapping.

When you use a WS-Trust V1.3 STS for identity mapping, a request is made to the security token server with the following parameters, which control the STS processing:

- RequestType
- Issuer
- AppliesTo

If you are using TFIM V6.2, these parameters are used in the selection of the module chain.

The security manager invokes the WS-Trust v1.3 provider only once, even if it is set for additional security operations (such as authentication or authorization). As a result, when you are using TFIM V6.2, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

When the security profile includes a mapping operation, the STS (for example, TFIM V6.2) must return a security token in its response. The STS can return the original unmodified token if no token exchange is required.

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

The WS-Trust v1.3 specification, published by OASIS, is available at:
`http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html`

For information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

Follow these steps to enable an existing message flow to perform identity mapping.

Procedure

Using the Broker Archive editor, select a security profile that has mapping enabled. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. In the Message Broker Toolkit, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the message flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, enter the name of a security profile that has mapping enabled.
5. Save the BAR file.

Configuring identity mapping with TFIM V6.1:

Configure Tivoli Federated Identity Manager (TFIM) V6.1 to map the incoming security token and, if required, to authenticate and authorize it.

Before you begin

Before you start:

Before you can configure a message flow to perform identity mapping, you need to check that an appropriate security profile exists, or create a new security profile.

For information about security profiles, see “Creating a security profile” on page 433.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of WebSphere Message Broker. If possible, upgrade to TFIM V6.2 and follow the instructions in “Configuring identity mapping with a WS-Trust V1.3 STS (TFIM V6.2)” on page 465.

To configure TFIM V6.1 to map the incoming security token, you need to create a custom module chain in TFIM, which performs the security operations. The TFIM configuration controls the token type that is returned from the mapping.

When you use TFIM for mapping, a request is made to the TFIM trust service with the following three parameters, which select the module chain:

- Issuer = Properties.IdentitySourceIssuedBy
- AppliesTo = The fully qualified name of the flow: *Brokername.Execution Group Name.Message Flow Name*
- Token = Properties.IdentitySourceToken

The security manager invokes the security provider only once, even if it is set for additional security operations (such as authentication or authorization). As a result, when you are using TFIM V6.1, you must configure a single module chain to perform all the required authentication, mapping, and authorization operations.

For information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

Follow these steps to enable an existing message flow to perform identity mapping.

Procedure

Using the Broker Archive editor, select a security profile that has mapping enabled. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. In the Message Broker Toolkit, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, enter the name of a security profile that has mapping enabled.
5. Save the BAR file.

Set up security on a message flow to control access based on the identity of a message passing through the message flow.

Configuring authorization with LDAP:

This topic describes how to configure a message flow to perform authorization on an identity using Lightweight Directory Access Protocol (LDAP).

Before you begin

Before you start:

Before you can configure a message flow to perform authorization, you need to check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for LDAP" on page 435.

About this task

When LDAP is used for authorization, the broker needs to determine whether the incoming username is a member of the given group. To do this, the broker requires the following information:

- To resolve the username to an LDAP entry, the broker needs to know the base distinguished name (Base DN) of the accepted login IDs. This is required to enable the broker to differentiate between different entries with the same name.
- To get an entry list from a group name, the group name must be the distinguished name of the group, not just a common name. An LDAP search is made for the group, and the username is checked by finding an entry matching the distinguished name of the user.
- If your LDAP directory does not permit login by unrecognized IDs, and does not grant search access rights on the subtree, you must set up a separate authorized login ID that the broker can use for the search. Use the **mqsisetdbparms** command to specify a username and password:

  ```
  mqsisetdbparms -n ldap::LDAP -u username -p password
  ```

  or

  ```
  mqsisetdbparms -n ldap::<servername> -u username -p password
  ```

  where <*servername*> is your base LDAP server name. For example: `ldap.mydomain.com`.

  If you specify `ldap::LDAP`, it creates a default setting for the broker, which the broker attempts to use if you have not explicitly used the **mqsisetdbparms** command to create a login ID for a specific <*servername*>. All servers that do not have an explicit `ldap::servername` entry then start using the credentials in the

`ldap::LDAP` entry. This means that any servers that were previously using anonymous bind by default will start using the details in `ldap::LDAP`.

The username that you specify in the **-u** parameter must be recognized by the LDAP server as a complete user name. In most cases this means that you need to specify the full DN of the user. Alternatively, by specifying a username to be anonymous, you can force the broker to bind anonymously to this LDAP server. This might be useful if you have specified a non-anonymous bind as your default (ldap::LDAP). For example:

```
mqsisetdbparms -n ldap::<servername> -u anonymous -p password
```

In this case, the value specified for *password* is ignored.

Steps for enabling LDAP authorization:

Procedure

To enable an existing message flow to perform authorization using LDAP, use the Broker Archive editor to select a security profile that has authorization enabled. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the BAR file and then click **Open with** > **Broker Archive Editor**.
3. Click the **Manage and Configure** tab.
4. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
5. In the **Security Profile Name** field, select a security profile that uses LDAP for authorization.
6. Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see “Policy sets” on page 774.

Configuring authorization with a WS-Trust v1.3 STS (TFIM V6.2):

You can configure supported message flow input nodes or SecurityPEP nodes to perform authorization of an identity or security token by using a WS-Trust v1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2.

Before you begin

Before you start:

Before you configure a message flow to perform authorization with a WS-Trust v1.3 STS:

- Check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440.

About this task

The message flow security manager issues an authorization request to the WS-Trust service with the following parameters, which select the TFIM module chain to be used:

- RequestType

- Issuer
- AppliesTo

For more information about these parameters, see:"Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

In addition to configuring Message Broker to perform authorization with a WS-Trust compliant STS, you must configure TAM. For information about how to do this, see the following topics:

- "Creating a module chain in TFIM V6.2" on page 478
- "Configuring TAM for authorization using TFIM V6.2" on page 480

Steps for enabling authorization using a WS-Trust v1.3 STS provider:

Procedure

To enable an existing message flow to enforce authorization using a WS-Trust v1.3 STS provider, use the Broker Archive editor to select a security profile that has authorization set for that provider. You can set a security profile on a message flow or on individual input nodes or SecurityPEP nodes. If you leave the **Security Profile** property blank, the node inherits the **Security Profile** property that is set at the message flow level. If you leave the property blank at both levels, security is turned off for the node.

1. In the Message Broker Toolkit, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, select a security profile that has authorization set for *WS-Trust V1.3 STS*.
5. Save the BAR file.

What to do next

For a SOAPInput node to use the token in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 774.

The WS-Trust v1.3 specification is available at: `http://docs.oasis-open.org/ws-sx/ws-trust/200512/ws-trust-1.3-os.html`.

Creating a module chain in TFIM V6.2:

This topic describes how to create a module chain in Tivoli Federated Identity Manager (TFIM) V6.2.

About this task

When you use a WS-Trust v1.3 security token server (STS) for authentication, authorization, or mapping (or any combination of those operations), a single WS-Trust request is made to the trust service with the required parameters, which control the STS processing.

To enable WebSphere Message Broker to use TFIM V6.2 for authorization, you need to configure TFIM to process the single WS-Trust request from the broker security manager. To configure TFIM, you must create a module chain to handle the request:

Procedure

1. Create a *Custom* module chain, and ensure that the chain performs all the actions that are specified in the broker security profile (Authenticate, Map, Authorize).
2. Set the *RequestType*, *Issuer* and *AppliesTo* properties of the module chain, so that it is invoked for the requests from the security enabled input node or SecurityPEP node. The parameters that are passed by the broker to TFIM are shown in the table in "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

What to do next

If your module chain includes an authorization module, and if the module specifies TAM, you must configure TAM to process the authorization requests from TFIM. For more information about how to do this, see "Configuring TAM for authorization using TFIM V6.2" on page 480.

Related concepts:

Configuring TAM for authorization using TFIM V6.2:

Configure Tivoli Access Manager (TAM) to enable authorization using Tivoli Federated Identity Manager (TFIM) V6.2.

About this task

To configure TAM for a TFIM V6.2 TAMAuthorizationSTSModule, complete the following steps using the pdadmin utility.

Procedure

1. Check that the **action group** used by the TFIM authorization module is available. The action group used is *WebService*:

   ```
   action group list
   ```

   If *WebService* is not listed, create it:

   ```
   action group create WebService
   ```

2. Display the **action** in the action group used by the TFIM authorization module. The action used is *"i"*:

   ```
   action list WebService
   ```

   If action *"i" <label> 0* is not listed, create it. The value of <*label*> can vary:

   ```
   action create i <label> 0 WebService
   ```

3. Create the Access Control List (ACL) that will be used to grant access to one or more message flows. First, create the ACL and give the administrators access to it. In this example, `iv-admin` is the administration group and `sec_master` is the main administrator:

   ```
   acl create <AclName>
   acl modify <AclName> set Group iv-admin TcmdbsvaBRxl[WebService]i
   acl modify <AclName> set User sec_master TcmdbsvaBRxl[WebService]i
   ```

4. Grant access to all authenticated users, or specific groups, by adding them to the ACL. Grant any authenticated identity access:

   ```
   acl modify <AclName> set Any-other Trx[WebService]i
   ```

   To add a specific group:

   ```
   acl modify <AclName> set group <GroupName> Trx[WebService]i
   ```

   In these strings, each occurrence of `Trx[ ]` is an action, and corresponds to the value of the stsuser Action context attribute that is passed into the TAMAuthorizationSTSModule. For more information, see "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

5. Create a protected object space path in TAM to correspond to the value of the stsuser ObjectName context attribute that is passed into the TAMAuthorizationSTSModule using the following command syntax:

   ```
   objectspace create /<ObjectName>
   ```

   For more information, see "Authentication, mapping, and authorization with TFIM V6.2 and TAM" on page 419.

6. Attach the ACL to the protected object space path that you have created. Each node in the object space inherits ACLs from its parent, and a lower level ACL can override a higher level one. Use the following command syntax to attach an ACL to a node in the object space path:

   ```
   acl attach /<ObjectSpacePath> <AclName>
   ```

What to do next

For further information about configuring TAM, see the IBM Tivoli Access Manager Information Center.

Configuring authorization with TFIM V6.1:

You can configure a message flow to perform authorization on an identity by using Tivoli Federated Identity Manager (TFIM) V6.1.

Before you begin

Before you start:

Before you configure a message flow to perform authorization with TFIM V6.1:

- Check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile for TFIM V6.1" on page 444.
- Define the required users and groups in TFIM.

About this task

Note: Support for TFIM V6.1 is included for compatibility with previous versions of WebSphere Message Broker. If possible, upgrade to TFIM V6.2 and follow the instructions in "Configuring authorization with a WS-Trust v1.3 STS (TFIM V6.2)" on page 475.

The broker security manager issues an authorization request to the TFIM trust service with the following three parameters, which select the TFIM module chain to be used:

- Issuer = Properties.IdentitySourceIssuedBy
- Applies To = The Fully Qualified Name of the Flow: <*Brokername*>.<*Execution Group Name*>.<*Message Flow Name*>
- Token = Properties.IdentitySourceToken

Authorization is performed with TFIM using an instance of the TFIM AuthorizationSTSModule in the selected module chain. The TFIM AuthorizationSTSModule must be set with `Mode = Other`. This AuthorizationSTSModule authorizes a user by checking an Access Control List (ACL) from Tivoli Access Manager (TAM). TFIM performs the authorization check by verifying that the action "i" (invoke) has been granted in an ACL for the `WebService` action group.

The ACL is found starting from the root of the TAM object space using a path formed from the Authorization module **`Web service protected object name`** parameter, followed by the **`Port Type`** and **`Operation Name`** from the authorization request. When the broker makes an authorization request to TFIM, the **`Port Type`** and **`Operation Name`** parameters have the following values:

- PortType:<*Message flow name*>
- Operation "MessageFlowAccess"

Therefore, the ACL is found at this location in the TAM object space:

```
/<WSProtectedObjectName>.<MessageFlowName>."MessageFlowAccess"
```

For more information about this process and the parameters, see “Authentication, mapping, and authorization with TFIM V6.1 and TAM” on page 416.

Steps for enabling TFIM authorization:

Procedure

To enable an existing message flow to perform authorization with TFIM, use the Broker Archive editor to select a security profile that has authorization enabled. You can set a security profile on a message flow or on individual input nodes. If no security profile is set for the input nodes, the setting is inherited from the setting on the message flow.

1. Switch to the Broker Application Development perspective.
2. In the Broker Development view, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
3. Click the **Manage and Configure** tab.
4. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
5. In the **Security Profile Name** field, select a security profile that has authorization enabled.
6. Save the BAR file.

What to do next

For a SOAPInput node to use the identity in the WS-Security header (rather than an underlying transport identity) an appropriate policy set and bindings must also be defined and specified. For more information, see "Policy sets" on page 774.

In addition to configuring Message Broker to perform authorization with TFIM, you must configure TFIM and TAM. For information about how to do this, see the following topics:

- "Creating a module chain in TFIM V6.1" on page 487
- "Configuring TAM for authorization using TFIM V6.1" on page 489.

For further information on how to configure TFIM, see the IBM Tivoli Federated Identity Manager Information Center.

Creating a module chain in TFIM V6.1:

This topic describes how to create a module chain in Tivoli Federated Identity Manager (TFIM) V6.1.

About this task

To enable Message Broker to use TFIM V6.1 for authorization, you need to configure TFIM to process the security request from the message flow. To do this you need to create a module chain in TFIM to handle the request:

Procedure

1. Create a *Custom* module chain, and ensure that the chain performs all the actions required (Authenticate, Map, Authorize).
2. Set the *Issuer* and *AppliesTo* properties of the module chain, so that it is invoked for the requests from the message flow. When the broker makes a request to TFIM, the **Port Type** and **Operation Name** parameters have the following values:
   - PortType:<*Message flow name*>
   - Operation "MessageFlowAccess"

   The *RequestType* is always set to *Validate*.
3. To perform authorization in a module chain, add an instance of the Authorization module in *other* mode, which allows the module parameter **Web Service protected object name** to be set for the Tivoli Access Manager (TAM) configuration.

What to do next

When you have created the module chain in TFIM, see "Configuring TAM for authorization using TFIM V6.1" on page 489 for information on how to configure TAM to process authorization requests from TFIM.

Configuring TAM for authorization using TFIM V6.1:

This topic describes how to configure Tivoli Access Manager (TAM) to enable authorization using Tivoli Federated Identity Manager (TFIM) V6.1.

About this task

To configure TAM to process an authorization request from TFIM, complete the following steps. The examples relate to the TAM Version 6.01 pdadmin utility:

Procedure

1. Check that the **action group** used by the TFIM authorization module is available. The action group used is *WebService*:

   ```
   action group list
   ```

   If *WebService* is not listed, create it:

   ```
   action group create WebService
   ```

2. Display the **action** in the action group used by the TFIM authorization module. The action used is *"i"*:

   ```
   action list WebService
   ```

   If action *"i" <label> 0* is not listed, create it. The value of <*label*> can vary:

   ```
   action create i <label> 0 WebService
   ```

3. Create the Access Control List (ACL) that will be used to grant access to one or more message flows. First, create the ACL and give the administrators access to it. In this example, `iv-admin` is the administration group and `sec_master` is the main administrator:

   ```
   acl create <AclName>
   acl modify <AclName> set Group iv-admin TcmdbsvaBRxl[WebService]i
   acl modify <AclName> set User sec_master TcmdbsvaBRxl[WebService]i
   ```

4. Grant access to all authenticated users, or specific groups, by adding them to the ACL. Grant any authenticated identity access:

   ```
   acl modify <AclName> set Any-other Trx[WebService]i
   ```

   To add a specific group:

   ```
   acl modify <AclName> set group <GroupName> Trx[WebService]i
   ```

5. Define protected object spaces in TAM for authorization of message flows:
   a. Create the *application container object* as the root of the protected object space. This is the name that is used to link an instance of a TFIM AuthorizationSTSModule (within a module chain) into the TAM object space. The container object name is specified to match the **Web Service protected object name** parameter on a TFIM Authorization module.

      ```
      objectspace create /<ContainerObjectName> <Description> 14
      ```

   b. Create the container objects in the tree for each broker message flow that is being authorized. The message flow name is used by TFIM to locate a point in the TAM Object Space tree for Authorization, through the attached ACL. The message flow name is passed as the **PortType** in the WS-Trust request to TFIM. Use the following command to create the object tree node representing each flow to be authorized:

```
object create /<ContainerObjectName>/<FlowName> <Description> 11 ispolicyattachable yes
```

The **ispolicyattachable** parameter applies to all levels, so you can attach an ACL at any level.

c. Create the leaf object that represents the authorized object to grant access to the message flow. This is the fixed string *MessageFlowAccess*, which the broker sends to TFIM through the TFIM **OperationName** extension to the WS-Trust request. A fixed name (MessageFlowAccess) is used instead of a true operation name, because the broker does not necessarily know at the input node which operation a flow is going to perform. The command syntax is:

```
object create /<ContainerObjectName>/<FlowName>/MessageFlowAccess <Description> 12 ispolicyattachable yes
```

where <*FlowName*> has been created in a previous step.

6. Attach the ACL to the relevant node in the protected object space tree. Each node in the object space inherits ACLs from its parent, and a lower level ACL can override a higher level one. Use the following command syntax to attach an ACL to a node in the object space:

```
acl attach /<ObjectSpacePath> <AclName>
```

To attach an ACL to the leaf node:

```
acl attach /<ContainerObjectName>/<FlowName>/MessageFlowAccess <AclName>
```

What to do next

For further information about configuring TAM, see the IBM Tivoli Access Manager Information Center.

Configuring for identity propagation

To enable a message flow to perform identity propagation, the input nodes must extract the identity and the output node must propagate it.

Before you begin

Before you start:

Before you can configure a message flow to perform identity propagation, you must check that an appropriate security profile exists, or create a new security profile. See "Creating a security profile" on page 433.

About this task

An input node extracts security tokens if it is configured with a security profile at deployment time. An output node propagates an identity if it is configured with a security profile that enables propagation at deployment time.

To enable a message flow to perform identity propagation, complete the following steps.

Procedure

By using the Broker Archive editor, select a security profile that has identity propagation enabled. You can use the Default Propagation profile, which is a predefined profile that requests only identity propagation. You can set a security profile on a message flow or on individual input and output nodes. If no security profile is set for the input and output nodes, the setting is inherited from the setting on the message flow.

1. In the Broker Development view, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.
2. Click the **Manage and Configure** tab.
3. Click the flow or node on which you want to set the security profile. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.
4. In the **Security Profile Name** field, select a security profile that has identity propagation enabled.
5. Save the BAR file.

What to do next

For a SOAPRequest or SOAPAsyncRequest node, you can define an appropriate policy set and bindings to specify how the propagated identity is placed in the

WS-Security header (rather than the underlying transport headers). For more information, see “Policy sets” on page 774.

On SOAPRequest and SOAPAsyncRequest nodes, only Username and SAML tokens can be propagated. However, on the SOAPRequest and SOAPAsyncRequest nodes with a Kerberos policy set and bindings, a Username and password token can be propagated into the node to provide the Kerberos client credentials.

For the SAPRequest node, you can propagate only the user name and password. For the CICSRequest and IMSRequest nodes, you can propagate the user name, or the user name and password.

If the message identity does not contain enough information for identity propagation, you can use any of the following methods to acquire the necessary information:

- Take the information from the message body. For example, if the message comes from WebSphere MQ with only a username token, and the output is an HTTP request node requiring a Username + Password token, the password might be present in the body of the incoming message. For more information, see “Configuring the extraction of an identity or security token” on page 447.
- Configure an identity mapper using TFIM. For more information, see the IBM Tivoli Federated Identity Manager Information Center.
- Use ESQL or Java to set the Mapped Identity fields in the Properties tree.

Database security

You can access databases from the message flows that you deploy to your brokers, and must therefore consider the steps you might want to take to secure that access.

About this task

After you have defined user IDs that you want the broker to use for database access by using the **mqsisetdbparms** command, you must authorize those IDs so that the broker can access your databases from deployed message flows.

If you have migrated your broker from a previous release, the broker accessed a database for its own use, and you might have defined the user ID and password used to access that database by specifying a database connection user ID and password with the **-u** and **-p** parameters on the **mqsicreatebroker** command. Alternatively, you might have used the broker service user ID and its password (specified with the **-i** and **-a** parameters on the same command). When you migrate the broker, these parameters are migrated and stored, and are used by the migrated broker for access to databases that do not have specific ID access defined. On WebSphere Message Broker Version 7.0, you can use only the **mqsisetdbparms** command to set or change values for database access by the broker, because the parameters have been deprecated. (The service user ID and password are required on Windows, but are no longer used for database access.)

WebSphere Message Broker does not provide special commands to administer databases. Discuss your database security requirements with the database administrator for the database manager that you are using, or refer to the documentation provided by your database supplier.

For further information about possible security requirements, and examples of setting up security for DB2 and Oracle databases, see "Authorizing access to user databases" on page 662.

Diagnosing security problems

This topic explains how to find out why access to a secured flow has been denied.

About this task

By default, security exceptions occurring in an input node are not processed in the same way as other errors (see "Security exception processing" on page 429). Security exceptions are not logged to the system event log, to prevent a security denial of service attack filling the logs and destabilizing the system.

This means that, by default, you cannot diagnose input node security exceptions in the same way as other errors. However, in a SecurityPEP node, a failing security operation causes a security exception to be raised, wrapped in a normal recoverable exception, which invokes the error handling that is provided by the message flow.

To see what might be causing the security exceptions, you can do either of the following things:

- Select the **Treat Security Exceptions as normal exceptions** property on the input nodes.
- Use the user trace.

The following steps show you how to use the user trace to find out why access to a secured message flow has been denied:

Procedure

1. Use the **mqsireloadsecurity** command to clear the security cache, so that the traced request goes to the security provider rather than using a result held in the cache. This ensures that the reason codes returned from the security provider are displayed in the traced exception.
2. Enable user trace for the message flow, using either the workbench or the **mqsichangetrace** command (see "Starting user trace" on page 3197 for more information).
3. Resend the request that has been rejected by the security provider.
4. Stop the user trace, using either the workbench or the **mqsichangetrace** command.
5. Use the **mqsireadlog** command to examine the trace information that was recorded by the user trace. This trace information contains the error codes provided by the broker and the security provider.

Broker component security

You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

About this task

For an introduction to various aspects of security, see "Security overview" on page 351.

This section does not apply to z/OS. Refer to "Setting up z/OS security" on page 556 and "Summary of required access (z/OS)" on page 3985 for information about setting up broker security on z/OS.

Before you start setting up security for your brokers, refer to “Planning for security when you install WebSphere Message Broker” on page 353, which contains links to security information that you need before, during, and after installation of WebSphere Message Broker.

Use the following list of tasks as a security checklist. Each item comprises a list of reminders or questions about the security tasks to consider for your brokers. The answers to the questions provide the security information that you require to configure your brokers, and also give you information about other security controls that you might want to employ.

- “Creating user IDs”
- “Considering security for the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer” on page 500
- “Considering security for a broker” on page 501
- “Implementing SSL authentication” on page 504
- “Using security exits” on page 555

The professionals in your organization require access to components and resources on z/OS.

Creating user IDs

When you plan the administration of your broker configuration, you might have to define one or more user IDs for the tasks associated with particular roles.

About this task

Some operating systems, and other products, impose restrictions on user IDs:

- On Windows systems, user IDs can be up to 12 characters long, but on Linux, UNIX, and z/OS systems, they are restricted to eight characters.
- Database products might also restrict user IDs to eight characters; for example DB2 has this restriction. If you have a mixed environment, ensure that the user IDs that you use are limited to a maximum of eight characters.

- Ensure that the case (upper, lower, or mixed) of user IDs is consistent. In some environments, uppercase and lowercase user IDs are considered the same, but in other environments, user IDs of different case are considered unique.

  For example, on Windows systems, the user IDs 'tester' and 'TESTER' are identical; on Linux and UNIX systems, they are recognized as different user IDs.
- Check the validity of spaces and special characters in user IDs to ensure that, if used, these characters are accepted by all relevant systems and products that you install.

Consider the following roles:

Procedure

- Administrator user IDs that can issue **mqsi*** commands. Ensure that all these user IDs are members of the mqbrkrs group.

  If you enable broker administration security, you must set up additional authorization for user IDs for the commands listed in "Commands and authorizations for broker administration security" on page 3646. For more information about broker administration security, see "Broker administration security overview" on page 362.
- On Windows only, service user IDs under which brokers run. For further information, see "Deciding which user account to use for the broker service ID" on page 502.
- Workbench users. See "Considering security for the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer" on page 500 for information about checking and securing connections from the WebSphere Message Broker Toolkit.

Considering security for the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer

Set up appropriate levels of security for the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer.

Before you begin

When you create a broker, a default SVRCONN channel, `SYSTEM.BKR.CONFIG`, is created. This channel supports connections from one or more remote clients to the broker. Clients that are running on the same computer as the broker connect directly to the queue manager; they do not require a connection through a channel.

If you want to secure the connection between your WebSphere Message Broker Toolkit session, or WebSphere Message Broker Explorer session, and the broker, you can configure the SVRCONN channel to specify security options.

You can use a single channel for all client connections, create a channel for each client connection, or share connections between two or more clients that have the same security requirements. You can use the default channel, and create additional channels if required. If you do not use the default channel, you must set the alternative name in the connection properties.

You can secure the connection between the WebSphere Message Broker Explorer, the WebSphere Message Broker Toolkit, a command that uses the CMP interface (**mqsichangeresourcestats**, **mqsicreateexecutiongroup**, **mqsideleteexecutiongroup**, **mqsideploy**, **mqsilist**, **mqsimode**, **mqsireloadsecurity**, **mqsireportresourcestats**, **mqsistartmsgflow**, **mqsistopmsgflow**), or a CMP application, by using one or both of the following options:

- WebSphere MQ channel security exits
- Secure Socket Layer (SSL)

See "Securing the channel between the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer and the broker" for details about how to set up the security you want.

Ensure that user IDs are not more than eight characters long.

Securing the channel between the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer and the broker

About this task

Implement one or both of the following options for the WebSphere Message Broker Toolkit and WebSphere Message Broker Explorer clients:

Procedure

- Create and enable a pair of WebSphere MQ security exits to run at the client and broker ends of the SVRCONN channel that connects the two components. Program these exits to verify client users with the security manager on the computer on which the broker is running.

  For more information about creating and enabling security exits, see "Security exits" on page 354.
- Implement SSL security on the channel. You must have the appropriate software to manage SSL certificate stores; for example, you can install either the

WebSphere MQ Client or the Server, and use the IBM Key Management tools for the client. You can use either JKS or PKCS12 stores.

1. Use WebSphere MQ facilities to update the SVRCONN definition to specify the required value in the SSLCIPH attribute.
2. In the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, define the connection to the broker. You can set the SSL fields only when you define the connection; you cannot change them later. If you have already defined your connection, delete it, and define it again.
3. Select the cipher suite that matches the value you set for the SSLCIPH property of the SVRCONN channel.
4. Enter the full path and name for the keystore and truststore, or click **Browse** to search for them.
5. Add the queue manager certificate to the client truststore.
6. If you want server-only (one way) certification, set the SVRCONN channel attribute SSLCAUTH to OPTIONAL.
7. If you want mutual (two way) certification:
   - Set the SVRCONN channel attribute SSLCAUTH to REQUIRED.
   - Add the client certificate to the queue manager truststore.

For further details about setting up SSL configuration, see "Enabling SSL on the WebSphere MQ Java Client" on page 540.

For more information about configuring connections to be secured with SSL, see the WebSphere MQ Java Client developerWorks article.

Considering security for a broker

Consider several factors when you are deciding which users can execute broker commands, and which users can control security for other broker resources.

About this task

Although most security for the broker and broker resources is optional, you might find it appropriate to restrict the tasks that some user IDs can perform. You can then apply greater control to monitor changes.

You can control all broker administration tasks by enabling broker administration security when you create a broker. You can also change existing brokers to enable administration security. This option is described in "Setting up broker administration security" on page 368, and is independent of the options described in this section.

When you are deciding which users are to perform the different tasks, consider the following steps:

Procedure

1. "Deciding which user account to use for the broker service ID"
2. "Setting security on the broker queues" on page 503
3. "Securing the broker registry" on page 503

Deciding which user account to use for the broker service ID

About this task

On a Linux or UNIX operating system, when you run the **mqsistart** command with a user ID that is a member of the mqm and mqbrkrs groups, the user ID under which you run the **mqsistart** command becomes the user ID under which the broker component process runs.

On the Windows platform the broker runs under a service user account. To decide which user ID to use for the broker service ID answer the following questions:

Procedure

1. Do you want your broker to run under a Windows local account?
   a. No: Go to the next question.
   b. Yes: Ensure that your user ID has the following characteristics:
      - It is defined in your local domain.
      - It is a member of the mqbrkrs group.

      Go to "Setting security on the broker queues" on page 503.
2. Do you want your broker to run under a Windows domain account?
   a. No: Go to the next question.
   b. Yes: Assume that your computer named, for example, WKSTN1, is a member of a domain named DOMAIN1. When you run a broker using, for example, DOMAIN1\user1, ensure that:
      - Your user ID has been granted the `Logon as a service` privilege (from the Local Security Policy).
      - DOMAIN1\user1 is a member of DOMAIN1\MyDomainGroup group, where MyDomainGroup is a domain group which you have defined on your domain controller.
      - DOMAIN1\MyDomainGroup is a member of WKSTN1\mqbrkrs.

      Go to "Setting security on the broker queues" on page 503.
3. Do you want your broker to run under theWindows built in `LocalSystem` account?

a. Yes: Specify `LocalSystem` for the *–i* parameter on the **mqsicreatebroker** or **mqsichangebroker** command.

   In either case you must enter the *–a* (password) parameter on the command line, but the value entered is ignored.

   Go to "Setting security on the broker queues."

Results

Note that for cases one and two above, the user ID chosen must be granted the `Logon as a service` privilege.

This is normally done automatically by the **mqsichangebroker** command or the **mqsichangeproperties** command when a service user ID is specified that does not have this privilege.

However, if you want to do this manually before running these commands, you can do this by using the Local Security Policy tool in Windows, which you can access by selecting **Control Panel** > **Performance and maintenance** > **Administrative Tools** > **Local Security Policy**.

Setting security on the broker queues

About this task

When you run the **mqsicreatebroker** command, the local mqbrkrs group is granted access to internal queues whose names begin with the characters SYSTEM.BROKER.

Securing the broker registry

About this task

Broker operation depends on the information in the broker registry, which you must secure to guard against accidental corruption. The broker registry is stored in the Windows registry or the Linux or UNIX file system. Set your operating system security options so that only user IDs that are members of the group mqbrkrs can read from or write to *brokername*`/CurrentVersion` and all subkeys.

"Security overview" on page 351
When you are designing a WebSphere Message Broker application it is important to consider the security measures that are needed to protect the information in the system.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

Setting up a public key infrastructure

Configure keystores, truststores, passwords, and certificates to enable SSL communication, and Web Services Security.

Before you begin

Decide how you will use the public key infrastructure (PKI). You can configure keystores and truststores at either broker level (one keystore, one truststore, and one personal certificate for each broker) or at execution group level (one keystore, one truststore, and one personal certificate for each execution group). Execution groups that do not have PKI configured use the broker-level PKI configuration.

Encryption strength

The WebSphere Message Broker Java runtime environment (JRE) is provided with strong but limited strength encryption. If you cannot import keys into keystores,

limited strength encryption might be the cause. Either start ikeyman by using the **strmqikm** command, or download unrestricted jurisdiction policy files from IBM developer kits: Security information.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country. Check its regulations and its policies concerning the import, possession, use, and re-export of encryption software, to determine whether it is permitted. Note that when applying a fix pack to an existing Message Broker installation, the JVM is overwritten, including any updated policy set files. These must be restored before you restart the broker.

WebSphere Message Broker currently supports up to 4096 bit keys. Larger keys require more CPU resources for encryption and decryption.

About this task

This topic uses the command line tool, **gsk7cmd**, to create and populate keystores and truststores. The **gsk7cmd** tool is a part of the Global Secure Toolkit, supplied with WebSphere MQ. Other options, supplied with the WebSphere Message Broker JVM, include:

- A command-line tool, **keytool**.
- A graphical tool, **iKeyman**.

To create the infrastructure, complete the following tasks:

1. "Creating a keystore file or a truststore"
2. "Creating a self-signed certificate for test use" on page 506
3. "Importing a certificate for production use" on page 506
4. "Viewing details of a certificate" on page 506
5. "Extracting a certificate" on page 507
6. "Adding a signer certificate to the truststore" on page 508
7. "Listing all certificates in a keystore" on page 509
8. "Configuring PKI at broker level" on page 509
9. "Configuring PKI at execution group level" on page 510

Creating a keystore file or a truststore:

The keystore file contains the personal certificate for the broker or for the execution group. You can have only one personal certificate in the keystore. You can store signer certificates in the same file, or create a separate file, known as a truststore.

Procedure

1. Set the JAVA_HOME environment variable, for example:

   ```
   set JAVA_HOME=C:\WMB70\7.0\jre15
   ```

2. Issue the following command:

   ```
   gsk7cmd -keydb -create
     -db keystore_name
     [-pw password]
     -type jks
   ```

   The *password* argument is optional. If you omit it, you are prompted to enter a password. For example:

```
gsk7cmd -keydb -create
  -db myBrokerKeystore.jks
  -type jks
A password is required to access this key database.
Please enter a password:
```

Creating a self-signed certificate for test use:

Use self-signed certificates only for testing SSL, not in production.

Procedure

Enter the following command:

```
gsk7cmd -cert -create
  -db keystore_name
  [-pw password]
  -label cert_label
  -dn "distinguished_name"
```

For example:

```
gsk7cmd -cert -create
  -db myBrokerKeystore.jks
  -label MyCert
  -dn "CN=MyBroker.Server,O=IBM,OU=ISSW,L=Hursley,C=GB"
A password is required to access this key database.
Please enter a password:
```

Importing a certificate for production use:

Import a personal certificate from a certificate authority for production use.

Procedure

Issue the following command:

```
gsk7cmd -cert -import
  -db pkcs12_file_name
  [-pw pkcs12_password]
  -label label
  -type pkcs12
  -target keystore_name
  [-target_pw keystore_password]
```

For example:

```
gsk7cmd -cert -import
  -db SOAPListenerCertificate.p12
  -label soaplistener
  -type pkcs12
  -target myBrokerKeystore.jks
  -target_pw  myBrokerKpass
A password is required to access this key database.
Please enter a password:
```

Viewing details of a certificate:
Procedure

Issue the following command:

```
gsk7cmd -cert -details
  -db keystore_name
  [-pw password]
  -label label
```

For example:

```
gsk7cmd -cert -details
  -db myKeyStore.jks
  -label MyCert
A password is required to access this key database.
Please enter a password:

Label: MyCert

```

Extracting a certificate:

Generate a copy of a self-signed certificate that you can import as a trusted (or signer certificate) into a truststore file. Use this procedure only for testing, not production.

About this task

Certificates can be extracted in two formats:

- Base64-encoded ASCII data (`.arm`). This format is convenient for inclusion in XML messages, and transmission over the Internet.
- Binary DER data (`.der`).

Procedure

Issue the following command:

```
gsk7cmd -cert -extract
  -db keystore_name
  -pw keystore_passwd
  -label label
  -target file_name
  [-format ascii | binary]
```

For example:

```
gsk7cmd -cert -extract
  -db myBrokerKeystore.jks
  -pw myKeyPass
  -label MyCert
  -target MyCert.arm
  -format ascii
```

You can then view the certificate in a text editor, such as Notepad:

```
notepad MyCert.arm
-----BEGIN CERTIFICATE-----

```

Adding a signer certificate to the truststore:

Add a signer certificate to the truststore of a broker or execution group.

About this task

The following steps show how to add an extracted certificate as signer certificate to the truststore file. Adding the broker self-signed certificate to a broker or execution group truststore enables request nodes (HTTP or SOAP) to send test messages to input nodes (HTTP or SOAP) when the flows are running on the broker or execution group.

Procedure

Issue the following command:

```
gsk7cmd -cert -add
  -db truststore_name
  [-pw password]
  -label label
  -file file_name
  -format [ascii | binary]
```

For example:

```
gsk7cmd -cert -add
  -db myBrokerTruststore.jks
  -label CACert
  -file TRUSTEDPublicCerticate.arm
  -format ascii
```

You can view details of the certificate:

```
gsk7cmd -cert -details -db myBrokerTruststore.jks -label CACert
A password is required to access this key database.
Please enter a password:

Configuring PKI at broker level:

Define the broker registry properties that identify the location, name, and password of the keystore and truststore files.

About this task

1. Start the broker:

   ```
   mqsistart broker_name
   ```

2. Display the current settings of the broker registry properties:

   ```
   mqsireportproperties broker_name
     -o BrokerRegistry
     –r
   ```

3. Set the keystore property:

   ```
   mqsichangeproperties broker_name
     -o BrokerRegistry
     -n brokerKeystoreFile
     -v C:\WMB\MQSI\7.0\MyBrokerKeystore.jks
   ```

4. Set the truststore property:

```
mqsichangeproperties broker_name
  -o BrokerRegistry
  -n brokerTruststoreFile
  -v C:\WMB\MQSI\7.0\MyBrokerTruststore.jks
```

5. Stop the broker:

```
mqsistop broker_name
```

6. Set the password for the keystore:

```
mqsisetdbparms broker_name
  -n brokerKeystore::password
  -u ignore
  -p keystore_pass
```

7. Set the password for the truststore:

```
mqsisetdbparms broker_name
  -n brokerTruststore::password
  -u ignore
  -p truststore_pass
```

8. Start the broker:

```
mqsistart broker_name
```

9. Display and verify the broker registry properties:

```
mqsireportproperties broker_name
  -o BrokerRegistry –r
```

Configuring PKI at execution group level:

Define the ComIbmJVMManager properties for the required execution group to identify the location, name, and password of the keystore and truststore files.

About this task

1. Start the broker.

```
mqsistart broker_name
```

2. Display the current settings of the ComIbmJVMManager properties.

```
mqsireportproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager -r
```

3. Set the keystore property.

```
mqsichangeproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager
  -n keystoreFile
  -v C:\WMB\MQSI\7.0\MyBrokerexec_grp_name Keystore.jks
```

4. Set the keystore password key property. The value for this property is in the format *any_prefix_name*::password. This value is used to correlate the password defined in the **mqsisetdbparms** command.

```
mqsichangeproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager
  -n keystorePass
  -v exec_grp_nameKeystore::password
```

5. Set the truststore property.

```
mqsichangeproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager
  -n truststoreFile
  -v C:\WMB\MQSI\7.0\MyBrokerexec_grp_name Truststore.jks
```

6. Set the truststore password key property. The value for this property is in the format *any_prefix_name*::password. This value is used to correlate the password defined in the **mqsisetdbparms** command.

```
mqsichangeproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager
  -n truststorePass
  -v exec_grp_nameTruststore::password
```

7. Stop the broker.

```
mqsistop broker_name
```

8. Set the password for the keystore.

```
mqsisetdbparms broker_name
  -n exec_grp_nameKeystore::password
  -u ignore
  -p keystore_pass
```

9. Set the password for the truststore.

```
mqsisetdbparms broker_name
  -n exec_grp_nameTruststore::password
  -u ignore
  -p truststore_pass
```

10. Start the broker.

```
mqsistart broker_name
```

11. Display and verify the ComIbmJVMManager properties.

```
mqsireportproperties broker_name
  -e exec_grp_name
  -o ComIbmJVMManager -r
```

For information about cipher-suite requirements (such as the cryptographic algorithm and corresponding key lengths), see the developerWorks article on the Java Secure Socket Extension (JSSE) IBMJSSE2 Provider.

Configure the HTTPRequest node to communicate with other applications that use HTTP over SSL.

Listing SSL cipher suites

You can view the available cipher suites in the WebSphere Message Broker Toolkit when you connect to a remote broker. You can also view a list of the cipher suites that are supported by WebSphere Message Broker.

About this task

A cipher suite is a collection of algorithms that are used to encrypt data. During SSL authentication, the client and server compare cipher suites and select the first

one that they have in common. If no suitable cipher suites exist, the server returns a handshake failure alert and closes the connection.

To use SSL encryption, you need a Java Secure Socket Extension (JSSE) provider. WebSphere Message Broker supports the ciphers that are provided by the JSSE provider. For more information about Java security, see IBM Java security web page.

You can view the available cipher suites in the WebSphere Message Broker Toolkit when you connect to a remote broker:

1. In the Brokers view, right-click **Brokers**, then click **Connect to a Remote Broker**.
2. Provide a queue manager name, host name, and port number, then click **Next**.
3. Click the arrow to the right of **Cipher suite**.

A list of the cipher suites that are available in the Toolkit is displayed.

For a list of all the cipher suites that are supported by WebSphere Message Broker, see Appendix A of the IBM JSSE2 Guide.

Implementing SSL authentication on z/OS

Use SSL authentication to enhance security in your broker environment.

About this task

Complete the following tasks to implement SSL authentication for brokers running on z/OS.

1. “Generate a broker certificate using RACF as the Certification Authority (z/OS)”
2. “Create and initialize the broker keystore and truststore (z/OS)” on page 514
3. “Configure WebSphere Message Broker on z/OS for SSL” on page 516

Alternatively, you can enable SSL for WebSphere Message Broker on z/OS by following the instructions in “Enabling SSL on z/OS by using AT-TLS” on page 517.

Generate a broker certificate using RACF as the Certification Authority (z/OS):

You can use RACF as the Certification Authority (CA) for internal certificates in your enterprise.

About this task

To generate broker certificates, take the following steps:

1. Create the RACF CA signer certificate. This self-signed certificate is used to sign any other personal certificates created or requested in RACF. This step is required once.
2. Export the RACF CA signer certificate in CERTDER format. This certificate must be extracted without private keys; CERTDER is a binary format that guarantees that no private keys are exported.
3. Create the broker personal certificate. A copy of the certificate and of the private keys is maintained in RACF for future reissue or validation. This certificate must be associated with the broker user ID. Create a personal certificate for each broker or execution group for which you want to enable SSL.
4. Export the broker personal certificate in PKCS12DER format. PKCS12DER is a password-protected, binary format that contains the broker certificate and its private keys. You will later import it into the broker keystore; see “Create and initialize the broker keystore and truststore (z/OS)” on page 514.

Example commands for each step are as follows:

Procedure

1. Create the RACF CA signer certificate. For example:

```
RACDCERT CERTAUTH GENCERT +
   SUBJECTSDN(CN('RACF Cert Authority') T('PROD') +
   OU('RACF Group') +
   O('IBM') +
   L('HURSLEY') SP('WINCHESTER') C('GB')) +
   KEYUSAGE(CERTSIGN) +
   WITHLABEL('RACFCA') +
   NOTAFTER(DATE(2020/01/30)) +
   SIZE(1024)
```

2. Export the RACFCA certificate in CERTDER format. For example:

```
RACDCERT CERTAUTH EXPORT(LABEL('RACFCA')) +
   DSN('CSQP.CSQPBRK.CACERT.DER') FORMAT(CERTDER)

OPUT 'CSQP.CSQPBRK.CACERT.DER' +
    '/u/CSQPBRK/ssl/csqpbrk.ca.der' +
   BINARY CONVERT(NO)
```

   The OPUT command is optional. It is used to copy the certificate into a HFS file before FTP to another server.

3. Create the broker personal certificate. For example:

```
RACDCERT ID(CSQPBRK) +
   GENCERT SUBJECTSDN(CN('BROKER.HTTP.CSQPBRK') T('PROD') +
   OU('ISSW') O('IBM') +
   L('HURSLEY') SP('WINCHESTER') C('GB')) +
   WITHLABEL('CSQPBRKCERT') SIZE(1024) +
   SIGNWITH(CERTAUTH LABEL('RACFCA')) +
   KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN) +
   NOTAFTER(DATE(2020/01/30))
```

4. Export the broker certificate in PKCS12 format. For example:

```
RACDCERT ID(CSQPBRK) EXPORT(LABEL('CSQPBRKCERT')) +
     DSN('CSQP.CSQPBRK.PERSCERT.P12') +
     FORMAT(PKCS12DER) PASSWORD('changeit')

OPUT 'CSQP.CSQPBRK.PERSCERT.P12' +
     '/u/CSQPBRK/ssl/csqpbrk.pers.p12' +
     BINARY CONVERT(NO)
```

What to do next

What to do next: Create the broker keystore and import the personal certificate and RACF CA signer certificates.

Related tasks:

"Implementing SSL authentication on z/OS" on page 512
Use SSL authentication to enhance security in your broker environment.

"Create and initialize the broker keystore and truststore (z/OS)"
Create a keystore and import your personal certificate and signer certificates.

"Configure WebSphere Message Broker on z/OS for SSL" on page 516
Define the location of the keystore and truststore, set passwords, and enable SSL.

Create and initialize the broker keystore and truststore (z/OS):

Create a keystore and import your personal certificate and signer certificates.

Before you begin

Before you start:

- Create the necessary certificates.

Note: Due to export restrictions, the IBM JDKs ship with a set of restricted policy files that limit the size of the cryptographic keys that are supported. To overcome these restrictions, use the unrestricted policy files in the `$JAVA_HOME/lib/security` directory:

- local_policy.jar
- US_export_policy.jar

The unrestricted policy files are the same for the IBM JDK 1.4.2, IBM JDK 5, and IBM JDK 6. These files are in the `JAVA_HOME/demo/jce/policy-files/unrestricted` directory.

About this task

This topic describes how to use the same file as keystore and truststore. To specify different files, complete the process twice:

- Do not import signer certificates into the keystore.

- Do not import personal certificates into the truststore.

The tasks use **keytool** to create the keystore. An alternative is the **ikeyman** graphical tool, which requires an X Window System.

The following are the steps required to create and initialize the broker keystore:

1. Create the keystore. **keytool** requires a dummy key to be created to force the creation of the keystore file. The dummy key is deleted after the keystore is created.
2. Import the CA signer certificate or certificates. These are certificates that have signed certificates of client applications that connect to the WebSphere Message Broker and that are accepted as trusted applications.

Example commands for each step are as follows:

Procedure

1. Create the JKS keystore. For example:

```
/usr/lpp/java/J6.0/bin/keytool -genkey
     -alias DUMMY
     -keystore  /u/CSQPBRK/ssl/csqpbrkKeystore.jks
     -storetype jks
     -dname  "CN=DUMMY,OU=BROKER,O=IBM,L=Hursley,C=GB"
     -storepass changeit
     -keypass changeit
```

2. Delete the dummy key. For example:

```
/usr/lpp/java/J6.0/bin/keytool -delete
     -alias DUMMY
     -keystore  /u/CSQPBRK/ssl/csqpbrkKeystore.jks
     -storepass changeit
```

3. Optional: Import the CA signer certificates. Omit this step if you require separate files for a keystore and truststore, and are creating a keystore. For example:

```
/usr/lpp/java/J6.0/bin/keytool -import
     -keystore /u/CSQPBRK/ssl/csqpbrkKeystore.jks
     -storepass changeit
     -alias RACFCA
     -file /u/CSQPBRK/ssl/csqpbrk.ca.der -v
```

4. Optional: Import the broker personal certificate. Omit this step if you require separate files for a keystore and truststore, and are creating a truststore. For example:

```
/usr/lpp/java/J6.0/bin/keytool -import
  -keystore /u/CSQPBRK/ssl/csqbrkKeystore.jks
  -storepass changeit
  -alias CSQPBRK
  -file /u/CSQPBRK/ssl/csqpbrk.pers.p12
  -v
  -pkcs12
  -keypass changeit
  -noprompt
```

5. List the contents of the broker keystore. For example:

```
/usr/lpp/java/J6.0/bin/keytool -list
   -keystore /u/CSQPBRK/ssl/csqbrkKeystore.jks
   -storepass changeit
```

What to do next

What to do next: "Configure WebSphere Message Broker on z/OS for SSL."

Related tasks:

"Implementing SSL authentication on z/OS" on page 512
Use SSL authentication to enhance security in your broker environment.

Define the location of the keystore and truststore, set passwords, and enable SSL.

Configure WebSphere Message Broker on z/OS for SSL:

Define the location of the keystore and truststore, set passwords, and enable SSL.

Before you begin

Before you start: complete the following tasks:

- "Generate a broker certificate using RACF as the Certification Authority (z/OS)" on page 513
- "Create and initialize the broker keystore and truststore (z/OS)" on page 514

About this task

The process is essentially the same as on Windows and UNIX. This topic describes how to enable SSL at broker level; it can also be done at execution group level for the SOAP nodes. See "Configuring SOAPInput and SOAPReply nodes to use SSL (HTTPS)" on page 532 and "Configuring SOAPRequest and SOAPAsyncRequest nodes to use SSL (HTTPS)" on page 533 for a description of the process on distributed platforms.

To execute the following commands, you can run the BIPCHPR job in the broker component library.

Procedure

1. Define the location of the keystore. This example shows how to define a keystore at broker level. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsichangeproperties -
  CSQPBRK -
  -o BrokerRegistry -
  -n brokerKeystoreFile -
  -v /u/CSQPBRK/ssl/csqbrkKeystore.jks
```

2. Define the location of the truststore. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsichangeproperties -
  CSQPBRK -
  -o BrokerRegistry -
  -n brokerTruststoreFile -
  -v /u/CSQPBRK/ssl/csqbrkKeystore.jks
```

3. Enable the HTTPS Connector. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsichangeproperties -
  CSQPBRK –
  -b httplistener -
  -o HTTPListener -
  -n enableSSLConnector -
  -v true
```

4. Optional: Enable client authentication. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsichangeproperties -
  CSQPBRK –
  -b httplistener -
  -o HTTPSConnector -
  -n clientAuth -
  -v true
```

5. Stop the broker. You must stop the broker before you can define passwords.
6. Define the keystore password. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsisetdbparms -
  CSQPBRK –
  -n brokerKeystore::password –
  -u ignore -
  -p changeit
```

7. Define the truststore password. For example:

```
BPXBATSL PGM -
  /usr/lpp/mqsi/V7R0M0/bin/-
mqsisetdbparms -
  CSQPBRK –
  -n brokerTruststore::password –
  -u ignore -
  -p changeit
```

8. Start the broker.
9. Verify and test your configuration.

Enabling SSL on z/OS by using AT-TLS:

You can use Application Transparent Transport Layer Security (AT-TLS) to provide Secure Sockets Layer (SSL) services on behalf of WebSphere Message Broker on z/OS. AT-TLS is part of z/OS Communication Server.

About this task

You can enable SSL on z/OS by following the instructions in "Implementing SSL authentication on z/OS" on page 512. This topic describes an alternative method that uses AT-TLS to enable SSL without the need to complete configuration steps in WebSphere Message Broker. AT-TLS provides the following benefits when using SSL/TLS protocols with WebSphere Message Broker on z/OS:

- AT-TLS uses RACF key rings and certificates.
- The Policy Agent (PAGENT) manages the rules and policies that define how SSL is used to connect to WebSphere Message Broker.
- PAGENT can distribute the rules and policies in a z/OS SYSPLEX environment.
- The WebSphere Message Broker administrator does not have to set any WebSphere Message Broker properties for SSL.
- HTTP or SOAP nodes in message flows can have standard HTTP settings (no SSL/HTTPS).

To configure AT-TLS in your z/OS environment for WebSphere Message Broker, complete the following steps.

Procedure

1. Create a RACF key ring by following the instructions in "Creating a RACF key ring" on page 520.
2. Configure and activate PAGENT by following the instructions in "Configuring and activating the policy agent (PAGENT)" on page 522.
3. Define and install AT-TLS policies for WebSphere Message Broker by following the instructions in "Defining and installing AT-TLS policies" on page 524.
4. Test and verify AT-TLS by using WebSphere Message Broker, as described in "Testing and verifying AT-TLS" on page 527.

Related concepts:

"Application Transparent Transport Layer Security" on page 519
AT-TLS is a service provided by the z/OS Communication Server Policy Agent (PAGENT) and the TCP/IP stack. The AT-TLS service manages SSL connections on behalf of applications that are running on z/OS. The z/OS applications are unaware that SSL is used in the connection with partner applications.

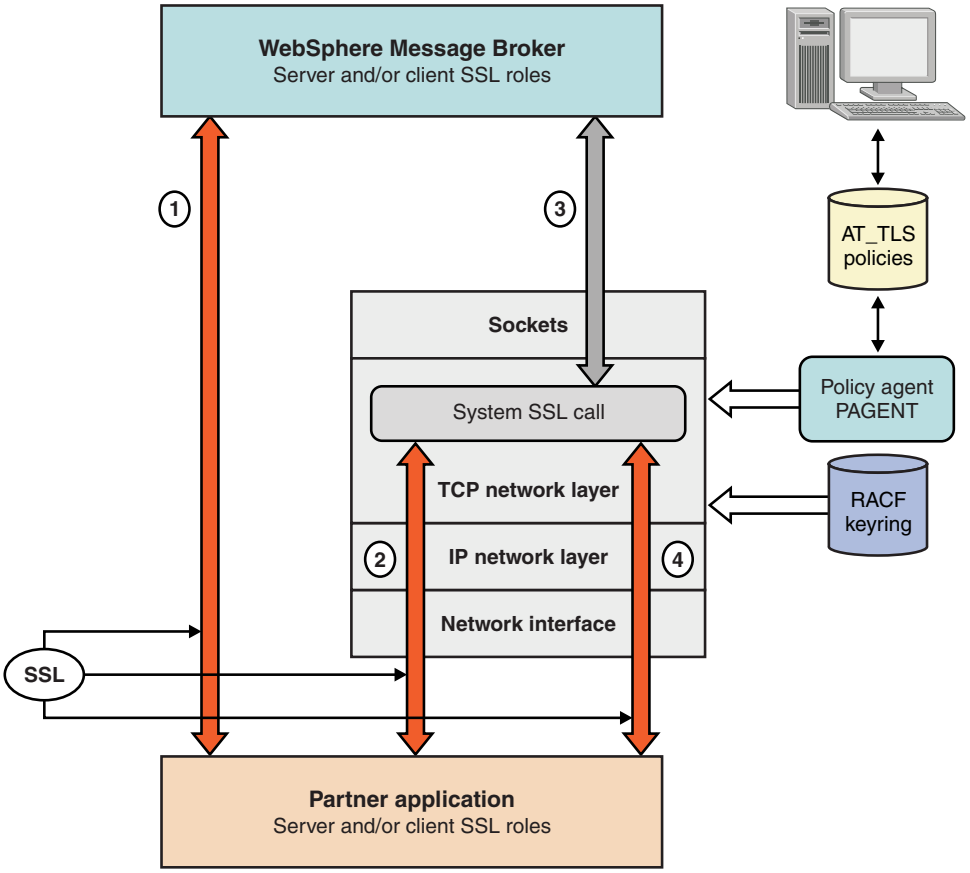
Application Transparent Transport Layer Security:

AT-TLS is a service provided by the z/OS Communication Server Policy Agent (PAGENT) and the TCP/IP stack. The AT-TLS service manages SSL connections on behalf of applications that are running on z/OS. The z/OS applications are unaware that SSL is used in the connection with partner applications.

The following diagram shows how AT-TLS works. The numbers in the diagram represent the steps that follow the diagram.



1. Step 1 represents an SSL connection when AT-TLS is not used, which requires that WebSphere Message Broker and the partner application are both enabled for SSL.
2. The SSL handshake is managed by AT-TLS in the TCP layer.
3. Inbound or outbound application data is received or sent in the clear by WebSphere Message Broker. The TCP layer validates and decrypts inbound data from partner applications, or encrypts outbound data to partner applications.
4. Inbound or outbound application data is protected by SSL.

AT-TLS components

RACF key ring
The RACF key ring contains the WebSphere Message Broker personal certificate and the partner application signer certificate.

AT-TLS policies
This file contains the rules and policies that control the SSL connections

that are managed by AT-TLS. These policies are created by the network administrator, and are checked and enforced by the TCP network layer of the TCP/IP stack.

Policy Agent
This component manages and distributes network policies, including AT-TLS policies, to the TCP/IP stack or stacks. The policy agent is also called PAGENT. For AT-TLS to function successfully, PAGENT must be configured correctly and operational.

TCP/IP stack
The TCP/IP stack is the component that implements the AT-TLS services. The TCP network layer is where SSL connections are intercepted, the SSL handshake is performed, and data is decrypted and encrypted. The TCP/IP stack uses RACF services to validate and accept certificates that are presented by the partner application during the handshake. RACF retrieves the WebSphere Message Broker personal certificate from the key ring.

Creating a RACF key ring:

To create a RACF key ring, you must first generate a RACF CA certificate and a personal certificate for WebSphere Message Broker, then connect the certificates to the key ring.

About this task

Each RACF key ring has its own name up to 237 characters long and is associated with a user ID. A RACF key ring is connected to a set of personal certificates and trusted certificates that are stored in the RACF database. The RACF command **RACDCERT** is used to create and delete key rings and to connect or disconnect certificates to the key rings. RACF key rings are also called System Authorization Facility (SAF) key rings. SAF is an open standard to access security services.

To create a RACF key ring to be used by AT-TLS on behalf of WebSphere Message Broker, complete the following steps.

Procedure

1. Generate a RACF certificate authority (CA) certificate.

   You can use RACF as a CA to generate and sign personal certificates for their internal systems or applications. This certificate must be created once, and it is used to sign every personal certificate that is generated by RACF. The following example shows how to use a RACF command to generate a RACF CA certificate.

   ```
   RACDCERT CERTAUTH GENCERT +
     SUBJECTSDN(CN('MQRootCA') +
     OU('ISSW') +
     O('IBM') +
     L('HURSLEY') SP('WINCHESTER') C('GB')) +
     KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN CERTSIGN) +
     WITHLABEL('MQRootCA') +
     NOTAFTER(DATE(2020/01/30)) +
     SIZE(1024)
   ```

2. Generate a personal certificate for WebSphere Message Broker.

   This certificate identifies a specific instance of WebSphere Message Broker. This certificate is presented to the partner application during the SSL handshake. This certificate must be associated with the user ID under which WebSphere Message Broker is running. The following example shows how to use a RACF command to generate the personal certificate for a broker called WI02BRK that is running under user ID WI02USR.

   ```
   RACDCERT ID(WI02USR) +
      GENCERT SUBJECTSDN(CN('WI02BRK') +
      OU('ISSW') O('IBM') +
      L('HURSLEY') SP('WINCHESTER') C('GB')) +
      WITHLABEL('WI02BRK') SIZE(1024) +
      SIGNWITH(CERTAUTH LABEL('MQRootCA')) +
      KEYUSAGE(HANDSHAKE DATAENCRYPT DOCSIGN) +
      NOTAFTER(DATE(2012/01/30))
   ```

3. Create a RACF key ring and connect the certificates to the key ring.

   The RACF key ring must be associated with a user ID (in this case, the WebSphere Message Broker user ID). The key ring must have a name (in this case, the same name as the broker), and the WebSphere Message Broker personal certificate must be connected to the key ring. The following example shows how to use a RACF command to create a key ring and connect the WebSphere Message Broker personal certificate.

   ```
   RACDCERT ID(WI02USR) ADDRING(WI02BRK)
   RACDCERT ID(WI02USR) +
    CONNECT(ID(WI02USR) LABEL('WI02BRK') RING(WI02BRK))
   RACDCERT ID(WI02USR) LISTRING(WI02BRK)
   ```

   For RACF to validate a partner application certificate, you must import the signer certificate of the CA that generated and signed the personal certificate of the partner application. Typically, this certificate is extracted from the partner application keystore, transferred to z/OS as a data set (WI02USR.VSR1BK.DER), imported to RACF, and connected to the RACF key ring as signer (trusted) certificate. The following example shows how to use a RACF command to add a signer certificate to RACF and connect it to the RACF key ring.

```
RACDCERT CERTAUTH ADD('WI02USR.VSR1BK.DER') +
WITHLABEL('VSR1BK') TRUST
RACDCERT CERTAUTH LIST(LABEL('VSR1BK')
RACDCERT ID(WI02USR) +
 CONNECT(CERTAUTH LABEL('VSR1BK') RING(WI02BRK))
RACDCERT ID(WI02USR) LISTRING(WI02BRK)
```

What to do next

Next: Configure and activate the policy agent by following the instructions in "Configuring and activating the policy agent (PAGENT)."

Related concepts:

"Application Transparent Transport Layer Security" on page 519
AT-TLS is a service provided by the z/OS Communication Server Policy Agent (PAGENT) and the TCP/IP stack. The AT-TLS service manages SSL connections on behalf of applications that are running on z/OS. The z/OS applications are unaware that SSL is used in the connection with partner applications.

Related tasks:

You can use Application Transparent Transport Layer Security (AT-TLS) to provide Secure Sockets Layer (SSL) services on behalf of WebSphere Message Broker on z/OS. AT-TLS is part of z/OS Communication Server.

"Configuring and activating the policy agent (PAGENT)"
Configure PAGENT by updating the TCP/IP profile, granting RACF permission to TCP/IP resources, preparing the PAGENT startup JCL, and activating syslogd.

"Defining and installing AT-TLS policies" on page 524
Define and install AT-TLS policies by using the IBM Configuration Assistant for z/OS Communications Server.

"Testing and verifying AT-TLS" on page 527
Test and verify AT-TLS by using the SOAP Nodes sample.

"Diagnosing problems with PAGENT and AT-TLS" on page 529
To help with problem determination with PAGENT and AT-TLS, activate tracing and logging.

Configuring and activating the policy agent (PAGENT):

Configure PAGENT by updating the TCP/IP profile, granting RACF permission to TCP/IP resources, preparing the PAGENT startup JCL, and activating syslogd.

Before you begin

Before you start:

- Create a RACF key ring by following the instructions in "Creating a RACF key ring" on page 520.

About this task

To enable PAGENT for AT-TLS, complete the following steps. For a more detailed description of how to install and configure PAGENT, see the *Policy-based networking* chapter of the z/OS Communications Server IP Configuration Guide on the z/OS library web page.

Procedure

1. Update the TCP/IP profile.

   You must make two changes to the TCP/IP profile to enable AT-TLS:

   - Add the statement `TCPCONFIG TTLS` to activate the functionality of AT-TLS inside the TCP/IP stack.
   - Add PAGENT to the AUTOLOG list.

2. Grant RACF permissions to TCP/IP resources.

   Users require permissions to the following resources as part of activating PAGENT:

   a. Define PAGENT as a started task with its own user ID.
   b. The `EZB.INITSTACK.sysname.tcpprocname` resource profile controls which users can have access to the TCP/IP stack before PAGENT is active. Give READ access to all users who do not require PAGENT policies to access the TCP/IP stack; for example, PAGENT, NETVIEW, DB2, and so on.
   c. The `EZB.PAGENT.sysname.tcpprocname.*` resource controls which users can start, stop, and refresh PAGENT. Give READ access to the users who are allowed to run the TSO/Unix commands **`Pagent`** or **`pasearch`**.
   d. The user ID of PAGENT must have READ access to the BPX.DAEMON facility.

   For more detailed information about the RACF permissions, check the sample `EZARACF` in the `TCPIP.SEZAINST` library.

3. Prepare the PAGENT startup JCL.

   a. Copy the sample JCL PAGENT in the `TCPIP.SEZAINST` library to the system procedure library (for example, `SYS1.PROCLIB`).
   b. Edit the JCL according to your installation standards. Specify the location of the PAGENT configuration file (for example, `/etc/pagent/pagent.config`). You can specify the location and name of the configuration file by setting the environment variable `PAGENT_CONFIG_FILE=/etc/pagent/pagent.config`. The environment variables for the TCP/IP stack are usually specified in a member (for example, ENVVARS) of the TCP/IP parameters library (for example, `TCPIP.PARMS`). The PAGENT JCL has ddname STDENV that points to the member with the environment variables definitions.

      The PAGENT configuration file (`/etc/pagent/pagent.config`) specifies the location and name of the PAGENT stack-specific configuration file by using the statement `TcpImage: TcpImage TCPIP /etc/pagent/TCPIP.image FLUSH NOPURGE 1800`.

      The stack-specific configuration file (`/etc/pagent/TCPIP.image`) specifies the location and name of the AT-TLS policies file by using the statement `TTLSConfig: TTLSConfig /etc/pagent/TCPIP_TTLS.policy`.

4. Activate the system log daemon (syslogd).

   Syslogd acts as the central message logging facility for PAGENT and AT-TLS. Syslogd is not specific to the policy infrastructure, but the policy infrastructure depends on syslogd to provide a central logging facility to maintain an audit trail. If you do not start syslogd, messages are lost. Start one syslog daemon per LPAR.

What to do next

Define and install AT-TLS policies for WebSphere Message Broker by following the instructions in “Defining and installing AT-TLS policies” on page 524.

You can use Application Transparent Transport Layer Security (AT-TLS) to provide Secure Sockets Layer (SSL) services on behalf of WebSphere Message Broker on z/OS. AT-TLS is part of z/OS Communication Server.

"Creating a RACF key ring" on page 520
To create a RACF key ring, you must first generate a RACF CA certificate and a personal certificate for WebSphere Message Broker, then connect the certificates to the key ring.

"Defining and installing AT-TLS policies"
Define and install AT-TLS policies by using the IBM Configuration Assistant for z/OS Communications Server.

"Testing and verifying AT-TLS" on page 527
Test and verify AT-TLS by using the SOAP Nodes sample.

"Diagnosing problems with PAGENT and AT-TLS" on page 529
To help with problem determination with PAGENT and AT-TLS, activate tracing and logging.

Defining and installing AT-TLS policies:

Define and install AT-TLS policies by using the IBM Configuration Assistant for z/OS Communications Server.

Before you begin

Before you start:

- Configure and activate PAGENT by following the instructions in "Configuring and activating the policy agent (PAGENT)" on page 522.

About this task

You can create the AT-TLS policies by using the IBM Configuration Assistant for z/OS Communications Server, a Java application that you can download from IBM. Complete the following steps to define the policies required to enable SSL support on behalf of WebSphere Message Broker for z/OS running SOAPInput and SOAPRequest nodes:

Procedure

1. Start the configuration assistant by clicking **Start** > **All Programs** > **IBM Programs** > **IBM Configuration Assistant for z/OS** > **Configuration Assistant V1R10**.
2. Click **Add a New z/OS Image**, enter the name of your z/OS image (LPAR) and a description, then click **OK**.
3. In the Configuration Assistant Navigation pane, select the image that you added in step 2, click **Add New TCP/IP Stack**, enter the stack name and description, then click **OK**.
4. In the Configuration Assistant Navigation pane, select the stack that you added in step 3, select **AT-TLS** from the list of technologies, then click **Enable**.

5. Click **Configure**.
6. Click **Add**. The Connectivity Rule wizard opens. Click **Next**
7. Identify the data endpoints by completing the following fields. A generic rule facilitates testing, but can be made more specific later.
   a. In the Local data endpoint field, select **ALL_IP_Addresses**.
   b. In the Remote data endpoint field, select **ALL_IP_Addresses**.
   c. In the Connectivity Rule Name field, enter a suffix for the name of the rules, then click **Next**.
8. Select a requirement map by clicking **Add**. The map is used to match the type of IP traffic with the security level to be implemented by AT-TLS.
9. Enter a name and description for the requirement map, then click **Work with Traffic Descriptors**. Two traffic descriptors are required: one for the inbound SOAP requests (WebSphere Message Broker is the server), and another for the outbound SOAP requests (WebSphere Message Broker is the client).
10. Create an inbound traffic descriptor by clicking **Add** , enter a name and description, then click **OK**.
11. Enter details about the inbound traffic descriptor:
    a. For the local port, select **Single port** and set the port number to **7800** (the port on which the SOAPInput node normally listens).
    b. For the remote port, select **All ports**.
    c. Set the Indicate the TCP connect direction field to **Inbound only**.
    d. In the Jobname field, enter an asterisk (*).
    e. In the User ID field, enter an asterisk (*).
    f. Select **Use the following key ring database**.
    g. Select **Key ring is in SAF produce (such as RACF)**, then enter the name of the key ring.
    h. Set the AT-TLS handshake role to **Server**, then click **AT-TLS Advanced**.
    i. Enter the label of the WebSphere Message Broker personal certificate, then click **OK**.
12. Click **OK** to save the traffic details for inbound SOAP traffic, then click **OK** to create the traffic descriptor for inbound SOAP.
13. Create an outbound traffic descriptor by clicking **Add**, add a name and description, then click **OK** .
14. Enter details about the outbound traffic descriptor:
    a. For the local port, select **All ports**.
    b. For the remote port, select **Single port** and set the port number to **7843**.
    c. Set the Indicate the TCP connect direction to **Outbound only**.
    d. In the Jobname field, enter an asterisk (*).
    e. In the User ID field, enter an asterisk (*).
    f. Select **Use the following key ring database**.
    g. Select **Key ring is in SAF produce (such as RACF)**, then enter the name of the key ring.
    h. Set the AT-TLS handshake role to **Client**, then click **AT-TLS Advanced**.
    i. Enter the label of the WebSphere Message Broker personal certificate, then click **OK**.
15. Click **OK** to save the traffic details for outbound SOAP traffic, then click **OK** to create the traffic descriptor for outbound SOAP.
16. Click **Close**.

17. To create a security level for WebSphere Message Broker, click **Work with Security Levels**, then click **Add**.
    a. On the Name and Type tab, enter a name and description.
    b. On the Ciphers tab, select **Use TLS V1**, **Use SSL V3**, and **Use System SSL defaults**, then click **OK**.
18. To add traffic descriptors to the requirement map, select **SOAP_Server** and **SOAP_Client** from the Objects list, then click **Add**.
19. For each traffic descriptor, select the AT-TLS security level that you created in step 17, then click **OK**.
20. Click **Next** and set the appropriate Optional Connectivity Rule Settings, which are used to set tracing levels, tuning parameters, and timings when the rule is in effect..
21. Click **Finish**.
22. To save changes to the AT-TLS rules, click **Apply changes**, then click **Main perspective**.
23. To install the AT-TLS policy, select **AT-TLS technology**, click **Install**, then click **FTP** to send the policy rules to the LPAR.
24. Specify the FTP parameters:
    a. Enter the LPAR host name and set the port number to 21.
    b. Enter your user ID and password.
    c. Enter the AT-TLS policy file location and name (for example, `/etc/pagent/TCPIP_TTLS.policy`.
    d. Select **Default transfer mode**.
    e. Click **Send**, wait for file transfer to complete, then check that the transfer was successful.
    f. Click **Close**.
    g. After the file transfer, refresh or restart PAGENT.

    The AT-TLS policies have been created and deployed.

What to do next

Next: Test and verify AT-TLS for WebSphere Message Broker by following the instructions in "Testing and verifying AT-TLS" on page 527.

Related concepts:

"Application Transparent Transport Layer Security" on page 519
AT-TLS is a service provided by the z/OS Communication Server Policy Agent (PAGENT) and the TCP/IP stack. The AT-TLS service manages SSL connections on behalf of applications that are running on z/OS. The z/OS applications are unaware that SSL is used in the connection with partner applications.

Related tasks:

"Enabling SSL on z/OS by using AT-TLS" on page 517
You can use Application Transparent Transport Layer Security (AT-TLS) to provide Secure Sockets Layer (SSL) services on behalf of WebSphere Message Broker on z/OS. AT-TLS is part of z/OS Communication Server.

"Creating a RACF key ring" on page 520
To create a RACF key ring, you must first generate a RACF CA certificate and a personal certificate for WebSphere Message Broker, then connect the certificates to the key ring.

"Configuring and activating the policy agent (PAGENT)" on page 522
Configure PAGENT by updating the TCP/IP profile, granting RACF permission to

TCP/IP resources, preparing the PAGENT startup JCL, and activating syslogd.

"Testing and verifying AT-TLS"
Test and verify AT-TLS by using the SOAP Nodes sample.

"Diagnosing problems with PAGENT and AT-TLS" on page 529
To help with problem determination with PAGENT and AT-TLS, activate tracing and logging.

Testing and verifying AT-TLS:

Test and verify AT-TLS by using the SOAP Nodes sample.

Before you begin

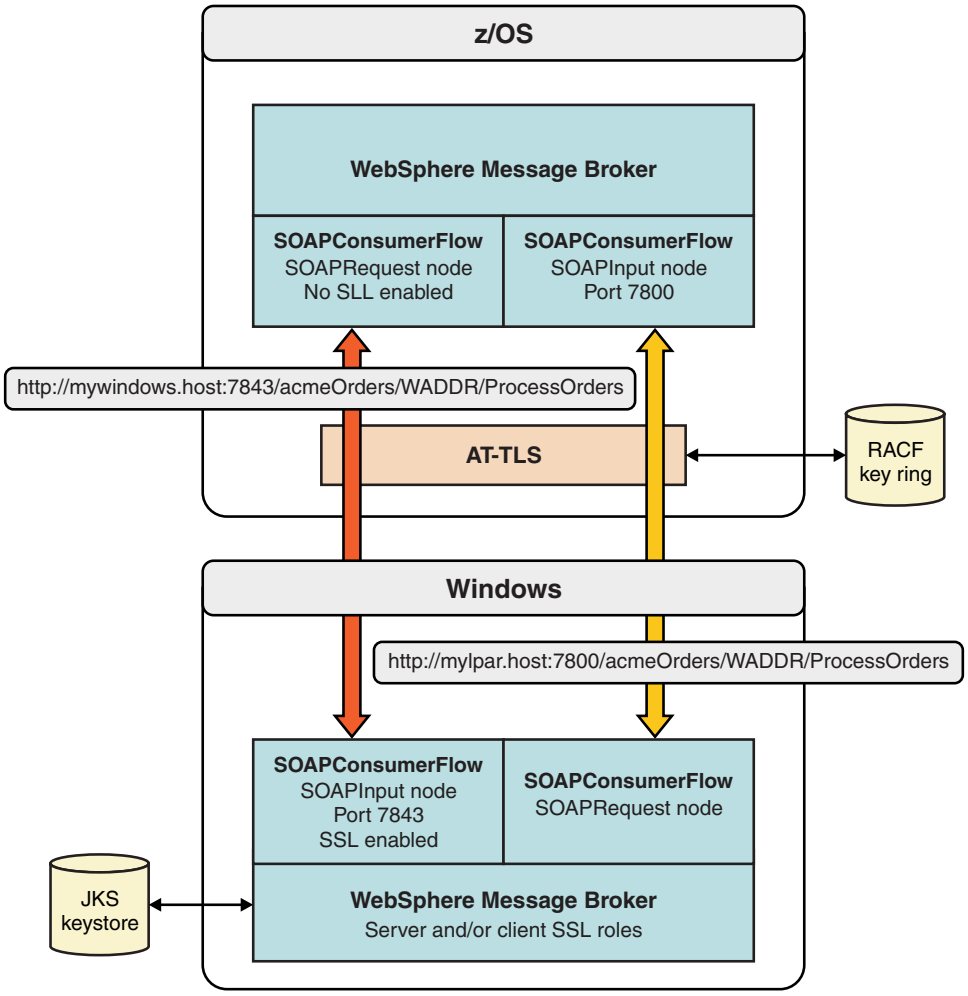
Before you start:

Complete the following tasks:

- "Creating a RACF key ring" on page 520
- "Configuring and activating the policy agent (PAGENT)" on page 522
- "Defining and installing AT-TLS policies" on page 524

About this task

Use the following scenario to test and verify AT-TLS with WebSphere Message Broker:



This scenario has the following components:

- One instance of WebSphere Message Broker is running on z/OS.
- Another instance of WebSphere Message Broker is running on Windows.
- SOAP node sample flows from the WebSphere Message Broker Toolkit samples gallery are deployed to the two WebSphere Message Broker instances.
- The broker instance running on z/OS is not enabled to use SSL. The SSL services are provided by AT-TLS.
- AT-TLS policies are active and PAGENT is running.
- The broker instance running on Windows is enabled to use SSL, and it has keystores defined with personal and signer certificates loaded.

The flows receive or send SOAP inbound and outbound requests between the two instances of WebSphere Message Broker. The SOAP consumer flow in one broker sends requests to the SOAP provider flow in the other broker. The SOAP nodes on the Windows broker are SSL enabled. The scenario shows the URLs that are configured on the SOAPRequest node on each broker.

For more information about how to configure, deploy, and run the SOAP Nodes sample, see “Samples” on page 98.

To help with problem determination with PAGENT and AT-TLS, activate tracing and logging.

Diagnosing problems with PAGENT and AT-TLS:

To help with problem determination with PAGENT and AT-TLS, activate tracing and logging.

About this task

PAGENT has its own log file with the default name `/tmp/pagent.log`, which contains messages about loading AT-TLS rules. Invalid rules are rejected, and errors are written to the PAGENT log file. You can specify different levels of logging in the PAGENT configuration file by using the statement `LogLevel`. `LogLevel 511` gives the most verbose logging.

The TCP/IP stack and the AT-TLS service log messages use SYSLOGD. The AT-TLS level of tracing is specified by using the advanced options in the connectivity rules. The highest (more verbose) level of tracing is 255.

The name and location of the log files are specified in the configuration file of the SYSLOGD (`/etc/syslog.conf`). The following example shows a configuration that can be used during testing:

```
*.* /var/log/%Y/%m/%d/errors
```

This syslogd configuration creates log files with names like `/var/log/2010/03/20/errors`. Every time syslogd is restarted, it creates a directory based on the current date. A good procedure is to restart syslogd once a day at midnight.

For more information, see the *Diagnosing Policy Agent problems* chapter of the z/OS Communications Server IP Diagnosis Guide on the z/OS library web page.

Configuring the broker to use SSL with JMS nodes

Configure your broker to work with a JMS provider that supports JMS clients that can connect by using the Secure Sockets Layer (SSL) protocol.

Before you begin

Before you start: Create a keystore file to store the broker's certificates: "Setting up a public key infrastructure" on page 504.

About this task

The JMS 1.1 Specification states that JMS does not provide features for controlling or configuring message integrity or message privacy. JMS providers typically support these additional features, and provide their own administration tools to configure these services. Clients can get the appropriate security configuration as part of the administered objects that they use.

If you want to apply SSL security to the JMS connections created by the three built-in nodes JMSInput, JMSOutput, and JMSReply, check the documentation supplied by your chosen JMS provider. The configuration of the JNDI administered objects that are used by the JMS nodes is specific to each JMS provider.

The three built-in nodes JMSInput, JMSOutput, and JMSReply are referred to in this topic by the generic term JMS nodes; apply the information and instructions here to the specific type of node that you are using.

One example of a JMS provider that provides SSL support for connecting JMS clients is TIBCO Enterprise Message Service (EMS). The following sections describe the authentication model used for JMS nodes, with specific reference to TIBCO EMS, and provide information about how to connect JMS nodes to a TIBCO EMS JMS Server securely by using SSL:

1. “SSL authentication model for the JMS nodes”
2. “Configuring your JMS nodes to use SSL-enabled JNDI administered objects”

SSL authentication model for the JMS nodes:
About this task

The JMS provider TIBCO EMS supports Java clients that can use either the Java Secure Sockets Extension (JSSE) Java package, or an SSL implementation supplied by Entrust. For details about the services provided, see the documentation provided with your chosen package.

TIBCO EMS supports a number of different authentication scenarios, but JMS nodes can use only client authentication to the server. In this scenario, the TIBCO EMS server requests the client's digital certificate during an SSL handshake, and checks its issuer against the server's list of trusted Certificate Authorities. If the authority is not in the server's list, further communications are prevented with the JMS node.

Therefore, you must configure the EMS server to explicitly enable client authentication of the SSL certificates in its configuration file; configure the JNDI administered SSL JMS connection factories for the same level of support.

Configuring your JMS nodes to use SSL-enabled JNDI administered objects:
About this task

The JMS nodes use JNDI to look up a connection factory object that is used to create JMS connections to a TIBCO EMS server.

Procedure

1. Configure the JMS node property Connection factory name to specify a pre-configured connection factory that is enabled for SSL connectivity.

   Make sure that you have set the appropriate parameters in the corresponding SSL JMS connection factory definition:

   - Enable client authentication
   - Specify the SSL protocol in the server URL
   - Set other parameters to define the support your require.

   See the provider's documentation for information about how to generate this JNDI administered object:
2. Configure the JMS node property Location JNDI Bindings with the URL that points to the JNDI bindings containing the JNDI administered objects for SSL connectivity.

   For TIBCO EMS , this URL takes the following format:

   `tibjmsnaming://server_name:ssl_port`

   - *server_name* is the host name of the computer where the server is installed.
   - *ssl_port* is the server port for SSL connectivity; typically, this is port 7243 for a TIBCO EMS server.
3. Make the TIBCO EMS client JAR files available to the broker to which you deploy the message flow that includes your JMS nodes. Use the **mqsicreateconfigurableservice** or the **mqsichangeproperties** command to set the JMSProviders configurable service property jarsURL to point to the directory that contains the JMS provider's client JAR files and the SSL vendor's JAR files.

If you are using JSSE for the SSL support, the following JAR files are typically located in the `jarsURL` directory:

- `jsse.jar`
- `net.jar`
- `jcert.jar`
- `tibcrypt.jar`

You can find standard non-SSL client JAR files in the same location.

Configuring SOAPInput and SOAPReply nodes to use SSL (HTTPS)

Configure the SOAP nodes to communicate with other applications that use HTTPS by creating a keystore file, and configuring the broker to use SSL.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker or execution group level: "Setting up a public key infrastructure" on page 504.

About this task

Follow these steps to configure the SOAPInput and SOAPReply nodes to communicate with other applications using HTTP over SSL:

1. Configure HTTP listener properties for an execution group
2. Test your configuration

Configuring HTTP listener properties for an execution group:

You do not need to set properties to enable the HTTP listener for an execution group, but can optionally change values.

Procedure

1. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties broker_name
  -e execution_group_name
  -o HTTPSConnector
  -n clientAuth -v true
```

2. Optional: Change the SSL protocol. The default protocol for the SOAPInput node is TLS. Issue the following command to change it to SSL:

```
mqsichangeproperties broker_name
  -e execution_group_name
  -o HTTPSConnector
  -n sslProtocol -v SSL
```

What to do next

If you have changed any of the HTTP listener properties for the execution group, take the following steps:

1. Restart the broker.
2. Use the following command to display HTTP listener properties:

```
mqsireportproperties broker_name
  -e execution_group_name
  -o HTTPSConnector  -r
```

Testing your configuration:

About this task

Use the SOAP Nodes sample to test your configuration. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Procedure

1. Import the sample.
2. Enable SSL in the SOAPNodesSampleConsumerFlow message flow:
   a. Open the Invoke_submitOP subflow.
   b. Change the HTTPTransport properties for the SOAPRequest node. Set an https **Web service URL**, and change other SSL properties as necessary.
3. Enable SSL in the SOAPNodesSampleProvider message flow. Select **Use HTTPS** in the HTTP Transport properties panel.
4. Refresh the BAR file and deploy.
5. Test the sample.

Use the HTTPRequest node to interact with a web service.

Configuring SOAPRequest and SOAPAsyncRequest nodes to use SSL (HTTPS)

Configure the SOAPRequest and SOAPAsyncRequest nodes to communicate with other applications that use HTTP over SSL.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker or execution group level: "Setting up a public key infrastructure" on page 504.

Configuring the nodes:
Procedure

1. On the HTTP Transport page of the properties for the node, set the Web Service URL to point to the HTTP server to call.
2. Set other SSL properties as appropriate.

What to do next

Test your configuration.

Testing your configuration:
About this task

Use the SOAP Nodes sample to test your configuration. You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. Use the HTTPRequest node to interact with a web service.

Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)

Configure the HTTPInput and HTTPReply nodes to communicate with other applications that use HTTPS by creating a keystore file, configuring the broker or execution group to use SSL, and creating a message flow to process HTTPS requests.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker level by following the instructions in "Setting up a public key infrastructure" on page 504.

About this task

Follow these steps to configure the HTTPInput and HTTPReply nodes to communicate with other applications using HTTP over SSL:

1. If you are using the broker listener:Configure the broker to use SSL
2. If you are using the execution group listener: Configure the execution group to use SSL
3. Create a message flow
4. Test your configuration

If you have configured your broker and execution groups such that the broker listener is used for some execution groups, and the execution group listener for other execution groups, you must complete step 1 for the first set of execution groups and step 2 for each execution group in the second set.

For information about which listener to use for HTTPS messages, see "HTTP listeners" on page 1589.

Configuring the broker to use SSL:
About this task

Complete the following steps:

Procedure

1. Turn on SSL support in the broker, by setting a value for **enableSSLConnector**

   ```
   mqsichangeproperties broker name
     -b httplistener -o HTTPListener
     -n enableSSLConnector -v true
   ```

2. Optional: If you do not want to use the default port 7083 for HTTPS messages, specify the **port** on which the broker listens:

```
mqsichangeproperties broker name
  -b httplistener -o HTTPSConnector
  -n port -v Port to listen on for https
```

On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024.For the broker to listen on these ports, the user ID under which the broker is started must be root.

3. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties broker_name -b httplistener -o HTTPSConnector
  -n clientAuth -v true
```

4. Restart the broker after changing one or more of the HTTP listener properties.
5. Optional: Use the following commands to display HTTP listener properties:

```
mqsireportproperties broker_name -b httplistener -o AllReportableEntityNames -a
mqsireportproperties broker_name -b httplistener -o HTTPListener -a
mqsireportproperties broker_name -b httplistener -o HTTPSConnector  -a
```

Configuring an execution group to use SSL:
About this task

Complete the following steps:

Procedure

1. Optional: Specify a specific port on which the execution group listens for HTTPS requests, or leave the value unset to use the next available port number.

```
mqsichangeproperties broker name
  -e execution_group_name -o HTTPSConnector
  -n explicitlySetPortNumber -v port_number
```

On UNIX systems, only processes that run under a privileged user account (in most cases, root) can bind to ports lower than 1024. For the execution group to listen on these ports, the user ID under which the broker is started must be root.

If you do not complete this step, the first available port in the default range (7843 - 7884) is used.

2. Optional: Enable Client Authentication (mutual authentication):

```
mqsichangeproperties broker_name
  -e execution_group_name -o HTTPSConnector
  -n clientAuth -v true
```

3. Optional: Change the SSL protocol. The default protocol for the HTTPInput node is TLS. Run the following command to change it to SSL:

```
mqsichangeproperties broker_name
  -e execution_group_name -o HTTPSConnector
  -n sslProtocol -v SSL
```

4. Restart the broker after changing one or more of the listener properties.
5. Optional: Use the following command to display HTTPS properties:

```
mqsireportproperties broker_name
  -e execution_group_name -o HTTPSConnector  -r
```

Creating a message flow to process HTTPS requests:
About this task

You can create a simple message flow to use HTTPS by connecting an HTTPInput node to an HTTPReply node. The two most important properties to set on the HTTPInput node are:

- Path suffix for URL; for example, /* or /testHTTPS.

- Use HTTPS.

/* means that the HTTPInput node matches against any request that is sent to the HTTP listener on a designated port. This option is useful for testing purposes, but is not suitable for production systems.

You can now deploy the message flow to the broker. If you have completed all the documented steps, message BIP3132 is written to the local system log (on Windows, the event log), stating that the HTTPS listener has been started.

You can now test the system.

Testing your configuration:
About this task

The simplest method of testing whether HTTPS is configured correctly is to use a Web browser to make a request to the broker over HTTPS.

Start a Web browser and enter the following URL:

```
https://localhost:7083/testHTTPS
```

Change values in the URL to reflect the changes that you have made in your broker configuration; for example, the port number. When a window is displayed asking you to accept the certificate, select **Yes**. The browser refreshes the window and displays an empty HTML page:

- In Mozilla browsers, the empty HTML page looks like the following example:

```
<html>
  <body/>
</html>
```

- In Internet Explorer, the following information is displayed:

```
XML document must have a top level element. Error processing resource
'https://localhost:7083/testHTTPS'
```

These responses mean that a blank page was returned, indicating that the setup worked correctly. To add content to the empty page, you can add a Compute node to the flow.

You can use another HTTPS client to process HTTPS requests. Read the documentation for the client to find out how to configure it to make client connections over SSL.

You can also use another HTTPS client, such as a Java or .net client, instead of the Web browser. Depending on the type of client, you might need to export the certificate (which was created with keytool) from the keystore file associated with the HTTP listener, then import it into the keystore for the client. Read the client documentation to find out how to configure the client to make client connections over SSL.

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

Configuring an HTTPRequest node to use SSL (HTTPS)

Configure the HTTPRequest node to communicate with other applications that use HTTP over SSL.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker level: "Setting up a public key infrastructure" on page 504

About this task

This topic describes the steps that you need to follow when configuring an HTTPRequest node on a Windows system. The steps that you must follow on other operating systems are almost identical.

To enable an HTTPRequest node to communicate using HTTP over SSL, an HTTPS server application is required. The information provided in this topic shows how to use the HTTPInput node for SSL as the server application, but the same details also apply when you are using any other server application.

Complete the following sub-tasks:

1. "Creating a message flow to make HTTPS requests" on page 539
2. "Testing your example" on page 539.

Creating a message flow to make HTTPS requests:
About this task

The following message flow creates a generic message flow for converting a WebSphere MQ message into an HTTP Request:

Procedure

1. Create a message flow with the nodes MQInput->HTTPRequest->Compute->MQOutput.
2. On the MQInput node, set the queue name to HTTPS.IN1 and create the WebSphere MQ queue.
3. On the MQOutput node, set the queue name to HTTPS.OUT1 and create the WebSphere MQ queue.
4. On the HTTPRequest node, set the Web Service URL to point to the HTTP server to call. To call the HTTPInput node, use `https://localhost:7083/testHTTPS`.
5. On the Advanced properties tab of the HTTPRequest node, set the **Response message location in tree** property to *OutputRoot.BLOB*.
6. On the Compute node, add the following ESQL code:

```
CREATE COMPUTE MODULE test_https_Compute
    CREATE FUNCTION Main() RETURNS BOOLEAN
    BEGIN
        -- CALL CopyMessageHeaders();
        CALL CopyEntireMessage();
        set OutputRoot.HTTPResponseHeader = null;
        RETURN TRUE;
    END;

    CREATE PROCEDURE CopyMessageHeaders() BEGIN
        DECLARE I INTEGER;
        DECLARE J INTEGER;
        SET I = 1;
        SET J = CARDINALITY(InputRoot.*[]);
        WHILE I < J DO
            SET OutputRoot.*[I] = InputRoot.*[I];
            SET I = I + 1;
        END WHILE;
    END;

    CREATE PROCEDURE CopyEntireMessage() BEGIN
        SET OutputRoot = InputRoot;
    END;
END MODULE;
```

What to do next

The message flow is now ready to be deployed to the broker and tested.

Testing your example:
About this task

To test that the example works, complete the following steps:

Procedure

1. Follow the instructions in "Configuring HTTPInput and HTTPReply nodes to use SSL (HTTPS)" on page 535, including testing the example.
2. Deploy the HTTPRequest message flow.

3. Put a message to the WebSphere MQ queue HTTPS.IN1. If successful, a message appears on the output queue. If the process fails, an error appears in the local error log (which is the event log on Windows).

Use the HTTPInput node to receive an HTTP message from an HTTP client for processing by a message flow.

"HTTPReply node" on page 4484
Use the HTTPReply node to return a response from the message flow to an HTTP client. This node generates the response to an HTTP client from which the input message was received by the HTTPInput node, and waits for confirmation that it has been sent.

"HTTPRequest node" on page 4488
Use the HTTPRequest node to interact with a web service.

Enabling SSL on the WebSphere MQ Java Client

The WebSphere MQ Java Client supports SSL-encrypted connections over the server-connection (SVRCONN) channel between an application and the queue

manager. Configure SSL support for connections between applications that use the CMP API (including the WebSphere Message Broker Toolkit and the WebSphere Message Broker Explorer) and a broker.

About this task

For one-way authentication, when the client CMP application authenticates the broker, perform the following steps:

Procedure

1. Generate or obtain all the appropriate keys and certificates. You must include a signed pkcs12 certificate for the server and the appropriate public key for the certificate authority that signed the pkcs12 certificate. See "Creating SSL certificates for the WebSphere MQ Java Client" on page 542, for some example steps for creating keys and certificates.
2. Add the pkcs12 certificate to the queue manager certificate store and assign it to the queue manager. Use the standard WebSphere MQ facilities; for example, WebSphere MQ Explorer.
3. Add the certificate of the certificate authority to the JSSE truststore of the Java Virtual Machine (JVM) at the CMP application end using a tool such as Keytool.
4. Decide which cipher suite to use and change the properties on the server-connection channel by using WebSphere MQ Explorer, to specify the cipher suite to be used. This channel has a default name of `SYSTEM.BKR.CONFIG`; this name is used unless you have specified a different name on the Connect to Remote Broker wizard; see "Connecting to a remote broker" on page 902 and "Connecting to a remote broker on z/OS in the WebSphere Message Broker Explorer" on page 904.
5. Add the required parameters (cipher suite, for example) to the CMP application. If a truststore other than the default is used, its full path must be passed in by the truststore parameter.

Results

When you have performed these steps, the CMP application connects to the broker if it has a valid signed key that has been signed by a trusted certificate authority.

What to do next

For two-way authentication, when the broker also authenticates the CMP application, perform the following additional steps:

1. Generate or obtain all the appropriate keys and certificates. You must include a signed pkcs12 certificate for the client and the appropriate public key for the certificate authority that signed the pkcs12 certificate. See "Creating SSL certificates for the WebSphere MQ Java Client" on page 542, for some example steps for creating keys and certificates.
2. Add the certificate of the certificate authority to the queue manager certificate store by using the standard WebSphere MQ facilities.
3. Set the server-connection channel to always authenticate. Specify SSLCAUTH(REQUIRED) in **runmqsc**, or in WebSphere MQ Explorer.
4. Add the pkcs12 certificate to the JSSE keystore of the JVM at the CMP application end by using a tool such as Keytool.

5. If you are not using the default keystore, its full path must be passed into the CMP through the keystore parameter

When you have performed these steps, the broker allows the CMP application to connect only if that application has a certificate signed by one of the certificate authorities in its keystore.

You can make further restrictions by using the sslPeerName field; for example, you can allow connections only from certificate holders with a specific company or department name in their certificates. In addition, you can invoke a security exit for communications between the CMP applications and the broker; see "Using security exits" on page 555.

WebSphere MQ Version 7 Information Center online

Creating SSL certificates for the WebSphere MQ Java Client:

The WebSphere MQ Java Client supports SSL-encrypted connections over the server-connection (SVRCONN) channel between an application and the queue manager. To configure SSL-encrypted connections you must first create key stores and certificates.

Before you begin

Before you start:

- Create a broker
- Start the broker
- Set the environment variable JAVA_HOME to the location of the IBM Key Management tools in the WebSphere MQ install, for example `C:\Program Files\IBM\WebSphere MQ\gskit\jre\` or `/opt/mqm/ssl/jre`.

About this task

Each WebSphere MQ queue manager has a key repository for certificates. When an application attempts to connect to a secure queue manager, the application's certificate must be validated against the contents of the queue manager's key repository. One option for configuring SSL for the queue manager is to use a self-signed certificate.

Two certificates must be signed and created. One must be created for the server queue manager, and a second created for the client, for example the WebSphere Message Broker Explorer.

The instructions in this topic use the **gsk7cmd** command to create and sign the certificates. Run the **gsk7cmd** for a full list of the parameters you can use on the command. To run the **gsk7cmd** command:

- On Windows, enter the following command on a command line:
  `C:\Program Files\IBM\gsk7\bin\gsk7cmd`
- On Linux, enter the following command on a command line:
  `/opt/mqm/ssl/jre/bin/gsk7cmd`

Refer to the WebSphere MQ security documentation for more information about SSL, and creating certificates.

Creating a server certificate for the queue manager:
About this task

Use the IBM Key Management tools on the command line to create a certificate for the queue manager. In the following example you must replace the following parameters with your own values:

password
A password for the certificate repository.

qmname
The name of the queue manager for which you want to create a certificate in lower case.

QMNAME
The name of the queue manager for which you want to create a certificate in upper case.

Procedure

1. Run the following command to create a key repository of type `cms`:

   ```
   gsk7cmd
     -keydb-create
     -dbkey.kdb
     -pwPASSWORD
     -typecms -stash
   ```

   The `key.crl`, `key.kdb`, `key.rdb`, and `key.sth` key files are created.
2. Run the following command to create a self-signed certificate, where the `-dn` flag contains details of your organization:

   ```
   gsk7cmd
     -cert-create
     -dbkey.kdb
   ```

```
  -pwPASSWORD
  -label"qmname"
  -dn"CN=My Queue Manager,O=My Company,C=UK"
  -expire1000
```

3. Run the following command to create a request for a personal certificate:

```
gsk7cmd
  -certreq-create
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
  -dn"CN=My Queue Manager,O=My Company,C=UK"
  -fileQMNAME_request.arm
```

4. Sign the certificate using a certificate authority.
   - To obtain a certificate from a certificate authority, you must send the file containing a certificate signing request to your chosen certificate authority.
   - Alternatively you can use the IBM Key Management tools on the command line to sign the certificate.

```
gsk7cmd
  -cert-sign
  -dbkey.kdb
  -pwPASSWORD
  -label"qmname"
  -fileQMNAME_request.arm
  -targetQMNAME_signed.arm
  -expire364
```

5. Run the following command to add the signed certificate to the repository:

```
gsk7cmd
  -cert-receive
  -dbkey.kdb
  -pwPASSWORD
  -fileQMNAME_signed.arm
```

6. Run the following command to export the signed client userid certificate in a transferable format (in this case PKCS12), with the associated private key and public CA certificate:

```
gsk7cmd
  -cert-export
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
  -targetQMNAME_personal.p12
  -target_pwPASSWORD
  -target_typepkcs12
```

7. Delete the certificate from the repository:

```
gsk7cmd
  -cert-delete
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
```

8. Create a subdirectory called *QMNAME*_CMS, and navigate to this directory on the command line.
9. Run the following command to create a certificate repository in the *QMNAME*_CMS directory:

```
gsk7cmd
  -keydb-create
  -dbkey.kdb
  -pwPASSWORD
  -typecms –stash
```

10. Run the following command to import the PKCS12 file into the repository:

```
gsk7cmd
  -cert-import
  -file"QMNAME_personal.p12"
  -pwPASSWORD
  -typepkcs12
  -targetkey.kdb
  -target_pwPASSWORD
  -target_typecms
```

11. Return to the original directory in which you created the key repository in step 1.

What to do next

Follow the steps in the next section to create a client certificate for the WebSphere Message Broker Explorer.

Creating a client certificate for the WebSphere Message Broker Explorer:
About this task

Use the IBM Key Management tools on the command line to create a certificate for the WebSphere Message Broker Explorer. In the following example you must replace the following parameters with your own values:

password
A password for the certificate repository.

qmname
The name of the queue manager for which you want to create a certificate in lower case. This is the same value used in the steps to create a client certificate for the queue manager.

USERID
The user id for which you want to create a certificate.

Procedure

1. In the directory where you created a key repository for the server queue manager in step 1 above, run the following command to create a request (private key plus certificate details) for a certificate to be signed for the server queue manager:

```
gsk7cmd
  -certreq-create
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
  -dn"CN=userid@mycompany.com,O=My Company,C=UK"
  -fileUSERID_request.arm
```

2. Run the following command to sign the certificate:

```
gsk7cmd
  -cert-sign
  -dbkey.kdb
  -pwPASSWORD
  -label"qmname"
  -fileUSERID_request.arm
  -targetUSERID_signed.arm
  -expire364
```

3. Run the following command to add the signed certificate to the repository:

```
gsk7cmd
  -cert-receive
  -dbkey.kdb
  -pwPASSWORD
  -fileUSERID_signed.arm
```

4. Run the following command to export the signed client userid certificate in a transferable format (in this case pkcs12), with the associated private key and public CA certificate:

```
gsk7cmd
  -cert-export
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
  -targetUSERID_personal.p12
  -target_pwPASSWORD
  -target_typepkcs12
```

5. Delete the certificate from the repository:

```
gsk7cmd
  -cert-delete
  -dbkey.kdb
  -pwPASSWORD
  -label"ibmwebspheremqqmname"
```

6. Create a subdirectory called *USERID*_JKS, and navigate to this directory on the command line.
7. Run the following command to create a certificate repository in the *USERID*_JKS directory:

```
gsk7cmd
  -keydb-create
  -dbkeyStore.jks
  -pwPASSWORD
  -typejks
```

8. Run the following command to import the pkcs12 file into the repository:

```
gsk7cmd
  -cert-import
  -file"USERID_personal.p12"
  -pwPASSWORD
  -typepkcs12
  -targetkeyStore.jks
  -target_pwPASSWORD
  -target_typejks"
```

9. Return to the original directory in which you created the key repository in step 1.

What to do next

You must now copy the files from the Label_CMS directory to your queue manager's SSL directory. For example, /var/mqm/qmgrs/*QM1*/ssl or C:\Program Files\IBM\WebSphere MQ\Qmgrs*QM1*\ssl. The keystore.jksfile in the LABEL_JKS directory must be on the same machine as the WebSphere Message Broker Explorer. You might also require the AMQCLCHL.TAB file to be copied to the same system as the WebSphere Message Broker Explorer. This file can be found in the queue manager's @ipcc directory, for example, /var/mqm/qmgrs/*QM1*/@ipcc or C:\Program Files\IBM\WebSphere MQ\qmgrs*QM1*\@ipcc.

When you configure the SSL settings in the WebSphere Message Broker Explorer you must specify the full path to the keystore.jksfile.

Securing the connection to CICS Transaction Server for z/OS by using SSL

Configure the CICSRequest node to communicate with CICS Transaction Server for z/OS over the Secure Sockets Layer (SSL) protocol by updating a CICSConnection configurable service or the CICSRequest node to use SSL.

Before you begin

Before you start:

Ensure that you have completed the following tasks:

1. The CICSRequest node does not support a separate truststore, so the keystore file must provide both personal and signer certificates. If client-authentication (CLIENTAUTH) is enabled in the TCPIPSERVICE in CICS, the broker keystore file must also contain a personal certificate that is trusted by CICS. To set up a public key infrastructure (PKI) at broker or execution group level, follow the instructions in "Setting up a public key infrastructure" on page 504.
2. Create a message flow project and message set project, as described in "Creating a message flow project" on page 1425 and "Working with a message set project" on page 2838.
3. Define the COMMAREA data structure as a message set, as described in "Defining a CICS Transaction Server for z/OS data structure" on page 2193.
4. Configure IP InterCommunications (IPIC) protocol on CICS, as described in "Preparing the environment for the CICSRequest node" on page 736.

About this task

To configure the CICSRequest node to use SSL, complete the following steps:

Procedure

1. For client-authenticated (CLIENTAUTH) SSL connections, CICS expects the SSL client certificate to be mapped to a RACF user ID. Therefore the SSL client certificate must be mapped to a RACF user ID before attempting to establish the SSL connection to CICS. If the client certificate is not mapped to a RACF user ID, the broker might display a `ECI_ERR_NO_CICS` response. You can map a client certificate to a RACF user ID by using the RACF command **RACDCERT**, which stores the client certificate in the RACF database and associates a user ID with it, or by using RACF certificate name filtering. Client certificates can be mapped one-to-one with a user ID, or a mapping from one to the other can be provided to allow a many-to-one mapping. You can achieve this mapping by using one of the following methods:
   - **Associating a client certificate with a RACF user ID**
     a. Copy the certificate that you want to process into an MVS™ sequential file. The file must have variable length, blocked records (RECFM=VB), and be accessible from TSO.
     b. Run the **RACDCERT** command in TSO by using the following syntax:

        ```
        RACDCERT ADD('datasetname') TRUST [ ID(userid) ]
        ```

        Where:
        - *datasetname* is the name of the data set containing the client certificate.
        - *userid* is the user ID to be associated with the certificate. This parameter is optional. If omitted, the certificate is associated with the user issuing the **RACDCERT** command.

        When you issue the **RACDCERT** command, RACF creates a profile in the DIGTCERT class. This profile associates the certificate with the user ID. You can then use the profile to translate a certificate to a user ID without giving a password. For full details of RACF commands, see z/OS Security Server RACF Command Language Reference.
   - **RACF certificate name filtering**

     With certificate name filtering, client certificates are not stored in the RACF database. The association between one or more certificates and a RACF user ID is achieved by defining a filter rule that matches the distinguished name of the certificate owner or issuer (CA). A sample filter rule might look like the following example:

     ```
     RACDCERT ID(DEPT3USR) MAP SDNFILTER
     (OU=DEPT1.OU=DEPT2.O=IBM.L=LOC.SP=NY.C=US)
     ```

     This sample filter rule would associate user ID DEPT3USR with all certificates when the distinguished name of the certificate owner contains the organizational unit DEPT1 and DEPT2, the organization IBM, the locality LOC, the state/province NY, and the country US.
2. Turn on SSL support in the broker by setting the `cicsServer` property on the CICSConnection configurable service, as shown in the following example. This example changes the CICSRequest node that is configured to use the *myCICSConnection* configurable service for the CICS instance that is running at `mycicsregion.com` port 56789. After you run this command, the CICSRequest node connects to CICS over SSL.

   ```
   mqsichangeproperties MB7BROKER -c CICSConnection -o myCICSConnection -n
   cicsServer -v ssl://mycicsregion.com:56789
   ```

   Alternatively you can configure the `CICS server` property directly on the CICSRequest node.

What to do next

Next: When you have configured the broker or the CICSRequest node to use SSL, develop a message flow that contains a CICSRequest node by following the steps in "Developing a message flow with a CICSRequest node" on page 2199.

Use the CICSRequest node to call CICS Transaction Server for z/OS programs over TCP/IP-based IP InterCommunications (IPIC) protocol.

Securing the connection to IMS by using SSL

Configure the IMSRequest node to communicate with IMS over the Secure Sockets Layer (SSL) protocol by creating a keystore file, and configuring the broker to use SSL.

Before you begin

Before you start:

Set up a public key infrastructure (PKI) at broker level by following the instructions in "Setting up a public key infrastructure" on page 504.

About this task

To configure the IMSRequest node to use SSL, complete the following steps.

Procedure

1. Turn on SSL support in the broker by setting the `UseSSL` and `SSLEncryptionType` properties on the IMSConnect configurable service, as shown in the following example.

   This example changes the IMSRequest node that is configured to use the *myIMSConnectService* configurable service. After you run this command, the IMSRequest node connects to IMS over SSL.

   ```
   mqsichangeproperties MB7BROKER -c IMSConnect -o myIMSConnectService -n
   UseSSL,SSLEncryptionType -v True,Weak
   ```

2. Optional: Develop a message flow that contains a IMSRequest node.
3. Test your configuration.

Related concepts:

"Implementing SSL authentication" on page 504
Use SSL authentication to enhance security in your broker environment.

Configuring TCP/IP client nodes to use SSL:

Configure a TCP/IP configuration to use SSL to secure connectivity to and from the TCPIP client nodes.

You can create or modify TCP/IP client connections that use SSL, by creating or modifying a configurable service. You can specify the type of protocol, and the allowed cipher suites. By default, SSL is not enabled for any configurable services. The nodes use the standard broker keystore and truststore configuration.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker or execution group level by following the instructions in "Setting up a public key infrastructure" on page 504.

About this task

Follow these steps to configure the TCPIP nodes to use SSL:

1. "Changing a TCP/IP client configuration to use SSL"
2. "Creating a TCP/IP client configuration that uses SSL" on page 552

Changing a TCP/IP client configuration to use SSL:
About this task

Use the **mqsichangeproperties** command to change an existing TCPIPClient configurable service.

Procedure

1. The following command specifies that the myTCPIPClientService configurable service must use SSLv3 as the protocol, with any available cipher suite.

```
mqsichangeproperties MYBROKER
  -c TCPIPClient
  -o myTCPIPClientService
  -n SSLProtocol
  -v SSLv3
```

2. Restart the execution group that contains the message flows.

Creating a TCP/IP client configuration that uses SSL:
About this task

Use the **mqsicreateconfigurableservice** command to create a TCPIPClient configurable service.

Procedure

1. The following command creates a TCPIPClient configurable service for making connections on port 1455 on the local machine. It uses the SSL protocol SSLv3 with a specific list of allowed cipher suites.

```
mqsicreateconfigurableservice MYBROKER
  -c TCPIPClient
  -o myTCPIPClientService
  -n Port,Hostname,SSLProtocol,SSLCiphers
  -v 1455,localhost,SSLv3,SSL_RSA_WITH_RC4_128_MD5;
     SSL_RSA_WITH_3DES_EDE_CBC_SHA
```

2. Restart the execution group that contains the message flows.

Testing your configuration:
About this task

Use either a TCPIPClientInput node, or a TCPIPClientOutput node to open a connection to a remote SSL server application that is listening on a TCP/IP port.

Related concepts:

"Configurable services properties" on page 3766
The supplied configurable services, and the configurable services that you create, are defined by their names and properties. You can use the supplied services.

Configuring TCP/IP server nodes to use SSL:

Configure a TCP/IP configuration to use SSL to secure connectivity to and from the TCPIP server nodes.

You can create or modify TCP/IP server connections that use SSL, by creating or modifying a configurable service. You can specify:

The type of protocol.

The allowed cipher suites.

A key alias.

Whether a connecting client should provide authentication information.

By default, SSL is not enabled for any configurable services. The nodes use the standard broker keystore and truststore configuration.

Before you begin

Before you start: Set up a public key infrastructure (PKI) at broker level by following the instructions in "Setting up a public key infrastructure" on page 504.

About this task

Follow these steps to configure the TCPIP nodes to use SSL:

1. "Changing a TCP/IP server configuration to use SSL"
2. "Creating a TCP/IP server configuration that uses SSL"

Changing a TCP/IP server configuration to use SSL:
About this task

Use the **mqsichangeproperties** command to change an existing TCPIPServer configurable service.

Procedure

1. The following command changes a TCPIPServer configurable service to use SSLv3 with any available cipher suite. Connecting clients are not asked to authenticate.

```
mqsichangeproperties MYBROKER
  -c TCPIPClient
  -o myTCPIPServerService
  -n SSLProtocol
  -v SSLv3
```

2. Restart the execution group that contains the message flows.

Creating a TCP/IP server configuration that uses SSL:
About this task

Use the **mqsicreateconfigurableservice** command to create a TCPIPServer configurable service.

Procedure

1. The following command creates a TCPIPServer configurable service for making connections on port 1455. It uses the SSL protocol SSLv3 with a specific list of allowed cipher suites. Connecting clients are required to authenticate.

```
mqsicreateconfigurableservice MYBROKER
     -c TCPIPServer
     -o myTCPIPServerService
     -n Port,SSLProtocol,SSLCiphers,SSLClientAuth
     -v 1455,SSLv3,SSL_RSA_WITH_RC4_128_MD5;
        SSL_RSA_WITH_3DES_EDE_CBC_SHA,require
```

2. Restart the execution group that contains the message flows.

Using an SSL key alias:
About this task

A key alias identifies the key that is to be used for the SSL connection, if the keystore for your broker or execution group contains more than one key. Use the **mqsichangeproperties** or **mqsicreateconfigurableservice** as appropriate, with the `SSLKeyAlias` property. The default value `""` or `none`, means that an SSL key alias is not used. Any other string identifies the alias.

Note: If the keystore contains more than one key, and no key alias is defined, the Java virtual machine arbitrarily chooses a key at run time.

The following command creates a TCPIPServer configurable service for making connections on port 1455. It uses the SSL protocol SSLv3 with the cipher suites SSL_RSA_WITH_RC4_128_MD5 and SSL_RSA_WITH_3DES_EDE_CBC_SHA. It requires the client to authenticate itself, and uses the key alias `MyKey` to identify the key to be used.

```
mqsicreateconfigurableservice MYBROKER
  -c TCPIPServer
  -o myTCPIPServerService
  -n Port,SSLProtocol,SSLCiphers,SSLClientAuth,SSLKeyAlias
  -v 1455,SSLv3,SSL_RSA_WITH_RC4_128_MD5;SSL_RSA_WITH_3DES_EDE_CBC_SHA
     ,require,MyKey
```

The following command changes a TCPIPServer configurable service to use the first key retrieved from the keystore, with SSL protocol SSLv3. SSLClientAuth is disabled.

```
mqsichangeproperties MYBROKER
  -c TCPIPClient
  -o myTCPIPServerService
  -n SSLProtocol
  -v SSLv3
```

Testing your configuration:
About this task

To test your configuration, connect an SSL-enabled client, such as another program, or a web browser, to the server port. Connection error messages, such as handshake failures, or untrusted keys, indicate that you must change the configuration.

Client identity:
About this task

If SSL client authentication is requested or required, and the client successfully authenticates, the distinguished name is present as an identity source token in the

properties parser, in the tree propagated from the Open terminal at connection time. This applies only to the TCPIPServerInput node.

The `IdentitySourceToken` field is set to the distinguished name from the client certificate.

The `IdentitySourceType` field is set to the string `username`.

The `IdentitySourceIssuedBy` field is set to the issuer of the certificate presented by the client.

If SSL client authentication is requested, and the client does not provide the required credentials, the fields are set to blank.

Using security exits

Define a security exit on the WebSphere MQ channel when you create a broker connection.

About this task

To create a security exit on the WebSphere MQ channel that you define for communications between the WebSphere Message Broker Toolkit, or WebSphere Message Broker Explorer and the broker, you must define a security exit when you create the connection.

Procedure

1. Select from the following options:
   - In the WebSphere Message Broker Toolkit, right-click the Brokers folder and click **Add Remote Broker**.
   - In the WebSphere Message Broker Explorer, right-click the Brokers folder and click **Connect** > **Remote Broker**.

   The Create a Broker Connection wizard opens.
2. Enter the values for **Queue Manager Name**, **Host**, and **Port** that you want to use. In the WebSphere Message Broker Explorer, click **Next**.
3. Enter the Security Exit **Class** name. The name must be a valid Java class name.

4. Set the **JAR File location** for the Security Exit that is required on this connection. Click **Browse** to find the file location.

Results

The security exit is started every time a message passes across the connection.

What to do next

Alternatively, use SSL to communicate between the Administration API for WebSphere Message Broker (also known as the CMP API) and the broker; see "Implementing SSL authentication" on page 504.

You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

Setting up z/OS security

On z/OS, you must complete several security configuration tasks before WebSphere Message Broker can work correctly.

About this task

The steps you need to follow are described in this topic and also in the following topics:

- "Setting up WebSphere MQ" on page 558
- "Setting up WebSphere Message Broker Toolkit access on z/OS" on page 559

Decide on the started task name of the broker. This name is used to set up started task authorizations, and to manage your system performance.

Decide on a data set naming convention for your WebSphere Message Broker PDSE. A typical name might be `WMQI.MQP1BRK.CNTL`, where `MQP1` is the queue manager name. You must give the WebSphere Message Broker, WebSphere MQ,

and z/OS administrators access to these data sets. You can give these professionals controlled access in several ways, for example:

- Give each user individual access to the specific data set.
- Define a generic data set profile, defining a group that contains the user IDs of the administrators. Grant the group control access to the generic data set profile.

Define an OMVS group segment for this group so that information can be extracted from the External Security Manager (ESM) database to enable you to use Publish/Subscribe security.

Define an OMVS segment for the started task user ID and give its home directory sufficient space for any WebSphere Message Broker dumps. Consider using the started task procedure name as the started task user ID. Check that your OMVS segment is defined by using the following TSO command:

```
LU userid OMVS
```

The command output includes the OMVS segment, for example:

```
USER=MQP1BRK NAME=SMITH, JANE OWNER=TSOUSER
CREATED=99.342 DEFAULT-GROUP=TSOUSER PASSDATE=01.198
PASS-INTERVAL=30
......
OMVS INFORMATION
----------------
UID=0000070594
HOME=/u/MQP1BRK
PROGRAM=/bin/sh
CPUTIMEMAX=NONE
ASSIZEMAX=NONE
FILEPROCMAX=NONE
PROCUSERMAX=NONE
THREADSMAX=NONE
MMAPAREAMAX=NONE
```

The command:

```
df -P /u/MQP1BRK
```

displays the amount of space used and available, where `/u/MQP1BRK` is the value from `HOME` (on a previous line). This command shows you how much space is currently available in the file system. Check with your data administrators that this space is sufficient. You require a minimum of 400 000 blocks available if a dump is taken.

Associate the started task procedure with the user ID to be used. For example, you can use the STARTED class in RACF. The WebSphere Message Broker and z/OS administrators must agree on the name of the started task.

WebSphere Message Broker administrators need an OMVS segment and a home directory. Check the setup previously described.

The started task user IDs and the WebSphere Message Broker administrators need access to the install processing files, the component-specific files, and the home directory of the started task. During customization, the file ownership can be changed to alter group access. This change might require super user authority.

When the service user ID is *root*, all libraries loaded by the broker, including all user-written plug-in libraries, and all shared libraries that they might access, also

have root access to all system resources (for example, file sets). Review and assess the risk involved in granting this level of authorization.

For more information about various aspects of security, see "Security overview" on page 351.

Setting up WebSphere MQ

This is part of the larger task of setting up security on z/OS, and gives details of the authorities that your user ID needs to perform the required operations.

About this task

The user ID of the person running the create broker (`BIPCRBK`) job needs *UPDATE* access to the component PDSE, *READ/EXECUTE* access to the installation directory, and *READ/WRITE/EXECUTE* access to the broker directory.

If you do not use queue manager security, you do not need to read the rest of this topic. Topic "Creating the broker component" on page 629 provides detailed statements on how to protect your queues.

By default, the broker's internal queues, which all have names of the form:

```
SYSTEM.BROKER.*
```

should be protected. These names cannot be changed. Restrict access to the broker started task user ID, and to WebSphere Message Broker administrators.

If you are using Publish/Subscribe, subscribers must have authority to PUT to SYSTEM.BROKER.CONTOL.QUEUE.

You can control which applications can use queues used by message flows. Applications must be able to PUT and GET to queues defined in all nodes.

Execution group user IDs on z/OS

On z/OS, you can specify an alternative user ID to run an execution group so that it accesses resources according to the permissions assigned to it, rather than the permissions assigned to the main broker user ID.

You can specify an alternative user ID to run an execution group, which means that you can run one or more message flows under a different user ID from the main broker ID. When external resources are accessed by a message flow, access is granted according to the permissions assigned to the user ID that is running the execution group. By having different user IDs for different execution groups, you can control the access to resources at the level of the execution group rather than at the level of the main broker user ID. The user IDs for the execution groups must be in the same group as the main broker user ID, so that shared resources can be read and updated.

On z/OS, the user ID assigned to the broker is the started task (STC) user ID that is assigned to the started task JCL. By default, each broker on z/OS has a single started task JCL, which is used to start the main broker address space and all associated execution group address spaces. However, you can specify a different started task JCL, and therefore a different user ID, for one or more execution groups. As a result, execution groups can be started using a different started task JCL and run under different user IDs with different permissions to access resources. For example, an execution group can access messages from WebSphere MQ through the execution group's task ID (rather than the main broker ID) by default. Execution groups can also access files according to the permissions that are assigned to the execution group's user ID.

You can specify the required environment variable in the main broker profile, BIPBPROF. You can use the `MQSI_STARTEDTASK_FIXED_`*`EG`*, `MQSI_STARTEDTASK_MULTI_`*`EG`*, or `MQSI_STARTEDTASK_DEFAULT` environment variables to specify a different started task and user ID, for one or more execution groups. These environment variables override the started task and user ID that are associated with the broker, and replace them with the started task and user ID associated with a specific execution group:

- Use the `MQSI_STARTEDTASK_FIXED_`*`EG=STC`* environment variable to specify the name of a single execution group (where *EG* is the 8-character name of the execution group, and *STC* is the name of the execution group started task JCL).
- Use the `MQSI_STARTEDTASK_MULTI_`*`EG=STC`* environment variable to override the user ID for multiple execution groups (where *EG* functions as a wildcard and *STC* is the name of the started task JCL that is used to start each of the execution groups). For example, specify `MQ05` in place of `EG` to override the user ID for any execution groups in which the last 8 characters start with `MQ05`.
- Use the `MQSI_STARTEDTASK_DEFAULT=`*`STC`* environment variable to override the started task JCL (STC) for all execution groups, unless it is overridden by the `MQSI_STARTEDTASK_FIXED_`*`EG`* or `MQSI_STARTEDTASK_MULTI_`*`EG`* environment variable.

For information about how to define a user ID on an execution group, see "Specifying an alternative user ID to run an execution group on z/OS" on page 561.

Specifying an alternative user ID to run an execution group on z/OS

You can change the user ID under which an execution group runs so that it can access resources according to the permissions assigned to it, rather than the permissions assigned to the main broker user ID.

Before you begin

Before you start

Before starting this task, read the following topics:

- "Creating a broker on z/OS" on page 620
- "Execution group user IDs on z/OS" on page 560

About this task

Complete the following steps to specify an alternative user ID for the execution group, to be used instead of the broker's user ID:

Procedure

1. Create the new RACF started task profile with a new user ID, which will be used to run the execution group. Consider the following points when you are creating the new started task:
   - The new started task must be created with an OMVS segment including a unique UID, home directory, and the ability to create data sets under the broker's HLQ and alias.
   - The started task procedure name to be used for the execution group address space must start with the same four characters as the main broker started task. For example, if the main broker started task is `MQ01BRK`, the started task name for the execution group could be `MQ01EG1` but not `MQ02EG2`. As a result, consistency is maintained between the main broker started task, the execution group, and the queue manager, which helps to identify the relationship between them. If the first four characters are not the same, the execution group is started using the main broker started task JCL.

2. Ensure that the new user ID associated with the new started task JCL has the same RACF primary group as the existing broker user ID, so that they can access shared resources. Also ensure that the new user ID has the required privileges to the existing broker filesystem and dataset (which it should have through the primary group access).
3. Ensure that the MQ and SMF authorizations are updated for the new user ID; for more information, see "Summary of required access (z/OS)" on page 3985.
4. Copy the existing broker started task JCL to the new started task JCL in the PROCLIB.
5. Ensure that the main broker user ID has been granted permission to the SUPERUSER.PROCESS.KILL RACF profile. This permission is required so that the main control address space can recover any existing execution group address spaces in the event of a failure.
6. Refresh the started RACF classes to implement the updates.
7. Change the user ID by adding the appropriate environment variable to the broker's profile.
   - The execution group name specified in the environment variable is the last 8 characters of the execution group, after any overrides have been applied. This is the same 8-character name that is displayed as the STEPNAME against the execution group address space in SDSF.
   - Ensure that the execution group name contains only characters that are valid in the environment variable. If invalid characters are used, the user ID cannot be overridden.
   - If you specify more than one environment variable, they are read in the following order (with MQSI_STARTEDTASK_FIXED_*EG* taking precedence):
     a. MQSI_STARTEDTASK_FIXED_*EG*
     b. MQSI_STARTEDTASK_MULTI_*EG*
     c. MQSI_STARTEDTASK_DEFAULT
8. Submit BIPGEN to the broker's ENVFILE.
9. Restart the broker.

Chapter 6. Configuring brokers for development environments

Set up application development environments on Linux on x86 or Windows to create, test, and deploy message flows and associated resources.

About this task

If you are new to WebSphere Message Broker, you can set up a basic development environment on either Windows or Linux on x86 by installing the broker component and the WebSphere Message Broker Toolkit, and creating a default configuration. Run the Default Configuration wizard to create a broker, and try the sample programs that are supplied in the WebSphere Message Broker Toolkit.

Some of the samples depend on the default configuration, which creates a broker that has the fixed name, MB7BROKER, and a queue manager for the broker that has the fixed name, MB7QMGR.

Details of the default configuration are provided in “Creating a default configuration” on page 564.

When you have tried out your first few samples, you can create and configure more brokers, and set up an environment that can support your application developers. Many samples are supplied, and provide education and guidance about how to use many of the facilities of WebSphere Message Broker.

See the full list of samples in “Samples” on page 98. The samples are grouped in sections according to the features that they use, and the operations that they perform. For example, the section "Web services samples" lists the samples that use Web services nodes to communicate with WebSphere Service Registry and Repository (WSRR) and other Web applications.

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

To create and configure brokers in addition to, or instead of, the default configuration, follow the instructions in “Creating a development environment” on page 567.

When you start the WebSphere Message Broker Toolkit, a workbench session opens, which you can use to create, configure, and manage your application development resources. You can configure your workbench session in various ways to suit your working environment and preferences. These options are described in “Configuring the workbench” on page 570.

Related tasks:

Chapter 7, “Configuring brokers for test and production environments,” on page 579
Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

Chapter 8, “Administering brokers and broker resources,” on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Chapter 9, “Developing message flow applications,” on page 1019
Develop message flows to process your business messages and data.

Creating a default configuration

Use the Default Configuration wizard to create and test a basic broker configuration.

Before you begin

Before you run the Default Configuration wizard, complete the following steps:

- Install the WebSphere Message Broker Toolkit, the Broker component, and the Broker component prerequisite products on this computer.
- Access the Default Configuration wizard through the WebSphere Message Broker Toolkit, which is available only on Linux on x86 and Windows.

About this task

By using the Default Configuration wizard, you create a default configuration on your local computer so that you can explore the product and run the samples. You can also remove the default configuration, if it exists, that has been created on your logon account.

- “Creating the default configuration”
- “Removing the default configuration” on page 565

The default configuration is described in more detail in “Verifying your WebSphere Message Broker installation” on page 290. This topic describes how to verify your installation on Linux on x86, Linux on x86-64, or Windows by using either the WebSphere Message Broker Toolkit or the WebSphere Message Broker Explorer.

Creating the default configuration

About this task

The wizard creates the following resources:

- A sample broker named MB7BROKER.
- A WebSphere MQ queue manager named MB7QMGR.

Procedure

1. Start the Default Configuration wizard from the WebSphere Message Broker Toolkit Welcome page, which is displayed the first time you start the WebSphere Message Broker Toolkit. If the Welcome page is not displayed, open it in the WebSphere Message Broker Toolkit by clicking **Help** > **Welcome**.
2. Click **Get Started** on the Welcome page, then click **Create the Default Configuration**.
3. Click **Start the Default Configuration wizard**. The Default Configuration wizard is displayed.
4. The Welcome page of the wizard describes what is about to happen, click **Next** to continue. You can click **Cancel** at any time to cancel the creation of the default configuration.

The wizard checks that the default configuration is not already created.

5. The Default Configuration Summary page lists the resources that will be created. Click **Next** to continue.
6. The Default Configuration Progress page lists the background configuration actions as they occur, and indicates successful completion. You can cancel the creation of the default configuration by clicking **Cancel**. The wizard backs out all the configuration tasks and displays the progress and success of the process. The configuration process is written to a log file in the Eclipse workspace directory:
   - Linux `/home/user_name/IBM/wmbt70/workspace/.metadata/DefaultConfigurationWizard.log`
   - Windows `C:\Documents and settings\user_name\IBM\wmbt70\workspace\.metadata\DefaultConfigurationWizard.log`

   If the default configuration is created successfully, you see an appropriate message. If errors occur, you see an appropriate message and the wizard backs out all the configuration tasks. If an error occurs during the back out process, the wizard displays a list of resources that you must remove manually.
7. You can use the samples to verify the default configuration. **Launch Samples Wizard when finished** is selected by default. Click **Finish** to open the Prepare the Samples wizard.

   If you do not want to open the Prepare the Samples wizard, clear **Launch Samples Wizard when finished** before clicking **Finish**.

   If you are viewing this information from within the WebSphere Message Broker Toolkit, you can open the samples manually by clicking the following sample:

   - Pager

   Alternatively, click **Product Overview** > **Samples** in the WebSphere Message Broker information center in the WebSphere Message Broker Toolkit, to display a list of the available samples.

   You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Removing the default configuration

Procedure

1. Start the Default Configuration wizard from the WebSphere Message Broker Toolkit Welcome page, which is displayed after you start the WebSphere Message Broker Toolkit. If the Welcome page is not displayed, open it in the WebSphere Message Broker Toolkit by clicking **Help** > **Welcome**.
2. Click **Get Started** on the Welcome page, then click **Create the Default Configuration**.
3. Click **Remove the Default Configuration wizard**. The Default Configuration wizard is displayed.
4. The Welcome page of the wizard describes what is about to happen. You can click **Cancel** at any time to cancel the removal of the default configuration.

   The wizard checks that the default configuration is already created.
5. The Remove Default Configuration Summary page lists the resources that will be removed. Click **Next** to continue.

6. The Default Configuration Progress page lists the removal actions as they occur, and indicates successful completion. The removal process is written to a log file in the Eclipse workspace directory:
   - Linux `/home/user_name/IBM/wmbt70/workspace/.metadata/DefaultConfigurationWizard.log`
   - Windows `C:\Documents and settings\user_name\IBM\wmbt70\workspace\.metadata\DefaultConfigurationWizard.log`
7. A message confirms that the default configuration has been removed successfully. Click **Finish** to close the wizard.

   If errors occur during the removal of the default configuration, the wizard displays the errors, and also writes them to the log file. Follow the advice in the log, and try each step again.

Results

If you experience problems when you are using the wizard to remove the default configuration, you might have to remove the default configuration manually. For more information, see "You experience problems with the default configuration" on page 3382.

Installation information for WebSphere Message Broker is provided in the *Installation Guide* that is supplied as a PDF file with your product package.

"WebSphere MQ resources for the broker" on page 585
Each broker depends on a number of WebSphere MQ resources: some are required, others are optional, and depend on your environment and requirements. Some of these resources are created for you, but others you must define for yourself.

Creating a development environment

Create a development environment on Linux on x86 or Windows to develop your message flow applications.

Before you begin

Before you start:

- "Installing the Broker component" on page 267
- "Installing the WebSphere Message Broker Toolkit" on page 276

On Windows, you can use the Launchpad to install both these components. For details, see "Installing by using the Windows Launchpad" on page 262.

If you are new to WebSphere Message Broker, and have not created a default configuration, you might want to use that option to set up your first configuration. You can use the default environment to run some of the supplied sample programs, and explore the features that are supported by WebSphere Message Broker. Follow the instructions in "Creating a default configuration" on page 564.

About this task

To create your own development environment on a computer that is running Linux on x86 or Windows, complete the following steps:

Procedure

1. Start the WebSphere Message Broker Toolkit in one of the following ways:
   - Linux From the main menu:
     - On Red Hat, click **Programming** > **IBM WebSphere Message Broker Toolkit**.
     - On SUSE Linux, click **All Applications** > **WebSphere Message Broker Toolkit**.
   - Windows Click **Start** > **All Programs** > **IBM WebSphere Message Broker Toolkit** > **IBM WebSphere Message Broker Toolkit 7.0** > **WebSphere Message Broker Toolkit 7.0**, or double-click the shortcut on your desktop.
   - Use the following commands in a command prompt from their location in the root directory for the package group:
     - Linux
       ```
       ./eclipse -product com.ibm.etools.msgbroker.tooling.ide
       ```
     - Windows
       ```
       eclipse.exe -product com.ibm.etools.msgbroker.tooling.ide
       ```

   A new session of the WebSphere Message Broker Toolkit opens, and prompts you for the name of a workspace in which to store the resources that you create in this session.

   You can accept the default value, `workspace`, type your preferred name into the text field, or click Browse to select the location of your choice. Select **Use this as the default and do not ask again** to inhibit the display of the workspace dialog next time you start the WebSphere Message Broker Toolkit.
2. Click **OK** to confirm the location of your workspace. Your WebSphere Message Broker Toolkit session opens, and displays the Welcome page. You can tailor various settings in the WebSphere Message Broker Toolkit to suit your

requirements and your working environment; for example, the colors and fonts. These options are described in "Configuring the workbench" on page 570.

3. Close the Welcome page. You can return to the Welcome page later by clicking **Help** > **Welcome**. If more than one option is listed, select WebSphere Message Broker.
4. In the Broker Application Development perspective, select the Brokers view. Alternatively, click **Window** > **Show view** > **Other** > **Broker Runtime** > **Brokers** to show the Brokers view.
5. Right-click **WebSphere Message Brokers**, and click **New** > **Local Broker** to create a broker, and complete the wizard for this task.

   If you want more detailed instructions, see "Creating a broker for a development environment" on page 569.

   Your configuration might be affected by the operation mode of your broker. The default operation mode is enterprise mode, in which your broker runs with no restrictions. Check with your broker administrator which operation mode applies to your organization; you might have to change the mode of your broker after you have created it. For more information about operation modes, see "Operation modes" on page 48.
6. You must create at least one execution group on your broker. To add additional execution groups to your broker, right-click the broker, and click **New** > **Execution Group**. Enter a name for your execution group, and click **OK**.

   The execution group is the runtime environment in which your message flows run. You can create many execution groups on a single broker, and you can deploy your message flows to one or more execution groups on one or more brokers.

   For more detailed instructions about this task, see "Creating an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 937.

Results

Your configuration is now ready to use.

What to do next

Next: You can start to develop resources to deploy to your broker. You can create your own message flows, or you can use the patterns and samples that are provided to get you started. For details of these options, see Chapter 9, "Developing message flow applications," on page 1019.

This task has covered the minimum set of steps that you must complete to create a broker and configure your development environment. Typically, as an application developer, you are working in a single platform environment to create, deploy, and test your message flows before they are ready for use in a test of production environment.

More options are available for enhanced configurations, including configurable services. When the requirements of your message flow applications extend beyond this basic configuration, and you need additional configuration to support those requirements, you can find details of these more advanced options in Chapter 7, "Configuring brokers for test and production environments," on page 579.

Creating a broker for a development environment

Create a broker by using the WebSphere Message Broker Toolkit on Linux on x86 or Windows.

Before you begin

Before you start:

If you are using the WebSphere Message Broker Explorer, see “Creating a broker using the WebSphere Message Broker Explorer” on page 618.

- On Windows, you must have administrator access rights to create brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer. When creating a broker, you might be prompted to agree to the use of administrator rights or be prompted to enter an administrator user ID and password.
- If you want to configure the broker as a WebSphere MQ trusted application, see “Using WebSphere MQ trusted applications” on page 613.
- Read “Considering security for a broker” on page 501.
- Check which operation mode you are licensed to use. If you do not set a mode, the automatic default is `enterprise` mode; see “Operation modes” on page 48.

About this task

When you create a broker, if the WebSphere MQ queue manager does not exist, the queue manager is automatically created. If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel auth security is automatically disabled.

If the specified queue manager already exists when creating the broker, then it is assumed that the user has applied the appropriate security configuration to meet their requirements, and therefore channel auth security is not disabled.

To create a broker by using the WebSphere Message Broker Toolkit:

Procedure

1. In the Broker Application Development perspective, select the Brokers view. Alternatively, click **Window** > **Show view** > **Other** > **Broker Runtime** > **Brokers** to show the Brokers view.
2. Right-click the Brokers folder, and click **New** > **Local Broker**. The New Local Broker wizard is displayed.
3. Enter a name for the broker and queue manager. You cannot create a broker on a queue manager that is already associated with a broker.
4. On Windows, enter your user name and password. These parameters are not required on Linux on x86.
5. Optional: On Windows, select whether to start the broker automatically when Windows starts.
6. Enter a name for the default execution group, or accept the value "default".
7. Optional: Enter a value for the flow debug port for the default execution group.
8. Click **Finish**.

Results

You have created and started a broker.

What to do next

Changing WebSphere Message Broker Toolkit preferences

The WebSphere Message Broker Toolkit has a large number of preferences that you can change to suit your requirements. Some of these are specific to the product plug-ins that you have installed within the workbench, including those for WebSphere Message Broker. Others control more general options, such as the colors and fonts in which information is displayed.

About this task

To access the WebSphere Message Broker Toolkit preferences:

Procedure

1. Select **Window** > **Preferences**.
2. Click the plus sign associated with **Workbench**, typically the first entry in the left pane. An expanded list of options appears, Select the aspect of the WebSphere Message Broker Toolkit that you want to modify. These options might be of interest:

   Startup and shutdown

   Switch on, or off, the prompt at toolkit startup that asks you to confirm the workspace location. Typically you switch this prompt off, so that it does not appear, but you can force it to appear next time you start the WebSphere Message Broker Toolkit if you want to specify a different location.

   You can also specify whether to display the dialog box that asks you to confirm shutdown of the WebSphere Message Broker Toolkit.

Colors and fonts
Change the default fonts and colors that appear in the WebSphere Message Broker Toolkit.

Perspectives
On this dialog, your choices include the option to open a new perspective in a new window.

3. When you have made your changes, click **OK** to close the Preferences dialog.

What to do next

Below the Workbench category in the Preference dialog are items that refer specifically to WebSphere Message Broker resources, such as message flows. Review the following topics for information about setting preferences and other values that are specific to your use of these resources:

- "Message flow preferences" on page 4016
- "Changing ESQL preferences" on page 2408
- "Configuring message set preferences" on page 2840
- Chapter 10, "Testing and debugging message flow applications," on page 3143
- Changing trace settings

Changing workbench capabilities

You can configure the workbench to disable access to some of the functional capabilities of WebSphere Message Broker.

About this task

Capabilities is an Eclipse concept that allows you to enable or disable the components of a product. By default, all components of the workbench are enabled.

To access the workbench capabilities:

Procedure

1. Select **Window** > **Preferences**.
2. Click the plus sign associated with **General**. An expanded list of options appears.
3. Click **Capabilities**. You can use the capabilities that are listed to enable or disable various product components; the capabilities are grouped according to a set of predefined categories.
4. Select **Message Broker Toolkit** from the list of capabilities that is displayed, and select the **Advanced** button. A window opens that has a check box for each of the predefined categories.

5. Select the check boxes for the categories that you want to either enable or disable; click either the **Enable All** or **Disable All** button and click **OK**. A pane describes the functionality that is enabled following this action.

What to do next

The predefined categories for the workbench are listed together with a reference to more information about the relevant functional area of WebSphere Message Broker:

- **Message Broker Toolkit - Administration**. See Chapter 8, "Administering brokers and broker resources," on page 899.
- **Message Broker Toolkit - Core**. See "WebSphere Message Broker Toolkit" on page 31.
- **Message Broker Toolkit - Development**. See Chapter 9, "Developing message flow applications," on page 1019.

Related concepts:

"WebSphere Message Broker Toolkit" on page 31

Configuring CVS to run with the WebSphere Message Broker Toolkit

Install CVS as a normal program by following the usual prompts. Not all versions of *CVSNT* are supported by Eclipse.

Procedure

1. Configure CVS by carrying out the following tasks:
   a. Create a directory on your computer, for example, on Windows - `c:\CVSRepository.`
   b. Start the *CVSNT* control panel. Select **Start** > **Programs** > **CVSNT** to see the icon on the desktop.
   c. Stop both the `CVS Service` and the `CVS Lock Service`.
   d. Select the `Repositories` tag, click **Add** and create a new repository. Note that no entry appears on the screen the first time that you do this.
   e. Use the `...` button on the next window to select the directory that you created in step 1a and click **OK**. Note that when CVS has finished formatting its repository the backslash in the directory name is changed to a forward slash.
   f. Select the `Service Status` tab and restart both the `CVS Service` and the `CVS Lock Service`.
2. Enable the CVS Revision tag to be populated in the Eclipse Version fields in the WebSphere Message Broker Toolkit. To do this on Windows:
   a. Select `Window->Preferences`
   b. Expand the `Team` section and click **CVS**
   c. Use the drop down in the **Default keyword substitution:** field and set the value to `ASCII with keyword expansion(-kkv)`

3. Add the WebSphere Message Broker file types to the Eclipse CVS configuration. To do this:
   a. Select **File Content** in the `Team` section of the window you opened in step 2 on page 573
   b. Click **Add** and add `msgflow` as an allowable file extension. Ensure that the value is set to ASCII.
   c. Repeat the above procedure for the following file extensions that the broker uses:
      - `esql`
      - `mset`
      - `mxsd`

      If you use CVS to store other file types, for example, COBOL copybooks add the appropriate file types as well.
   d. Click **OK** when you have finished.

You can change preferences that determine properties of message flows when you create them.

"Message set preferences" on page 5366
Preferences for message sets.

Configuring the WebSphere Message Broker Toolkit to run Rational ClearCase

To use Rational ClearCase with the WebSphere Message Broker Toolkit, enable the capability in the Preferences page.

About this task

To enable Rational ClearCase in the WebSphere Message Broker Toolkit:

Procedure

1. Click **Window** > **Preferences** to open the Preferences window.
2. Expand **General** in the left pane, and click **Capabilities**.
3. In the Capabilities pane, click **Advanced**. The Advanced window opens.
4. Expand **Team**, and ensure that **ClearCase SCM Adapter** is selected.
5. Click **OK** to close the Advanced window.
6. Click **OK** or **Apply** to apply your changes.

Results

After you enable the ClearCase capability, the ClearCase menu is displayed in the Broker Application Development perspective.

What to do next

To work with ClearCase:

1. Click **ClearCase** > **Connect to Rational ClearCase**.
2. Right-click your project and click **Team** > **Add to Version Control** to add your projects to the ClearCase source control.
3. After you have added your projects to the ClearCase source control, you can perform ClearCase operations.

Creating a working set

Create a working set to limit the number of resources that are displayed in the Broker Development view.

Before you begin

Before you start:

To read about working sets, see "Working sets" on page 42.

About this task

By creating and using a working set, you can reduce the visual complexity of what is displayed in the Broker Development view, making it easier to manage and work with your projects.

To create a new working set, complete the following steps:

Procedure

1. Click the down arrow of the working set section, <all resources>, in the Broker Development view. A list is displayed containing existing working sets and options for editing and deleting existing working sets, and for creating a new working set.
2. Click **New Working Set**. The New Working Set wizard opens.

3. Enter a name for the working set.
4. Select the resources that you want to include in this working set. You can also include all the projects that are dependent on your selected resources by selecting **Automatically include dependent projects in this working set**.
5. Click **Finish**.

Results

The new working set and its associated resources are displayed in the Broker Development view.

What to do next

Next:

In addition to creating new working sets, you can also select, edit, and delete existing working sets by using the options in the Broker Development view menu.

Related concepts:

"Resources" on page 36
The projects, folders, and files that you work with in the WebSphere Message Broker Toolkit workspace are called *resources*. By default, these resources are stored with their metadata in the workspace directory in your local file system. The workspace directory is created the first time that you start the WebSphere Message Broker Toolkit.

"Quick Start wizards overview" on page 1409
You can use a Quick Start wizard to set up the basic resources that are required to develop a message flow application. The wizard sets up and gives names to containers for the resources that you need when you develop a message flow.

Integrating the Rational Team Concert client with the WebSphere Message Broker Toolkit

How you integrate the Rational Team Concert™ client with the WebSphere Message Broker Toolkit.

About this task

To integrate the Rational Team Concert client with the WebSphere Message Broker Toolkit, you must have the Rational Team Concert client in the same package group as the WebSphere Message Broker Toolkit.

The supported version of Rational Team Concert is V2.0.0.2.

Procedure

Use the Installation Manager to install the Rational Team Concert client into the same package group as the WebSphere Message Broker Toolkit.
Using the Installation Manager adds all the Rational Team Concert client capability into the WebSphere Message Broker Toolkit workspace.
You can also install the WebSphere Message Broker Toolkit into the Rational Team Concert client package group.
If the products are in the same package group, they can be installed in any order.

What to do next

To work with Rational Team Concert source control:

1. Start the WebSphere Message Broker Toolkit.
2. Open the Work Items perspective and click **Window** > **Open Perspective** > **Other** > **Work Items**.
3. Click the **Create Repository Connection** link in the Team Artifacts view.
4. Follow the dialog and enter the information given to you by your Jazz™ administrator.
5. To add your project to the repository, right-click the project and select **Team** > **Share Project**.
6. In the Share Project window, select Jazz Source Control as the repository type.

See Getting started in your Rational Team Concert source control workspace for more details about the Rational Team Concert source control operations.

You can also use the Jazz Team Build as your build engine for the WebSphere Message Broker Toolkit; see Building with Jazz Team Build for more information.

Related reference:

Chapter 7. Configuring brokers for test and production environments

Create one or more brokers on one or more computers, and configure them on your test and production systems to process messages that contain your business data.

About this task

On Linux on x86 and Windows, you can install the broker and the WebSphere Message Broker Toolkit, and create an initial configuration to learn about WebSphere Message Broker, and start to develop your applications. You can also configure an environment for more advanced application development and unit test. These tasks are described in Chapter 6, "Configuring brokers for development environments," on page 563.

To configure your test and production environments, use the information in this section to plan and configure the resources that you want:

Procedure

1. Plan the system.
2. If you are configuring a broker on z/OS, Customize the z/OS environment.
3. Ensure that you have the correct authorization and permissions to create and access components. For more information, see "Authorization for configuration tasks" on page 353 and "Broker component security" on page 497.
4. Create the components.
5. If you are using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, Configure brokers in the developer or administrator workbench.
6. If you want to ensure that you are using the correct operation mode for your license, Check the operation mode of your broker.
7. Create and configure the databases.
8. If you want to ensure the data integrity of transactions, Configure global coordination of transactions.
9. If you want to connect to external resources such as Enterprise Information Systems, IMS, or JMS, Configure properties to connect to external resources.
10. If you want to configure the storage of events for aggregation, Collector, or timeout nodes, or configure monitoring event sources, Configure internal resources that are required by message flows.
11. If you want to view objects in a different language or code page, Change the locale.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Execution groups" on page 53
An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes.

"Authorization for configuration tasks" on page 353
Authorization is the process of granting or denying access to a system resource.

Related tasks:

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

"Broker component security" on page 497
You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

"Developing applications that use the Administration API" on page 956
Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

Planning a broker environment

When you start to plan your broker environment, you must first consider your resource naming conventions and the design of the WebSphere MQ infrastructure.

About this task

The following topics describe these factors:

- "Considering resource naming conventions" on page 581
- "Designing the WebSphere MQ infrastructure" on page 584

You might also want to consider how your configuration might affect performance of your brokers and message flows. See "Considering performance in the broker environment" on page 586 for information about these aspects.

Procedure

You must also consider how to configure your brokers:

1. Performance: What is the required message throughput? See "Optimizing message flow throughput" on page 587.

   What is the size of the messages that are being processed? Larger messages take longer to process. A few brokers handling many messages might degrade overall performance. See "Considering performance in the broker environment" on page 586.
2. Operation mode: The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657. (This option does not apply to brokers that you create on z/OS systems.)
3. Application independence: Do you need to isolate applications from each other? You might want to separate applications that serve different functions; for example, personnel and finance.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Routing using publish/subscribe applications" on page 2215
You can route your messages to applications using the publish/subscribe method of messaging.

Configure databases to hold application or business data that you can access from your message flows.

Considering resource naming conventions

When you plan a new WebSphere Message Broker network, one of your first tasks must be to establish a convention for naming the resources that you create within this network.

Information is provided about the following resources:

- Product component naming conventions
- WebSphere MQ naming conventions
- Database naming conventions

Related reference:

"Designing the WebSphere MQ infrastructure" on page 584
You must create and manage the WebSphere MQ resources that are required to support your brokers, and the applications that connect to them to supply or receive messages.

Naming conventions for brokers and associated resources

Establish a naming convention for all the WebSphere Message Broker resources in your broker environment to ensure that names are unique, and that users creating new resources can be confident of not introducing duplication or confusion.

Consider the names that you use for your brokers and resources:

Brokers

When you create a broker, give it a name that is unique within your broker environment. You must use the same name for that broker when you create it on the system in which it is installed, using the command **mqsicreatebroker**. Broker names are case sensitive except on Windows platforms.

Execution groups

Each execution group name must be unique within a broker.

Message flows and message processing nodes

Each message processing node must be unique within the message flow it is assigned to. For example, if you include two MQOutput nodes in a single message flow, provide a unique name for each one.

Message flow names must be unique within the broker. All references to that name are always to the same message flow. If you assign the same message flow to more than one broker, you must ensure that you maintain unique message flow names across those brokers.

Message sets and messages

Each message name must be unique within the message set to which it belongs.

Message set names must be unique within the broker. All references to that name are always to the same message set. If you assign the same message set to more than one broker, you must ensure that you maintain unique message set names across those brokers.

"Naming conventions for WebSphere Message Broker for z/OS" on page 3984
Decide upon a naming convention for your WebSphere Message Broker for z/OS broker to make customizing, operating, and administering easier.

WebSphere MQ naming conventions

All WebSphere Message Broker resources have dependencies on WebSphere MQ services and objects. You must therefore also consider what conventions to adopt for WebSphere MQ object names. If you already have a WebSphere MQ naming convention, use a compatible extension of this convention for WebSphere Message Broker resources.

When you create a broker, you must specify a queue manager name. This queue manager is created for you if it does not already exist. Every broker must have a dedicated queue manager.

Ensure that every queue manager name is unique within your network of interconnected queue managers, whether or not every queue manager is in your WebSphere Message Broker network. This ensures that each queue manager can unambiguously identify the target queue manager to which any given message must be sent, and that WebSphere Message Broker applications can also interact with basic WebSphere MQ applications.

WebSphere MQ supports a number of objects defined to queue managers. These objects (queues, channels, and processes) also have naming conventions and restrictions.

In summary, the restrictions are:

- All names must be a maximum of 48 characters in length (channels have a maximum of 20 characters).
- The name of each object must be unique within its type (for example, queue or channel).
- Names for all objects starting with the characters SYSTEM. are reserved for use by IBM.

Additionally, there is a restriction to the length of the user identifier on each platform:

- On AIX, UNIX systems, and z/OS, the maximum length is eight characters.
- On Windows, the maximum length is 20 characters.

There are a few restrictions for naming resources: see "Naming conventions for WebSphere Message Broker for z/OS" on page 3984.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Create and configure the brokers that you want on the operating system of your choice.

Designing the WebSphere MQ infrastructure

You must create and manage the WebSphere MQ resources that are required to support your brokers, and the applications that connect to them to supply or receive messages.

Brokers

A broker uses WebSphere MQ messages to provide information, status, and instructions about its internal operations. Connections are also required by each WebSphere Message Broker Toolkit with each broker with which it communicates.

Some of these resources that are required are created for you when you create brokers and execution groups. The requirements associated with the broker are described in "WebSphere MQ resources for the broker" on page 585.

Applications and message flows

Your applications exchange messages and other data by communicating with message flows that are running in the broker. You can connect your applications to the broker by using one of the supported communications methods. If your applications are written to use WebSphere MQ, the requirement for the channels or client connections are determined by the types of nodes that you include in your message flows. These resources are application-specific, and you must create these resources yourself.

The following nodes might require WebSphere MQ resources:

- MQInput and MQOutput
- MQReply and MQGet

For more information about creating resources, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

WebSphere MQ resources for the broker

Each broker depends on a number of WebSphere MQ resources: some are required, others are optional, and depend on your environment and requirements. Some of these resources are created for you, but others you must define for yourself.

WebSphere MQ resources created for you

When you create a broker, the following WebSphere MQ resources are created for you:

- On distributed systems, the queue manager for the broker. Each broker must be associated with a dedicated queue manager. Specify a queue manager name when you create the broker. If this queue manager does not exist, it is created for you.
- Fixed-name queues on the queue manager that hosts this broker. The broker uses these queues to send messages to provide information, status, and instructions about its internal operations

WebSphere MQ resources that you must create yourself

Depending on the setup of your broker, you might need to create some WebSphere MQ resources yourself. You might need some or all the following resources:

- If you create a broker on z/OS, you must create the queue manager. See "Creating a broker on z/OS" on page 620 for more details.
- Define listener connections on the broker queue manager. You must define one listener connection for every protocol that your applications use; for example, TCP/IP.

Create WebSphere MQ resources by using one of the following commands and utilities:

- **runmqsc**
- The PCF interface
- WebSphere MQ Explorer
- WebSphere Message Broker Explorer

For more information about creating resources, see the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

Considering performance in the broker environment

When you design your broker environment, and the resources associated with the brokers, decisions that you make can affect the performance of your brokers and applications.

About this task

Message flows

A message flow includes an input node that receives a message from an application over a particular protocol; for example, WebSphere MQ. The message must be parsed by the input node, although some parsers support partial parsing which might reduce processing, because only the parts of the message that are referenced are parsed. Other processing in a message flow that might affect performance are the amount, efficiency, and complexity of ESQL, access to databases, and how many message tree copies are made.

You must consider how you split your business logic; how much work should the application do, and how much should the message flow do? Every interaction between an application and a message flow involves I/O and message parsing, and therefore adds to processing time. Design your message flows, and design or restructure you applications, to minimize these interactions.

For more information about these factors, see “Optimizing message flow response times” on page 3264.

Messages and message models

The type, format, and size of the messages that are processed can have a significant effect on the performance of a message flow. For example, if you process persistent messages, they have to be stored for safekeeping.

You might need to process messages with a well-defined structure; if so, you can create MRM models for your messages. If you do not plan to interrogate the structure, you can work with undefined messages, such as BLOB messages.

If you are working in XML, be aware that it can be verbose, and therefore produce large messages, but XML message content is easier to understand than other formats, such as CWF. Field size and order might be important; these factors can be included in your MRM model.

For more information about these factors, see “Optimizing message flow response times” on page 3264 and Performance considerations for regular expressions in TDS messages.

Broker configuration

You can create and configure one or more brokers, on one or more computers, and for each broker you can create multiple execution groups, and multiple message flows. Your configuration decisions can influence message flow performance, and how efficiently messages can be processed.

For more information about these factors, see “Tuning the broker” on page 3254, “Optimizing message flow throughput” on page 587.

All these factors are examined in more detail in the Designing for Performance SupportPac (IP04).

For a description of common performance scenarios, review “Resolving problems with performance” on page 3504.

Related reference:

“Performance considerations when using regular expressions” on page 6309
Take care when specifying regular expressions: some forms of regular expression can involve a large amount of work to find the best match, which might degrade performance.

Optimizing message flow throughput

Each message flow that you design must provide a complete set of processing for messages received from a certain source. This design might result in very complex message flows that include large numbers of nodes that can cause a performance overhead, and might create potential bottlenecks. You can increase the number of message flows that process your messages to provide the opportunity for parallel processing and therefore improved throughput.

About this task

The mode that your broker is working in can affect the number of message flows that you can use; see “Restrictions that apply in each operation mode” on page 3657.

You can also consider the way in which the actions taken by the message flow are committed, and the order in which messages are processed.

Consider the following options for optimizing message flow throughput:

Multiple threads processing messages in a single message flow
When you deploy a message flow, the broker automatically starts an

instance of the message flow for each input node that it contains. This behavior is the default. However, if you have a message flow that handles a very large number of messages, the input source (for example, a WebSphere MQ queue) might become a bottleneck.

You can update the `Additional Instances` property of the deployed message flow in the BAR file: the broker starts additional copies of the message flow on separate threads, providing parallel processing. This option is the most efficient way of handling this situation, if you are not concerned about the order in which messages are processed.

If the message flow receives messages from a WebSphere MQ queue, you can influence the order in which messages are processed by setting the `Order Mode` property of the MQInput node:

- If you set `Order Mode` to By User ID, the node ensures that messages from a specific user (identified by the UserIdentifier field in the MQMD) are processed in guaranteed order. A second message from one user is not processed by an instance of the message flow if a previous message from this user is currently being processed by another instance of the message flow.
- If you set `Order Mode` to By Queue Order, the node processes one message at a time to preserve the order in which the messages are read from the queue. Therefore, this node behaves as though you have set the `Additional Instances` property of the message flow to zero.
- If you set `Order Mode` to `User Defined`, you can order messages by any message element, by setting an XPath or ESQL expression in the Order field location property. The node ensures that messages with the same value in the order field message element are processed in guaranteed order. A second message with the same value in the order field message element is not processed by an instance of the message flow if a previous message with the same value is currently being processed by another instance of the message flow.

  If the field is missing, an exception is raised, and the message is rolled back. NULL and empty values are processed separately, in parallel.

  If you set `Order Mode` to By User ID or `User Defined`, and the message flow uses transformation nodes, it is advisable to set the `Parse Timing` to Immediate.

For publish/subscribe applications that communicate with the broker over any supported protocol, messages for a particular topic are published by brokers in the same order as they are received from publishers (subject to reordering based on message priority, if applicable). Therefore each subscriber receives messages from a particular broker, on a particular topic, from a particular publisher, in the order that they are published by that publisher.

However, it is possible for messages, occasionally, to be delivered out of order. This situation can happen, for example, if a link in the network fails and subsequent messages are routed by another link.

If you need to ensure the order in which messages are received, you can use either the **SeqNum** (sequence number) or **PubTime** (publish time stamp) parameter on the **Publish** command for each published message, to calculate the order of publishing.

For more information about the techniques recommended for all MQI and AMI users, see the *Application Programming Reference* and *Application Programming Guide* sections in the WebSphere MQ Version 7 Information

Center online for programs written to the MQI, and the *WebSphere MQ Application Messaging Interface* book for programs written to the AMI.

The *WebSphere MQ Application Messaging Interface* book is available from the WebSphere MQ Library web page (listed under Version 5.3), or from SupportPac MA0F on the WebSphere MQ SupportPacs web page.

See also the *Publish/Subscribe User's Guide* section in the WebSphere MQ Version 7 Information Center online.

The broker does not provide message ordering for messages received across WebSphere MQ Web Services Transport.

Multiple copies of the message flow in a broker

You can also deploy several copies of the same message flow to different execution groups in the same broker. This option has similar effects to increasing the number of processing threads in a single message flow, although typically provides less noticeable gains.

This option also removes the ability to determine the order in which the messages are processed, because, if there is more than one copy of the message flow active in the broker, each copy can be processing a message at the same time, from the same queue. The time taken to process a message might vary, and multiple message flows accessing the same queue might therefore read messages from the input source in a random order. The order of messages produced by the message flows might not correspond to the order of the original messages.

Ensure that the applications that receive message from these message flows can tolerate out-of-order messages. Additionally, ensure that the input nodes in these message flows are suitable for deployment to different processes.

Copies of the message flow in multiple brokers

You can deploy several copies of the same message flow to different brokers. This option requires changes to your configuration, because you must ensure that applications that supply messages to the message flow can put their messages to the right input queue or port. You can often make these changes when you deploy the message flow by setting the message flow's configurable properties.

The scope of the message flow

You might find that, in some circumstances, you can split a single message flow into several different flows to reduce the scope of work that each message flow performs. If you do split your message flow, be aware that it is not possible to run the separate message flows in the same unit of work, and if transactional aspects to your message flow exist (for example, the updating of multiple databases), this option does not provide a suitable solution.

The following two examples show when you might want to split a message flow:

1. In a message flow that uses a RouteToLabel node, the input queue has become a bottleneck. You can use another copy of the message flow in a second execution group, but this option is not appropriate if you want all of the messages to be handled in the order in which they are shown on the queue. You can consider splitting out each branch of the message flow that starts with a Label node by providing an input queue and input node for each branch. This option might be

appropriate, because when the message is routed by the RouteToLabel node to the relevant Label node, it has some level of independence from all other messages.

You might also need to provide another input queue and input node to complete any common processing that the Label node branches connect to when unique processing has been done.

2. If you have a message flow that processes very large messages that take a considerable time to process, you might be able to:
   a. Create other copies of the message flow that use a different input queue (you can set this option up in the message flow itself, or you can update this property when you deploy the message flow).
   b. Set up WebSphere MQ queue aliases to redirect messages from some applications to the alternative queue and message flow.

   You can also create a new message flow that replicates the function of the original message flow, but only processes large messages that are immediately passed on to it by the original message flow, that you modified to check the input message size and redirect the large messages.

The frequency of commits

If a message flow receives input messages on a WebSphere MQ queue, you can improve its throughput for some message flow scenarios by modifying its default properties after you have added it to a BAR file. (These options are not available if the input messages are received by other input nodes; commits in those message flows are performed for each message.)

The following properties control the frequency with which the message flow commits transactions:

- `Commit Count`. This property represents the number of messages processed from the input queue before an MQCMIT is issued.
- `Commit Interval`. This property represents the time interval that elapses before an MQCMIT is started.

Customizing the z/OS environment

If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

About this task

Although you might be installing only one broker initially, you might want to consider how the product will be used in your organization in a few years time. Planning ahead makes developing your WebSphere Message Broker configuration easier.

The following rules apply to the configuration:

- A broker requires access to a queue manager.
- A broker cannot share its queue manager with another broker.
- You cannot use WebSphere MQ shared queues to hold data related to WebSphere Message Broker as SYSTEM.BROKER queues, but you can use shared queues for your message flow queues.

You can find details of the WebSphere MQ queues that are created and used by WebSphere Message Broker on z/OS in "**mqsicreatebroker** command" on page 3831.

When planning to work in a z/OS environment, you must complete the following tasks:

- Create started task procedures for each broker that you plan to use. These procedures must be defined, in the started task table, with an appropriate user ID.
- Decide on your recovery strategy. As part of your systems architecture, you must have a strategy for restarting systems if they end abnormally. Common solutions are to use automation products like Tivoli NetView® for z/OS or the Automatic Restart Manager (ARM) facility. You can configure WebSphere Message Broker to use ARM.
- Plan for corequisite products, including UNIX System Services, Resource Recovery Services (RRS), WebSphere MQ, and Java.

  You might also want to include DB2 in your configuration, if your message flows access databases.
- Ensure that the runtime library system (RTLS) for the broker is turned off in the default options of the Language Environment® for the system. This setting is required because the broker code is compiled using `XPLINK`, and `XPLINK` applications cannot be started while RTLS is active.
- Collect broker statistics on z/OS.

See the following topics for more information:

- "z/OS customization overview" on page 592

The *component directory* is the root directory of the component's runtime environment.

Related tasks:

"Mounting file systems" on page 604
WebSphere Message Broker requires several directories to be defined on the file system at run time.

Components on z/OS

A *component* is a set of runtime processes that perform a specific set of functions, and comprises a broker.

A broker that is running has a control address space and one additional address space for each deployed execution group. When the control address space is started, the broker component is started automatically. This behavior can be changed by an optional start parameter in the started task.

The *component name* is the external name of the component and is used, for example, in the WebSphere Message Broker WebSphere Message Broker Toolkit.

Each component requires a name, which is usually the name of the started task that runs the component. This is typically the queue manager name with a suffix of the facility; for example, MQP1BRK for the broker.

Each component has its own runtime environment in UNIX System Services and needs its own WebSphere MQ queue manager.

Related concepts:

On z/OS, the SMP/E installation places all the product executable files into a directory of a file system under UNIX System Services (USS).

XPLink on z/OS

XPLink is a z/OS technology used by the C and C++ compilers to reduce the cost of function calling for programs written in these languages.

Many products, including WebSphere Message Broker for z/OS, use XPLink technology to improve their performance. To ensure the highest possible performance gains, WebSphere Message Broker requires as many as possible of the software components it uses to be XPLink-compliant. These include the broker, Java runtime, ODBC, and z/OS Language Environment.

The WebSphere Message Broker broker has been compiled by IBM to use XPLink technology and has been link-edited within the SMP/E environment to call the

appropriate XPLink routines of the software components it uses. Normally, these XPLink-enabled components are configured during their customization, and the broker needs only to locate the appropriate libraries to become XPLink-enabled.

Related concepts:

"z/OS customization overview" on page 592
After you have used SMP/E to install WebSphere Message Broker for z/OS, the installed executable code is located inside the file system. JCL samples are located in the PDS `<hlq>.SBIPSAMP`, the JCL procedures are located in the PDS `<hlq>.SBIPPROC`, and load module for synchronizing statistics with SMF are located in the PDS `<hlq>.SBIPAUTH`.

Using the file system on z/OS

If you have more than one MVS image, consider how you will use the file system. You can share files in a file system with different members of a sysplex. The file system is mounted on one MVS image and requests to the file are routed to the owning system using XCF from systems which do not have it mounted.

About this task

This is part of the larger task of customizing your z/OS environment.

Moving a broker from one image to another is straightforward and the files can be shared.

However, there is a performance overhead when using files shared between images in a file system because the data flows through the Coupling Facility (this is true for trace and other diagnostic data).

For further information on mounting file systems and allocating space, including performance considerations, see "Mounting file systems" on page 604

Space requirements:
About this task

For details of the disk space required, see "Disk space requirements on z/OS" on page 3586.

Administration log messages on z/OS
About this task

This is part of the larger task of customizing your z/OS environment.

On z/OS, all address spaces have a job log where BIP messages issued by WebSphere Message Broker appear. Additionally, all messages appear on the `syslog` and important operator messages are filtered to the console using MPF (Message Processing Facility).

To prevent the operator's console receiving unnecessary BIP messages, you must configure MPF to suppress all BIP messages, with the exception of important messages. Note that you do not need to have the `USS SYSLOG` configured.

Security considerations on z/OS
About this task

This is part of the larger task of customizing your z/OS environment.

The role of the WebSphere Message Broker administrator includes customizing and configuring, running utilities, performing problem determination, and collecting diagnostic materials. People involved in these activities need WebSphere Message Broker authorities. You must set up some security for WebSphere Message Broker to work properly. The information that you need to do this is in "Setting up z/OS security" on page 556.

Customizing UNIX System Services on z/OS

WebSphere Message Broker requires the setup of some UNIX System Services system parameters.

About this task

This task is part of the larger task of customizing your z/OS environment.

You can use the **SETOMVS** operator command for dynamic changes or the BPXPRMxx PARMLIB member for permanent changes. See the *z/OS UNIX System Services* section in the z/OS V1R9.0 LibraryCenter.

Use the **DISPLAY OMVS,OPTIONS** command to display your current OMVS options.

Do not include the broker addresses if you use the IEFUSI exit to limit the region size of OMVS address spaces.

Set the UNIX System Services parameters shown in the following table.

Description	Parameter	Value
The maximum core dump file size (in bytes) that a process can create. Allow an unlimited size.	MAXCORESIZE	2 147 483 647
The CPU time (in seconds) that a process is allowed to use. Allow an unlimited CPU time. If you do not set MAXCPUTIME to the maximum value, shown here, you can set it on the TIME parameter of the broker started task JCL. For more information, see *Statements and parameters for BIPXPRMxx* in the MVS Initialization Tuning and Reference of the z/OS V1R9.0 LibraryCenter.	MAXCPUTIME	2 147 483 647
The address space region size. Set to the size of the biggest address space.	MAXASSIZE	> 1 073 741 824 A minimum value of 393 216 000 bytes is required.
The maximum number of processes for each user.	MAXPROCUSER	Set to a number greater than all brokers and associated execution groups, as well as any queue managers and channel initiators that are running with the same user ID.
The maximum number of file descriptors that a single process can have open concurrently.	MAXFILEPROC	The number of descriptors includes all open files, directories, sockets, and pipes. A minimum value of 65536 is required.

Description	Parameter	Value
Specifies the maximum number of threads that a single process can have active. Depends on the definitions of message flows.	MAXTHREADS MAXTHREADTASKS	The value of MAXTHREADS and MAXTHREADTASKS depends on your application. To calculate the value needed for each message flow: 1. Multiply the number of input nodes by the number of instances (additional threads +1). 2. Sum the values of all message flows, then add 10 to the sum. 3. Add to the sum the number of threads used for each HTTP listener.

Deploying a message flow that starts an execution group in a new address space uses z/OS UNIX System Services Semaphore and SharedMemorySegment resources. Each new address space uses a semaphore and SharedMemorySegment. The SharedMemorySegment is deleted immediately after the new address space has started, but the semaphore remains for the life of the new address space.

Certain z/OS UNIX System Services system parameters can affect the start of a new execution group address space, if you set them incorrectly. These parameters include:

- IPCSEMNIDS
- IPCSHMNIDS
- IPCSHMNSEGS

You must have a minimum of three semaphores for each execution group address space that is started.

You must set IPCSEMNIDS to a value four times the number of potential execution group address spaces on a system.

You must have one SharedMemorySegment for each execution group address space that is started. You must set IPCSEMNIDS to a value that exceeds the number of potential execution group address spaces on a system.

A control address space (BIPSERVICE and BIPBROKER processes) can be attached to many SharedMemorySegments - potentially, one for each execution group address space started for that broker. You must set IPCSHMNSEGS to a value that exceeds the potential number of execution groups for each broker.

Ensuring sufficient space for temporary files

The environment variable TMPDIR is the path name of the directory being used for temporary files. If it is not set, the z/OS shell uses `/tmp`.

When starting WebSphere Message Broker components, sufficient space is required in the directory referenced by TMPDIR. In particular, Java requires sufficient space to hold all JAR files required by WebSphere Message Broker.

If you do not allocate sufficient space, the execution group address spaces abend with a 2C1 code.

Allow at least 50 MB of space in this directory for WebSphere Message Broker components. More space might be needed if you deploy large user-defined nodes or other JAR files to the broker component.

Defining WebSphere Message Broker files as shared-library programs

The shared library region is a z/OS feature that enables address spaces to share dynamic link library (DLL) files. This feature enables brokers to share DLLs rather than each broker having to load the DLLs individually. The shared DLLs can be broker DLLs, or DLLs from other products such as Java. The amount of real storage used by MVS, and the time it takes for each broker to start, can thus be greatly reduced.

If you plan to deploy to more than one execution group on z/OS, you can reduce the amount of storage required by the execution group address spaces. Set the shared-library extended attribute on the following files:

```
/usr/lpp/mqsi/bin/*
/usr/lpp/mqsi/lil/*
/usr/lpp/mqsi/lib/*
/usr/lpp/mqsi/lib/wbimb/*
```

To set the shared-library attribute, use the OMVS **extattr** command with the +1 option. For example:

```
extattr +l /usr/lpp/mqsi/bin/*
```

To find out if the shared-library extended attribute has been set, use the **ls -E** command. For example, use the command **ls -E bipimain** to generate the following response:

```
-rwxr-x---  a-l-  1 USER  GROUP   139264 Mar 15 10:05 bipimain
```

where l (lowercase L, as in a-l-) shows that the program is enabled to run in a shared address space.

For more information, on using the shared library extended attribute, see the z/OS V1R9.0 LibraryCenter .

The storage that is reserved for the shared library region is allocated in each broker address space when the first address space is started. The amount of storage that is allocated is controlled by the SHRLIBRGNSIZE parameter in z/OS, which is in the BPXPRMxx member of SYS1.PARMLIB. You can tune the amount of storage that is allocated for the shared library region. Investigate how much space you need, bearing in mind that other applications besides WebSphere Message Broker might be using the shared library region. Then, adjust the SHRLIBRGNSIZE parameter accordingly.

Use the following MVS command to check that you have enough SHRLIBRGNSIZE to contain all the shared-library programs that are to be used on the system:

```
DISPLAY OMVS,LIMITS
```

If there is unused space in the shared library region, modify SHRLIBRGNSIZE to reduce the amount of storage allocated for the shared library region.

Storage is carved out of the high end of private storage of each address space that loads a system shared library object. The amount of storage allocated from each of these address spaces is based on the value of the SHRLIBRGNSIZE parameter in

the BPXPRMxx PARMLIB member. If this value is too high, the storage set aside for mapping the shared library region might interfere with the private storage requirements of individual address spaces. Therefore, specify the minimum size that is required to contain all of the shared library programs that are to be used on the system.

Note: z/OS UNIX attempts to map the entire SHRLIBRGNSIZE into the private region, not just the portion that contains programs. If the private region is too small to map the entire SHRLIBRGNSIZE, this shared library region is not used. No message is issued to indicate what has happened.

Use the **SETOMVS** operator command to change SHRLIBRGNSIZE dynamically, or the BPXPRMxx PARMLIB member for permanent changes. See the *z/OS UNIX System Services* section in the z/OS V1R9.0 LibraryCenter.

WebSphere MQ planning for z/OS

This is part of the larger task of customizing your z/OS environment.

About this task

You are required to have a separate WebSphere MQ queue manager for each broker.

All WebSphere Message Broker for z/OS system queues are defined during customization.

Your queue manager must have a dead-letter queue. Check that this queue exists by using the WebSphere MQ command:

```
+cpf  DIS QMGR DEADQ
```

Check that the queue exists by using the command:

```
 +cpf DIS QL(name) STGCLASS
```

Then use the:

```
+cpf DIS STGCLASS(...)
```

to check the `STGCLASS` value is valid. If the queue manager does not have a valid dead-letter queue, you must define one.

Creating and deleting components on z/OS requires the command server on the WebSphere MQ queue manager to be started. This component is normally started automatically (refer to the see the *z/OS System Administration Guide* section of the WebSphere MQ Version 7 Information Center online for more details).

The command server requires a reply-to queue based on SYSTEM.COMMAND.REPLY.MODEL; by default, this model queue is defined as permanent dynamic. However, if you leave the queue defined in this way, each time you run a create or delete component command these reply-to queues remain defined to the queue manager. To avoid these queues persisting, you can set the SYSTEM.COMMAND.REPLY.MODEL queue as temporary dynamic.

Resource Recovery Service planning on z/OS

About this task

This is part of the larger task of customizing your z/OS environment.

WebSphere Message Broker for z/OS uses Resource Recovery Service (RRS) to coordinate changes to WebSphere MQ and DB2 resources. Ensure it is configured and active on your system, because your broker cannot connect to DB2 unless RRS is active.

Refer to the following manuals for detailed information about RRS: *z/OS V1R5.0 MVS Setting Up a Sysplex* and *z/OS V1R5.0 MVS Programming: Resource Recovery SA22-7616*.

Defining the started tasks to z/OS Workload Manager (WLM)

This is part of the larger task of customizing your z/OS environment.

About this task

With z/OS workload management (WLM), you define performance goals and assign a business importance to each goal. You define the goals for work in business terms, and the system decides how much resource, such as CPU and storage, should be given to it to meet the goal. Workload Manager constantly monitors the system, and adapts processing to meet the goals.

WebSphere Message Broker automatically defines the JOBACCT token for each execution group started, so that the broker systems administrator can use WLM classification to map the JOBACCT token to specific Service and Report classes.

Each execution group can be assigned to a different Service and Report class. Whenever an execution group address space is started, the STEPNAME is assigned to the JOBACCT token.

When an execution group address space is started on z/OS, the STEPNAME is derived from the execution group label; the STEPNAME is defined as the last eight characters. Any characters that are not valid for a STEPNAME are replaced with the `@` character.

For example, an execution group address space with the label `MyExecutionGroup`, has a STEPNAME of `IONGROUP` and assigns this same value to the JOBACCT.

The STEPNAME/JOBACCT is not guaranteed to be unique across multiple execution group address spaces on the same LPAR. If you require a unique STEPNAME/JOBACCT across multiple execution groups, you must use a suitable execution group naming standard.

Automatic Restart Manager planning

This is part of the larger task of customizing your z/OS environment.

WebSphere Message Broker for z/OS allows you to register a component to the Automatic Restart Manager (ARM).

When customizing a component, you register it with ARM by editing the following environment variables in the component profile:

Description	Name
Switch that determines whether ARM is used (`YES` or `NO`).	`MQSI_USE_ARM`
ARM element name	`MQSI_ARM_ELEMENTNAME`
ARM element type	`MQSI_ARM_ELEMENTTYPE`

By default components do not register to ARM; the initial setting is `MQSI_USE_ARM=NO`. You can override this default value by setting `MQSI_USE_ARM=YES` and providing an ARM element name and type.

MQSI_ARM_ELEMENTNAME must be a maximum of eight characters in length, because WebSphere Message Broker adds a prefix of SYSWMQI. For example, if you supply the value MQP1BRK to ARM_ELEMENTNAME, the element you define in your ARM policy is SYSWMQI_MQP1BRK.

To enable automatic restart you must also:

- Set up an ARM couple data set.
- Define the automatic restart actions that you want z/OS to perform in an ARM policy.
- Start the ARM policy.

The following manuals provide detailed information about ARM couple data sets, including samples:

- *z/OS MVS Programming: Sysplex Services Guide*
- *z/OS MVS Programming: Sysplex Services Reference*
- *z/OS MVS Setting up a Sysplex*

You can access these manuals from the z/OS V1R8.0 LibraryCenter

Related concepts:

If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

Mounting file systems

WebSphere Message Broker requires several directories to be defined on the file system at run time.

About this task

++HOME++ is the location of the environment file (ENVFILE) used to create the runtime environment in which WebSphere Message Broker runs.

++INSTALL++ refers to the WebSphere Message Broker installation directories.

++COMPONENTDIRECTORY++ is the location where all deployed configuration is written to and read from by the WebSphere Message Broker runtime libraries.

++JAVA++ is the location of the Java installation.

++MQPATH++ is the location of theWebSphere MQ installation.

Because WebSphere Message Broker can run in a shared file system sysplex environment, it is important for performance reasons that these directories are mounted locally to the LPAR in which WebSphere Message Broker is started. This is particularly important for startup performance; if the WebSphere Message Broker installation directories are not mounted locally, startup times can increase significantly.

You can check file system ownership from USS using the command **df -v**. For example, the following output shows that the broker installation file system is owned by MVS1:

```
/usr/lpp/mqsi/V7R0M0:>df -v .
Mounted on     Filesystem               Avail/Total    Files      Status
/usr/lpp/mqsi/V7R0M0 (OMVS.PLEXS.MQSI.V700.WBIMB) 7984/806400    4294966503
   Available
HFS, Read/Write, Device:89, ACLS=Y
File System Owner : MVS1        Automove=Y      Client=N
Filetag : T=off   codeset=0
```

To create a directory in an already mounted file system use the `mkdir` command. For example:

```
mkdir -p /mqsi/brokers/MQP1BRK
```

To mount a new file system, follow the instructions given in the *z/OS UNIX System Services Planning* manual.

From USS, use the following instructions:

```
mkdir -p /mqsi/brokers/MQP1BRK
mount -f MQSI.BROKER.MQP1BRK /mqsi/brokers/MQP1BRK
```

From TSO, use the following instructions:

```
ALLOCATE DATASET('MQSI.BROKER.MQP1BRK') DSNTYPE(HFS) SPACE(5,5) DIR(1) CYL
FREE DATASET('MQSI.BROKER.MQP1BRK')
MOUNT FILESYSTEM('MQSI.BROKER.MQP1BRK') TYPE(HFS)
      MOUNTPOINT('/mqsi/brokers/MQP1BRK')
```

Note that the preceding `ALLOCATE` command is an example; the dataset should be allocated the correct amount of storage as described in "Disk space requirements on z/OS" on page 3586

The installation of WebSphere Message Broker for z/OS uses approximately 400 MB of disk space; plan on using 500 MB to allow for the component directories, and for new service fixes to be applied.

Checking the permission of the installation directory

This is part of the larger task of customizing your z/OS environment.

About this task

You must ensure that the appropriate user IDs, for example, the WebSphere Message Broker Administrator and all component Started Task user IDs, have READ and EXECUTE permission to the WebSphere Message Broker installation directory.

Using group access control to set these permissions.

Procedure

1. Display the permissions on the installation directory using the `ls` command.

   ```
   ls -l /usr/lpp/mqsi
   ```

   This command displays lines like the following response:

   ```
   drwxr-xr-x   2 TSOUSER  MQM     8192 Jun 17 09:54 bin
   ```

   In this example, MQM is the group associated with the directory. Those user IDs requiring permission to the directory must be a member of this group.

   This example also shows the permissions defined for the directory. User `TSOUSER` has `rwx` (READ, WRITE, and EXECUTE), group MQM has `rx`, and any other user ID has `rx`.
2. Ensure that the user IDs requiring permission have a group that matches that of the installation directory. Use the following command, where `userid` is the ID you want to check:

   ```
   id <userid>
   ```
3. If the installation directory does not have a valid group, use the command `chgrp` to set the group of the directory:

   ```
   chgrp -R <group> <pathname>
   ```

   For example:

   ```
   chgrp -R MQSI /usr/lpp/mqsi
   ```

   You must be the owner of the group or have superuser authority to use this command.
4. If the installation directory does not have the correct permissions for the group (READ / EXECUTE), use the command `chmod` to change the permissions:

   ```
   chmod -R g=rx <pathname>
   ```

   For example:

   ```
   chmod -R g=rx /usr/lpp/mqsi
   ```

Use the **mqsicreatebroker** command to create a broker and its associated resources.

Customizing the version of Java on z/OS

Check the version of Java in your enterprise, and change it, if necessary.

About this task

This task is part of the larger task of customizing your z/OS environment.

For information about the levels of Java that WebSphere Message Broker supports, see WebSphere Message Broker Requirements. The 64 bit version of Java is required.

To check the current version of Java in a broker component, complete the following steps.

Procedure

1. Change to the `bin` directory in which you installed your Java product.

   For example, if Java is installed in `/usr/lpp/java`, change to the `/usr/lpp/java/bin` directory, and type `./java -fullversion`. You receive the following response, or a response with similar content:

```
java version "1.6.0"
Java(TM) 2 Runtime Environment, Standard Edition (build 1.6.0)
Classic VM (build 1.6.0 J2RE 1.6.0 IBM z/OS Persistent Reusable VM build cm142-20040917
 (JIT enabled: jitc))
```

   The response in this example confirms that Java 1.6.0 is the current version, which is the minimum level required for this platform.
2. If you want to set, or change, the current Java version, edit `JAVAHOME` in the broker profile (`BIPBPROF`).

   For further details about the broker profile, see "Creating a broker on WebSphere Message Broker for z/OS" on page 609.
3. Run `BIPGEN` to re-create the broker `ENVFILE` and any execution group specific `ENVFILEs`
4. Restart the broker to pick up changes to the `ENVFILE`.

Checking APF attributes of `bipimain` on z/OS

This task is part of the larger task of setting up your z/OS environment.

About this task

Use the `extattr` command to display the attributes of the object `bipimain`. For example:

```
extattr /usr/lpp/mqsi/bin/bipimain
```

The attribute APF authorized must be set to YES. If it is not, use extattr +a bipimain to set this attribute. For example:

```
extattr +a /usr/lpp/mqsi/bin/bipimain
```

You must have the appropriate authorization to issue this command.

Related concepts:

Use the **mqsichangeflowstats** command to control the accumulation of statistics about message flow operation.

Configuring an execution group address space as non-swappable on z/OS

About this task

Because broker execution groups run as processes in UNIX System Services they cannot be set as NOSWAP in the PPT.

Instead, you can set the following environment variables in the broker environment file so that some, or all, of the address spaces of the broker execution groups request that they become non-swappable by the system; see "Creating the environment file" on page 626 for further information on adding an environment variable to a broker.

```
MQSI_NOSWAP=yes
```

sets the address spaces of all the execution groups to be non-swappable.

```
MQSI_NOSWAP_egname=yes
```

issues a request to the system, for each execution group labelled `egname`, that the address space be set as non-swappable.

```
MQSI_NOSWAP_uuid=yes
```

issues a request to the system, for each execution group with the UUID labelled `uuid`, that the address space be set as non-swappable.

In order for the above requests to succeed, the broker's started task ID needs `READ` access to the `BPX.STOR.SWAP` facility class through their external security manager, for example, RACF.

When an application makes an address space non-swappable, it can cause additional real storage in the system to be converted to preferred storage. Because preferred storage cannot be configured offline, using this service can reduce the installation's ability to re-configure storage in the future.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

Create the broker component and the other resources on which it depends.

"Creating the environment file" on page 626
This is part of the larger task of creating a broker on z/OS.

Creating a broker on WebSphere Message Broker for z/OS

An overview of how you create a broker on WebSphere Message Broker for z/OS.

About this task

Before you start

Before starting this task, you must have installed:

- WebSphere MQ for z/OS, with the optional JMS feature applied; for example, mounted at `/usr/lpp/mqm`.
- WebSphere Message Broker for z/OS, with a broker file system mounted; for example, `/usr/lpp/mqsi`.

If you want to connect a WebSphere Message Broker Toolkit directly to your z/OS system, you *must* install the optional WebSphere MQ Client Attach feature.

If you do not have the WebSphere MQ Client Attach feature installed, you can connect the WebSphere Message Broker Toolkit through an intermediate queue manager.

Read through all the sub topics in the "Customizing the z/OS environment" on page 591 section, and follow the guidance within those topics.

Procedure

1. Determine the customization information for your environment. The following list of topics contains tables of information that needs to be gathered before you can proceed with creating a broker on z/OS. Complete the information that your enterprise requires.

   If necessary, discuss the requirements with your system and WebSphere MQ administrators.

   - Broker:
     - "Installation information - broker" on page 621
     - "Component information - broker" on page 622
2. Set up security for the started task user IDs. Start with "Setting up z/OS security" on page 556.
3. Create the broker by carrying out the tasks listed in "Creating a broker on z/OS" on page 620. Start with "Creating the broker PDSE" on page 622.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related information:

Configuring brokers

Create and configure the brokers that you want on the operating system of your choice.

Before you begin

Before you start:

Ensure that the following requirements are met:

- Your user ID has the correct authorizations to perform the task. The authorizations are defined in "Security requirements for administrative tasks" on page 3644.
- Windows On Windows: you have created a user ID to be used as the service user ID. You specify this ID when you create the broker; it is used to run the broker.

  For more information about user ID authorization and creation, refer to "Planning for security when you install WebSphere Message Broker" on page 353.
- You have initialized the command environment on distributed systems; see "Setting up a command environment" on page 213.

About this task

To set up a default configuration, or an environment for application development on Linux on x86 or Windows, see Chapter 6, "Configuring brokers for development environments," on page 563. If you are creating brokers for test and production environments, use the tasks included in this section.

When you have created your physical components, you can administer your test and production environments either by using the WebSphere Message Broker Explorer, or programmatically by using the Administration API (the CMP API).

This collection of tasks uses specific resource names and user IDs. These names are examples only; you can use your own names. Follow existing naming conventions for WebSphere MQ and other resources.

Procedure

- "Creating a broker"
- "Verifying brokers" on page 630

What to do next

Next: Continue your broker configuration tasks in the WebSphere Message Broker Explorer. For day to day administration of your brokers and associated resources, see Chapter 8, "Administering brokers and broker resources," on page 899.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

"Planning for security when you install WebSphere Message Broker" on page 353
The Installation Guide describes the security tasks that you must complete before, during, and after installation.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

Creating a broker

You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Before you begin

Before you start:

Complete the following tasks:

- Ensure that your user ID has the correct authorizations to perform the task. Refer to "Security requirements for administrative tasks" on page 3644.

- On distributed systems, you must set up your command-line environment before creating a broker, by running the product profile or console; refer to "Setting up a command environment" on page 213.
- On z/OS, you must create and start the queue manager for this broker before you create the component.

About this task

Create a broker by using the command line on the computer on which you have installed the broker component. On Windows and Linux on x86, you can alternatively use the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer to complete this task.

- You must give the broker a name that is unique on the local computer.
- Broker names are case sensitive on all supported platforms, except Windows.
- You must associate each broker with its own dedicated WebSphere MQ queue manager.
- Brokers can access only local queue managers, so you cannot create a broker on a queue manager that is on a remote system.

The mode in which your broker is working can affect the number of execution groups and message flows that you can deploy, and the types of node that you can use. See "Restrictions that apply in each operation mode" on page 3657.

To create a broker, follow the link for the appropriate platform. Alternatively, follow the link to create a broker using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

- Linux and UNIX
- Windows
- z/OS
- "Creating a broker using the WebSphere Message Broker Explorer" on page 618

“**mqsicreatebroker** command” on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

“Security requirements for administrative tasks” on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

“Support for 32-bit and 64-bit platforms” on page 3589
WebSphere Message Broker operates in 32-bit mode or 64-bit mode, on supported operating systems.

Using WebSphere MQ trusted applications

Configure a broker to run as a WebSphere MQ trusted application.

Before you begin

Before you start:

You must complete the following tasks:

- Ensure that your user ID is a member of the mqm group. On UNIX and Linux, specify the user ID mqm as the service user ID when you create the broker. On Windows, use any service user ID that is a member of mqm. Refer to “Security requirements for administrative tasks” on page 3644.
- Review the restrictions that WebSphere MQ places on trusted applications that apply to your environment. See the section "Connection to a queue manager using the MQCONNX call" in the *Application Programming Guide* section of the WebSphere MQ Version 7 Information Center online.

About this task

You can configure a broker to run as a trusted (fastpath) application on all supported platforms except z/OS, where the option is not applicable. If the broker is configured as a trusted application, it runs in the same process as the WebSphere MQ queue manager agent, and all broker processes benefit from an improvement in the overall system performance.

A broker does not run as a trusted application by default; you either create a trusted application by using the “**mqsicreatebroker** command” on page 3831, or modify an existing broker by using the “**mqsichangebroker** command” on page 3723.

Configuring a broker as a trusted application does not affect the operation of WebSphere MQ channel agents or listeners. For more information about running these as trusted applications, see the section "Running channels and listeners as trusted applications" in the *Intercommunication* section of the WebSphere MQ Version 7 Information Center online.

Take care when deploying user-defined nodes or parsers. Because a trusted application (the broker) runs in the same operating system process as the queue manager, a user-defined node or parser might compromise the integrity of the queue manager. Consider fully the restrictions that apply to your environment and test user-defined nodes and parsers in a non-trusted environment before deploying them in a trusted broker.

You can either configure a broker to run as a trusted application when you create it, or modify an existing broker.

Procedure

- To create a broker on a command line, run the **mqsicreatebroker** command with the `-t` flag, which specifies that the broker is created as a trusted application.

  For example, enter the following command to create a broker called MB7BROKER as a trusted application:

  ```
  mqsicreatebroker MB7BROKER -q MB7QMGR -i mqm -t
  ```

  See "Creating a broker" on page 611 for more detailed information about how to create a broker for your platform.
- To modify an existing broker:
  1. Run the **mqsistop** command on the command line to stop the broker.
  2. Run the **mqsichangebroker** command with the `-t` flag. For example, enter the following command to modify a broker called MB7BROKER to run as a trusted application:

     ```
     mqsichangebroker MB7BROKER -t
     ```

     See "Modifying a broker" on page 631 for more detailed information about how to modify a broker for your platform.
  3. Restart the broker by using the **mqsistart** command. The broker restarts with fastpath set.

WebSphere MQ Version 7 Information Center online

Creating a broker on Linux and UNIX systems

On Linux and UNIX systems, create brokers on the command line; on Linux on x86, you can also create brokers in the WebSphere Message Broker Toolkit.

Before you begin

Before you start:

- If you want to configure the broker as a WebSphere MQ trusted application, see "Using WebSphere MQ trusted applications" on page 613.
- Read "Considering security for a broker" on page 501.
- Check which operation mode you are licensed to use. If you do not set a mode, the automatic default is `enterprise` mode; see "Operation modes" on page 48.

About this task

When you create a broker, if the WebSphere MQ queue manager does not exist, the queue manager is automatically created. If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel auth security is automatically disabled.

If the specified queue manager already exists when creating the broker, then it is assumed that the user has applied the appropriate security configuration to meet their requirements, and therefore channel auth security is not disabled.

To create a broker:

Procedure

1. Ensure that you are logged in using a user ID that has authority to run the **mqsicreatebroker** command.
2. Run the **mqsiprofile** script to set up the command environment for the broker:

   ```
   . install_dir/bin/mqsiprofile
   ```

   You must run this script before you can run the WebSphere Message Broker commands.

   For more information, see "Setting up a command environment" on page 213.
3. The command **mqsicreatebroker** defaults to using the primary installation of WebSphere MQ, if present, for the creation of queue managers.

   If you are creating a broker on a queue manager that already exists, there is no need to configure your WebSphere MQ environment.
4. Use the **mqsicreatebroker** command to create the broker.

   For example, if you want to create a broker called MB7BROKER on a queue manager called MB7QMGR, enter the following command:

   ```
   mqsicreatebroker MB7BROKER -q MB7QMGR
   ```
5. To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

Results

You have created a broker.

What to do next

Next: Complete the following tasks:

1. Start the broker by using the **mqsistart** command.
2. Connect to the broker from the WebSphere Message Broker Toolkit, the WebSphere Message Broker Explorer, or a CMP API application.

When you have completed these tasks, you can create the resources that you want to associate with the broker; for example message flows. You can create and work with resources by using either the WebSphere Message Broker Toolkit or the CMP API.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Develop Java applications that use the Administration API (also known as the CMP API) to communicate with, deploy to, and manage brokers and their associated resources.

"Controlling the functional level of WebSphere Message Broker" on page 51
You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

Related reference:

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

Creating a broker on Windows

On Windows, you can create brokers on the command line.

Before you begin

Before you start:

- If you want to configure the broker as a WebSphere MQ trusted application, see "Using WebSphere MQ trusted applications" on page 613.
- Read "Considering security for a broker" on page 501.
- Check which operation mode you are licensed to use. If you do not set a mode, the automatic default is `enterprise` mode; see "Operation modes" on page 48.

About this task

When you create a broker, if the WebSphere MQ queue manager does not exist, the queue manager is automatically created. If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel auth security is automatically disabled.

If the specified queue manager already exists when creating the broker, then it is assumed that the user has applied the appropriate security configuration to meet their requirements, and therefore channel auth security is not disabled.

To create a broker by using the command line, complete the following steps:

Procedure

1. Open a WebSphere Message Broker command prompt for the runtime installation in which you want to create the broker. For more information about initializing the runtime environment, see "Command environment: Windows systems" on page 306.

   On Windows 7 and Windows Server 2008 systems, you must open a command console with elevated privileges. To open a command console with elevated privileges, use the **mqsicommandconsole** command. For more information, see "**mqsicommandconsole** command" on page 3830.
2. The command **mqsicreatebroker** defaults to using the primary installation of WebSphere MQ, if present, for the creation of queue managers.

   If you are creating a broker on a queue manager that already exists, there is no need to configure your WebSphere MQ environment.
3. Use the **mqsicreatebroker** command to create the broker.

   For example, if you want to create a broker called MB7BROKER on a queue manager called MB7QMGR, enter the following command:

   ```
   mqsicreatebroker MB7BROKER -i wbrkuid -a wbrkpw -q MB7QMGR
   ```

   where *wbrkuid* and *wbrkpw* are the user name and password under which the broker runs.

   For more information about the command options, see "**mqsicreatebroker** command" on page 3831.

Results

You have created a broker.

What to do next

Next: Complete the following tasks:

1. Start the broker by using the **mqsistart** command.
2. Connect to the broker from the WebSphere Message Broker Toolkit or a CMP API application.

When you have completed these tasks, you can create the resources that you want to associate with the broker; for example message flows. You can create and work with resources by using either the WebSphere Message Broker Toolkit or the CMP API.

Related concepts:

"**mqsicreatebroker** command" on page 3831
Use the **mqsicreatebroker** command to create a broker and its associated resources.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

Creating a broker using the WebSphere Message Broker Explorer

On Linux on x86 or Windows, you can create brokers by using the WebSphere Message Broker Explorer.

Before you begin

Before you start:

If you are using the WebSphere Message Broker Toolkit, see "Creating a broker for a development environment" on page 569.

- On Windows, you must have administrator access rights to create brokers by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer. When creating a broker, you might be prompted to agree to the use of administrator rights or be prompted to enter an administrator user ID and password.
- If you want to configure the broker as a WebSphere MQ trusted application, see "Using WebSphere MQ trusted applications" on page 613.
- Read "Considering security for a broker" on page 501.
- Check which operation mode you are licensed to use. If you do not set a mode, the automatic default is `enterprise` mode; see "Operation modes" on page 48.

About this task

When you create a broker, if the WebSphere MQ queue manager does not exist, the queue manager is automatically created. If WebSphere MQ Version 7.1, or later, has been selected for the queue manager, the channel auth security is automatically disabled.

If the specified queue manager already exists when creating the broker, then it is assumed that the user has applied the appropriate security configuration to meet their requirements, and therefore channel auth security is not disabled.

To create a broker by using the WebSphere Message Broker Explorer:

Procedure

1. Right-click the Brokers folder, and click **New** > **Local Broker**. The Create Broker wizard is displayed.
2. Enter a name for the broker, and click **Next**.
3. Enter a name for the queue manager, or select an existing queue manager from the list of available local queue managers. You cannot create a broker on a queue manager that is already associated with a broker, or on a queue manager that is on a remote system.
4. Enter values for your user name and password. On Windows only, the default user ID is LocalSystem (for the Windows Local System Account). Local System is a special account and has no password, therefore the password entry field is unavailable.
5. You must create an execution group for the broker. By default, an execution group called default is created. If you want to create an execution group with a different name, enter the new name in **Create execution group**. You can create additional execution groups using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer after the broker is created.
6. Optional: On Windows, select whether to start the broker automatically when Windows starts.
7. Optional: Select **Enable administration security** to activate broker administration security to control which users can complete specific tasks against that broker and its resources.
8. The wizard starts processing your request. If the action succeeds, the wizard displays messages in the summary panel. If an action fails, the wizard reports the error in a message dialog.

   If you know what is causing the error, and can fix it, correct the error and click **Yes**. The wizard reissues the command. If you do not know what is causing the error, or you cannot fix it, click **No**. The wizard backs out any actions that have already completed and returns your system to its initial state.
9. Click **Finish** to close the wizard.

Results

You have created and started a broker.

You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

Collecting the information required to create a broker:

This is part of the larger task of creating a broker on z/OS.

About this task

You must complete the information in each of the tables, at the following links, before continuing:

- "Installation information - broker"
- "Component information - broker" on page 622

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

"Creating a broker on z/OS" on page 620
Create the broker component and the other resources on which it depends.

Related reference:

"Customization planning checklist for z/OS" on page 3991
Use the information contained in the following tables to make a note of the values to use when you customize your system variables on z/OS.

Installation information - broker:

Decide on the values for the list of the JCL variables for your system; an example installation value is provided for each one.

Collect the information shown in the Description column, and complete the values that you require for your particular system. You can see a complete list of the variables that you can customize in "z/OS JCL variables" on page 3994.

Description	JCL variable	Example installation value	Your installation value
Fully qualified name of the product's SBIPPROC data set	N/A	<hlq>.SBIPPROC	
Fully qualified name of the product's SBIPSAMP data set	N/A	<hlq>.SBIPSAMP	
File system directory where the product has been installed	++INSTALL++	/usr/lpp/mqsi	
The letter for the language in which you want messages shown.	++LANGLETTER++[2]	E (English)	E
Locale of environment where commands are run by submitting JCL	++LOCALE++	C	
Time zone of environment where commands are run by submitting JCL	++TIMEZONE++	GMT0BST	
Location of Java installation	++JAVA++	/usr/lpp/java/IBM/J1.6	
WebSphere MQ high-level qualifier	++WMQHLQ++	MQM.V700	

Notes:

1. See the WebSphere MQ documentation for a list of supported national languages.

Related tasks:

This is part of the larger task of creating a broker on z/OS.

Related information:

WebSphere MQ Version 7 Information Center online

Component information - broker:

Decide on the details of your broker component.

Collect the information shown in the Description column and complete the values you require for your particular system. You can see a complete list of variables you can customize in "z/OS JCL variables" on page 3994.

Description	JCL variable	Example component value	Your component value
Home directory of the file system for the broker user ID	++HOME++	/u/mqp1usr/mqp1brk	
Queue Manager associated with the broker	++QUEUEMANAGER++	MQP1	
File system directory where the broker is to exist	++COMPONENTDIRECTORY++	/mqsi/brokers/MQP1BRK	
Broker name	++COMPONENTNAME++	MQP1BRK	
Data set where all JCL relevant to the broker is saved	++COMPONENTDATASET++	TESTDEV.BROKER.MQP1BRK	
Name of the Started Task JCL; can be a maximum of eight characters	++STARTEDTASKNAME++	MQP1BRK	
mqsicreatebroker options	++OPTIONS++	Any additional optional parameters for the **mqsicreatebroker** command	

Related tasks:

"Creating a broker on z/OS" on page 620
Create the broker component and the other resources on which it depends.

"Collecting the information required to create a broker" on page 620
This is part of the larger task of creating a broker on z/OS.

Creating the broker PDSE:

This is part of the larger task of creating a broker on z/OS.

About this task

Each broker requires a PDSE or a PDS. A PDSE is preferable to a PDS because free space is available without the need to compress the data set.

Create the broker PDSE, for example using option 3.2 on ISPF. The name of the PDSE must be the same as the JCL variable ++COMPONENTDATASET++. Allocate a data set that has the following characteristics:

- Eight directory blocks
- 15 tracks (or 1 cylinder) of 3390 DASD with a record format of fixed blocked 80
- A suitable block size (for example 27920)
- A data set type of `library`

Related concepts:

Create the broker component and the other resources on which it depends.

"Creating the broker directory on z/OS"
This is part of the larger task of creating a broker on z/OS.

Creating the broker directory on z/OS:

This is part of the larger task of creating a broker on z/OS.

About this task

Before you start

Before starting this task, you must have completed "Collecting the information required to create a broker" on page 620 and "Creating the broker PDSE" on page 622.

Procedure

1. Use the TSO command OMVS to get into OMVS.
2. Create the broker root directory using the command:

   ```
   mkdir -p <ComponentDirectory>
   ```

   The name of the directory must be the same as the JCL variable ++COMPONENTDIRECTORY++.
3. Display the contents of the directory, which is currently empty, using the command:

   ```
   ls -dl /var/wmqi/MQP1BRK
   ```
4. Display the permissions on the directory using the command:

   ```
   ls -al /var/wmqi/MQP1BRK
   ```
5. Ensure that the user ID of the person doing the customization has a group that matches the group of the directory. Use the following command, where `userid` is the ID you want to check:

   ```
   id <userid>
   ```
6. Check that the directory has a valid group, and that the group has rwx permissions. If they do not, use the following command to set the group of the directory:

   ```
   chgrp <group> <pathname>
   ```

   For example:

```
chgrp WMQI /var/wmqi/MQP1BRK
```

You must be the owner of the group, or have superuser authority, to use this command.

7. To give the group READ, WRITE, and EXECUTE access, use the following command:

```
chmod g=rwx <pathname>
```

For example:

```
chmod g=rwx /usr/wmqi/MQP1BRK
```

8. To display the amount of space used and available, use the following command:

```
df -P /var/wmqi/MQP1BRK
```

Customizing the broker component data set:

This is part of the larger task of creating a broker on z/OS.

About this task

Before you start

Before starting this task, you must have completed "Collecting the information required to create a broker" on page 620.

Create the broker data set in TSO, identified by `++COMPONENTDATASET++`, as instructed in the following steps:

Procedure

1. Copy all the listed files from `<hlq>.SBIPSAMP` to `++COMPONENTDATASET++`.
2. Copy all the listed files from `<hlq>.SBIPPROC` to `++COMPONENTDATASET++`.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

"Contents of the broker PDSE" on page 3991
After you have successfully customized the broker, the broker PDSE members have been set up.

Customizing the broker JCL:

This subtask is part of the larger task of creating a broker on z/OS.

About this task

Before you start

Before starting this task, you must have completed "Customizing the broker component data set" on page 624.

All JCL has a standard header, which includes the following items:

- A brief description of its function.
- A description where further information can be found, relating to the function of the JCL.
- If appropriate, a topic number.
- The section listing the JCL variables themselves.

Each JCL file defines its own `STEPLIB`.

You can customize the files using an ISPF edit macro that you have to tailor, or you can change each of the PDSE members manually.

`BIPEDIT` is a REXX program that you can use to help you customize your JCL. After you have customized `BIPEDIT`, you can run this REXX program against the other JCL files to change their JCL variables.

When you update `BIPBPROF` (the broker profile), the changes are not accessible until you run `BIPGEN` to copy the profile to the file system and create the `ENVFILE`. You must run `BIPGEN` each time you update `BIPBPROF` for the changes to take effect. If you have execution group specific profiles, and you change either `BIPBPROF` or `BIPEPROF` (renamed to the execution group label), you must also run `BIPGEN`.

Procedure

1. Customize the renamed `BIPEDIT` file. Use the information you collected in:
   - "Installation information - broker" on page 621
   - "Component information - broker" on page 622
2. Activate the renamed `BIPEDIT` file before you customize other JCL files, by running the following TSO command:

   ```
   ALTLIB ACTIVATE APPLICATION(EXEC) DA('COMPONENTDATASET')
   ```

   where `'COMPONENTDATASET'` is identical to `++COMPONENTDATASET++`.

   This command is active for the local ISPF session for which it was issued. If you have split screen sessions, the other sessions are not able to use this command. If you use ISPF option 6 to issue the command, use ISPF option 3.4 to edit the data set, which enables you to use the edit command.
3. Edit each JCL file. Run the renamed `BIPEDIT` file by typing its name on the command line (for example `MQ01EDBK`). Instead of editing a member, you might want to `View` it until you have resolved all problems in your REXX program. Alternatively, you can `Cancel` the `Edit` session instead of saving it.

You must set a value for all the variables listed in the JCL; if you do not do so, the JCL does not work correctly.

What to do next

Some JCL files include ++OPTIONS++ for a command; you must replace them with additional optional parameters specific to the command on z/OS, or remove them. Typically, you must replace or remove these options in addition to running BIPEDIT. If you do not require additional options, remove ++OPTIONS++ by using the following command:

```
"c ++OPTIONS++ '' all"
```

where ' ' represents two single quotation marks.

Save the edit macro and run this macro against all the members except the edit macro itself.

If the user ID submitting the BIPCRBK command has the appropriate WebSphere MQ authorities, you can ignore the optional **mqsicreatebroker** parameters -1 and -2.

If you expect different administrators to create the WebSphere MQ resources, you can consider using one of these optional parameters; see "**mqsicreatebroker** command" on page 3831 for further information.

You must be aware that another process might be using the current ENVFILE, therefore you must consider whether updating the current ENVFILE in the file system might have other effects.

Use the **mqsicreatebroker** command to create a broker and its associated resources.

Creating the environment file:

This is part of the larger task of creating a broker on z/OS.

About this task

Before you start

Before starting this task, you must have completed "Customizing the broker JCL" on page 625

Procedure

1. Review the BIPBPROF member. If you define parameters for all users, you can configure BIPBPROF to use these parameters.

Note that the BIPBPROF environment file is the main broker file, and it is used by default for any execution group address spaces, unless a specific execution group environment file exists.

For example, if the time zone option TZ is set as a system-wide parameter for all users, you can remove it from BIPBPROF.

2. Submit member BIPGEN. Review the job output and make sure that the environment file in the output contains the parameters that you expect.

   If you change BIPBPROF, or system-wide parameters, you must submit BIPGEN again to pick up the changes.

Related concepts:

Create the broker component and the other resources on which it depends.

"Customizing the broker JCL" on page 625
This subtask is part of the larger task of creating a broker on z/OS.

Creating an execution group specific environment file:

You can create an execution group specific environment file, which is used instead of the default broker environment file when you restart the execution group.

Before you begin

Before you start

Before starting this task, you must have completed "Customizing the broker JCL" on page 625

About this task

This task forms an optional step of the larger task of creating a broker on z/OS.

By default a broker has a single environment file (ENVFILE), which is created from BIPBPROF by submitting BIPGEN. The main broker address space and any execution group address spaces use this environment file.

You might find it necessary to have an execution group specific environment file and you can achieve this by carrying out the following procedure. In this situation, on restart, the execution group address space uses the specific environment file and not the default broker environment file.

This functionality is enabled only when the function level of the WebSphere Message Broker fix packs is set, for example, 7.0.0.7. To enable function that becomes available in WebSphere Message Broker fix packs, use the **-f** parameter on the **mqsichangebroker** command. For more information, see "**mqsichangebroker** command" on page 3723.

Procedure

1. Review the BIPBPROF member. If you define parameters required by the broker and all execution group address spaces, you can configure BIPBPROF to use these parameters.

2. Take a copy of BIPEPROF and rename the copy of the file to be the same as the execution group label in the component dataset, using the following rule.

   The name should equal the last eight characters of the execution group label. Note that any characters that are not valid for a STEPNAME are replaced with the @ character.

   Furthermore, if the first character of a STEPNAME is not an alphabetic character, that character is replaced with an A.

   For more information about characters that you can use, see "Administration in z/OS" on page 3979.

   For example, an execution group address space with the label MyExecutionGroup, has an execution group specific profile called IONGROUP.
3. Customize the renamed BIPEPROF file to include any environment variable settings specific to the execution group.
4. Edit BIPGEN, adding an additional step at the end for the new execution group specific profile, for example:

   ```
   //BIPEG01 EXEC PROC=BIPEGEN,EG=IONGROUP
   ```
5. Submit member BIPGEN to re-create the default broker environment file, and to create the new execution group specific environment file. Review the job output and make sure that the environment file in the output contains the parameters that you expect.

   If you change BIPBPROF, or the renamed BIPEPROF file, or system-wide parameters, you must submit BIPGEN again to pick up the changes.

What to do next

Multiple Execution Group specific environment files

If you have a requirement for multiple execution group specific files, carry out the following tasks:

1. Create an execution group specific profile for each, following the naming rules specified in Step 2 above.
2. Add additional steps to the end of BIPGEN giving each step a different name, and specifying the correct eight character execution group label.
3. Resubmit BIPGEN to create all the environment files.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

This is part of the larger task of creating a broker on z/OS.

"Controlling the functional level of WebSphere Message Broker" on page 51
You can control the functional level of your broker to enable new functionality added in WebSphere Message Broker fix packs.

Creating the broker component:

When you are creating a broker on z/OS, one of the tasks is to create the broker component.

About this task

If the user ID submitting the BIPCRBK command has the appropriate WebSphere MQ authority, you can ignore the optional **mqsicreatebroker** parameters -1 and -2. If it is your intention to have different administrators create the WebSphere MQ resources, you can consider using one of these optional parameters; see "**mqsicreatebroker** command" on page 3831 for further information.

Procedure

1. Submit job BIPCRBK with option -1. This job creates the files and directories that are placed in the default storage group. You must run this job first; to run this job you need authority to access the broker root directory.
2. Edit BIPCRBK and submit the job with option -2. This job creates the WebSphere MQ queues. If you do not have the requisite authority, ask your WebSphere MQ system administrator to run the job.
3. Ensure that the jobs have run successfully by:

   Checking the STDOUT stream in the JOBLOG.

   Viewing STDOUT for any errors and checking for `BIP8071I: Successful command completion`.

What to do next

If you encounter any problems, delete the broker and re-create it using the following procedure. You must have the appropriate authority to run the jobs.

1. Edit and configure job BIPDLBK.
2. Run job BIPDLBK with the same option, or options, that caused the problems when you ran the BIPCRBK job.
3. Correct the problems and run the BIPCRBK job again.

Copying the broker started task to the procedures library:

This is part of the larger task of creating a broker on z/OS.

About this task

Before you start

Before starting this task, you must have completed “Creating the broker component” on page 629.

Procedure

1. Ensure that the user ID for the broker started task is defined and that the broker procedure is associated with the user ID. If you are using a security manager, for example RACF, update the started class for your broker. See “Setting up z/OS security” on page 556 and “Summary of required access (z/OS)” on page 3985 for more information.
2. Copy the Started Task JCL (`BIPBRKP`) to the procedures library, for example `USER.PROCLIB`.

Related concepts:

“The broker environment” on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

The professionals in your organization require access to components and resources on z/OS.

Verifying brokers

Use the **mqsilist** command to display the brokers that you have created on your computer.

About this task

If you run the **mqsilist** command with no parameters, a one line summary for every broker that you have created for the current installation is displayed. For example:

```
BIP1281I: Broker 'BrokerA' on queue manager 'QMA' is running.

BIP1281I: Broker 'MB7BROKER' on queue manager 'MB7QM' is running.

BIP1281I: Broker 'MBTEST1' on queue manager 'TESTQM' is stopped.

BIP8071I: Successful command completion.
```

You can request further details about all resources by specifying parameter **-d 1** or **-d 2** on the command, You can also specify the **-r** parameter so that the command recursively returns information about execution groups, and the message flows and files that you have deployed to those execution groups.

You can also use this command to display a list of brokers that you have created for all concurrent installations on this computer. For example, you might have installed both Version 6.0 and Version 7.0 for assessment and migration.

```
mqsilist -a
```

In earlier versions, only brokers that you have created are displayed. If you want to view information about other components, you must run the corresponding command for that version

Related reference:

"**mqsilist** command" on page 3882
Use the **mqsilist** command to list installed brokers and their associated resources.

Modifying a broker

Modify a broker by using the command line on the system where the broker component is installed.

Before you begin

Before you start:

You must have completed the following tasks:

- Ensure that your user ID has the correct authorizations to perform the task; see "Security requirements for administrative tasks" on page 3644.
- Create a broker.
- On Windows, Linux, and UNIX systems, you must set up your command-line environment before performing this task by running the product profile or console; see "Setting up a command environment" on page 213.

About this task

The parameters you can change on the broker affect the physical broker that was created by using the command line.

You can also modify the broker in the WebSphere Message Broker Explorer, where you can change broker properties, such as security settings.

Choose the appropriate task for your platform from the following links:

- "Modifying a broker on Windows, Linux, and UNIX systems" on page 632
- "Modifying a broker on z/OS" on page 634
- "Configuring brokers in the WebSphere Message Broker Explorer" on page 635

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to route, transform, and enrich in flight messages.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

"Deleting a broker" on page 930
Delete a broker using the command line on the system where the broker

component is installed.

"Starting and stopping a broker" on page 921
Run the appropriate command to start or stop a broker.

"Viewing broker properties" on page 927
You can view broker properties by using the **mqsireportbroker** command. You can also use the WebSphere Message Broker Explorer to view broker properties.

Related reference:

"Security requirements for administrative tasks" on page 3644
You can configure access permissions to govern which users and groups can manipulate objects in the broker network. Security requirements for administrative tasks depend on the platform that you use.

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

"**mqsireportbroker** command" on page 3919
Use the **mqsireportbroker** command to display broker registry entries.

Modifying a broker on Windows, Linux, and UNIX systems

Use the **mqsichangebroker** command on Windows, Linux, and UNIX to modify your broker.

Before you begin

Before you start:

You must have completed the following task for the appropriate platform:

- "Creating a broker on Linux and UNIX systems" on page 615
- "Creating a broker on Windows" on page 616

About this task

To modify a broker on Windows, Linux, and UNIX:

Procedure

1. Stop the broker by using the **mqsistop** command.
2. Enter the **mqsichangebroker** command, specifying the broker name and one or more parameters that you want to change.

   ```
   mqsichangebroker brokername
   <<-i ServiceUserID> -a ServicePassword>
   <-t | -n> <-l UserLilPath>
   <-g ConfigurationTimeout> <-k ConfigurationDelayTimeout>
   <-v StatisticsMajorInterval> <-P httpListenerPort> <-y ldapPrincipal>
   <-z ldapCredentials> <-c ICUconverterpath> <-x userExitPath>
   <-e activeUserExits> <-o operationMode>  <-f functionlevel>
   ```

   where:

   brokername
   Is the broker name.

   -i Is the service user ID that is used to run the broker (applicable on Windows only).

   -a Is the password for the service user ID (applicable on Windows only).

   -t Indicates that the broker runs as a WebSphere MQ trusted application.

-n Indicates that the broker must cease to run as a WebSphere MQ trusted application.

-l Indicates from where LIL (loadable implementation libraries) files are loaded.

-g Is the maximum time (in seconds) to allow a broker to process a deployed message.

-k Is the maximum time (in seconds) to allow a broker to process a minimum size deployed message.

-v Is the time (in minutes) for the duration of the interval for collecting statistics archive records.

-P Is the port that the broker HTTP listener will use.

The broker starts this listener when a message flow that includes HTTP nodes or Web Services support is started

-y Is the user principal for access to an LDAP directory.

-z Is the user password for access to LDAP.

-c Is a delimited set of directories to search for additional code page converters.

-x Is the path that contains the location of all user exits to be loaded for execution groups in this broker.

-e Is the list of active user exits.

-o Is the operation mode that the broker will use.

-f Indicates the maximum function level of your broker that you want to enable.

-s Indicates whether broker administration security is enabled.

For example:

- To change the user ID that is used to run the broker on Windows, enter the following command:

  ```
  mqsichangebroker MB7BROKER -i wbrkuid -a wbrkpw
  ```

- To change the configuration timeout, enter the following command:

  ```
  mqsichangebroker MB7BROKER -g 500
  ```

- To activate broker administration security, enter the following command:

  ```
  mqsichangebroker MB7BROKER -s active
  ```

For further information about these parameters, and more examples, see "**mqsichangebroker** command - Linux and UNIX systems" on page 3724 and "**mqsichangebroker** command - Windows systems" on page 3729.

3. Restart the broker by using the **mqsistart** command. The broker restarts with the new properties.

Results

You cannot change all the parameters with which you created a broker. If you cannot change a property by using the **mqsichangebroker** command, delete the broker and create another broker with the new properties.

Related concepts:

"The broker environment" on page 46
A broker is a set of execution processes that hosts one or more message flows to

route, transform, and enrich in flight messages.

Modifying a broker on z/OS

Use the **mqsichangebroker** command on z/OS to modify your broker.

Before you begin

Before you start:

You must have completed the following task:

- "Creating a broker on z/OS" on page 620

About this task

To modify a broker:

Procedure

1. Ensure that the broker is running.
2. Stop the broker components by issuing the following command:
   ```
   /F BROKERNAME, PC
   ```
3. When the broker has stopped, use the **MVS MODIFY** command with the **changebroker** parameters that you want to change. For example:
   ```
   /F <BROKERNAME>,cb g=100,k=200
   ```
4. Restart the broker components by issuing the following command:
   ```
   /F BROKERNAME, SC
   ```
   The broker now uses the changed parameters.

What to do next

You cannot change all the parameters with which you created a broker. If you cannot modify a parameter that you want to change by using the **changebroker** command, delete the broker and create a new one. By creating another broker you can redefine all the parameters.

You can change the following parameters:

g ConfigurationChangeTimeout

k InternalConfigurationTimeout

l UserLilPath

v StatisticsMajorInterval

P HTTPListenerPort

y LdapPrincipal

z LdapCredentials

c ICUConverterPath

x UserExitPath

e ActiveUserExits

f functionlevel

For further information about these parameters, see "**mqsichangebroker** command - z/OS" on page 3733.

Configuring brokers in the WebSphere Message Broker Explorer

Configure your local and remote brokers by using the WebSphere Message Broker Explorer.

Before you begin

If you are using systems other than Linux on x86 or Windows, you must first create your brokers on those systems; see “Configuring brokers” on page 610.

If you are using Windows, you must have administrator access rights to create brokers by using the WebSphere Message Broker Explorer. When creating a broker, you might be prompted to agree to the use of administrator rights or be prompted to enter an administrator user ID and password.

About this task

On Linux on x86 or Windows, use the WebSphere Message Broker Explorer to create local brokers, and to configure, modify, and administer your local and remote brokers.

To start the WebSphere Message Broker Explorer:

- Linux Open a command shell in which the **mqsiprofile** command has not been run and enter the `strmqcfg` command, or run `/usr/bin/strmqcfg`.
- Windows Click **Start** > **All Programs** > **IBM WebSphere MQ** > **WebSphere MQ Explorer**, or double-click the shortcut on your desktop labeled 'WebSphere MQ Explorer'. On Windows Vista and Windows Server 2008 systems, you must right-click **WebSphere MQ Explorer**, and select **Run as Administrator** to start the application with the appropriate privileges.

In the WebSphere Message Broker Explorer you can configure broker, execution group and message flow properties including security and configurable services. See the following tasks for more information:

- “Configuring broker properties in the WebSphere Message Broker Explorer” on page 637
- “Using the WebSphere Message Broker Explorer to work with configurable services” on page 644

Related concepts:

“WebSphere Message Broker Explorer” on page 57
The WebSphere Message Broker Explorer is a graphical user interface based on the Eclipse platform for administering your brokers.

Configure your local and remote brokers by using the WebSphere Message Broker Explorer.

"Configuring brokers" on page 610
Create and configure the brokers that you want on the operating system of your choice.

Chapter 8, "Administering brokers and broker resources," on page 899
Administering brokers and associated broker resources includes the tasks that you perform frequently to activate and manage those resources. Choose the method you prefer to administer your brokers and associated resources.

Configuring description properties in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to configure the `Long Description` and `Short Description` on your brokers, execution groups and deployed message flows. Alternatively, you can use the Administration API to configure the `Long Description` properties.

About this task

The `Short Description` is stored and used by the WebSphere Message Broker Explorer. The `Long Description` is stored by the broker, and can be viewed within

the WebSphere Message Broker Explorer or Administration API. You can also use the Long Description to add keywords to your message flows.

To configure the Long Description and Short Description on your brokers, execution groups, or message flows:

Procedure

1. In the Navigator view, expand the Brokers folder.
2. Right-click the object with which you want to work, and click **Properties**. This object can be a broker, execution group, or message flow. The Properties window is displayed. The Long Description and Short Description are fields on the **General** tab.
3. Enter the values for the Long Description, Short Description, or both. If you are working with a message flow, you can add keywords into the Long Description field. When you define a keyword, you must follow certain rules to ensure that the information can be parsed. The following example shows some values that you might want to define in the Long Description property:

   ```
   $MQSI Author=John Smith MQSI$
   $MQSI Flow 1 Version=v1.3.2 MQSI$
   ```

   Do not use the following characters within keywords, because they cause unpredictable behavior:

   ```
   ^ $ . | \ < > ? + * = & [ ] ( )
   ```

   You can use these characters in the values that are associated with keywords; for example:

   - `$MQSI RCSVER=$id$ MQSI$` is acceptable
   - `$MQSI $name=Fred MQSI$` is not acceptable
4. Click **Apply** to update the description properties.
5. Click **OK** to exit the Properties window.

Results

The description properties for the selected object are now updated, and you can view these properties in the **Properties QuickView** for the object in the WebSphere Message Broker Explorer.

Configuring DataPower security settings

Use the DataPower Security wizard in the WebSphere Message Broker Explorer to configure an external DataPower appliance to handle the WS-Security Policy for your HTTP, HTTPS input, and SOAP nodes within your message flow. The DataPower box is configured to decrypt incoming messages to your flow and encrypt outgoing messages from your flow without requiring any changes to the message flows or broker configuration.

Before you begin

Before you start:

To use the DataPower Security wizard you must have access to the SYSTEM.DEF.SVRCONN channel on the broker's queue manager. Your clients must send their messages direct to the DataPower appliance on a Client port you specify.

About this task

The following steps are required to configure a DataPower appliance for WS-Security for your message flows:

- Select which HTTP(S)Input and SOAP nodes you want to configure your security for.
- Create a DataPower connection profile or edit an existing profile.
- Use or alter the default Policy Sets to specify your encryption and decryption WS- Security parameters.
- Specify which specific Crypto Keys to use from the DataPower box

On the DataPower appliance the following configuration is created after you run the DataPower Security wizard:

- An XML Firewall with optionally Back (for HTTPSInput Nodes) and Front (Client) SSL connection.
- An XML Firewall Policy consisting of a list of inbound/ request rules and an outbound/ response rule per HTTP Input or SOAP Node.
- Each inbound/ request rule consists of a decryption action with parameters specified from the Policy Set.
- Each outbound/ response rule consists of an encryption action with parameters specified from the Policy Set.

To configure DataPower security for your message flows:

Procedure

1. Right-click on the message flow or execution group with which you want to work, and click **Properties**. You can enable security handling on a single message flow containing HTTP, HTTPS input and SOAP nodes, or you can select an execution group to enable security handling for these nodes in all the message flows in the execution group.

2. In the Properties window, click **DataPower** on the left to open the DataPower tab.
3. Click **Configure Security** to open the Security on DataPower Appliance window. The HTTP, HTTPS input, and SOAP nodes from your message flows are displayed in the Flow Details table.
4. Select a Policy Set Binding from the list of options. If you select the No Policy Set Bindings option, no encryption or decryption nodes are specified in your policy rules. You can use this option as a test for the communication channels before applying a policy set binding. To create a policy set binding, click **Edit Policy Sets**. See "Policy Sets and Policy Set Bindings editor" on page 6841, for more information about the Policy Sets and Policy Set Bindings editor.
5. In the DataPower details section, select a User profile from the list of options. Click **Edit Profiles** to create or edit connection profiles. To create a profile:
   a. In the DataPower Connection Profiles window, click **Add**.
   b. Click in the relevant cell in the table to edit the values. You must provide a valid user name, domain, and the host name of your DataPower appliance.
   c. Click **Finish**. The new or edited profile is now available to select in the Security on DataPower Appliance window.
   d. Add a password for the profile in the Password field.

   You can also use the DataPower Connection Profiles window to import and export profiles in the WebSphere Message Broker Explorer on different machines.
6. You must now decide whether to create a new Policy or merge with an existing Policy. If you attempt to merge with a policy that does not exist, a new one is created. A merge adds request and response rules to your policy, but it does not overwrite any preexisting rules. A merge also does not alter your existing firewall settings.
7. Enter the name or names of your XML Firewalls, and the Client Ports on which your HTTP clients connect to your DataPower box.
8. Optional: Select the nodes to configure in the Flow Details section, and click **Next** to select XML Firewall SSL settings, Decryption, and Encryption rules for your DataPower device.
9. Click **Finish**. An attempt is made to connect to your domain on your DataPower box to retrieve your Crypto Profiles.
10. Click **Yes** to confirm that you want to alter the configuration of your DataPower appliance.

Results

You have configured DataPower security settings for your message flow or execution group.

Configuring the flow debug port in the WebSphere Message Broker Explorer

Before you can debug a message flow, you must configure and enable the flow debug port. The flow debug port is also known as the Java debug port, and the JVM debug port.

About this task

Use the WebSphere Message Broker Explorer, or WebSphere Message Broker Toolkit to set the flow debug port value to enable the flow debugger to be connected to an execution group. Alternatively, you can use the command console or the Administration API to configure this property.

Using the WebSphere Message Broker Toolkit:
Procedure

1. Select the broker with which you want to work in the Brokers view.
2. Right-click the execution group which you want to work, and click **Launch Debugger**. If the flow debug port is already configured, the port number is displayed in the Enable window.
3. To change the flow debug port, click **Configure**.
4. Set a port number for the debug port. The port number must be a number that is not already in use.
5. Click **OK**. The execution group is stopped and restarted, and the flow debug port is configured to use the specified port.
6. If you want to continue to attach the debugger to the execution group for debugging, click **OK**. To exit the Enable window without attaching the debugger, click **Cancel**.

What to do next

To start debugging your message flows, switch to the Debug perspective. Right-click the execution group, and click **Terminate Debugger** to stop debugging on the selected execution group.

Using the WebSphere Message Broker Explorer:
Procedure

1. Expand the Brokers folder in the Navigator view.
2. Right-click the execution group which you want to work, and click **Properties**. The Properties window is displayed.
3. Click **Flow Debug Port** on the left to display the Flow Debug Port tab.
4. Set a port number for the debug port. The port number must be a number that is not already in use.

5. Click **Apply**.
6. Click **OK** to exit the Properties view.
7. Right-click the execution group, and click **Flow Debug Port** > **Enable** to enable debugging on the selected execution group.

What to do next

You can connect the flow debugger to your execution group by using the WebSphere Message Broker Toolkit, see the instructions in "Using the WebSphere Message Broker Toolkit" on page 641. Click **Flow Debug Port** > **Disable** to disable debugging on the selected execution group.

Changing the operation mode of your broker using the WebSphere Message Broker Explorer

You must ensure that your brokers are running in the operation mode for which you have purchased a license. You can change the operation mode of your broker WebSphere Message Broker Explorer. Alternatively, you can use the **mqsimode** command to change the operation mode.

About this task

To change the operation mode of your broker by using the WebSphere Message Broker Explorer:

Procedure

1. Switch to the WebSphere Message Broker Explorer, and expand the Brokers folder in the Navigator view.
2. Right-click the broker which you want to work, and click **Properties**. The Properties window is displayed.
3. Enter the value for the mode of your broker in the Operation Mode field, in the **General** tab. The options you can set in this field are:
   - `enterprise`

- `starter`
- `adapter`
- `entry`

4. Click **Apply**.
5. Click **OK** to exit the Properties view.

Results

The operation mode of your broker is updated. You can see the operation mode of your broker in the Properties QuickView.

Changing the broker security settings in the WebSphere Message Broker Explorer

Use the WebSphere Message Broker Explorer to configure security settings for your broker. Alternatively, you can use the command line to change these values.

About this task

You can use the WebSphere Message Broker Explorer to configure the following security settings on your broker:

- Cache Sweep Interval
- Cache Timeout
- Security Profiles
- Policy Sets

Procedure

1. In the WebSphere Message Broker Explorer, expand the Brokers folder in the Navigator view.
2. Right-click the execution group which you want to work with, and click **Properties**. The Properties window is displayed.
3. Click **Security** on the left to display the Security tab.
4. Enter a value in seconds for the **Cache Sweep Interval** field. The default value for this field is 300.

5. Enter a value in seconds for the **Cache Timeout** field. The default value for this field is 60.
6. Click **Apply** to update the Cache Sweep Interval and Cache Timeout properties.
7. Click **Security Profiles** to configure security profiles on your broker. See "Creating a security profile" on page 433, for more information about the creating Security Profiles.
8. Click **Policy Sets** See "Policy Sets and Policy Set Bindings editor" on page 6841, for more information about the Policy Sets and Policy Set Bindings editor.
9. Click **OK** to exit the Properties view.

Results

Using the WebSphere Message Broker Explorer to work with configurable services

Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view, add, modify and delete configurable services.

Instead of defining properties on the node or message flow, you can create configurable services so that nodes and message flows can refer to them to find properties at run time. If you use this method, you can change the values of attributes for a configurable service on the broker, which then affects the behavior of a node or message flow without the need for redeployment.

Unless it is explicitly stated by the function that is using the configurable service, you need to stop and start the execution group, or the applicable message flows, for the change of property value to take effect.

You can create and name new configurable services, based on IBM defined templates. Alternatively, you can modify the existing IBM defined configurable services. If you modify an IBM defined configurable services, their default values are overwritten in the system registry.

Use the WebSphere Message Broker Explorer to complete the following tasks for configurable services:

- "Creating a new configurable service"
- "Viewing configurable services" on page 647
- "Modifying an IBM defined configurable service" on page 648
- "Modifying a configurable service" on page 649
- "Importing a configurable service" on page 650
- "Exporting a configurable service" on page 651
- "Deleting a configurable service" on page 652

Alternatively, you can use the runtime commands to work with configurable services, see "Configurable services" on page 1296.

For a full list of configurable services and their properties, see "Configurable services properties" on page 3766.

Related concepts:

Creating a new configurable service

Use the WebSphere Message Broker Explorer to create a new configurable service to define properties for an external service on which the broker relies.

About this task

You can add a new configurable service to your broker based on an IBM defined configurable service template using the WebSphere Message Broker Explorer. You must provide a name for your configurable service, which must not duplicate an existing configurable service name.

As an alternative to creating a new configurable service, you can modify an IBM defined configurable service, see "Modifying an IBM defined configurable service" on page 648.

Not all configurable service types are available to select within WebSphere Message Broker Explorer. If you want to create a configurable service and the type is not listed, you must first create an instance of that type via the command line. For information about creating configurable services by using the command line, see "**mqsicreateconfigurableservice** command" on page 3849.

To add a new configurable service using the WebSphere Message Broker Explorer:

Procedure

1. In the Navigator view, expand the broker on which you want to add a new configurable service.
2. Right-click the Configurable Services folder and click **New** > **Configurable service**. The Configurable services window is displayed.
3. Enter a name for your configurable service.
4. Select the type of configurable service to create.
5. For some configurable services, you can select an IBM defined template to provide default values you can use or update. If appropriate, select the IBM defined template to use for your configurable service.
6. Enter values for the configurable service properties. The properties are populated with default values.
7. Click **OK** to create the new configurable service.

What to do next

The properties for the configurable service are not used by the broker until you restart the message flows that use the configurable service. You can stop and start the broker to ensure that the configurable service is available to all resources running on the broker.

Related concepts:

Viewing configurable services

Configurable services are used to define properties that are related to external services on which the broker relies. Use the WebSphere Message Broker Explorer to view the properties of configurable services defined on your broker.

About this task

You can view the properties of configurable services that you have defined on the broker, or you can view the properties of IBM defined configurable services.

To view a configurable service:

Procedure

1. In the Navigator view, expand the broker on which you want to view the configurable services.
2. Expand the Configurable Services folder. If you want to view IBM defined configurable services, right-click the Configurable Services folder, and click **Show IBM Templates**.
3. Right-click the configurable service that you want to view, and click **Properties**. The Configurable services window is displayed, and shows the properties for the selected configurable service.
4. Click **OK** to close the Configurable services.

Related concepts:

Modifying an IBM defined configurable service

You can create a new configurable service for an external service on which the broker relies, by modifying predefined configurable services provided by IBM. Use the WebSphere Message Broker Explorer to view and modify existing configurable services.

About this task

You can modify IBM defined configurable services to add a new configurable service to your broker. You cannot change the name of an IBM defined configurable service, and you cannot delete it. If you want to use a custom name for a configurable service, or if you want to create different configurable services of the same type, see "Creating a new configurable service" on page 645.

To modify an IBM defined configurable service:

Procedure

1. In the Navigator view, expand the broker on which you want to modify an IBM defined configurable service.
2. Expand the Configurable Services folder.
3. Right-click the configurable service that you want to modify, and click **Properties**. The Configurable services window is displayed.
4. Enter values for the configurable service properties. The **Basic** tab shows the key properties for the configurable service. Additional properties to configure can be found on the **Advanced** tab. The properties are populated with default values.
5. Click **OK** to update the configurable service.

What to do next

The properties for the configurable service are not used by the broker until you restart the message flows that use the configurable service. You can stop and start the broker to ensure that the configurable service is available to all resources running on the broker.

Related concepts:

Deleting a configurable service

Use the WebSphere Message Broker Explorer to delete custom configurable services.

About this task

You can delete custom configurable services that you have defined on a broker, but you cannot delete the IBM defined configurable services on a broker, even if you have previously modified the IBM defined configurable service.

To delete a configurable service:

Procedure

1. In the Navigator view, expand the broker on which you want to delete a configurable service.
2. Expand the Configurable Services folder.
3. Right-click the configurable service that you want to delete, and click **Delete**.
4. Click **OK** to confirm you want to delete the configurable service.

What to do next

You must restart the message flows that used the configurable service for the change to be recognized by the message flows. You can stop and start the broker to ensure that the configurable service is updated for all the resources running on the broker.

Related concepts:

Working with UserDefined configurable services

Use the WebSphere Message Broker Explorer to create, view, and modify a UserDefined configurable service.

About this task

For further information on using the WebSphere Message Broker Explorer with configurable services, see:

- "Creating a new configurable service" on page 645
- "Viewing configurable services" on page 647
- "Modifying a configurable service" on page 649

To add a new configurable service:

Procedure

1. Switch to the WebSphere MQ Explorer perspective.
2. In the Domains view, expand the broker on which you want to add a new configurable service.
3. Right-click the Configurable Services folder and click **New** > **Configurable service**. The Configurable Service window is displayed.
4. Enter a name for your configurable service.
5. Select `UserDefined` as the type of configurable service to create.
6. Enter the values you require for the configurable service properties, using the add and delete buttons that become enabled for UserDefined configurable services. There are no predefined values for a UserDefined configurable service.
7. Click **Finish** to create the new configurable service.

Related concepts:

Changing WebSphere Message Broker Explorer preferences

Change preferences in the WebSphere Message Broker Explorer.

About this task

You can change the following preferences to tailor how you work in the WebSphere Message Broker Explorer:

- Display resources in the Broker Explorer view.
- Warn before deleting Administration log events.
- Broker connection wait times.
- DataPower configuration properties.
- Service trace properties
- SSL parameters.

To change WebSphere Message Broker Explorer preferences:

Procedure

1. Start the WebSphere Message Broker Explorer.
2. Click **Window** > **Preferences**.
3. Expand the **Broker Explorer** category in the left pane.
4. Make your selections.
5. Click **OK**.

Changing the operation mode of your broker

Change the operation mode in which your broker is working by using the **mqsimode** command.

About this task

You must change your broker configuration to ensure that your brokers are running in the operation mode for which you have purchased a license. You can change the mode to `starter`, `adapter`, `entry`, or `enterprise`.

When you view the broker in the WebSphere Message Broker Explorer, the current mode of each broker is displayed. If the resources deployed to a broker exceed the permitted amounts, the display indicates these violations. You can change the broker mode in the WebSphere Message Broker Explorer, see "Changing the operation mode of your broker using the WebSphere Message Broker Explorer" on page 642. Alternatively, you can use the **mqsimode** command to make any required changes.

Procedure

1. Open a command prompt.
   - Linux On Linux, run the **mqsiprofile** command to initialize the command environment.
   - Windows On Windows, click **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console** to open a command console.
2. Run the **mqsimode** command with the **-o** parameter to change the mode of the broker, or without the **-o** parameter to view the current setting; see "**mqsimode** command" on page 3899.
3. Check for error messages. If you attempt to reconfigure the broker to a mode which is not sufficient for the deployed resources, the **mqsimode** command issues a warning indicating that changing the mode is not allowed. Resolve any violations, if required; see "Resolving problems that occur during deployment of message flows" on page 3440.
4. (Optional) Run the **mqsimode** command again to confirm that there are no violations.

Example

See further examples of changing the mode of your broker:

- "Example: Changing the operation mode of your broker" on page 3904
- "Example: Changing the Trial Edition to the full edition" on page 3903

What to do next

Related concepts:

"**mqsichangebroker** command" on page 3723
Use the **mqsichangebroker** command to change one or more of the configuration parameters of the broker.

Moving from Trial Edition

You want to convert from Trial Edition mode to an alternative edition.

Before you begin

Before you start: Contact your IBM representative to upgrade your license.

Procedure

1. Open a command prompt:
   - Linux On Linux and UNIX, run the **mqsiprofile** command to initialize the command environment.
   - Windows On Windows, click **Start** > **Programs** > **IBM WebSphere Message Broker 7.0** > **Command Console** to open a command console.
2. Use the **mqsimode** command to change the mode of each broker. Specify the mode that you require for each broker by setting the **-o** parameter (*Mode_Type*) to `enterprise`, `starter`, `entry`, or `adapter`. For example, to change a local broker to run in `enterprise` mode, run the following command:

   ```
   mqsimode  MB7BROKER –o enterprise
   ```

   where MB7BROKER is the name of your broker.

To change a remote broker, specify a configuration file that defines the broker (*brokername*.broker), or one or more connection parameters that identify the broker **-i**, **-p**, **-q**).

3. Restart all your brokers; see "Starting and stopping a broker" on page 921.

What to do next

Next: Ensure that you upgrade other required products (for example, WebSphere MQ) if you have trial versions of those products.

You must change your broker configuration to ensure that your brokers are running in the operation mode for which you have purchased a license; see "Changing the operation mode of your broker" on page 655.

Note: If you installed WebSphere Message Broker using the Trial Edition package, all brokers are created in trial mode by default and you have to follow these steps for every newly created broker. In order to create brokers with a default mode of operation other than trial, you have to uninstall the WebSphere Message Broker Trial Edition product and install the full WebSphere Message Broker product; see "Uninstalling" on page 331 and "Installing the Broker component" on page 267.

Related concepts:

"Operation modes" on page 48
The operation mode that you use for your broker is determined by the license that you purchase.

"**mqsimode** command" on page 3899
Use the **mqsimode** command to configure and retrieve operation mode information.

Checking the operation mode of your broker

Use the **mqsimode** command to find out the operation mode of your broker.

About this task

Run the **mqsimode** command to report the mode that is being used by your broker. Use one form of the connection parameters to identify the broker that you want to check.

Running this command also reports all mode violations.

Example

For example:

```
mqsimode –i localhost –p 1414 –q MB7QMGR
```

where **-i** (IP address), **-p** (port), and **-q** (queue manager) parameters represent the connection details for the queue manager associated with your broker. If you have created the broker on the computer on which you run this command, you can specify the broker name instead.

If your broker is running in `starter` mode, and the name of your broker is *Broker_Name*, this command displays the following messages:

```
BIP1044: Connecting to the broker's queue manager...
BIP1807: Discovering mode information from broker 'Broker_Name'...
BIP1802: Broker 'Broker_Name' is in starter mode.
BIP8071: Successful command completion.
```

Advanced configuration

Change your broker configuration to use one or more of the advanced options available.

About this task

- If you are developing message flows that include resources such as the WebSphere Adapters nodes, IMS nodes, or the CICSRequest node, you must set up your broker environment to support these applications. Details of the setup that you require is in "Configuring for applications" on page 659.
- You can use WS-Security with your web services message flows to provide quality of protection through message integrity, message confidentiality, and single message authentication. See "WS-Security" on page 765.
- If you have been working with WebSphere Message Broker on z/OS, and want to move your configuration to a distributed platform, see "Moving from WebSphere Message Broker on a distributed system to z/OS" on page 818.
- WebSphere Message Broker supports a number of locales on each platform; details of what is supported, and how to use code converters, are provided in "Changing locales" on page 819.

Related tasks:

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

"Configuring brokers" on page 610
Create and configure the brokers that you want on the operating system of your choice.

"Working with IMS" on page 2128
You can use the IMSRequest node to connect to IMS, a message-based transaction manager and hierarchical-database manager for z/OS.

"Working with CICS Transaction Server for z/OS" on page 2172
Use the CICSRequest node to connect to CICS Transaction Server for z/OS applications.

"Processing email messages" on page 1786
You can configure the EmailOutput node to deliver an email from a message flow to an email server that supports Simple Mail Transfer Protocol (SMTP). You can also configure the EmailInput node to retrieve an email from an email server that supports Post Office Protocol 3 (POP3) or Internet Message Access Protocol (IMAP).

Configuring user databases

Configure databases to hold application or business data that you can access from your message flows.

About this task

Databases that hold application or business data are known as *user databases*, and are read from and written to by nodes within the message flows that you deploy to one or more brokers in your domain.

In some situations, and for some applications, you might need to ensure the integrity of the data that you hold in user databases across multiple systems and resource managers by coordinating table updates and the writing to one database with the deletion of data in another. To achieve these goals, you must configure your databases, your brokers, and your message flows to be globally coordinated.

For more information about the requirement for, and set up of, user databases, and the restrictions that apply, see "Databases overview" on page 2109.

The process of making databases available has the following phases:

1. Optional: Create and configure user databases. If your message flows interact with databases, you must create and configure those databases ready for connection by the broker on behalf of the message flows. For user databases, you can configure ODBC and JDBC connections.
2. Optional: If your user databases contain critical information, coordinate their updates through a transaction manager.

   On distributed systems, the WebSphere MQ queue manager is the transaction manager that interacts with the resource managers (the database providers). On z/OS, RRS provides equivalent coordination.

To complete these phases:

Procedure

1. If you want to access user databases from your deployed message flows, create and configure the databases and the connections to them:
   a. Create the databases.
   b. Authorize access to the databases.
   c. Optional: If you want your databases to participate in globally coordinated transactions, configure the databases for global coordination.
2. On distributed platforms, create and configure connections to the databases that you have created:
   a. If your message flows use an ODBC connection to a database, enable an ODBC connection for that database. Repeat this step for each database that you want to access in this way.

      Note that you can use the **mqsicvp** command as an ODBC test tool; see "Enabling ODBC connections to the databases" on page 668 for further information.
   b. If your message flows use a JDBC connection to a database, enable a JDBC connection for that database. Repeat this step for each database that you want to access in this way.
3. On z/OS, connect to the database.
4. Optional: If you want your databases to participate in globally coordinated transactions, configure the environment for global coordination.

Related tasks:

"Configuring brokers" on page 610
Create and configure the brokers that you want on the operating system of your choice.

"Customizing the z/OS environment" on page 591
If you are planning to use a z/OS environment, consider whether to create your brokers on z/OS. You must also complete a number of tasks to configure your environment.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Creating the user databases:

If your message flows create, update, retrieve, or delete application and business data in one or more user databases, create the databases before you deploy the message flows to a broker.

About this task

For information about which databases you can use, see "Supported databases" on page 3591.

To create the databases on distributed systems:

Procedure

1. Create the databases that you require. Discuss your requirements with your database administrator, or see the documentation supplied with the database product that you are using. Make sure that you run a database profile, if required for your platform and database manager.

   The following samples use databases, and provide outline instructions for creating DB2 and Oracle databases:

   - Airline Reservations
   - Data Warehouse
   - Error Handler
   - Message Routing
   - Simplified Database Routing
   - TLOG Processor (DB2 only)

   You might find it helpful to use the instructions in these samples as a starting point for database creation.

   You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.
2. If you are creating Sybase databases on AIX, run the Sybase profile before you run **mqsiprofile**. For more information about using **mqsiprofile** to initialize command environments on Linux and UNIX platforms, see "Command environment: Linux and UNIX systems" on page 310.

Results

You have now created a database for business data.

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Authorizing access to user databases" on page 662.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"Database locations" on page 3595
The broker can access databases set up on the local computer or on a remote server, subject to restrictions.

Authorizing access to user databases:

When you have created a user database, you must authorize the broker and its execution groups to access it.

Before you begin

Before you start: create the databases.

Use the **mqsisetdbparms** command to specify a user ID and password that the broker can use to access each database. If you want to define a default user ID and password that the broker can use if you have not defined specific values for a particular database, run the **mqsisetdbparms** command and set the **ResourceName** to the value `dsn::DSN` with your chosen default user ID and password.

If you have migrated your broker from a previous release, the broker accessed a database for its own use, and you might have defined the user ID and password used to access that database by specifying a database connection user ID and password with the **-u** and **-p** parameters on the **mqsicreatebroker** command. Alternatively, you might have used the broker service user ID and its password (specified with the **-i** and **-a** parameters on the same command). When you migrate the broker, these parameters are migrated and stored, and are used by the migrated broker for access to databases that do not have specific ID access defined.

The following values and order of preference are used by the broker:

1. First, on all platforms: The user ID and password that you have set for the specific database, by using the **mqsisetdbparms** and specifying the database in the **-n** parameter.
2. Second, on all platforms: The user ID and password that you have set for all other databases, by using the **mqsisetdbparms** and specifying `dsn::DSN` in the **-n** parameter.
3. Third, the values are platform-specific:
   a. Windows On Windows: The broker service ID and password that you specified on the **mqsicreatebroker** command.
   b. Linux UNIX On Linux and UNIX: The user ID `mqsiUser` and password `********` (these values are fixed).
   c. z/OS On z/OS: The user ID `""` and password `""`, which cause the connection to be made with the broker started task user ID.

On z/OS only, if you do not specify a password when you specify `dsn::DSN` in the **-n** parameter, the broker connects to the DB2 database with its started task user ID. The broker uses the user ID that you have specified on the command when it creates a fully-qualified SQL statement, such as in ESQL, for stored procedures. For non-stored procedure SQL statements, where the schema is not specified, DB2 uses the CURRENTSQLID value. If you have not specified a CURRENTSQLID value,

the broker uses the user ID that you specified on the **mqsisetdbparms** command. If you have not provided a user ID by using that command, DB2 uses the broker started task ID.

The user ID that the broker uses to access databases must have the following authorizations:

- The user ID must be authorized to connect to the database.
- The user ID must have appropriate privileges on the user database objects that are accessed by the message flow; for example, tables, procedures, and indexes.

If you expect to deploy message flows that participate in globally coordinated transactions to a broker, you must provide additional authorization. For more information, see "Configuring databases for global coordination of transactions" on page 665.

About this task

The way that you authorize access depends on the database manager that you are using, and the platform on which you have created the database. The instructions might also vary from release to release of a single database. Consult your database administrator, or see the documentation for the appropriate database when you perform this task.

The following sections provide examples of the steps that you can take to provide the required authorization for specific databases:

- "DB2 authorization"
- "Oracle authorization" on page 664

DB2 authorization:
About this task

To authorize access to a DB2 database, you can use either the DB2 Control Center or the DB2 command line:

Procedure

- To use the DB2 Control Center:
  1. Start the DB2 Control Center.
  2. Expand the object tree until you find the database that you created.
  3. Expand the tree under the database then click the **User and Group Objects** folder. The **DB Users** and **DB Groups** folders are displayed in the right pane.
  4. In the right pane, right-click the **DB Users** folder then click **Add**. The Add User notebook opens.
  5. From the list, click the user ID that you want to authorize to access the database (for example, `mqsiuid`). The user ID that you select must be the user ID that you specify to be used for access to this database when you run the **mqsisetdbparms** command. The user ID must exist on the operating system before you can select it; if it does not exist, define the user ID on the operating system.
  6. Select the appropriate options from the choices in the dialog box that is labeled **Choose the appropriate authorities to grant to the selected user** for the database. The following options are available:
     - Connect database
     - Create tables

- Create packages
- Register functions to run in database manager process

7. Click **OK**. The authorities are granted. The dialog box closes.
8. Close the DB2 Control Center.

- To use the DB2 command line:
  1. Open a DB2 command window.
  2. Connect to the database with a user ID that has DB2 system administration (SYSADM or DBADM) authority. Substitute the correct database and ID in the following example command:

     ```
     db2 connect to broker_db user SysAd_id
     ```

  3. Run the following command to grant the required privileges to the user ID that the broker will use to connect to the database. Substitute the correct ID for your broker in the following example command, if you are not using `mqsiuid`:

     ```
     db2 grant connect, createtab, bindadd, create_external_routine on
        database to user mqsiuid
     ```

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring databases for global coordination of transactions" on page 665.

Oracle authorization:
About this task

You must have database administrator (DBA) privileges to authorize access to an Oracle database.

To authorize access to an Oracle database:

Procedure

1. Log on as the Oracle database administrator (DBA) to the database using SQL*Plus.
2. Modify the privileges of the user ID that you have specified for database connection to ensure that the broker can successfully access the database.
3. If appropriate, increase the quota (disk space) available for table spaces associated with this database.

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring databases for global coordination of transactions" on page 665.

Related concepts:

"Message flow transactions" on page 1281
A transaction describes a set of updates that are made by an application program, which must be managed together. The updates might be made to one or more systems. The updates made by the program are controlled by the environment in which the program executes, and either all are completed, or none. This property of a transaction is known as *consistency*: transactions might have other properties of *atomicity*, *isolation*, and *durability*.

Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Related information:

DB2 V9.1 Information Center (distributed systems)

Configuring databases for global coordination of transactions:

If your message flow interacts with a user database, and you want to globally coordinate the updates made to the database with other actions within the message flow, configure your databases for global coordination.

Before you begin

Before you start: Create your database and authorize access to it.

About this task

If you restart a user database while the broker is still running, you must also restart the broker. The broker cannot detect that the database has stopped, and WebSphere MQ therefore retains its old connections to the database. When the database starts again, the broker tries, and fails, to use these connections.

To configure databases for coordinated message flows, follow the instructions relevant to your database manager:

- DB2
- Oracle
- Sybase

Configuring DB2 for global coordination of transactions:
Before you begin

You must complete these steps for databases that you connect to with an ODBC or a JDBC connection.

You must have database administrator (DBA) privileges to perform the following tasks.

About this task

To configure DB2 database instances for global coordination of transactions:

Procedure

1. Windows Linux Windows and Linux on x86 systems only: for each 32-bit instance that is involved in the global coordination, run the following commands to set the Transaction Process Monitor name (TP_MON_NAME) to MQ:

   ```
   db2 update dbm cfg using TP_MON_NAME MQ
   db2stop
   db2start
   ```

   UNIX Linux On Linux and UNIX systems (except for Linux on x86), do not set this variable for 32-bit or 64-bit instances.
2. Ensure that you have adequate connection resources and find out from the broker administrator whether the broker uses TCP/IP or shared memory to connect to databases.

   To use TCP/IP connections, see the example in the section about message SQL1224N in "Resolving problems when using databases" on page 3491.

   To enable extended shared memory:

   a. On the DB2 server, run the following commands:

      ```
      export EXTSHM=ON
      db2set DB2ENVLIST=EXTSHM
      db2stop
      db2start
      ```

   b. Ensure that shared memory support is enabled in the broker environment. For more information, see "Configuring global coordination with DB2" on page 700.
3. If you are connecting a broker on a distributed platform to a DB2 instance on z/OS, you must configure DB2 Connect™ to enable support for global coordination. Ensure that you have already configured a DB2 alias to represent the database by using DB2 Connect.

   Perform the following tasks on the system that hosts the broker:

   a. Turn on the Connection Concentrator by configuring the DB2 database manager configuration parameters so that the value of the **MAX_CONNECTIONS** parameter is greater than the value of the **MAX_COORDAGENTS** parameter:

      ```
      db2 update dbm cfg using MAX_CONNECTIONS max_connections_value
      ```

      where *max_connections_value* is greater than the existing value of the **MAX_COORDAGENTS** parameter.

   b. Define the SPM name as the name of the system that hosts the broker:

      ```
      db2 update dbm cfg using SPM_NAME host_name
      ```

      where *host_name* is the TCP/IP name of the system that hosts the broker.

   c. Stop, then restart DB2 on the system that hosts the broker to apply the changes:

      ```
      db2stop
      db2start
      ```

DB2 Connect is now configured to enable global coordination of message flows that are deployed to the broker (on a distributed platform) and that access DB2 on z/OS.

Results

The DB2 database instances are now configured for global coordination.

What to do next

Next: See "Configuring ODBC connections for globally coordinated transactions" on page 699.

Configuring Oracle for global coordination of transactions:
Before you begin

You must complete these steps for databases that you connect to with an ODBC connection only.

You must have database administrator (DBA) privileges to perform the following tasks.

About this task

To configure Oracle databases for global coordination of transactions:

Procedure

1. Ensure that the JAVA_XA package is present on the Oracle database by using, for example, the following Oracle SQLPLUS command:

   ```
   describe JAVA_XA;
   ```

   For more information, see the Oracle product documentation.
2. Ensure that the user ID that the broker uses to access the database has the necessary Oracle privileges to access the DBA_PENDING_TRANSACTIONS view. You can grant the required access by using, for example, the following Oracle SQLPLUS command:

   ```
   grant select on DBA_PENDING_TRANSACTIONS to userid;
   ```

Results

The Oracle databases are now configured for global coordination.

What to do next

Next: See "Configuring ODBC connections for globally coordinated transactions" on page 699.

Configuring Sybase for global coordination of transactions:
Before you begin

You must complete these steps for databases that you connect to with an ODBC connection only.

You must have database administrator (DBA) privileges to perform the following tasks.

Procedure

To configure Sybase databases for global coordination of transactions, ensure that the user ID that the broker uses to access the database has been granted the Sybase role of `dtm_tm_role`.

Results

The Sybase databases are now configured for global coordination.

What to do next

Next: See "Configuring ODBC connections for globally coordinated transactions" on page 699.

Related concepts:

"The transactional model" on page 1285
The transactional model describes the way in which you can use transactions in message flows to accomplish certain tasks and results.

Related tasks:

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

"Configuring ODBC connections for globally coordinated transactions" on page 699
Configure the definition of your ODBC databases to the transaction manager (the queue manager).

"Enabling ODBC connections to the databases"
Set up the resources and environment that the broker requires for Open Database Connectivity (ODBC) connections to user databases on distributed systems.

"Enabling JDBC connections to the databases" on page 683
Configure connections to a user database through a JDBCProvider service.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Related information:

WebSphere MQ Version 7 Information Center online

Enabling ODBC connections to the databases:

Set up the resources and environment that the broker requires for Open Database Connectivity (ODBC) connections to user databases on distributed systems.

About this task

You can configure both ODBC and Java Database Connectivity (JDBC) connections for access to user databases:

- To set up ODBC connections to user databases, follow the instructions in this section.

Optionally, after configuring the ODBC connection parameters, run the mqsicvp command to verify that the broker can connect to the data source, and to provide useful information about the data source and its interface.On Linux and UNIX systems, this command also checks that the ODBC environment is set up correctly.

- To set up JDBC connections to user databases, see "Enabling JDBC connections to the databases" on page 683.
- On z/OS systems, see "Data sources on z/OS" on page 4014 for information about enabling connections to databases. You do not have to follow the tasks described in this section.

Delete the ODBCINI64 environment variable if it exists; it is not required by WebSphere Message Broker Version 7.0.

For more information, see "User database connections" on page 2110.

The sample `odbc.ini` file that is supplied, and the information contained in these configuration topics, include all the connection parameters that are supported for connections to your databases. Any additional parameters that are provided by the DataDirect drivers are not tested or supported in a broker environment; consider your requirements carefully before specifying other parameters in your tailored ODBC `.ini` files.

To enable connections on distributed systems:

Procedure

Define the ODBC DSNs according to your platform:

Windows **On Windows:**
Follow the instructions in "Connecting to a database from Windows systems" on page 670.

Linux UNIX **On Linux and UNIX systems using the DataDirect Drivers:**
These drivers are used to access DB2, Informix, Oracle, Sybase, and SQLServer databases.

Follow the instructions in "Connecting to a database from Linux and UNIX systems using the DataDirect drivers" on page 674.

Linux UNIX **On Linux and UNIX systems using the WebSphere Message Broker Database Extender:**
Follow the instructions in "Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02)" on page 682.

You have now configured the ODBC DSNs for your user databases.

Results

You have now enabled the broker to make connections to your user databases.

What to do next

Next: If you have been using the instructions in "Working with databases" on page 2109, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 699 (optional).

Related concepts:

"User database connections" on page 2110
User databases contain business data that is written and accessed by deployed message flows. You must create connections from the broker to the user database by using ODBC or JDBC.

A copy of the sample DataDirect ODBC definition file that is supplied with WebSphere Message Broker.

"Sample WebSphere Message Broker ODBC Database Extender (IE02) configuration files" on page 3596
How you use WebSphere Message Broker ODBC Database Extender (IE02) to load the correct data source driver.

"**mqsicvp** command" on page 3857
Use the **mqsicvp** command to perform verification tests on a broker, or to verify ODBC connections.

Connecting to a database from Windows systems:

To enable a broker to connect to a database, define the ODBC data source name (DSN) for the database.

Before you begin

Before you start: check that you have set up your environment so that the broker can connect to the database. Most database managers set up the required environment when you install, but others supply a database profile that you must run. For information about environments and running database profiles, see Setting up a command environment: Windows platforms.

For 32-bit Data Flow Engines (DFEs), you must use the 32-bit ODBC driver manager to make the 32-bit ODBC definitions. Similarly, for 64 bit DFEs, you must

use the 64-bit ODBC driver manager to make the 64-bit ODBC definitions.

About this task

Configure an ODBC data source by using the ODBC Data Source Administrator:

1. Click **Start** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)**.

   If you are using 32-bit DFEs on Windows 64-bit systems, complete the following steps:

   a. Make a copy of **Data Sources (ODBC)**.
   b. Right-click the **Data Sources (ODBC)** shortcut and select properties.
   c. In the 64 bit ODBC dialogue, by default the target points to `%SystemRoot%\system32\odbcad32.exe`. Copy the shortcut, modify the target to point to `%SystemRoot%\SysWoW64\Odbcad32.exe`, and use the revised copy of the shortcut instead.

2. Click the **System DSN** tab and click **Add**.
3. Complete the steps in the following sections for the databases that you are working with.

   If you need more information about a particular database product, see the product-specific documentation.

DB2 UDB

Define a data source for DB2 UDB:

1. Select the driver `IBM DB2 ODBC DRIVER`.
2. Enter the data source name (DSN) and description.
3. Select the correct database alias from the list.
4. Click **Finish** to save your definition.
5. Click **OK** to close the ODBC Data Source Administrator.

You must register the data source as a system data source.

If you prefer, you can use the Configuration Assistant instead of the ODBC Data Source Administrator:

1. Open the DB2 Configuration Assistant.
2. Right-click the database and select **Change Database**.
3. Select **Data Source**.
4. Select **Register this database for ODBC**. Select the system data source option.
5. Click **Finish**.
6. The Test Connection dialog opens automatically and you can test the various connections.

Informix Dynamic Server

Define a data source for Informix Dynamic Server:

1. Select the driver `IBM INFORMIX ODBC DRIVER`.
2. On the **Connection** tab, specify:
   - The Informix server name.
   - The server host name.
   - The Informix network service name (as defined in the services file).
   - The network protocol (for example, `olsoctcp`).
   - The Informix data source name.
   - The user identifier to access the data source within.

- The password for that user identifier.

3. Click **Apply**.
4. Click **Test Connection** to check your supplied values.
5. Click **OK** to close the ODBC Data Source Administrator.

Microsoft SQL Server

Define a data source for Microsoft SQL Server:

1. Select the driver for the version of SQL Server that you are using:
   - `SQL Native Client` for SQL Server 2005.
   - `SQL Native Client` 10.0 for SQL Server 2008.
2. Specify a name and description.
3. Select the correct server from the list.
4. Click **Finish** to save your definition.
5. Click **OK** to close the ODBC Data Source Administrator.

Oracle

Define a data source for Oracle:

1.
   - If you are using WebSphere Message Broker for Windows 32-bit , select the driver `WebSphere Message Broker DataDirect Technologies 6.0 32-BIT Oracle Wire Protocol`.
   - If you are using WebSphere Message Broker for Windows 64-bit , select the driver `WebSphere Message Broker DataDirect Technologies 6.0 64-BIT Oracle Wire Protocol`.

   The ODBC Oracle Driver Setup dialog box opens.
2. On the **General** tab:
   a. Enter the DSN name, description, and host name of the machine where Oracle is running, the port number on which Oracle is listening, and the Oracle SID that you want to connect to.
3. On the **Advanced** tab:
   a. Select **Enable SQLDescribeParam**.
   b. Select **Procedure Returns Results**. The resultant ODBC definition in the Windows registry has a string value called **`ProcedureRetResults`** with the value `1`.
   c. Select **Login Timeout** and set the value to `0`.
4. Click **OK** to close the ODBC Data Source Administrator.
5. Click **Start** > **Run**.
6. Type `REGEDIT` in the **Open** field and click **OK**.
7. In the Registry Editor, navigate to the correct location.
   - If you are using WebSphere Message Broker for Windows 32-bit on Windows 32-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI`
   - If you are using WebSphere Message Broker for Windows 32-bit on Windows 64-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\ODBC\ODBC.INI`
   - If you are using WebSphere Message Broker for Windows 64-bit on Windows 64-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI`
8. Expand that location, and right-click your DSN entry. Select **New** > **String Value**.

9. Specify **WorkArounds** for the string name.
   a. Right-click **WorkArounds**.
   b. Select **Modify**.
   c. Type the data value `536870912`.
10. Close the Registry Editor.

Sybase Adaptive Server Enterprise

Define a data source for Sybase Adaptive Server Enterprise:

1.
   - If you are using WebSphere Message Broker for Windows 32-bit , select the driver `WebSphere Message Broker DataDirect Technologies 6.0 32-BIT Sybase Wire Protocol`.
   - If you are using WebSphere Message Broker for Windows 64-bit , select the driver `WebSphere Message Broker DataDirect Technologies 6.0 64-BIT Sybase Wire Protocol`.
2. Enter the DSN name, description, and network address of the server, where the network address is made up of **`MyHostMachineName,MyHostMachinePortNumber`**.
3. On the **Advanced** tab:
   - Select **Enable Describe Parameter**.
   - Select **Login Timeout** and set the value to `0`.
4. On the **Performance** tab:
   - Ensure that the **Prepare Method** setting is `1 - Partial`.
5. Click **Start** > **Run**.
6. Type `REGEDIT` in the **Open** field and click **OK**.
7. In the Registry Editor, navigate to the correct location:
   - If you are using WebSphere Message Broker for Windows 32-bit on Windows 32-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI`
   - If you are using WebSphere Message Broker for Windows 32-bit on Windows 64-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\ODBC\ODBC.INI`
   - If you are using WebSphere Message Broker for Windows 64-bit on Windows 64-bit editions: `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI`
8. Expand that location, and right-click your DSN entry. Select **New** > **String Value**. Specify **SelectUserName** for the string, and set the value to `1`.
9. Right-click your DSN again, and select **New** > **String Value**. Specify **EnableSPColumnTypes** for the string, and set the value to `2`.
10. Right-click your DSN again, and select **New** > **String Value**. Specify **TimestampTruncationBehavior** for the string, and set the value to `1`.
11. Right-click your DSN again, and select **New** > **String Value**. Specify **XAConnOptBehaviour** for the string, and set the value to `3`.
12. Close the Registry Editor.

solidDB

Define a data source for solidDB:

1. Select the driver IBM solidDB - (Unicode) DRIVER.
2. Enter the description.

3. Enter the communication port in the network location field, for example, `tcp 2315`.
4. Click **Finish** to save your definition.
5. Click **OK** to close the ODBC Data Source Administrator.

The solidDB is only supported on Windows 32-bit operating systems.

Results

You have now configured your ODBC data source names on Windows.

What to do next

Next: Configure the environment for issuing console commands, and for running the broker, so that the broker can access the required database libraries. For more information, see "Setting your environment to support 32-bit access to databases" on page 681.

Related tasks:

"Setting up a command environment" on page 213
After you have installed the product on one of the distributed systems, you must initialize the environment before you can use a runtime component or command.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

Connecting to a database from Linux and UNIX systems using the DataDirect drivers:

To enable a broker to connect to a database, define the ODBC data source name (DSN) for the database.

Before you begin

The following information is for DB2, Informix, Oracle, Sybase, and SQLServer databases only. For all other supported databases, see "Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02)" on page 682.

Before you start:
- Ensure that the database has been created, see "Creating the user databases" on page 661.
- Ensure that the broker is authorized to access the database, see "Authorizing access to user databases" on page 662.
- Check that you have set up your environment so that the broker can access the database; you might have to run a database profile supplied by the database vendor. For further information, see Setting up a command environment: Linux and UNIX systems.

Procedure

1. Copy the `odbc.ini` sample file that is supplied in the `install_dir/ODBC/V6.0` directory to a location of your choice. For example, copy the file to `/var/mqsi` which is the user directory for WebSphere Message Broker, and the preferred location for this copied file. Each broker service user ID on the system can therefore use its own DSN definitions.

See the sample file contents in "Sample DataDirect odbc.ini file" on page 3660.

2. Ensure that the `odbc.ini` file has file ownership of `mqm:mqbrkrs` and has the same permissions as the supplied sample file.
3. Set the ODBCINI environment variable to point to your `odbc.ini` file, specifying a full path and file name. Make sure that you point to the copy, do not point to the `odbc.ini` file in the installation directories.
4. If you are connecting to DB2 or Informix databases, set the library search path environment variable to show the location of the libraries for the database manager that you are using.

   For more information about the library search path, ask your database administrator (DBA), or see the documentation for your database manager.

   The library search path environment variable depends on your platform:

   - Linux Solaris On Linux and Solaris, set LD_LIBRARY_PATH.
   - HP-UX On HP-UX, set SHLIB_PATH.
   - AIX On AIX, set LIBPATH.

   Updates to the library search path are not required for other supported databases.
5. If you are using a DB2 database instance that is installed on AIX, a single process can make a maximum of 10 connections that use shared memory to a DB2 database. Use TCP/IP mode to connect to the database instance; see "DB2 error message SQL1224N is issued when you connect to DB2" on page 3494.
6. Edit the final stanza in the `odbc.ini` file, the [ODBC] stanza, to specify the location of the ODBC Driver Manager and to control tracing. The exact details in the stanza depend on the platform.

   To ensure that you edit the correct `odbc.ini` file, you can open the file in the vi text editor by using the following command:

   ```
   vi $ODBCINI
   ```

   a. In **InstallDir**, add the WebSphere Message Broker installation location to complete the fully qualified path to the ODBC directory. If you do not specify this value correctly, the ODBC definition does not work.

   b. In **TraceFile**, type the fully qualified path and file name to which the ODBC trace is written. Trace files can become large; specify a directory with plenty of free disk space.

   c. In **TraceDll**, add the WebSphere Message Broker installation location to complete the fully qualified path to the ODBC trace DLL.

   d. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

      For example on AIX:

      ```
      ;########################################
      ;###### Mandatory information stanza ######
      ;########################################

      [ODBC]
      ;# To turn on ODBC trace set Trace=1
      Trace=0
      TraceOptions=3
      TraceFile=<A Directory with plenty of free space to hold trace
      output>/odbctrace.out
      TraceDll=<Your Broker install directory>/ODBC/V6.0/lib/odbctrac.so
      InstallDir=<Your Broker install directory>/ODBC/V6.0
      UseCursorLib=0
      IANAAppCodePage=4
      UNICODE=UTF-8
      ```

7. Edit the first stanza in the odbc.ini file, the [ODBC Data Sources] stanza, to list the DSN of each database.

   For example on AIX:

   ```
   ;########################################
   ;###### List of data sources stanza #######
   ;########################################
   [ODBC Data Sources]
   DB2DB=IBM DB2 ODBC Driver
   ORACLEDB=DataDirect 6.0 Oracle Wire Protocol
   ORACLERACDB=DataDirect 6.0 Oracle Wire Protocol (Real Application Clusters)
   SYBASEDB=DataDirect 6.0 Sybase Wire Protocol
   SYBASEDBUTF8=DataDirect 6.0 Sybase UTF8 Wire Protocol
   SQLSERVERDB=DataDirect 6.0 SQL Server Wire Protocol
   INFORMIXDB=IBM Informix ODBC Driver
   ```

   List all your DSNs in your odbc.ini file, regardless of the database manager. On Oracle and Sybase, you can define multiple DSNs to resolve to the same database; however, if you are using global coordination of transactions, do not use this option because it might cause data integrity problems.

8. For each database that you listed in the [ODBC Data Sources] stanza, create a stanza in the odbc.ini file after the [ODBC Data Sources] stanza. The entries in the stanza depend on the database manager. Slight differences also occur between operating systems, for example the file paths to the drivers.

   For a DB2 database instance:

   For Linux on x86:

   a. In **Driver**, add the full path of your DB2 installation.
   b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.
   c. In **Database**, type the DB2 alias. The data source name must be the same as the database alias name. If you are using a remote DB2 database, you must set up your client-server connection to resolve this alias to the correct database.

      If the requirement is to have multiple stanzas that refer to the same DB2 database, aliases must be created in DB2 by using the DB2 CATALOG command. These aliases can then have their own stanza in the ODBCINI file.

      The ODBCINI file cannot be used to set up aliases for DB2.

      For more information, see the DB2 documentation.

      For example:

      ```
      ;# DB2 stanza
      [DB2DB]
      Driver=<Your DB2 install directory>/lib32/libdb2.so
      Description=DB2 ODBC Database
      Database=DB2DB
      ```

   For all other platforms:

   a. In **Driver**, accept the value as shown in the sample odbc.ini file.
   b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.
   c. In **Database**, type the DB2 alias. The data source name must be the same as the database alias name. If you are using a remote DB2 database, you must set up your client-server connection to resolve this alias to the correct database. For more information, see the DB2 documentation.

If the requirement is to have multiple stanzas that refer to the same DB2 database, aliases must be created in DB2 by using the DB2 CATALOG command. These aliases can then have their own stanza in the ODBCINI file.

The ODBCINI file cannot be used to set up aliases for DB2.

For example, on AIX:

```
;# DB2 stanza
[DB2DB]
DRIVER=libdb2Wrapper.so
Description=DB2DB DB2 ODBC Database
Database=DB2DB
```

For an Oracle database:

For all platforms:

a. In **Driver**, add the WebSphere Message Broker installation location to complete the fully qualified path to the driver shown in the sample `odbc.ini` file.

b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In **HostName**, type the name or IP address of the machine that is hosting your Oracle system.

d. In **PortNumber**, type the number of the port on which your Oracle server is listening on the machine you specified in **HostName**.

e. In **SID**, type the Oracle service name that you want to connect to on the system you specified in **HostName**.

f. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example on AIX:

```
;# Oracle stanza
[ORACLEDB]
Driver=<Your Broker install directory>/ODBC/V6.0/lib/UKora24.so
Description=DataDirect 6.0 Oracle Wire Protocol
HostName=<Your Oracle Server Machine Name>
PortNumber=<Port on which Oracle is listening on HostName>
SID=<Your Oracle SID>
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
```

For an Oracle database that uses Real Application Clusters:

For all platforms:

a. In **Driver**, add the WebSphere Message Broker installation location to complete the fully qualified path to the driver shown in the sample `odbc.ini` file.

b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In **HostName**, type the name or IP address of the machine that is hosting your primary (preferred) Oracle instance.

d. In **PortNumber**, type the number of the port on which your Oracle server is listening on the machine you specified in **HostName**.

e. In **ServiceName**, type the Oracle Real Application Cluster service name that you want to connect to on the instance you specified in **HostName**.

f. In **AlternateServers**, provide a list of alternative locations for this service for situations when the primary location, defined in **HostName**, is unavailable. Each location specification consists of three parts, separated by colons. Enter these values as one continuous string; the text in this example has been split to improve readability.

```
HostName=<Alternative host name>
:PortNumber=<Oracle listner port on alternative server>
:ServiceName=<Service name on the alternative server>
```

If you want to specify more than one AlternateServer, separate each additional location specification with a comma. Whenever a new database connection is required, for example after an Oracle instance failover, the primary location will be tried first. However, if the primary location is unavailable, the driver will try the list of alternative locations in turn.

g. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example on AIX:

```
;# Oracle Real Application Clusters stanza
[ORACLERACDB]
Driver=<Your Broker install directory>/ODBC/V6.0/lib/UKora24.so
Description=DataDirect 6.0 Oracle Wire Protocol
HostName=<Your Oracle Server Machine Name>
PortNumber=<Port on which Oracle is listening on HostName>
ServiceName=<Your Oracle Real Application Cluster Service Name>
AlternateServers=(HostName=<Your alternative host name>:PortNumber=<Port on
which Oracle is listening on the alternative host>:ServiceName=<Your
Oracle Real Application Cluster Service Name>)
CatalogOptions=0
EnableStaticCursorsForLongData=0
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
WorkArounds=536870912
ProcedureRetResults=1
ColumnSizeAsCharacter=1
LoginTimeout=0
```

For a Sybase database:

For all platforms except Linux on IBM z Systems:

a. In **Driver**, add the WebSphere Message Broker installation location to complete the fully qualified path to the driver shown in the sample `odbc.ini` file.

b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In **Database**, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database defined by your system administrator for each user.

d. In **NetworkAddress**, type the network address of your Sybase ASE server (this address is required for local and remote databases). Specify an IP address or server name as follows:

```
<Your Sybase server name or IP address>,<Your Sybase port number>
```

For example: `Sybaseserver,5000`. You can also specify the IP address directly, for example `199.226.224.34,5000`. You can find the port number in the Sybase interfaces file that is named `interfaces`.

e. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example on AIX:

```
;# Sybase Stanza
[SYBASEDB]
Driver=<Your Broker install directory>/ODBC/V6.0/lib/UKase24.so
Description=DataDirect 6.0 Sybase Wire Protocol
Database=<Your Database Name>
ApplicationUsingThreads=1
EnableDescribeParam=1
OptimizePrepare=1
SelectMethod=0
NetworkAddress=<Your Sybase Server Name>,<Your Sybase Port Number>
SelectUserName=1
ColumnSizeAsCharacter=1
EnableSPColumnTypes=2
LoginTimeout=0
TimestampTruncationBehavior=1
XAConnOptBehaviour=3
```

If you want to use a UNICODE UTF8 Sybase data source, add the following line to the end of your Sybase stanza:

```
Charset=UTF8
```

For remote access to an SQL Server database

For all platforms except Linux on POWER, Linux on IBM z Systems, and Solaris on x86-64:

a. In **Driver**, add the WebSphere Message Broker installation location to complete the fully qualified path to the driver shown in the sample `odbc.ini`.

b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.

c. In **Address**, either:

1) Specify an IP address or server name and a port number to locate the SQLServer database you want to connect to, as follows:

```
<Your SQLServer machine name or IP address>,<Your SQLServer port number>
```

or

2) Specify an IP address or server name and an instance name to locate the SQLServer database you want to connect to, as follows:

```
<Your SQLServer machine name or IP address>\<Your SQLServer instance name>
```

If your instance name is blank, specify `<Your SQLServer machine name or IP address>`

d. In **Database**, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database defined by your system administrator for each user.

e. Accept the default values shown in the sample `odbc.ini` file for all the other entries in the stanza.

For example, on AIX:

```
;# UNIX to SQLServer stanza
[SQLSERVERDB]
Driver=<Your Broker install directory>/ODBC/V6.0/lib/UKmsss24.so
Description=DataDirect 6.0 SQL Server Wire Protocol
Address=<Your SQLServer Machine Name>,<Your SQLServer Port Number>
;# Alternative way to locate server using a named instance
;# Address=<Your SQLServer Machine Name>\<Your SQLServer Instance Name>
AnsiNPW=Yes
Database=db
QuotedId=No
ColumnSizeAsCharacter=1
```

For an Informix database

For Linux on x86

a. In **Driver**, add the full path of your Informix Client library.
b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.
c. In **ServerName**, type the name of the Informix IDS server.
d. In **Database**, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

   For example

```
;# Informix Stanza
[INFORMIXDB]
Driver=<Your Informix Client Directory>/lib/cli/iclit09b.so
Description=IBM Informix ODBC Driver
ServerName=<Your Informix Server Name>
Database=<Your Database Name>
```

For all other platforms:

a. In **Driver**, accept the value as shown in the sample `odbc.ini` file.
b. In **Description**, type a meaningful description of the database. This field is for information only and does not affect the connection.
c. In **ServerName**, type the name of the Informix IDS server.
d. In **Database**, type the name of the database to which you want to connect by default. If you do not specify a value, the default value is the database that is defined by your system administrator for each user.

   For example, on AIX:

```
;# Informix Stanza
[INFORMIXDB]
Driver=libinfWrapper.so
Description=IBM Informix ODBC Driver
ServerName=<Your Informix Server Name>
Database=<Your Database Name>
```

9. Ensure that you have edited all three parts of the `odbc.ini` file:
   - The [ODBC Data Source] stanza at the top of the `odbc.ini` file.
   - A stanza for each data source.
   - The [ODBC] stanza at the end of the `odbc.ini` file.

   If you do not configure all three parts correctly, the ODBC DSNs do not work and the broker is unable to connect to the database.

Results

You have now configured database connections on Linux and UNIX. You can check that the ODBC environment is configured correctly by running the **mqsicvp** command. For more information, see "**mqsicvp** command" on page 3857.

Setting your environment to support 32-bit access to databases:

When you have configured your ODBC data source names (DSNs), you must also configure the environment so that you can issue console commands, and the brokers that you start can access the required database libraries. For example, if you have a DB2 database, you must add the DB2 client libraries to your library search path.

About this task

Windows On Windows platforms, the environment is typically set up for you when you install the database product, and no further action is required. However, some database managers provide a database profile that you must run to enable the connection from the broker; for further information, see Setting up a command environment: Windows platforms.

Linux UNIX On Linux and UNIX systems, run a profile for each database you want to access. For example, on DB2 you must run `db2profile`; other database vendors have similar profiles. For further information, see Setting up a command environment: Linux and UNIX systems.

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 699 (optional).

Connecting to a database from Linux and UNIX systems using the WebSphere Message Broker ODBC Database Extender (IE02):

WebSphere Message Broker ODBC Database Extender encapsulates the unixODBC driver manager and this topic describes how you set up and configure the broker to use it.

Before you begin

Before you start:

Read the information about the unixODBC Project and the IBM solidDB product family.

About this task

WebSphere Message Broker ODBC Database Extender is required when using WebSphere Message Broker to interface with an ODBC data source that is not supported through the DataDirect ODBC drivers.

Procedure

To configure the broker:

1. Make a copy of the sample `odbc.ini` file supplied in `install_dir/ODBC/unixodbc/odbc.ini`, where `install.dir` is the directory in which you installed WebSphere Message Broker. For example, copy the file to `/var/mqsi` which is the user directory for WebSphere Message Broker, and the preferred location for this copied file.
2. Set up the environment variable `ODBCUOINI` to point to the full path and name of this file. Make sure that you point to the copy, do not point to the `odbc.ini` file in the installation directories.
3. Make a copy of the sample `odbcinst.ini` file supplied in `install_dir/ODBC/unixodbc/odbcinst.ini`, where `install.dir` is the directory in which you installed WebSphere Message Broker. For example, copy the file to `/var/mqsi` which is the user directory for WebSphere Message Broker, and the preferred location for this copied file.
4. Set up the environment variable `ODBCSYSINI` to point to the directory containing your `odbcinst.ini` file. Make sure that you point to the copy, do not point to the `odbcinst.ini` file in the installation directories.

For information about how to populate the configuration files see "Sample WebSphere Message Broker ODBC Database Extender (IE02) configuration files" on page 3596

Enabling JDBC connections to the databases:

Configure connections to a user database through a JDBCProvider service.

About this task

Use a JDBC connection from Java programs that are associated with a JavaCompute node or a user-defined node that is written in Java.

You must also set up JDBC connections if your message flows include DatabaseRetrieve or DatabaseRoute nodes.

If you configure a JDBC type 4 connection from an application running on a Linux, UNIX, or Windows system, you can configure your broker and queue manager to include interactions with the databases in globally-coordinated transactions. On z/OS, JDBC connections can be broker-coordinated only.

The information provided in this section is independent of whether your operating systems, brokers, execution groups, queue managers, and databases operate in 32-bit or 64-bit mode, except where stated.

When you write Java classes for a JavaCompute node or a user-defined node, your code must comply with the following restrictions:

- Do not include any code that performs a COMMIT or a ROLLBACK function.
- Do not close the connection to the database. The broker manages all connections, and closes a connection if it is idle for approximately one minute, or if the message flow completes.

To configure JDBC type 4 connections:

Procedure

1. Set up your JDBC provider definition.
2. Optional: Set up security.
3. Optional: Configure for global-coordination of transactions.
4. Optional: If your broker is running on a Windows system, authorize access to JDBCProvider resources.

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Setting up a JDBC provider for type 4 connections" on page 684.

When you have completed configuration of the databases, add or modify Java code in your JavaCompute or user-defined nodes to access the database that is identified in the JDBCProvider service.

Related concepts:

"Databases overview" on page 2109
Brokers can access *user databases* to manipulate your business data. If you have user databases, you must configure them before you can access them from your message flow.

Setting up a JDBC provider for type 4 connections:

Use the **mqsicreateconfigurableservice** or the **mqsichangeproperties** command to configure a JDBC provider service.

Before you begin

Before you start:

- Create a broker
- Create your database following the database documentation.

About this task

When you include a DatabaseRetrieve, DatabaseRoute, JavaCompute, Mapping, or Java user-defined node in a message flow, and interact with a database in that node, the broker must establish a connection with the database to fulfill the operations that are performed by the node. You must define a JDBCProvider configurable service to provide the broker with the information that it needs to complete the connection.

A JDBCProvider configurable service supports connections to one database only; you must create a service for each database that your nodes or Java applications connect to.

To set up a JDBC provider for type 4 connections by using the WebSphere Message Broker Explorer, see "Creating a new configurable service" on page 645.

To set up a JDBC provider for type 4 connections by using the **mqsicreateconfigurableservice** or **mqsichangeproperties** commands, complete the following steps:

Procedure

1. Identify the type of database for which you require a JDBCProvider service.

Supported JDBC drivers and databases are shown in "Supported databases" on page 3591; support for globally coordinated (XA) transactions is restricted on some platforms and for some databases.

2. Run the **mqsireportproperties** command to view the list of available JDBCProvider services. Substitute the name of your broker in place of *broker_name*.

```
mqsireportproperties broker_name -c JDBCProviders -a -o AllReportableEntityNames
```

The command response lists all the JDBCProvider configurable services that are defined. If you have not created your own definitions, the following list of default supplied services is shown:

- DB2
- Informix
- Informix_With_Date_Format
- Microsoft_SQL_Server
- Oracle
- Sybase_JConnect6_05

If you are connecting to an Informix database:

- Use Informix_With_Date_Format for compatibility with client applications that are dependent on the date format connection attribute that was used by earlier versions of Informix servers.
- Use Informix for client applications that are not dependent on the date format attribute.

3. View the contents of the relevant JDBCProvider service definition. For example, run the following command to display the supplied Oracle definition:

```
mqsireportproperties broker_name -c JDBCProviders -o Oracle -r
```

The command response lists all the properties for the Oracle definition. If you have not changed this definition, the properties are set to initial values, some of which you must change to create a viable definition. For example, the property **databaseName** is set to `default_Database_Name`, and you must change it to identify the specific database that you want to connect to.

A JDBCProvider service has the following properties:

- **connectionUrlFormat**. A pattern that represents the connection URL definition, which is specific to a particular database type. For example, the pattern for DB2 is defined with the following content:

  ```
  jdbc:db2://[serverName]:[portNumber]/[databaseName]:user=[user];password=[password];
  ```

  The pattern is used and completed by the broker at run time when it connects to the database. The values in brackets, for example `[serverName]`, are substituted by the broker into the pattern by using the values that you have specified on the **mqsicreateconfigurableservice**, **mqsichangeproperties**, or **mqsisetdbparms** commands.

  The following values and order of preference are used by the broker to substitute the user ID and password in the pattern:

  a. First, on all platforms: The user ID and password that you have set for the specific database, by using the **mqsisetdbparms** and specifying the database in the **-n** parameter.

  b. Second, on all platforms: The user ID and password that you have set for all other databases, by using the **mqsisetdbparms** and specifying `jdbc::JDBC` in the **-n** parameter.

  c. Third, the values are platform-specific:

     1) Windows On Windows: The broker service ID and password that you specified on the **mqsicreatebroker** command.

2) Linux UNIX On Linux and UNIX: The user ID `mqsiUser` and password `********` (these values are fixed).

3) z/OS On z/OS: The user ID `""` and password `""`.

If you are using one of the supplied JDBCProvider services, do not use the **mqsichangeproperties** command to change the pattern itself; changes made to the pattern might cause unpredictable results.

If you use the **mqsicreateconfigurableservice** command to define your own JDBCProvider service, use the **mqsireportproperties** command to check that the content of the **connectionUrlFormat** string exactly matches the default supplied provider for the database type that you are using.

In addition, if you are working on z/OS, and are using the JCL files BIPCRCS and BIPCHPR to define your JDBCProvider service, ensure that your 3270 emulator is configured to use the same code page that the broker is running in. If the code pages do not match, the **connectionUrlFormat** string pattern that you define might not be recognized correctly by the broker.

- **connectionUrlFormat Attr1-5**. If the defined URL pattern for a database contains non-standard JDBC data source properties, such as a server identifier, specify these properties in addition to the standard attributes by using one of five general-purpose connection URL attributes. For example:
  - If **connectionURLFormat** = `jdbc:oracle:thin:[user]/[password]@[serverName]:[portNumber]:[connectionUrlFormatAttr1]`, **connectionUrlFormatAttr1** must contain an Oracle server identifier, which you must supply by defining the value for the property **connectionUrlFormatAttr1** on the **mqsicreateconfigurableservice** or **mqsichangeproperties** command. The broker can then substitute all the required values into the required pattern.
  - If **connectionURLFormat** = `jdbc:informix-sqli://[serverName]:[portNumber]/[databaseName]:informixserver=[connectionUrlFormatAttr1];user=[user];password=[password]`, **connectionUrlFormatAttr1** must contain the name of the Informix instance on the server (typically specified by the INFORMIXSERVER environment variable). This value is case-sensitive.
- **databaseName**. The name of the database to which the data source entry enables connections; for example, `employees`.
- **databaseType**. The database type; for example, `DB2`.
- **databaseVersion**. The database version; for example, `9.1`.
- **description**. An optional property to describe the data source definition.
- **environmentParms**. ForDB2 only. An optional property specifying a list of data source properties of the form `name=value` each separated by a semicolon.
- **jarsURL**. The local directory path, on the system on which the broker is running, where the JAR file that contains the type 4 driver class is located.

  In addition, a storage area network disk can be used for the directory path, but a mapped network drive to a remote computer cannot be used.
- **maxConnectionPoolSize**. Optionally set this property to create a JDBC connection pool. For more information, see “Using a JDBC connection pool to manage database resources used by an execution group” on page 1003.
- **portNumber**. The port number on which the database server is listening; for example, `50000`.

- **securityIdentity**. A unique security key to perform a second broker registry lookup to find an entry under the broker security identities, which store the encrypted password for the user on the associated host system; for example, `mysecurityIdentity`.

  Create a security identity by using the **mqsisetdbparms** command, as described in "Securing a JDBC type 4 connection" on page 689. The value of **securityIdentity** (for example, `mysecurityIdentity`) must match the value that you specify following the prefix `jdbc::` for the parameter **-n** on that command.

  The security identity provides a user ID and password value pair, which are used to access the specified data source defined for a particular JDBCProvider service entry. This property is ignored if the connection URL does not contain both a user ID and password pair, which require property values to be substituted for such inserts.

  The default values, which you can set by specifying a **ResourceName** of `jdbc::JDBC` on the **mqsisetdbparms** command, are used under the following conditions:

  – If the **securityIdentity** is blank, or if you have not changed it from the default value `default_User@default_Server`, but the identity is required for the connection URL pattern.

  – If you have entered a valid unique security identity key, but it cannot be found under the DSN key.

- **serverName**. The name of the server; for example, `host1`.
- **type4DatasourceClassName**. The name of the JDBC data source class name that is used to establish a type 4 connection to a remote database, and to coordinate transaction support. For example, specify `com.ibm.db2.jcc.DB2XADataSource` for DB2, or specify `oracle.jdbc.xa.client.OracleXADataSource` for Oracle. You must specify the XA class name when using the **getJDBCType4Connection()** API call for coordinated transactions. If the database server does not support XA transactions, or you do not want to use the XA protocol, this property is optional and you must set the **jdbcProviderXASupport** property to false.
- **type4DriverClassName**. The name of the JDBC type 4 driver class name that is used to establish a connection. For example, specify `com.ibm.db2.jcc.DB2Driver` for DB2, or specify `oracle.jdbc.OracleDriver` for Oracle.
- **jdbcProviderXASupport**. An optional property that controls whether the broker connects to a database server using the XA Protocol. By default this property is set to true. If the database server is not enabled for XA Support, or coordinated transactions are not required, set the value to false. In which case the type 4 driver specified using the **type4DriverClassName** property is used, instead of the type 4 datasource specified in the **type4DatasourceClassName** property.

4. If you want to use the provided definition, run the **mqsichangeproperties** command to replace default values with the values specific to your database and environment. If you are in any doubt about the required values, consult your database administrator, or check the documentation that is provided with your chosen database. Some values depend on how and where you have installed the database product; for example, the property **jarsURL** identifies the location of the JAR files supplied and installed by the database provider.
5. If you want to create a new configurable service, perhaps because you want to retain the supplied service as a template for future definitions, run the **mqsicreateconfigurableservice** command to create the definition.

```
mqsicreateconfigurableservice broker_name -c JDBCProviders -o provider_name
-n list of properties -v list of values
```

Enter the command on a single line; the example is split to enhance readability.

Specify all the properties that are required by the database provider that you have chosen. To specify a list of properties and values, separate the items after each flag with a comma. For example, `-n databaseName,databaseType -v EmployeeDB,DB2`. If you do not specify all the properties on the **mqsicreateconfigurableservice** command, you can update them later with the **mqsichangeproperties** command.

6. When you have set up or modified your JDBCProvider service, you must reload any execution groups which currently use, or intend to use, the JDBCProvider service.

What to do next

Next: If required, set up security for the JDBC connection, set up the environment to include the JDBCProvider service in globally coordinated transactions, or both.

Securing a JDBC type 4 connection:

Set up security for the JDBC connection if required by the database provider.

Before you begin

Before you start: Set up your JDBC provider definition.

About this task

Some databases require all access to be associated with a known user ID; for others this association is optional. For example, DB2 requires a data source login name and password on all connections. If the database requires secure access to be defined, or if you choose to implement security in an optional situation, complete the task described here.

Procedure

1. Identify the user ID that you want to associate with the JDBC connection, or create a user ID with a password, following the appropriate instructions for your operating system and database.
2. Run the **mqsisetdbparms** command to associate the user ID and password with the security identity that is associated with the database that you will access using the JDBCProvider configurable service.

   The following values and order of preference are used by the broker for the JDBC connection:

   a. First, on all platforms: The user ID and password that you have set for the specific database, by using the **mqsisetdbparms** and specifying the database in the **-n** parameter.
   b. Second, on all platforms: The user ID and password that you have set for all other databases, by using the **mqsisetdbparms** and specifying `jdbc:JDBC` in the **-n** parameter.
   c. Third, the values are platform-specific:
      1) Windows On Windows: The broker service ID and password that you specified on the **mqsicreatebroker** command.
      2) Linux UNIX On Linux and UNIX: The user ID `mqsiUser` and password `********` (these values are fixed).
      3) z/OS On z/OS: The user ID `""` and password `""`.

   Use the following command format:

```
mqsisetdbparms broker_name -n security_identity -u userID -p password
```

   For example, if you want user ID `myuserid` with a password of `secretpw` to access a database on broker BROKER1, run the following command:

```
mqsisetdbparms BROKER1 -n jdbc::mySecurityIdentity -u myuserid -p secretpw
```

In the example, the *mySecurityIdentity* is prefixed with `jdbc::` to indicate the type of the connection for which the user ID and password are defined.

If you want to use the same user ID and password for more than one database, you can specify a resource name of `jdbc::JDBC` on this command, as shown in the following example:

```
mqsisetdbparms BROKER1 -n jdbc::JDBC -u defaultuid -p defaultpw
```

3. Update the corresponding **securityIdentity** property for the JDBCProvider configurable service to associate the connection with the security identity that you have defined. Use the following command format:

```
mqsichangeproperties broker_name -c JDBCProviders -o service_name -n securityIdentity -v security_identity
```

For example, if you are using the supplied JDBCProvider definition for Oracle:

```
mqsichangeproperties BROKER1 -c JDBCProviders -o Oracle -n securityIdentity -v mySecurityIdentity
```

You can use the same user ID and password definition for more than one JDBCProvider service if appropriate; specify the same security identity that you specified on the **mqsisetdbparms** command as the value for the **securityIdentity** property in each JDBCProvider service definition that uses the same access security. If you are using a default user ID and password that you have defined by specifying a **ResourceName** of `jdbc::JDBC` on the **mqsisetdbparms** command, do not change this property; retain the default value `default_User@default_Server` to cause the broker to use the default values that you have set.

What to do next

Next: if you are setting up a connection on Windows, see "Authorizing access to JDBC type 4 JDBCProvider resources on Windows" on page 694. Otherwise, see "Configuring a JDBC type 4 connection for globally coordinated transactions" on page 691.

Configuring a JDBC type 4 connection for globally coordinated transactions:

If you want the database that you access through a JDBC type 4 connection to participate in globally coordinated transactions, set up the appropriate environment.

Before you begin

Before you start: Set up your JDBC provider definition.

About this task

Updates that you make to a database across a JDBC type 4 connection can be coordinated with other actions taken within the message flow, if you set up the resources to support coordination.

Complete the following steps:

Procedure

1. Check that the definition of your JDBCProvider service is appropriate for coordinated transactions.

   For example, to set up the required JDBC classes:

   - For DB2, set **type4DatasourceClassName** to `com.ibm.db2.jcc.DB2XADataSource` and **type4DriverClassName** to `com.ibm.db2.jcc.DB2Driver`
   - For Oracle, set **type4DatasourceClassName** to `oracle.jdbc.xa.client.OracleXADataSource` and **type4DriverClassName** to `oracle.jdbc.OracleDriver`

   Consult your database administrator or the documentation provided by your database supplier, to confirm that all the JDBCProvider service properties are set appropriately. For example, a database supplier might require secure access if it is participating in coordinated transactions.

2. Define the switch file and the database properties:

   a. Linux UNIX On Linux and UNIX systems, open the `qm.ini` file for the broker queue manager with a text editor. Add the following stanza for each database:

   ```
   XAResourceManager:
          Name=Database_Name
          SwitchFile=JDBCSwitch
          XAOpenString=JDBC_DataSource
          ThreadOfControl=THREAD
   ```

   Database_Name is the database name (DSN) of the database defined to the JDBCProvider configurable service (for example, specified by `-n databaseName -v` *Database_Name* on the **mqsichangeproperties** command).

   `JDBCSwitch` is a fixed generic name that represents the switch file for XA coordination. Use this value, or another single fixed value, in each stanza; the specific switch file that the queue manager uses is defined by the symbolic links you create in the next step.

   JDBC_DataSource is the identifier of the JDBCProvider configurable service (the value that you specified for the **-o** parameter on the **mqsichangeproperties** command).

   Define a stanza for each database (DSN) that you connect to from this broker. You must create separate definitions even if the DSNs resolve to the same physical database. Therefore, you must have a stanza for each JDBCProvider configurable service that you have defined, because each service can define the properties for a single database.

   b. Windows On Windows on x86 systems, open WebSphere MQ Explorer and select the queue manager for your broker, for example BROKERQM.

   Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

   Enter the fully qualified file name in **SwitchFile**; *install_dir*`\bin\JDBCSwitch.dll`.

   c. Windows On Windows on x86-64 systems, open WebSphere MQ Explorer and select the queue manager for your broker, for example BROKERQM.

   Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

   Enter *JDBCSwitch* in **SwitchFile**.

3. Set up queue manager access to the switch file:

   a. Linux UNIX On Linux and UNIX systems, create a symbolic link to the switch files that are supplied in your *install_dir*`/lib` directory.

   install_dir is the directory to which you installed the Broker component. The default location for this directory is `/opt/ibm/mqsi/`*v.r* on Linux, or `/opt/IBM/mqsi/`*v.r* on UNIX systems. The default directory includes the version and release of the product, in the format v.r (version.release).

   Set up links in the `/var/mqm/exits` directory, or the `/var/mqm/exits64` directory, or both. The file names for each platform are shown in the following table.

Platform	32-bit file	64-bit file
AIX		libJDBCSwitch.so
HP-Itanium		libJDBCSwitch.so
Linux on POWER		libJDBCSwitch.so
Linux on IBM z Systems		libJDBCSwitch.so
Linux on x86	libJDBCSwitch.so	
Linux on x86-64		libJDBCSwitch.so
Solaris on SPARC		libJDBCSwitch.so
Solaris on x86-64		libJDBCSwitch.so

Specify the same name of the switch file, JDBCSwitch or your own value, in both the /exits and /exits64 directories. For example, on AIX:

```
ln -s install_dir/lib/libJDBCSwitch.so /var/mqm/exits/JDBCSwitch

and

ln -s install_dir/lib/libJDBCSwitch.so /var/mqm/exits64/JDBCSwitch
```

b. Windows On Windows, for the 32-bit version of WebSphere Message Broker, copy the JDBCSwitch.dll file from the *install_dir*\bin directory to the \exits subdirectory in the WebSphere MQ installation directory.

c. Windows On Windows, for the 64-bit version of WebSphere Message Broker, copy the JDBCSwitch32.dll file from the *install_dir*\bin directory to the \exits subdirectory in the WebSphere MQ installation directory, and rename the file to JDBCSwitch.dll. Then, copy the JDBCSwitch.dll file from the *install_dir*\bin directory to the \exits64 subdirectory in the WebSphere MQ installation directory.

4. Configure the message flow that includes one or more nodes that access databases that are to participate in a globally coordinated transaction.
   a. Open a WebSphere Message Broker Toolkit session.
   b. Switch to the Broker Application Development perspective.
   c. Add the message flow that includes the node or nodes that connect to the database that is to participate in a globally coordinated transaction to a new or existing BAR file.
   d. Build the BAR file.
   e. Click the **Configure** tab, select the message flow that you have added, and select the **Coordinated Transaction** check box.

What to do next

Next: If your broker is running on Windows, authorize the broker and its queue manager to access resources associated with the JDBCProvider configurable service.

If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 699 (optional).

Related concepts:

"Databases overview" on page 2109
Brokers can access *user databases* to manipulate your business data. If you have user databases, you must configure them before you can access them from your

message flow.

You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

Authorizing access to JDBC type 4 JDBCProvider resources on Windows:

Authorize the broker and queue manager to access shared resources that are associated with the JDBCProvider. This task is required only if you want the database updates to be included in globally coordinated transactions on Windows systems.

Before you begin

Before you start: Set up your JDBC provider definition.

About this task

When the queue manager coordinates transactions, both queue manager and broker access shared memory to control a connection to the databases with which the message flow interacts. Therefore, they require the same access control of the shared memory. One method to achieve this control is to use the same ID for the broker service ID and the queue manager administrative ID.

Complete the following steps on the Windows system on which the broker is running:

Procedure

- If you defined the broker queue manager when you created the broker by running the **mqsicreatebroker** command, the two components share the same administrative ID, defined as the broker service ID, and you do not have to take further action.
- If you specified an existing queue manager when you created the broker, check that its administrative ID is the same ID as the one used for the service ID of the broker. If the ID is not the same, change the queue manager ID to be the same as the broker service ID:
  1. Click **Start** > **Run** and enter dcomcnfg. The Component Services window opens.
  2. In the left pane, expand **Component Services** > **Computers** > **My Computer** and click **DCOM Config**.
  3. In the right pane, right-click the WebSphere MQ service labeled **IBM MQSeries Services**, and click **Properties**.
  4. Click the **Identity** tab.
  5. Select **This user** and enter the user ID and password for the broker service ID to associate that ID with the queue manager.
  6. Click **OK** to confirm the change.

What to do next

Next: If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 699 (optional).

Connecting to a user database on z/OS:

Complete these tasks to connect to your user databases on z/OS.

Before you begin

Before you start: Create the broker and the database.

Procedure

1. Obtain the following DB2 values for the DB2 subsystem that you want to connect your broker to. Use these values to customize the `BIPEDIT`, `BIPDSNAO`, and `BIPBRKP` files.

JCL variable	Description	Example value
++DB2CONVERSION++	The DB2 converter	SINGLE
++DB2SUBSYSTEM++	The DB2 subsystem ID which the component connects	DFK4
++DB2LOCATION++	The DB2 location value of the DB2 subsystem to which the component connects	DSN910PK
++DB2CURRENTSQLID++	The default DB2 user ID for connecting	MQP1BRK
++DB2DSNACLIPLAN++	The DB2 plan name.	DSNACLI
++DB2HLQ++	The DB2 high-level-qualifier	SYS2.DB2.V910
++DB2RUNLIB++	The DB2 run library value	DSN910PK.RUNLIB.LOAD

2. Copy the supplied sample `BIPDSNAO` file into the component data set, and customize its content based on the values obtained in step 1. The stanza for your database will look like the following content:

```
[COMMON]
APPLTRACE=0
APPLTRACEfilename="DD:APPLTRC"
TRACETIMESTAMP=3
CONNECTTYPE=2
DIAGTRACE=0
DIAGTRACE_NO_WRAP=0
MAXCONN=0
MULTICONTEXT=0
MVSDEFAULTSSID=DFK4

; SUBSYSTEM
[DFK4]
MVSATTACHTYPE=RRSAF
PLANNAME=DSNACLI

; DATASOURCES
[DSN910PK]
CURRENTSQLID=MQP1BRK
```

3. Update the broker profile `BIPBPROF` in the component data set.
   a. Check that the environment variable `DSNAOINI` points to your copy of the `BIPDSNAO` file in the component data set. By default, it is set to the correct value; update this variable if you use a different name.
   b. Check that the environment variable `MQSI_DB2_CONVERSION` is set correctly.
4. Submit `BIPGEN` to re-create the broker `ENVFILE` and any execution group specific profiles.

5. Update the EGENV and EGNOENV steps in the broker started task JCL to include the following DB2 data sets:

```
//STEPLIB DD DISP=SHR,DSN=&DB2HLQ..SDSNEXIT
//        DD DISP=SHR,DSN=&DB2HLQ..SDSNLOAD
//        DD DISP=SHR,DSN=&DB2HLQ..SDSNLOD2
//        DD DISP=SHR,DSN=++DB2RUNLIB++
```

   Check that the PROC variable DB2HLQ='++DB2HLQ++' is not commented out.

6. Start the broker by using the **start (/S)** command.

What to do next

Next: You can set up your databases to participate in coordinated transactions by using the Resource Recovery Service (RRS). For more information, see "Resource Recovery Service planning on z/OS" on page 602.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"Database locations" on page 3595
The broker can access databases set up on the local computer or on a remote server, subject to restrictions.

"Sample BIPDSNAO file" on page 4008
The sample BIPDSNAO file that is shipped with WebSphere Message Broker is included here for your reference.

"Sample BIPBPROF file" on page 3995
The sample BIPBPROF file that is shipped with WebSphere Message Broker is included here for your reference.

"**mqsistart** command" on page 3965
Use the **mqsistart** command to start the specified broker if all initial verification tests complete successfully.

Configuring global coordination of transactions (two-phase commit)

Globally coordinate message flow transactions with a transaction manager to ensure the data integrity of transactions. On distributed systems, the WebSphere MQ queue manager that is associated with the broker performs the transaction manager role.

Before you begin

Before you start:

Read "Message flow transactions" on page 1281 to understand how the broker handles transactions. Depending on the external resource managers that the broker accesses during the processing of its deployed message flows, you must complete the appropriate resource-dependent set of tasks to ensure that all resources are configured correctly. For example, you might have to create and configure databases.

You, or your message flow developer, must also ensure that the message flows deployed to the broker are set up to support coordination. The tasks involved in configuring the message flows correctly are described in "Configuring transactionality for message flows" on page 1290.

About this task

You can access the following external resources in a message flow transaction:

- WebSphere MQ queues and messages
- Databases
- JMS providers

On distributed platforms, the default behavior of the broker is to manage all message flow transactions by using a one-phase commit approach. In many contexts this approach is sufficient, but if your business requires assured data integrity and consistency (for example, for audit reasons, or for financial transactions), you can configure the broker and its WebSphere MQ queue manager to manage the message flow transactions in a two-stage commit approach, by using the XA protocol standard.

You configure the WebSphere MQ queue manager by updating its `qm.ini` file, to add definitions of the additional resource managers with which you want WebSphere MQ to coordinate updates. Follow the instructions provided for the resource managers that are relevant in your environment:

- ODBC connections to databases
- JDBC connections to databases
- JMS providers

z/OS On z/OS, all transactions are globally coordinated by Resource Recovery Service (RRS), therefore the instructions in this topic do not apply. However, you must ensure that RRS is available; see "Resource Recovery Service planning on z/OS" on page 602.

Results

When you have completed these steps, your message flows are processed by using global coordination, which is managed by the queue manager.

You must complete all the steps correctly; if you do not, global coordination will not work.

Example

For an example of how you can use WebSphere MQ to globally coordinate transactions, look at the following sample:

- Error Handler

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Related concepts:

"The transactional model" on page 1285
The transactional model describes the way in which you can use transactions in message flows to accomplish certain tasks and results.

Related tasks:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Configuring ODBC connections for globally coordinated transactions:

Configure the definition of your ODBC databases to the transaction manager (the queue manager).

Before you begin

Before you start:

You must create and configure the databases by following the instructions in "Working with databases" on page 2109.

You, or your message flow developer, must also ensure that the message flows deployed to the broker are set up to support coordination. The tasks involved in configuring the message flows correctly are described in "Configuring transactionality for message flows" on page 1290.

Procedure

1. Ensure that your databases are configured for global coordination. For the databases that your message flows connect to, complete the tasks described in "Configuring databases for global coordination of transactions" on page 665.
2. Configure the broker environment so that the broker queue manager coordinates transactions with database resource managers. The steps to configure the broker environment depend on the database manager that you are using.
   - "Configuring global coordination with DB2" on page 700
   - "Configuring global coordination with Oracle" on page 705
   - "Configuring global coordination with Sybase" on page 710

Results

When you have completed these steps, your message flows are processed by using global coordination, which is managed by the queue manager.

You must complete all the steps correctly; if you do not, global coordination will not work.

Related concepts:

"Creating a broker" on page 611
You can create brokers on every platform that is supported by WebSphere Message Broker. The broker runs as a 64-bit application on all platforms except Linux on x86 and Windows on x86.

Configuring global coordination with DB2:

Configure your broker environment to globally coordinate message flow transactions with updates in DB2 databases under the control of your broker queue manager.

Before you begin

Ensure that the databases are configured for global coordination of transactions, see "Configuring databases for global coordination of transactions" on page 665.

Procedure

Follow the instructions appropriate to your platform:

- Linux UNIX "Linux and UNIX"
- Windows "Windows 32-bit" on page 702
- Windows "Windows 64-bit" on page 703

Linux and UNIX: Linux UNIX
Procedure

1. Linux On Linux on x86: decide whether the broker needs to connect to databases by using TCP/IP or shared memory.

   For more information about TCP/IP connections, see the example in the section about message SQL1224N in "Resolving problems when using databases" on page 3491.

To enable shared memory:

a. Stop the broker by running the following command, where *broker* is the name of your broker:

```
mqsistop broker
```

b. Run the following command to ensure that the broker is run in an environment with the extended memory variable exported:

```
export EXTSHM=ON
```

c. Restart the broker by running the following command, where *broker* is the name of your broker:

```
mqsistart broker
```

d. On the DB2 server, ensure that shared memory support is turned on. For more information, see "Configuring databases for global coordination of transactions" on page 665.

2. Linux UNIX Run the **mqsimanagexalinks** command. For more information, see "**mqsimanagexalinks** command" on page 3891.

3. Linux UNIX Configure the broker queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

a. Open the queue manager's `qm.ini` file in a text editor. The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`, where *queue_manager_name* is the name of the broker that is associated with the queue manager.

b. At the end of the `qm.ini` file, paste the following stanza:

```
XAResourceManager:
Name=DB2
SwitchFile=db2swit
XAOpenString=db=MyDataSource,uid=MyUserId,pwd=MyPassword,toc=t
XACloseString=
ThreadOfControl=THREAD
```

The switch file is supplied by WebSphere Message Broker.

c. On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:

- *MyDataSource* is the name of the data source to which you want to connect.
- *MyUserId* must be the user name that the broker uses to connect to the database.

  You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

  1) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.
  2) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.
  3) A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

     This parameter is valid only for brokers that you have migrated from previous releases.
  4) The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

- *MyPassword* is the password that is associated with the user name.

d. Accept the default values for all the other lines in the stanza. For example:

```
XAResourceManager:
Name=DB2
SwitchFile=db2swit
XAOpenString=db=MYDB,uid=wbrkuid,pwd=wbrkpw,toc=t
XACloseString=
ThreadOfControl=THREAD
```

4. Linux UNIX Stop then restart the queue manager to apply the changes, because `qm.ini` is read only while the queue manager is running.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/`*queue_manager_name*`/errors`, where *queue_manager_name* is the name of the queue manager that you restarted. When the queue manager restarts successfully, the changes that you made to `qm.ini` are applied.

Results

DB2 is now configured for global coordination with the broker queue manager coordinating transactions.

What to do next

Next: you can deploy globally coordinated message flows to the broker.

Windows 32-bit: Windows
Procedure

1. Windows Configure the broker queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.
   a. From the **Start** menu, open WebSphere MQ Explorer.
   b. Open the queue manager Properties dialog box, then open **XA resource managers**.
   c. Click the **Add** button to create a resource manager.
      1) In the **Name** field, enter a name to refer to a resource manager.
      2) In the **SwitchFile** field, enter the full path to the switch file, as shown in the following example where *install_dir* is the location in which the broker is installed:

         ```
         install_dir\sample\xatm\db2swit.dll
         ```

      3) In the **XAOpenString** field, paste the following string:

         ```
         db=MyDataSource,uid=MyUserId,pwd=MyPassword,toc=t
         ```

      4) In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:
         a) *MyDataSource* is the name of the data source to which you want to connect.
         b) *MyUserId* must be the user name that the broker uses to connect to the database.

You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

i. A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

ii. A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

iii. A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

This parameter is valid only for brokers that you have migrated from previous releases.

iv. The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

c) *MyPassword* is the password that is associated with the user name.

For example:

```
db=MYDB,uid=wbrkuid,pwd=wbrkpw,toc=t
```

5) Accept the default values for all the other fields on the page.

2. Windows Stop then restart the queue manager to apply the changes.

To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

```
endmqm queue_manager_name
strmqm -si queue_manager_name
```

When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in *install_dir*\WebSphere MQ\Qmgrs\MB7QMGR\errors, where *install_dir* is the location in which the broker is installed. When the queue manager restarts successfully, the changes that you made are applied.

Results

DB2 is now configured for global coordination with the broker queue manager coordinating transactions.

What to do next

Next: you can deploy globally coordinated message flows to the broker.

Windows 64-bit: Windows

Procedure

1. Windows Configure the broker queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

a. From the **Start** menu, open WebSphere MQ Explorer.

b. Open the queue manager Properties dialog box, then open **XA resource managers**.

c. Click the **Add** button to create a resource manager.

1) In the **Name** field, enter a name to refer to a resource manager.

2) In the **SwitchFile** field, enter *db2swit*

3) Copy the provided DB2 switch files from the broker install location to the queue managers exits and *exits64* directories (by default under `C:\Program Files (x86)\IBM\WebSphere MQ`).

   Copy the file:

   ```
   install_dir\sample\xatm\db2swit32.dll
   ```

   into the queue managers exits directory, and rename it to *db2swit.dll*. Copy the file

   ```
   install_dir\sample\xatm\db2swit.dll
   ```

   into the queue managers *exits64* directory.

4) In the **XAOpenString** field, paste the following string:

   ```
   db=MyDataSource,uid=MyUserId,pwd=MyPassword,toc=t
   ```

5) In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

   a) *MyDataSource* is the name of the data source to which you want to connect.

   b) *MyUserId* must be the user name that the broker uses to connect to the database.

      You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

      i. A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.

      ii. A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

      iii. A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

      This parameter is valid only for brokers that you have migrated from previous releases.

      iv. The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

   c) *MyPassword* is the password that is associated with the user name.

   For example:

   ```
   db=MYDB,uid=wbrkuid,pwd=wbrkpw,toc=t
   ```

6) Accept the default values for all the other fields on the page.

2. Windows Stop then restart the queue manager to apply the changes.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm -si queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in *install_dir*`\WebSphere MQ\Qmgrs\MB7QMGR\errors`, where *install_dir* is the location in which the broker is installed. When the queue manager restarts successfully, the changes that you made are applied.

Results

DB2 is now configured for global coordination with the broker queue manager coordinating transactions.

What to do next

Next: you can deploy globally coordinated message flows to the broker.

Related tasks:

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

Configuring global coordination with Oracle:

Configure your broker environment to globally coordinate message flow transactions with updates in Oracle databases under the control of a WebSphere MQ queue manager.

Before you begin

Before you start:

- Ensure that you have configured the databases for global coordination of transactions.

About this task

Configure your broker environment for global coordination by using a 64-bit queue manager as the transaction manager with the DataDirect drivers:

Procedure

1. Linux UNIX On Linux and UNIX, run the **mqsimanagexalinks** command.

2. Configure the broker queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

   Linux UNIX **On Linux (except Linux on x86) and UNIX:**

   a. Open the queue managers `qm.ini` file in a text editor. The `qm.ini` file is located at `/var/mqm/qmgrs/`*queue_manager_name*`/qm.ini`. Where *queue_manager_name* is the name of the broker that is associated with the queue manager.

   b. Add one of the following stanzas to the end of the `qm.ini` file:

      - If you are not using Oracle Real Application Clusters:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc24.so
XAOpenString=ORACLE_XA
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +Sid=MySID
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2+
XACloseString=
ThreadOfControl=THREAD
```

      - If you are using Oracle Real Application Clusters:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc24.so
XAOpenString=ORACLE_XA
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +ServiceName=MyServiceName
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2+
XACloseString=
ThreadOfControl=THREAD
```

   c. On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:

      - *MyHostName* is the name of the TCP/IP host that hosts the Oracle database listener. When you are using Oracle Real Application Clusters with multiple listeners for the given Service Name, if the Oracle listener identified by the values for *MyHostName* and *MyPortNumber* in the **XAOpenString** is unavailable, the alternative Oracle listeners that you might have defined in the **AlternateServers** list in your `odbc.ini` file are also tried.
      - *MyPortNumber* is the TCP/IP port on which the Oracle database listener is listening.
      - *MySID* is the Oracle System Identifier (SID) of the database.
      - *MyUserId* must be the user name that the broker uses to connect to the database.

        You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

1) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.
2) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.
3) A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

   This parameter is valid only for brokers that you have migrated from previous releases.
4) The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

- *MyPassword* is the password that is associated with the user name.
- *MyDataSourceName* is the ODBC data source name for the database, as defined in your `odbc.ini` file.
- *MyServiceName* is the value set for the Service Name in the stanza for *MyDataSourceName* in your `odbc.ini` file.

Note: The **XAOpenString** might also contain the lines `+SQLNET=MyNetServiceName` and `+DB=MyDataSourceName`, but these lines are ignored.

d. Accept the default values for all the other lines in the stanza. For example:
   - On AIX:
     - If you are not using Oracle Real Application Clusters:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc24.so
XAOpenString=ORACLE_XA
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521+Sid=diaz
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+K=2+
XACloseString=
ThreadOfControl=THREAD
```

     - If you are using Oracle Real Application Clusters:

```
XAResourceManager:
Name=OracleXA
SwitchFile=UKoradtc24.so
XAOpenString=ORACLE_XA
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521
   +ServiceName=racxa.test.com
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+K=2+
XACloseString=
ThreadOfControl=THREAD
```

e. If you are using Oracle Real Application Clusters:
   - Set the ODBCINI environment variable to be visible in the environment from which you start your queue manager. The ODBCINI variable must reference the same file as the one being used by your broker.
   - An optional additional property, `CTO=`*`Value`*, is available for the **XAOpenString**. `CTO` is the value set for a Connection TimeOut, indicating the number of seconds that the Oracle XA switch file will wait for a response from the Oracle database to an XA request. For example, the timeout can be used to prevent long delays in the broker failing over to

an alternative Oracle Real Application Clusters node, when the active Oracle instance fails abruptly leaving socket connections hanging. The *Value* should be set to a value larger than the Oracle session timeout `sestm` value set in the **XAOpenString**. If this property is not used, or is set to zero, there will be no timeout (this is the default behaviour).

Windows **On Windows 32-bit**

a. From the **Start** menu, open WebSphere MQ Explorer.

b. Open the queue manager Properties dialog box, then open **XA resource managers**.

c. In the **SwitchFile** field, enter the full path to the switch file, as shown in the following example. Where *install_dir* is the location in which the broker is installed:

```
install_dir\bin\UKora24.dll
```

d. In the **XAOpenString** field, paste the following string:

- If you are not using Oracle Real Application Clusters:

```
ORACLE_XA
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +Sid=MySID
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2+
```

- If you are using Oracle Real Application Clusters:

```
ORACLE_XA
   +HostName=MyHostName
   +PortNumber=MyPortNumber
   +ServiceName=MyServiceName
   +ACC=P/MyUserId/MyPassword
   +sestm=100+threads=TRUE
   +DataSource=MyDataSourceName
   +K=2+
```

e. In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

- *MyHostName* is the name of the TCP/IP host that hosts the Oracle database listener. When you are using Oracle Real Application Clusters with multiple listeners for the given Service Name, if the Oracle listener identified by the values for *MyHostName* and *MyPortNumber* in the **XAOpenString** is unavailable, the alternative Oracle listeners that you might have defined in the **AlternateServers** list in your `odbc.ini` file arealso tried.
- *MyPortNumber* is the TCP/IP port on which the Oracle database listener is listening.
- *MySID* is the Oracle System Identifier (SID) of the database.
- *MyUserId* must be the user name that the broker uses to connect to the database.

  You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

  1) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.
  2) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.

3) A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

   This parameter is valid only for brokers that you have migrated from previous releases.

4) The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command

- *MyPassword* is the password that is associated with the user name.
- *MyDataSourceName* is the ODBC data source name for the database, as defined in your `odbc.ini` file.
- *MyServiceName* is the value set for the Service Name in the stanza for *MyDataSourceName* in your `odbc.ini` file.

Note: The **XAOpenString** might also contain the lines `+SQLNET=MyNetServiceName` and `+DB=MyDataSourceName`, but these lines are ignored.

For example:

- If you are not using Oracle Real Application Clusters:

```
ORACLE_XA+SQLNET=diaz
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521+Sid=diaz
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+DB=MYDB+K=2+
```

- If you are using Oracle Real Application Clusters:

```
ORACLE_XA+SQLNET=WMBSERVICE
   +HostName=diaz.hursley.ibm.com
   +PortNumber=1521
   +ServiceName=racxa.test.com
   +ACC=P/wbrkuid/wbrkpw
   +sestm=100+threads=TRUE
   +DataSource=MYDB+DB=MYDB+K=2+
```

f. Accept the default values for all the other fields on the page.

3. AIX On AIX, if you want to enable Oracle data sources for use in global coordination from a queue manager and broker to perform dynamic XA registration, set the following environment variable:
   `DDTEK_XA_DYNAMIC_REGISTRATION=1`

4. Linux UNIX Stop then restart the queue manager to apply the changes, because `qm.ini` is read only while the queue manager is running.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm queue_manager_name
   ```

   When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/`*queue_manager_name*`/errors`, where *queue_manager_name* is the name of the queue manager that you restarted. When the queue manager restarts successfully, the changes that you made to `qm.ini` are applied.

5. Windows Stop then restart the queue manager to apply the changes.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

   ```
   endmqm queue_manager_name
   strmqm -si queue_manager_name
   ```

When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/queue_manager_name/errors`, where *queue_manager_name* is the name of the queue manager that you restarted. When the queue manager restarts successfully, the changes that you made are applied.

Results

Oracle is now configured for global coordination with the broker queue manager coordinating transactions.

Configuring global coordination with Sybase:

Configure your broker environment to globally coordinate message flow transactions with updates in Sybase databases under the control of a queue manager.

Before you begin

Before you start:
- Ensure that the databases are configured for global coordination of transactions.

About this task

To configure your broker environment for global coordination using a WebSphere MQ queue manager as the transaction manager with the DataDirect drivers:

Procedure

1. Linux UNIX On Linux and UNIX, run the **mqsimanagexalinks** command.
2. Configure the broker queue manager with XA resource manager information for each database that is involved in the transaction that the queue manager will globally coordinate.

   Linux UNIX **On Linux and UNIX:**

   a. Open the queue manager's `qm.ini` file in a text editor. The `qm.ini` file is located at `/var/mqm/qmgrs/queue_manager_name/qm.ini`, where *queue_manager_name* is the name of the broker that is associated with the queue manager.

   b. At the end of the `qm.ini` file, paste the following stanza:

   ```
   XAResourceManager:
       Name=SYBASEXA
       SwitchFile=UKasedtc24.so
       XAOpenString=-NSYBASEDB -AMyServerName,MyPortNumber -Uuid -Ppwd -K2
       XACloseString=
       ThreadOfControl=THREAD
   ```

   c. On the **XAOpenString** line, replace the following values with values that are appropriate for your configuration:
      - *MyServerName* is the name of the TCP/IP host that hosts the Sybase ASE server.
      - *MyPortNumber* is the TCP/IP port on which the Sybase ASE server is listening.
      - *uid* must be the user name that the broker uses to connect to the database.

        You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

        1) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.
        2) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.
        3) A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

           This parameter is valid only for brokers that you have migrated from previous releases.
        4) The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command
      - *pwd* is the password that is associated with the user name.

   d. Accept the default values for all the other lines in the stanza. For example:
      - On AIX:

```
XAResourceManager:
    Name=SYBASEXA
    SwitchFile=UKasedtc24.so
    XAOpenString=-NSYBASEDB -Adiaz,1521 -Uwbrkuid -Pwbrkpw -K2
    XACloseString=
    ThreadOfControl=THREAD
```

Windows **On Windows 32-bit:**

a. From the **Start** menu, open WebSphere MQ Explorer.

b. Open the Properties dialog box for the queue manager, then open **XA resource managers**.

c. In the **SwitchFile** field, enter the full path to the switch file, as shown in the following example where *install_dir* is the location in which the broker is installed:

install_dir\bin\ukase24.dll

d. In the **XAOpenString** field, paste the following string:

-NSYBASEDB -A*MyServerName*,*MyPortNumber* -WWinsock -U*uid* -P*pwd* -K2

e. In the **XAOpenString** field, replace the values with values that are appropriate for your configuration:

- *install_dir* is the location in which the broker is installed.
- *MyServerName* is the name of the TCP/IP host that hosts the Sybase ASE server.
- *MyPortNumber* is the TCP/IP port on which the Sybase ASE server is listening.
- *uid* must be the user name that the broker uses to connect to the database.

  You can define the user name that the broker uses in a number of ways; make sure that you specify the correct name in this file. The broker determines the user name by checking the following conditions in the order listed:

  1) A specific user name and password for this data source name (DSN), that you have defined by running the **mqsisetdbparms** command.
  2) A default user name and password for all DSNs, that you have defined by running the **mqsisetdbparms** command.
  3) A default user name and password for all DSNs, that you have defined by specifying the **-u** parameter on the **mqsicreatebroker** command.

     This parameter is valid only for brokers that you have migrated from previous releases.
  4) The broker service user name, which you define with the **-i** parameter on the **mqsicreatebroker** command
- *pwd* is the password that is associated with the user name.

  For example:

  -NSYBASEDB -Adiaz,1521 -WWinsock -Uwbrkuid -Pwbrkpw -K2

f. Accept the default values for all the other fields on the page.

3. Stop then restart the queue manager to apply the changes, because qm.ini is read only while the queue manager is running.

   To stop and restart the queue manager, enter the following commands, where *queue_manager_name* is the name of the queue manager:

```
endmqm queue_manager_name
strmqm queue_manager_name
```

When the queue manager restarts, check the queue manager log for all warnings that are associated with the restart. The log files are located in `/var/mqm/qmgrs/queue_manager_name/errors`, where *queue_manager_name* is the name of the queue manager that you restarted. When the queue manager restarts successfully, the changes that you made to `qm.ini` are applied.

Results

Sybase is now configured for global coordination with your queue manager coordinating transactions.

What to do next

Next: you can deploy globally coordinated message flows to the broker.

WebSphere MQ Version 7 Information Center online

Configuring a JDBC type 4 connection for globally coordinated transactions:

If you want the database that you access through a JDBC type 4 connection to participate in globally coordinated transactions, set up the appropriate environment.

Before you begin

Before you start: Set up your JDBC provider definition.

About this task

Updates that you make to a database across a JDBC type 4 connection can be coordinated with other actions taken within the message flow, if you set up the resources to support coordination.

Complete the following steps:

Procedure

1. Check that the definition of your JDBCProvider service is appropriate for coordinated transactions.

   For example, to set up the required JDBC classes:

   - For DB2, set **type4DatasourceClassName** to `com.ibm.db2.jcc.DB2XADataSource` and **type4DriverClassName** to `com.ibm.db2.jcc.DB2Driver`
   - For Oracle, set **type4DatasourceClassName** to `oracle.jdbc.xa.client.OracleXADataSource` and **type4DriverClassName** to `oracle.jdbc.OracleDriver`

   Consult your database administrator or the documentation provided by your database supplier, to confirm that all the JDBCProvider service properties are set appropriately. For example, a database supplier might require secure access if it is participating in coordinated transactions.

2. Define the switch file and the database properties:

   a. Linux UNIX On Linux and UNIX systems, open the `qm.ini` file for the broker queue manager with a text editor. Add the following stanza for each database:

   ```
   XAResourceManager:
          Name=Database_Name
          SwitchFile=JDBCSwitch
          XAOpenString=JDBC_DataSource
          ThreadOfControl=THREAD
   ```

   Database_Name is the database name (DSN) of the database defined to the JDBCProvider configurable service (for example, specified by `-n databaseName -v` *Database_Name* on the **mqsichangeproperties** command).

   `JDBCSwitch` is a fixed generic name that represents the switch file for XA coordination. Use this value, or another single fixed value, in each stanza; the specific switch file that the queue manager uses is defined by the symbolic links you create in the next step.

   JDBC_DataSource is the identifier of the JDBCProvider configurable service (the value that you specified for the **-o** parameter on the **mqsichangeproperties** command).

   Define a stanza for each database (DSN) that you connect to from this broker. You must create separate definitions even if the DSNs resolve to the same physical database. Therefore, you must have a stanza for each JDBCProvider configurable service that you have defined, because each service can define the properties for a single database.

   b. Windows On Windows on x86 systems, open WebSphere MQ Explorer and select the queue manager for your broker, for example BROKERQM.

   Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

Enter the fully qualified file name in **SwitchFile**; *install_dir*\bin\JDBCSwitch.dll.

c. Windows On Windows on x86-64 systems, open WebSphere MQ Explorer and select the queue manager for your broker, for example BROKERQM.

Open the **XA resource manager** page, and modify the attributes to create the definition of the database. The attributes are the same as those shown for Linux and UNIX; **Name**, **SwitchFile**, **XAOpenString**, and **ThreadofControl**. Leave the additional attribute, **XACloseString**, blank.

Enter *JDBCSwitch* in **SwitchFile**.

3. Set up queue manager access to the switch file:

a. Linux UNIX On Linux and UNIX systems, create a symbolic link to the switch files that are supplied in your *install_dir*/lib directory.

install_dir is the directory to which you installed the Broker component. The default location for this directory is /opt/ibm/mqsi/*v.r* on Linux, or /opt/IBM/mqsi/*v.r* on UNIX systems. The default directory includes the version and release of the product, in the format v.r (version.release).

Set up links in the /var/mqm/exits directory, or the /var/mqm/exits64 directory, or both. The file names for each platform are shown in the following table.

Platform	32-bit file	64-bit file
AIX		libJDBCSwitch.so
HP-Itanium		libJDBCSwitch.so
Linux on POWER		libJDBCSwitch.so
Linux on IBM z Systems		libJDBCSwitch.so
Linux on x86	libJDBCSwitch.so	
Linux on x86-64		libJDBCSwitch.so
Solaris on SPARC		libJDBCSwitch.so
Solaris on x86-64		libJDBCSwitch.so

Specify the same name of the switch file, JDBCSwitch or your own value, in both the /exits and /exits64 directories. For example, on AIX:

```
ln -s install_dir/lib/libJDBCSwitch.so /var/mqm/exits/JDBCSwitch

and

ln -s install_dir/lib/libJDBCSwitch.so /var/mqm/exits64/JDBCSwitch
```

b. Windows On Windows, for the 32-bit version of WebSphere Message Broker, copy the JDBCSwitch.dll file from the *install_dir*\bin directory to the \exits subdirectory in the WebSphere MQ installation directory.

c. Windows On Windows, for the 64-bit version of WebSphere Message Broker, copy the JDBCSwitch32.dll file from the *install_dir*\bin directory to the \exits subdirectory in the WebSphere MQ installation directory, and rename the file to JDBCSwitch.dll. Then, copy the JDBCSwitch.dll file from the *install_dir*\bin directory to the \exits64 subdirectory in the WebSphere MQ installation directory.

4. Configure the message flow that includes one or more nodes that access databases that are to participate in a globally coordinated transaction.

a. Open a WebSphere Message Broker Toolkit session.

b. Switch to the Broker Application Development perspective.
c. Add the message flow that includes the node or nodes that connect to the database that is to participate in a globally coordinated transaction to a new or existing BAR file.
d. Build the BAR file.
e. Click the **Configure** tab, select the message flow that you have added, and select the **Coordinated Transaction** check box.

What to do next

Next: If your broker is running on Windows, authorize the broker and its queue manager to access resources associated with the JDBCProvider configurable service.

If you have been following the instructions in "Working with databases" on page 2109, the next task is "Configuring ODBC connections for globally coordinated transactions" on page 699 (optional).

Related concepts:

"Databases overview" on page 2109
Brokers can access *user databases* to manipulate your business data. If you have user databases, you must configure them before you can access them from your message flow.

Related tasks:

"Setting up a JDBC provider for type 4 connections" on page 684
Use the **mqsicreateconfigurableservice** or the **mqsichangeproperties** command to configure a JDBC provider service.

"Authorizing access to JDBC type 4 JDBCProvider resources on Windows" on page 694
Authorize the broker and queue manager to access shared resources that are associated with the JDBCProvider. This task is required only if you want the database updates to be included in globally coordinated transactions on Windows systems.

"Configuring transactionality for message flows" on page 1290
A message flow runs in a single transaction, which is started when data is received by an input node, and can be committed or rolled back when all processing has completed.

"Interacting with databases by using the JavaCompute node" on page 2661
Access databases from Java code included in the JavaCompute node.

"Extending the capability of a Java message processing or output node" on page 3069
Within a message processing or output node, you can add extended functions to your Java node.

Related reference:

"Supported databases" on page 3591
You can optionally configure databases to contain data that is accessed by your message flows. Databases from IBM and other suppliers are supported at specific versions on supported operating systems.

"**mqsichangeproperties** command" on page 3756
Use the **mqsichangeproperties** command to modify broker properties and properties of broker resources.

Configuring properties to connect to external resources

You can use configurable services to prepare the environment for external resources, or change connection details for external resources.

About this task

The following topics describe how to prepare your environment to connect to external resources.

- "Configuring for Enterprise Information Systems"
- "Configuring for IMS" on page 731
- Configuring for CORBA
- "Configuring for CICS Transaction Server for z/OS" on page 736
- "Configuring for JMS" on page 747
- Configuring for WS-Security
- Configuring for email

Configuring for Enterprise Information Systems:

You can use configurable services to enable the WebSphere Adapters nodes in the broker runtime environment to connect with Enterprise Information Systems such as SAP, Siebel, and PeopleSoft.

About this task

The following topics describe how to prepare the environment to connect to Enterprise Information Systems, and how to change the connection details for adapters without the need to redeploy them.

- "Preparing the environment for WebSphere Adapters nodes"
- "Changing connection details for SAP adapters" on page 719
- "Changing connection details for Siebel adapters" on page 720
- "Changing connection details for PeopleSoft adapters" on page 722
- "Changing connection details for JD Edwards adapters" on page 724
- "Configuring EIS connections to expire after a specified time" on page 726

Preparing the environment for WebSphere Adapters nodes:

Before you can use the WebSphere Adapters nodes, you must set up the broker runtime environment so that you can access the Enterprise Information System (EIS).

Before you begin

Before you start:

Read "WebSphere Adapters nodes" on page 1914.

About this task

To enable the WebSphere Adapters nodes in the broker runtime environment, configure the broker with the location of the EIS provider JAR files and native libraries. (On Windows, the location of the JAR files cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a Storage Area Network (SAN) disk.)

Procedure

1. The WebSphere Adapters nodes require libraries from the EIS vendors. For more information on how to obtain and use these libraries, see "Developing message flows that use WebSphere Adapters" on page 2033.
2. Use the following commands to make the JAR files and shared libraries available to the WebSphere Adapters nodes.
   - To set up the dependencies, use the following command.

     ```
     mqsichangeproperties broker name -c EISProviders -o EIS type -n jarsURL -v jar directory
     mqsichangeproperties broker name -c EISProviders -o EIS type -n nativeLibs -v bin directory
     ```

     For example:

     ```
     mqsichangeproperties brk6 -c EISProviders -o SAP -n jarsURL -v c:\sapjco\jars
     mqsichangeproperties brk6 -c EISProviders -o SAP -n nativeLibs -v c:\sapjco\bin
     ```

     After you have run the **mqsichangeproperties** command, restart the broker so that the changes take effect.
   - To report the dependencies, use the following command.

     ```
     mqsireportproperties broker name -c EISProviders -o EIS type -r
     ```

     For example:

     ```
     mqsireportproperties brk6 -c EISProviders -o SAP -r
     ```

   - On z/OS, run this command by customizing and submitting BIPJADPR.

   You can also connect to different versions of Siebel by creating a custom EISProviders configurable service and setting the location of the appropriate library files. For more information, see "Connecting to different versions of Siebel" on page 2077.

What to do next

When you have set up the environment for the WebSphere Adapters nodes, you can perform the preparatory tasks that are listed in "Developing message flows that use WebSphere Adapters" on page 2033.

Related concepts:

"WebSphere Adapters nodes" on page 1914
A WebSphere Adapters node is a message flow node that is used to communicate with Enterprise Information Systems (EIS), such as SAP, Siebel, JD Edwards, and PeopleSoft.

Related tasks:

Use the Adapter Connection wizard to create the resources that enable the WebSphere Adapters to connect to an Enterprise Information System (EIS).

"Debugging message flows that contain WebSphere Adapters nodes" on page 3192
You can use various methods to monitor message flows that include WebSphere Adapters nodes.

Related reference:

"WebSphere Adapters properties" on page 4024
Reference information about the properties that you set for WebSphere Adapters nodes.

Changing connection details for SAP adapters:

SAP nodes can get SAP connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Before you begin

Before you start:

- Read "WebSphere Adapters nodes" on page 1914 and "Configurable services" on page 1296 for background information.

About this task

Use the SAPConnection configurable service to change connection details for an SAP adapter. The SAP node reads all connection properties from the adapter component that it is configured to use. If a configurable service exists that has the same name as the node's adapter component, the node uses the values that are defined in that configurable service to override the corresponding properties from the adapter. If any properties on the configurable service are set to an empty string, the values that are configured in the `.inadapter` or `.outadapter` file are used. The properties of the SAP configurable services are described in "Configurable services properties" on page 3766.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates an SAPConnection configurable service for the SAP adapter *mySAPAdapter.outadapter* that connects to the SAP host `test.sap.ibm.com`, and uses client *001* for the connections into that server:

  ```
  mqsicreateconfigurableservice MB7BROKER -c SAPConnection
  -o mySAPAdapter.outadapter -n applicationServerHost,client
  -v test.sap.ibm.com,001
  ```

  To pick up the new values in the configurable service, restart the execution group and message flow.
- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. This example changes the connections that are used by the adapter *mySAPAdapter.outadapter*. After you run this command, all adapters connect to the production system (`production.sap.ibm.com`) instead of the test system (`test.sap.ibm.com`):

  ```
  mqsichangeproperties MB7BROKER -c SAPConnection -o mySAPAdapter.outadapter
  -n applicationServerHost -v production.sap.ibm.com
  ```

  To pick up the updated values in the configurable service, restart the execution group and message flow.

- To display all SAPConnection configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

  ```
  mqsireportproperties MB7BROKER -c SAPConnection -o AllReportableEntityNames -r
  ```

- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

  ```
  mqsideleteconfigurableservice MB7BROKER -c SAPConnection
  -o mySAPAdapter.outadapter
  ```

  You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Changing connection details for Siebel adapters:

Siebel nodes can get Siebel connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the adapters. To pick

up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Before you begin

Before you start:

- Read "WebSphere Adapters nodes" on page 1914 and "Configurable services" on page 1296 for background information.

About this task

Use the SiebelConnection configurable service to change connection details for a Siebel adapter. The Siebel node reads all connection properties from the adapter component that it is configured to use. If a configurable service exists that has the same name as the adapter component of the node, the node uses the values that are defined in that configurable service to override the corresponding properties from the adapter. If a configurable service is being used, all properties that are exposed by the configurable service are taken from the configurable service. The only properties that are taken from the adapter are those that you cannot set on the configurable service. The properties of the Siebel configurable service are described in "Configurable services properties" on page 3766.

You can also connect to different versions of Siebel by creating a custom EISProviders configurable service and setting the location of the appropriate library files. For more information, see "Connecting to different versions of Siebel" on page 2077.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates a SiebelConnection configurable service for the Siebel instance that is running on *my.siebel.qa.com*:

```
mqsicreateconfigurableservice MB7BROKER -c SiebelConnection -o mySiebelAdapter.outadapter
-n connectString -v "siebel://my.siebel.qa.com/SBA_80/SSEObjMgr_enu"
```

  To pick up the new values in the configurable service, restart the execution group and message flow.

- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. This example changes the connections that are used by the adapter *mySiebelAdapter.outadapter*. After you run this command, all adapters connect to the production system (`my.siebel.production.com`) instead of the test system (`my.siebel.qa.com`):

```
mqsichangeproperties MB7BROKER -c SiebelConnection -o mySiebelAdapter.outadapter -n connectString
-v "siebel://my.siebel.production.com/SBA_80/SSEObjMgr_enu"
```

  To pick up the updated values in the configurable service, restart the execution group and message flow.

- To display all SiebelConnection configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

```
mqsireportproperties MB7BROKER -c SiebelConnection -o AllReportableEntityNames -r
```

- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

```
mqsideleteconfigurableservice MB7BROKER -c SiebelConnection -o mySiebelAdapter.outadapter
```

You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Changing connection details for PeopleSoft adapters:

PeopleSoft nodes can get PeopleSoft connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the

adapters. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Before you begin

Before you start:

- Read "WebSphere Adapters nodes" on page 1914 and "Configurable services" on page 1296 for background information.

About this task

Use the PeopleSoftConnection configurable service to change connection details for a PeopleSoft adapter. The PeopleSoft node reads all connection properties from the adapter component that it is configured to use. If a configurable service exists that has the same name as the node's adapter component, the node uses the values that are defined in that configurable service to override the corresponding properties from the adapter. If a configurable service is being used, all properties that are exposed by the configurable service are taken from the configurable service. The only properties that are taken from the adapter are those that you cannot set on the configurable service. The properties of the PeopleSoft configurable service are described in "Configurable services properties" on page 3766.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates a PeopleSoftConnection configurable service for the PeopleSoft instance that is running on *my.peoplesoft.qa.com*:

```
mqsicreateconfigurableservice MB7BROKER -c PeopleSoftConnection -o myPeopleSoftAdapter.outadapter
-n hostName,port -v "my.peoplesoft.qa.com",9000
```

  To pick up the new values in the configurable service, restart the execution group and message flow.

- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. This example changes the connections that are used by the adapter *myPeopleSoftAdapter.outadapter*. After you run this command, all adapters connect to the production system (`my.peoplesoft.production.com`) instead of the test system (`my.peoplesoft.qa.com`):

```
mqsichangeproperties MB7BROKER -c PeopleSoftConnection -o myPeopleSoftAdapter.outadapter -n hostName
-v "my.peoplesoft.production.com"
```

  To pick up the updated values in the configurable service, restart the execution group and message flow.

- To display all PeopleSoftConnection configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

```
mqsireportproperties MB7BROKER -c PeopleSoftConnection -o AllReportableEntityNames -r
```

- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

```
mqsideleteconfigurableservice MB7BROKER -c PeopleSoftConnection -o myPeopleSoftAdapter.outadapter
```

  You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Changing connection details for JD Edwards adapters:

JD Edwards nodes can get JD Edwards EnterpriseOne connection details from either the adapter component or a configurable service. By using configurable services, you can change the connection details for adapters without the need to redeploy the adapters. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the adapter was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Before you begin

Before you start:

- Read "WebSphere Adapters nodes" on page 1914 and "Configurable services" on page 1296 for background information.

About this task

Use the JDEdwardsConnection configurable service to change connection details for a JD Edwards adapter. The JD Edwards node reads all connection properties from the adapter component that it is configured to use. If a configurable service exists that has the same name as the nodes adapter component, the node uses the values that are defined in that configurable service to override the corresponding properties from the adapter. If a configurable service is being used, all properties that are exposed by the configurable service are taken from the configurable service. The only properties that are taken from the adapter are the ones that you cannot set on the configurable service. The properties of the JD Edwards configurable service are described in "Configurable services properties" on page 3766.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates a JDEdwardsConnection configurable service to connect to the DV7333 development Environment for a user with the Role of administrator.

```
mqsicreateconfigurableservice MYBROKER -c JDEdwardsConnection -o myJdedwardsAdapter.outadapter
-n Environment,Role -v "dv7333,administrator"
```

  To pick up the new values in the configurable service, restart the execution group and message flow.

- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. This example changes the connection that is used by the adapter *myJdedwardsAdapter.outadapter* to connect to the PD7333 production Environment. After you run this command, all adapters connect to the production Environment (PD7333) instead of the development system (DV7333).

```
mqsichangeproperties MYBROKER -c JDEdwardsConnection -o myJdedwardsAdapter.outadapter -n Environment,Role
-v PD7333,administrator
```

  To pick up the updated values in the configurable service, restart the execution group and message flow.

- To display all JDEdwardsConnection configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

```
mqsireportproperties MYBROKER -c JDEdwardsConnection -o AllReportableEntityNames -r
```

- You can delete a configurable service that has been created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

```
mqsideleteconfigurableservice MYBROKER -c JDEdwardsConnection -o myJdedwardsAdapter.outadapter
```

You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Configuring EIS connections to expire after a specified time:

You can configure connections to SAP, Siebel, and PeopleSoft to expire after a specified time by using a configurable service.

About this task

You can use the connectionIdleTimeout property on a configurable service to control the number of connections to SAP, Siebel and PeopleSoft by closing connections that have not been used for a specified time.

Procedure

Use the **mqsicreateconfigurableservice** command to set up connections that expire when they have not been used for a specified length of time.

In the following example, the SAPConnection configurable service is configured to close connections when they have not been used for 120 seconds.

```
mqsicreateconfigurableservice MB7BROKER -c SAPConnection -o mySAPAdapter.outadapter
-n connectionIdleTimeout -v 120
```

Advanced configuration properties when using IBM Sterling Connect:Direct nodes:

CDInput and CDOutput nodes can get connection details and staging directories in conjunction with a configurable service. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

Before you begin

Before you start:

- Read "IBM Sterling Connect:Direct overview and concepts" on page 1810 and "Configurable services" on page 1296 for background information.

About this task

Use the *CDServer* configurable service to change connection details for a IBM Sterling Connect:Direct node. The properties of the *CDServer* configurable services are described in "*CDServer* configurable service properties" on page 3798.

Use the following scenarios as examples of how you use the staging directories.

Procedure

- **What should I do if I have WebSphere Message Broker and IBM Sterling Connect:Direct on the same machine, and want the files to be staged for output within the WebSphere Message Broker work path?**

  You need not set any of the properties; the default settings allow this to happen.
- **Output**
  1. **What should I do if I have WebSphere Message Broker and IBM Sterling Connect:Direct on the same machine but want to use a specified location to create files for output?** Set the `brokerPathToStagingDir` to the location you want. You do not need to set the `cdPathToStagingDir`, as WebSphere Message Broker assumes this to be the same as the `brokerPathToStagingDir`.
  2. **Can I have WebSphere Message Broker and IBM Sterling Connect:Direct on separate machines?** You can, but you must ensure that both machines have:
     - Access to the same shared filesystem.
     - The same timezone setting.

     As IBM Sterling Connect:Direct does not support NFS file systems on z/OS, this configuration does not work on z/OS
  3. **Can I have this shared filesystem mounted at different places on my WebSphere Message Broker and IBM Sterling Connect:Direct machines for platforms other than Windows?** Set the `brokerPathToStagingDir` to be the location where it is mounted on the WebSphere Message Broker machine, and the `cdPathToStagingDir` to where it is mounted on the IBM Sterling Connect:Direct machine.
  4. **Can I have this shared filesystem mounted at different places on my WebSphere Message Broker and IBM Sterling Connect:Direct machines for Windows platforms?** You must use the `\\hostname\directory` path syntax to the shared drive, rather than a mapped drive letter. Moreover, the user ID accessing the `\\hostname\directory` path, that is the:

     WebSphere Message Broker user ID, or

     IBM Sterling Connect:Direct user ID

     - depending on which one is running on Windows, must have full (write) access to the file system, using the same password.

     Set the `brokerPathToStagingDir` to be the location where it is mounted on the WebSphere Message Broker machine, and the `cdPathToStagingDir` to where it is mounted on the IBM Sterling Connect:Direct machine.
- **Input**
  1. **Can I process files in the CDInput node if the WebSphere Message Broker and receiving Connect:Direct server are on different machines?** You can, but you must ensure that both machines have:
     - Access to the same shared filesystem.
     - The same timezone setting.

As IBM Sterling Connect:Direct does not support NFS file systems on z/OS, this configuration does not work on z/OS

2. **Can I have this shared filesystem mounted at different places on my WebSphere Message Broker and IBM Sterling Connect:Direct machines for platforms other than Windows?** Set the `brokerPathToInputDir` to be the location where it is mounted on the WebSphere Message Broker machine, and the `cdPathToInputDir` to where it is mounted on the IBM Sterling Connect:Direct machine.
3. **Can I have this shared filesystem mounted at different places on my WebSphere Message Broker and IBM Sterling Connect:Direct machines for Windows platforms?** You must use the UNC path syntax to the shared drive, rather than a mapped drive letter. Moreover, the user ID accessing the UNC path, that is the:

   WebSphere Message Broker user ID, or

   IBM Sterling Connect:Direct user ID

   - depending on which one is running on Windows, must have full (write) access to the file system, using the same password.

   Set the `brokerPathToInputDir` to be the location where it is mounted on the WebSphere Message Broker machine, and the `cdPathToInputDir` to where it is mounted on the IBM Sterling Connect:Direct machine.

Results

To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command.

```
mqsicreateconfigurableservice MYBROKER -c CDServer -o myCDServer
```

where

MYBROKER
is the name of the broker

CDServer
is the name of the configurable service

myCDServer
is the object name.

Note the -o *ObjectName* parameter can take any value.

Output

This example transfers a file using the CDOutput node called *CDOutput*, in a message flow called *messageflow1*, in execution group *default*, on broker *MYBROKER*.

The broker stages the file in the local file path `/tmp/cdtransfer/MYBROKER/default/messageflow1/CDOutput`.

The Connect:Direct server then tries to transfer the file using the file path `/cdserver/transfers/MYBROKER/default/messageflow1/CDOutput`.

These properties are used when the files systems are mounted differently on the broker and Connect:Direct server machines.

```
mqsichangeproperties MYBROKER -c CDServer
-o myCDServer -n brokerPathToStagingDir,cdPathToStagingDir
-v /tmp/cdtransfer,/cdserver/transfers
```

To pick up the updated values in the configurable service, restart the execution group and message flow.

Input

This example receives a file using the CDInput node called *CDInput*, in a message flow called *messageflow1*, in execution group *default*, on broker *MYBROKER*.

A file is transferred to the Connect:Direct server, to the directory `/cdserver/transfers/example1`.

WebSphere Message Broker attempts to process the same file, but using the path `/tmp/cdtransfer/example1`.

These properties are used when the file systems are mounted differently on the WebSphere Message Broker and Connect:Direct server machines.

```
mqsichangeproperties MYBROKER -c CDServer -o myCDServer
-n brokerPathToInputDir,cdPathToInputDir
-v /tmp/cdtransfer/example1,/cdserver/transfers/example1
```

To pick up the updated values in the configurable service, restart the execution group and message flow.

To display Connect:Direct server configurable services, use the **mqsireportproperties** command, as shown in the following example:

```
mqsireportproperties MYBROKER -c CDServer -o AllReportableEntityNames -r
```

Configuring for IMS:

You can use configurable services to enable the IMS nodes in the broker runtime environment to connect with the IMS system.

About this task

The following topics describe how to prepare the environment to connect to the IMS system, and how to change the connection details without the need to redeploy your message flow.

- "Preparing the environment for IMS nodes"
- "Changing connection information for the IMSRequest node" on page 732

Preparing the environment for IMS nodes:

Before you can use the IMS nodes, you must set up the broker runtime environment so that you can access the IMS system.

Before you begin

Before you start:

Read "IBM Information Management System (IMS)" on page 2129.

About this task

Complete the following steps to ensure that WebSphere Message Broker can connect to the IMS system.

Procedure

1. Ensure that IMS Connect is installed and started on the IMS system.
2. If you do not want to configure IMS connection properties directly on the IMSRequest node, define a configurable service for each IMS system to which you want to connect.

   For example, to create an IMSConnect configurable service for the IMS instance *IMSA* that is running on *test.ims.ibm.com*, port *9999*, run the **mqsicreateconfigurableservice** command as shown:

   ```
   mqsicreateconfigurableservice MB7BROKER -c IMSConnect -o myIMSConnectService
   -n Hostname,PortNumber,DataStoreName -v test.ims.ibm.com,9999,IMSA
   ```

For details about how to create, change, and report configurable services, see "Changing connection information for the IMSRequest node." You can use the IMSConnect configurable service to configure the IMSRequest node to use Secure Sockets Layer (SSL) protocol. For more information, see "Securing the connection to IMS by using SSL" on page 549.

3. Use the **mqsisetdbparms** command to set security details in the broker store.

   For example, to associate a user ID and password pair with an IMS Connect connection, run the **mqsisetdbparms** command as shown:

   ```
   mqsisetdbparms MB7BROKER -n ims::mySecurityIdentity -u myuserid -p mypassword
   ```

"**mqsisetdbparms** command" on page 3954
Use the **mqsisetdbparms** command to associate a specific user ID and password (or SSH identity file) with one or more resources that are accessed by the broker.

Changing connection information for the IMSRequest node:

You can create a configurable service that the IMSRequest node or message flow refers to at run time for connection information, instead of defining the connection

properties on the node or the message flow. The advantage being that you can change the host name, performance, and security values without needing to redeploy your message flow.

Before you begin

Before you start:

- Read "Configurable services" on page 1296 to find out more about configurable services.
- Read "IBM Information Management System (IMS)" on page 2129 for background information.

About this task

Use the IMSConnect configurable service to change the connection information for the IMSRequest node. Two configurable services can connect to the same instance of IMS Connect. The properties of the IMSConnect configurable service are described in "Configurable services properties" on page 3766.

You can use the IMSConnect configurable service to configure the IMSRequest node to use Secure Sockets Layer (SSL) protocol. For more information, see "Securing the connection to IMS by using SSL" on page 549.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates an IMSConnect configurable service for the IMS instance IMSA that is running on `test.ims.ibm.com` port 9999:

  ```
  mqsicreateconfigurableservice MB7BROKER -c IMSConnect -o myIMSConnectService
  -n Hostname,PortNumber,DataStoreName -v test.ims.ibm.com,9999,IMSA
  ```

- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. This example changes all the nodes that are configured to use the *myIMSConnectService* configurable service. After you run this command, the IMSRequest node connects to the production system (`production.ims.ibm.com`) instead of the test system (`test.ims.ibm.com`). The command also changes to coded character set identifier (CCSID) to 37.

  ```
  mqsichangeproperties MB7BROKER -c IMSConnect -o myIMSConnectService -n Hostname,CodedCharSetID
  -v production.ims.ibm.com,37
  ```

  See "Securing the connection to IMS by using SSL" on page 549 for information about how to turn on SSL support in the broker by setting the `UseSSL` and `SSLEncryptionType` IMSConnect configurable service properties.

- To display all IMSConnect configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

  ```
  mqsireportproperties MB7BROKER -c IMSConnect -o AllReportableEntityNames -r
  ```

- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

```
mqsideleteconfigurableservice MB7BROKER -c IMSConnect -o myIMSconnectService
```

You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Use the IMSRequest node to send a request to run a transaction on a local or remote IMS system, and wait for a response. IMS Connect must be configured and running on the IMS system.

Defining where the CORBARequest node gets the object reference:

You can specify an object reference name either on the CORBARequest node or by using a configurable service.

Before you begin

Before you start:

- Read “Common Object Request Broker Architecture (CORBA)” on page 2145 and “Configurable services” on page 1296 for background information.

About this task

By using configurable services, you can specify the location from which the CORBARequest node gets the object reference without the need to redeploy the message flow. You can also use the configurable service to specify this location for multiple CORBARequest nodes. To pick up new values when a configurable service is created or modified, you must reload the broker or execution group to which the message flow was deployed, by using the **mqsistop** and **mqsistart** commands, or the **mqsireload** command.

The properties of the CORBA configurable services are described in “Configurable services properties” on page 3766.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer (as described in “Using the WebSphere Message Broker Explorer to work with configurable services” on page 644) or the **mqsicreateconfigurableservice** command shown in the following example.

  This example creates a CORBA configurable service called "myCORBAService" that connects to the CORBA host on the local host on port 2809, and looks for the object reference called "Europe.region/Market.object". (For more information about how to specify the object reference, see “CORBA naming service” on page 2154.)

  ```
  mqsicreateconfigurableservice MB7BROKER -c CORBA -o myCORBAService
  -n namingService,objectReferenceName -v localhost:2809,Europe.region/Market.object
  ```

  To pick up the new values in the configurable service, restart the execution group and message flow.
- To change a configurable service, use the WebSphere Message Broker Explorer or the **mqsichangeproperties** command shown in the following example.

  This example changes the location of the object reference.

  ```
  mqsichangeproperties MB7BROKER -c CORBA -o myCORBAService -n namingService,objectReferenceName
  ```

  To pick up the updated values in the configurable service, restart the execution group and message flow.
- To display all CORBA configurable services, use the WebSphere Message Broker Explorer or the **mqsireportproperties** command shown in the following example.

  ```
  mqsireportproperties MB7BROKER -c CORBA -o AllReportableEntityNames -r
  ```
- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer or the **mqsideleteconfigurableservice** command shown in the following example.

  ```
  mqsideleteconfigurableservice MB7BROKER -c CORBA -o myCORBAService
  ```

  You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

Configuring for CICS Transaction Server for z/OS:

You can use configurable services to enable the CICSRequest node in the broker runtime environment to connect with CICS Transaction Server for z/OS.

About this task

The following topics describe how to prepare the environment to connect to CICS, and how to change the connection details without the need to redeploy your message flow.

- "Preparing the environment for the CICSRequest node"
- "Changing connection information for the CICSRequest node" on page 738

Preparing the environment for the CICSRequest node:

Before you can use the CICSRequest node, you must configure IP InterCommunications (IPIC) protocol on the target CICS Transaction Server for z/OS.

Before you begin

Before you start:

Read "CICS Transaction Server for z/OS connectivity" on page 2174 for background information.

About this task

The CICSRequest node can send IPIC requests over TCP/IP to CICS Transaction Server for z/OS Version 3.2 and later. Complete the following steps on CICS to perform this configuration:

Procedure

1. Set the System Initialization (SIT) parameter **TCPIP=YES**.
2. Define the TCP/IP address and host name for CICS. By default, they are defined in the PROFILE.TCPIP and TCPIP.DATA data sets.
3. Add a TCP/IP listener to CICS by using the following **CEDA** command to define a TCPIPSERVICE resource in a group:

   ```
   CEDA DEF TCPIPSERVICE(service-name) GROUP(group-name)
   ```

   Ensure that the group in which you define the service is in the GRPLIST system initialization parameter, so that the listener starts when CICS is started. Key fields are explained as follows:

   POrtnumber:
   The port on which the TCP/IP service listens.

   PROtocol:
   The protocol of the service is IPIC.

   TRansaction:
   The transaction that CICS runs to handle incoming IPIC requests. Set the field to CISS, which is the default.

   Backlog:
   The Backlog field is the number of TCP/IP connection requests are sent to CICS, which are placed in a TCP/IP queue to be assigned an IPCONN connection to CICS. The default value is 1. Do not use a value of 0; a value of 0 indicates that no TCP/IP connection requests are to be assigned an IPCONN connection to CICS, which disables incoming connection requests.

   Ipaddress:
   The IP address, in dotted decimal form, on which the TCPIPSERVICE resource listens. For configurations with more than one IP stack, specify ANY to make the TCPIPSERVICE resource listen on all addresses.

   SOcketclose:
   Whether CICS waits before closing the socket after issuing a receive for incoming data on that socket. To ensure that the connection from the CICSRequest node always remains open, set SOcketclose to NO for IPIC connections.

   SSl: Whether the CICS TCP/IP service is to use Secure Sockets Layer (SSL) protocol for encryption and authentication. Valid values are NO, YES, or CLIENTAUTH. Where:

   - NO indicates that SSL is not to be used.

- YES indicates that the personal certificate of the CICS region must be trusted by WebSphere Message Broker.
- CLIENTAUTH indicates that the personal certificate of the CICS region must be trusted by WebSphere Message Broker, and the WebSphere Message Broker personal certificate must be trusted by CICS.

  The CICSRequest node does not support a separate truststore, so the keystore file must provide both personal and signer certificates. For more information, see "Securing the connection to CICS Transaction Server for z/OS by using SSL" on page 547.

4. Use the following command to install the TCPIPSERVICE definition:

   ```
   CEDA INS TCPIPSERVICE(service-name) GROUP(group-name)
   ```

Changing connection information for the CICSRequest node:

You can create a configurable service that the CICSRequest node or message flow refers to at run time for connection information, instead of defining the connection properties on the node or the message flow. The advantage being that you can change the host name and performance values without needing to redeploy your message flow.

Before you begin

Before you start:

- Read "Configurable services" on page 1296 to find out more about configurable services.
- Read "CICS Transaction Server for z/OS overview" on page 2173 for background information.

About this task

Use the CICSConnection configurable service to change the CICS Transaction Server for z/OS connection information for the CICSRequest node. The advantage being that you can change the host name, performance, and security identity values without needing to redeploy your message flow. The properties of the CICSConnection configurable service are described in "Configurable services properties" on page 3766.

You can use the CICSConnection configurable service to configure the CICSRequest node to use Secure Sockets Layer (SSL) protocol. For more information, see "Securing the connection to CICS Transaction Server for z/OS by using SSL" on page 547.

Creating, changing, reporting, and deleting configurable services

Procedure

- To create a configurable service, use the WebSphere Message Broker Explorer; see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644 for more information, or the **mqsicreateconfigurableservice** command, as shown in the following example. This example creates a CICSConnection configurable service for the CICS instance that is running at `test.cics.ibm.com` port 12345. The broker is identified by APPLID *BRKApp* and qualifier *BRKQual*. The connection timeout is 10 seconds, the request timeout is 5 seconds, and the security identity is identified by *mySecurityIdentity* in this example:

  ```
  mqsicreateconfigurableservice MB7BROKER -c CICSConnection -o myCICSConnectionService
  -n cicsServer,clientApplid,clientQualifier,connectionTimeoutSecs,requestTimeoutSecs,
  securityIdentity
  -v tcp://test.cics.ibm.com:12345,BRKApp,BRKQual,10,5,mySecurityIdentity
  ```

- To change a configurable service, use the WebSphere Message Broker Explorer, or the **mqsichangeproperties** command, as shown in the following example. You must stop and start the execution group for the change of property value to take effect. This example changes the CICSRequest node that is configured to use the *myCICSConnectionService* configurable service. After you run this command, the CICSRequest node connects to the production system (`tcp://production.cics.ibm.com:12345`) instead of the test system (`tcp://test.cics.ibm.com:12345`).

  ```
  mqsichangeproperties MB7BROKER -c CICSConnection -o myCICSConnectionService
    -n cicsServer -v tcp://production.cics.ibm.com:12345
  ```

  See "Securing the connection to CICS Transaction Server for z/OS by using SSL" on page 547 for information about how to turn on SSL support in the broker by setting the `cicsServer` CICSConnection configurable service property.
- To display all CICSConnection configurable services, use the WebSphere Message Broker Explorer, or the **mqsireportproperties** command, as shown in the following example:

```
mqsireportproperties MB7BROKER -c CICSConnection -o AllReportableEntityNames -r
```

- You can delete a configurable service that you have created by using the WebSphere Message Broker Explorer, or the **mqsideleteconfigurableservice** command, as shown in the following example:

  ```
  mqsideleteconfigurableservice MB7BROKER -c CICSConnection -o myCICSConnectionService
  ```

  You can delete only custom-named configurable services; you cannot delete IBM-defined configurable services.

- "Determining the agent name" on page 743

Preparing the file system:

WebSphere Message Broker uses a location in its work path to store transfers to remote agents. It uses another location as the default directory for received files. The high-level directory path for both locations is:

- *workpath*/common/FTE

Ensure that enough space is available here for files that you will transfer to and from the broker by WebSphere MQ File Transfer Edition.

Preparing the queue manager:

WebSphere Message Broker tries to create all the required artifacts on the queue manager for the agent, and the coordination queue manager, if appropriate. It might not be possible to create all artifacts, due to the configuration of your machine, or permissions. If it fails to create them, or you want to create them yourself in advance, see "Scripts to create artifacts required for WebSphere MQ File Transfer Edition" on page 744.

Setting the coordination queue manager:

When a message flow that contains a WebSphere MQ File Transfer Edition node is deployed to an execution group, an agent is automatically created and started in that execution group. By default, the agent uses the broker's local queue manager as the coordination queue manager.

- If the broker's queue manager is being used as the coordination queue manager, the broker configures it as a coordination queue manager.
- If you are using a different queue manager as the coordination queue manager, refer to the WebSphere File Transfer Edition Information Center for details of how to configure it as a coordination queue manager.

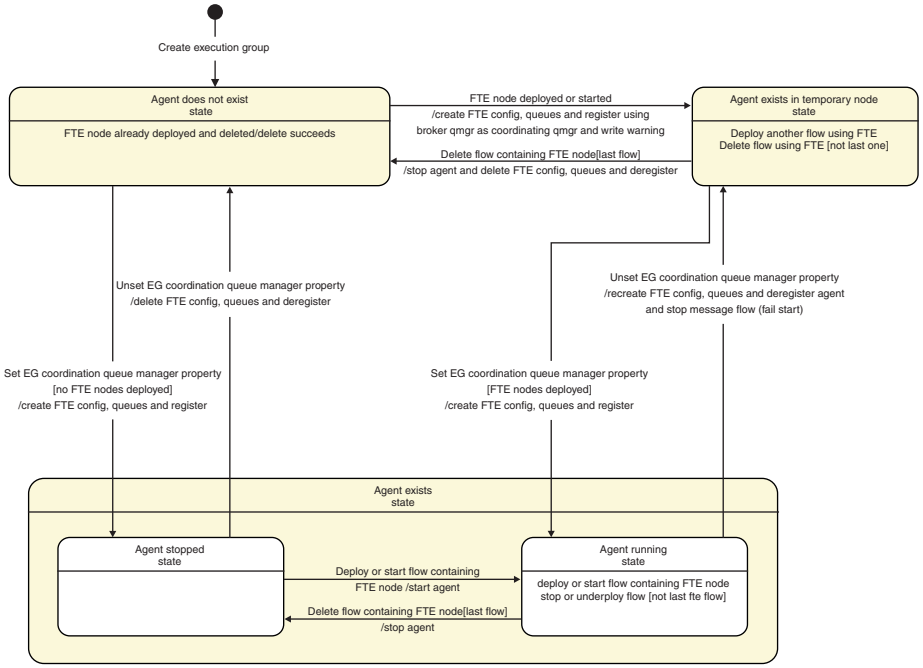
Unless you have previously defined the coordination queue manager, the agent is temporary; it is deleted when the flow is undeployed or the broker is stopped. This behavior is acceptable in a test environment. However, for production, the administrator must specify the coordination queue manager for the execution group. Specifying a coordination queue manager:

Ensures that the correct queue manager is used when the agent is created.

Makes the agent permanent. If a coordination queue manager has been defined, the agent is deleted only after you undefine the coordination queue manager (for example, by setting it to an empty string), and restart the execution group.

A warning is written to the log if the coordination queue manager is not changed from the default.

The following state diagram illustrates how the presence of nodes and a defined coordination queue manager affect the state of the agent.



About this task

Use one of the following methods to set the coordination queue manager.

Procedure

1. Optional: Use the **mqsichangeproperties** command.

   For example, to set the coordination queue manager to *QM2* for execution group myExecutionGroup in broker MB7BROKER:

   ```
   mqsichangeproperties MB7BROKER -e myExecutionGroup
   -o FTEAgent -n coordinationQMgr -v QM2
   ```

   After running this command, you must reload the execution group for the change to take effect.
2. Optional: Use the WebSphere Message Broker Explorer. Right-click the execution group, and select the appropriate options from the pop-up menu.

Naming execution groups:
About this task

The execution group name is used to form the queue name for WebSphere MQ File Transfer Edition queues. Consequently, the names of your execution groups must conform to the rules for naming WebSphere MQ objects. You cannot deploy a flow that contains a WebSphere MQ File Transfer Edition node unless this requirement is met. Permitted characters are:

- Uppercase A-Z
- Lowercase a-z (but there are restrictions on the use of lowercase letters for z/OS console support)

  On systems using EBCDIC Katakana you cannot use lowercase characters.
- Numerics 0-9
- Period (.)

- Forward slash (/)
- Underscore (_)
- Percent sign (%)

See the WebSphere MQ Version 7 Information Center online for full details of naming requirements.

Determining the agent name:
About this task

To send a file to a given execution group, users need to know the name of the agent that the broker creates. The agent name is derived from *Broker.ExecutionGroup*, and is not configurable. The total name length is limited to 28 characters, with a maximum 12 characters for the broker name, and 15 characters for the execution group. Broker and execution group names longer than these limits are truncated to form the agent name. The name must be a valid format for generating MQ Series queue name. Ensure that:

- The broker name is 12 characters or fewer (or at least unique in the first 12 characters).
- The execution group names are 15 characters or fewer (or at least unique in the first 15 characters).
- The broker and execution groups do not contain any characters that are invalid for queue names.
- The *broker.executiongroup* tuples are all unique, even if case is ignored.

The value used is written to the event log in message BIP3358. Use one of the following methods to determine the agent name.

Procedure

1. Optional: Use the **mqsireportproperties** command.

   For example, to display the FTE agent name for execution group FTESAMPLE in broker MB7BROKER:

   ```
   mqsireportproperties MB7BROKER -e FTESAMPLE -o FTEAgent -n agentName
   ```

   If the agent has been created, the command returns the agent name. If the agent has not been created, the command returns an empty string.
2. Optional: Use the WebSphere Message Broker Explorer. Right-click the execution group, and select the appropriate options from the pop-up menu.

"Preparing the environment for WebSphere MQ File Transfer Edition nodes" on page 740
Prepare the file system and queue managers, and determine the name of the broker agent.

Configuring for JMS:

You can use configurable services to configure WebSphere Message Broker for JMS.

About this task

- "Configuring the broker to enable a JMS provider's proprietary API" on page 748
- "Connecting to different versions of the same JMS provider" on page 750
- "Configuring the JMSInput node for batch message processing" on page 751

Configuring the broker to enable a JMS provider's proprietary API:

Some JMS providers provide an alternative interface to the standard JMS specification for particular JMS API calls. In these cases, IBM supplies a Java class to interface with that proprietary API.

About this task

For example, BEA WebLogic uses a component called a *Client Interposed Transaction Manager* to allow a JMS client to obtain a reference to the XAResource that is associated with a user transaction.

If the WebSphere Message Broker JMS nodes use BEA WebLogic as the JMS provider, and the nodes must participate in a globally coordinated message flow, you must modify the configurable services properties that are associated with that vendor. The following table shows the properties that have been added to the configurable service for BEA WebLogic.

JMS provider	Property	Purpose	Default value
BEA_WebLogic	`proprietaryAPIHandler`	The name of the IBM supplied Java class to interface with a JMS provider's proprietary API.	`com.ibm.broker.apihandler. BEAWebLogicAPIHandler`
	`proprietaryAPIAttr1`	The Initial Context Factory class name for the vendor	`weblogic.jndi. WLInitialContextFactory`
	`proprietaryAPIAttr2`	The URL of the WebLogic bindings	*URL JNDI bindings*
	`proprietaryAPIAttr3`	The DNS name of the JMS server	*Server name*

In the list of JMS provider configurable services, the name of the IBM supplied Java class is set to the default value for the `proprietaryAPIHandler` property. Typically, you do not need to change this value, unless you are instructed to do so by an IBM Service team representative.

Procedure

- Use the **mqsichangeproperties** command to modify values of the properties for this JMS provider.

  The following example shows how to change the values of the properties `proprietaryAPIAttr2` and `proprietaryAPIAttr3` for the JMS provider configurable service definition called BEA_Weblogic, where these properties represent the URL of the WebLogic bindings and the DNS Server name of the BEA WebLogic JMS Server:

  ```
  mqsichangeproperties MB7BROKER -c JMSProviders -o BEA_Weblogic
  -n proprietaryAPIAttr2,proprietaryAPIAttr3 -v t3://9.20.94.16:7001,BEAServerName
  ```

- Use the **mqsireportproperties** command to display the properties for a JMS provider.

  The following example shows how to display the properties for all the broker's JMS provider resources (the default JMS provider resources and those configurable services that are defined with the **mqsicreateconfigurableservice** command):

  ```
  mqsireportproperties MB7BROKER -c JMSProviders -o BEA_WebLogic –r
  ```

  The result of this command has the following format:

```
ReportableEntityName=''
JMSProviders
  BEA_Weblogic=''
    jarsURL='default_Path'
    nativeLibs='default_Path'
    proprietaryAPIAttr1='weblogic.jndi.WLInitialContextFactory'
    proprietaryAPIAttr2='t3://9.20.94.16:7001'
    proprietaryAPIAttr3='BEAServerName'
    proprietaryAPIAttr4='default_none'
    proprietaryAPIAttr5='default_none'
    proprietaryAPIHandler='com.ibm.broker.apihandler.BEAWebLogicAPIHandler'
```

The default location for the JMS provider JAR files is the broker's shared-classes directory. You can specify an alternative location for the JAR files by using the **mqsichangeproperties** command, as shown in the following example:

```
mqsichangeproperties MB7BROKER -c JMSProviders -o BEA_WebLogic -n jarsURL
-v /var/mqsi/WebLogic
```

On Windows, the file location cannot be a mapped network drive on a remote Windows computer; the directory must be local or on a Storage Area Network (SAN) disk.

- Use the **mqsicreateconfigurableservice** command to add a JMS provider.

  The following example shows how to add a JMS provider called BEAV91 for broker MB7BROKER, specifying the name of an IBM supplied Java class called `com.ibm.broker.apihandler.BEAWebLogicAPIHandler` to handle vendor-specific API calls:

  ```
  mqsicreateconfigurableservice MB7BROKER -c JMSProviders -o BEAV91
  -n proprietaryAPIHandler,proprietaryAPIAttr1,proprietaryAPIAttr2,proprietaryAPIAttr3
  –v com.ibm.broker.apihandler.BEAWebLogicAPIHandler,weblogic.jndi.WLInitialContextFactory,
  t3://9.20.94.16:7001,BEAServerName
  ```

- If you have defined a user-defined JMS provider configurable service, set the value for the `proprietaryAPIHandler` property manually.

Configuring the JMSInput node for batch message processing:

Configure JMS message flows to send a batch acknowledgment for receipt of non-transactional JMS messages.

About this task

When the JMSInput node works in non-transactional mode, receipt and acknowledgment of messages take place in one step, followed by the message processing. In some scenarios, this acknowledgment response to the JMS server for each message might create an unacceptable level of network traffic. For example, using this messaging model to receive JMS messages across a wide area network that is already handling large volumes of traffic might result in non-optimal throughput rates for JMS messages.

The JMSInput node can acknowledge message receipt in batches rather than individually for non-transactional messages. Batch acknowledgment is enabled using the JMSProviders configurable service properties **clientAckBatchSize** and **clientAckBatchTime**. You can set these properties separately, or use them together, to tune the number of messages that are received and processed by the node before an acknowledgment response is returned to the source JMS server.

clientAckBatchSize
: This an integer value that represents the threshold number of messages received before the batch acknowledgment is sent.

clientAckBatchTime
: This is an integer value that represents the length, in milliseconds, of a repeating interval. At the end of each interval a batch acknowledgment is sent for all unacknowledged non-transactional JMS messages that were received during the preceding interval.

A batch acknowledgment is also sent when:

- There are no more input messages on the JMS server
- An error occurs during message processing. In this case, all previous messages in the batch that were successfully processed are first acknowledged, before handling the error.
- The message flow stops.

To disable batch acknowledgment, set both **clientAckBatchSize** and **clientAckBatchTime** to `0`.

Importing a policy set and policy set binding:

Use the **mqsichangeproperties** command to import a policy set and associated binding.

About this task

This topic shows how to import policy set *myPolicySet* to broker *myBroker* from a file called *myPolicySet.xml*. The associated binding is *myPolicySetBinding*, which you import from *myPolicySetBinding.xml*.

Procedure

1. Create a configurable service for the policy set, if one does not already exist.

   ```
   mqsicreateconfigurableservice myBroker -c PolicySets -o myPolicySet
   BIP8071I: Successful command completion.
   ```

2. Create a configurable service for the policy set binding, if one does not already exist.

   ```
   mqsicreateconfigurableservice myBroker -c PolicySetBindings -o myPolicySetBinding
   BIP8071I: Successful command completion.
   ```

3. Import the policy set.

   ```
   mqsichangeproperties myBroker -c PolicySets -o myPolicySet -n ws-security -p myPolicySet.xml
   ```

4. Import the policy set binding.

   ```
   mqsichangeproperties myBroker -c PolicySetBindings -o myPolicySetBinding
      -n ws-security -p myPolicySetBinding.xml
   ```

5. Change the value of the associatedPolicySet attribute. Set it to the name of the policy set with which this policy set binding was originally associated.

   ```
   mqsichangeproperties myBroker -c PolicySetBindings -o myPolicySetBinding
      -n associatedPolicySet -v myPolicySet
   ```

Configuring for email:

You can use configurable services to enable the EmailOutput node and EmailInput node in the broker runtime environment to connect with email servers.

About this task

The following topics describe how to prepare the environment to connect to email servers, and how to change the connection details without the need to redeploy your message flow.

- "Changing connection information for the EmailOutput node" on page 1798
- "Changing connection information for the EmailInput node" on page 1805

Configuring internal resources required by flows

You can use configurable services to configure the internal resources that are required by some message flows.

About this task

The following topics describe how to configure the storage of events for certain message flow nodes.

- "Configuring the storage of events for aggregation nodes"
- "Configuring the storage of events for Collector nodes" on page 755
- "Configuring the storage of events for Resequence nodes" on page 758
- "Configuring the storage of events for timeout nodes" on page 760
- "Configuring the XPath cache" on page 765
- "Configuring monitoring event sources using a monitoring profile" on page 762

Configuring the storage of events for aggregation nodes:

You can use an Aggregation configurable service to control the storage of events for AggregateControl and AggregateReply nodes.

About this task

By default, the storage queues used by all aggregation nodes are:

- SYSTEM.BROKER.AGGR.CONTROL
- SYSTEM.BROKER.AGGR.REPLY
- SYSTEM.BROKER.AGGR.REQUEST
- SYSTEM.BROKER.AGGR.UNKNOWN
- SYSTEM.BROKER.AGGR.TIMEOUT

However, you can control the queues that are used by different aggregation nodes by creating alternative queues containing a *QueuePrefix*, and using an Aggregation configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry time of an aggregation:

Procedure

1. Create the storage queues to be used by the aggregation nodes. The following queues are required:

- SYSTEM.BROKER.AGGR.*QueuePrefix*.CONTROL
- SYSTEM.BROKER.AGGR.*QueuePrefix*.REPLY
- SYSTEM.BROKER.AGGR.*QueuePrefix*.REQUEST
- SYSTEM.BROKER.AGGR.*QueuePrefix*.UNKNOWN
- SYSTEM.BROKER.AGGR.*QueuePrefix*.TIMEOUT

The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.

2. Use the **mqsicreateconfigurableservice** command to create an Aggregation configurable service. You can create a configurable service to be used with either a specific aggregation or with all aggregations in an execution group.
   a. If the configurable service is to be used with a specific aggregation, ensure that the name of the configurable service is the same as the name that you specify in the `Aggregate name` property on the AggregateControl and AggregateReply nodes. If the configurable service is to be used with all aggregations in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Timeout** property to control the expiry time of an aggregation.

   For example, create a configurable service called `myAggregation`, which specifies queues prefixed with SYSTEM.BROKER.AGGR.SET1 and a timeout of 60 seconds:

   ```
   mqsicreateconfigurableservice MYBROKER -c Aggregation -o myAggregation
   -n queuePrefix,timeoutSeconds -v SET1,60
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Aggregation configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see “Configurable services properties” on page 3766
3. In the AggregateControl and AggregateReply nodes:
   a. Ensure that the name of the Aggregation configurable service is the same as the name specified in the `Aggregate name` property on the **Basic** tab; for example, `myAggregation`. If no Aggregation configurable service exists with the same name as the `Aggregate name` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see “Using the WebSphere Message Broker Explorer to work with configurable services” on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for Collector nodes:

You can use a Collector configurable service to control the storage of events for Collector nodes.

About this task

By default, the storage queues used by all Collector nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Resequence node.

However, you can control the queues that are used by different Collector nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Collector configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the expiry for the collection:

Procedure

1. Create the storage queues to be used by the Collector node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Collector configurable service. You can create a configurable service to be used with either a specific collection or with all collections in an execution group.
   a. If you are creating a configurable service to be used with a specific collection, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Collector node. If you are creating a configurable service to be used with all collections in the execution group, ensure that the configurable service has the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Collection expiry** property.

   For example, create a Collector configurable service called `myCollectorService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, and with a collection expiry of 60 seconds:

   ```
   mqsicreateconfigurableservice MYBROKER -c Collector -o myCollectorService
   -n queuePrefix,collectionExpirySeconds -v SET1,60
   ```

   You can use the **mqsideleteconfigurableservice** command to delete the Collector configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.

   For more information, see "Configurable services properties" on page 3766
3. In the Collector node:
   a. If the configurable service is to be used for a specific collection, specify the name of the configurable service in the `Configurable service` property on

the **Advanced** tab; for example, `myCollectorService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.

b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for Resequence nodes:

You can use a Resequence configurable service to control the storage of events for Resequence nodes.

About this task

By default, the storage queues used by all Resequence nodes are:

- SYSTEM.BROKER.EDA.EVENTS
- SYSTEM.BROKER.EDA.COLLECTIONS

These queues are also used by the Collector node.

However, you can control the queues that are used by different Resequence nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Resequence configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queues that are used to store event states, and to set the timeout and the start and end of the sequence:

Procedure

1. Create the storage queues to be used by the Resequence node. The following queues are required:
   - SYSTEM.BROKER.EDA.*QueuePrefix*.EVENTS
   - SYSTEM.BROKER.EDA.*QueuePrefix*.COLLECTIONS

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queues, WebSphere Message Broker creates the set of queues when the node is deployed; these queues are based on the default queues. If the queues cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Resequence configurable service. You can create a configurable service to be used with either a specific sequence or with all sequences in an execution group.
   a. If you are creating a configurable service to be used with a specific sequence, ensure that the name of the configurable service is the same as the name that you specify in the `Configurable service` property on the Resequence node. If you are creating a configurable service to be used with all sequences in the execution group, ensure that the configurable service has the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.
   c. Optional: Set the **Missing message timeout**, **Start of sequence**, and **End of sequence** properties.

   For example, create a Resequence configurable service called `myResequenceService`, which uses queues prefixed with SYSTEM.BROKER.EDA.SET1, with a missing message timeout of 60 seconds, and which waits five seconds before determining the start and end numbers in a sequence:

```
mqsicreateconfigurableservice MYBROKER -c Resequence -o myResequenceService
-n queuePrefix,missingMessageTimeoutSeconds,startSequenceSeconds,endSequenceSeconds -v SET1,60,5,
```

You can use the **mqsideleteconfigurableservice** command to delete the Resequence configurable service. However, the storage queues are not deleted automatically when the configurable service is deleted, so you must delete them separately.For more information, see "Configurable services properties" on page 3766

3. In the Resequence node:
   a. If the configurable service is to be used for a specific sequence, specify the name of the configurable service on the **Advanced** tab; for example, `myResequenceService`. If you do not set the `Configurable service` property, and if a configurable service exists with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring the storage of events for timeout nodes:

You can use a Timer configurable service to control the storage of events for TimeoutNotification and TimeoutControl nodes.

About this task

By default, the storage queue used by all timeout nodes is the SYSTEM.BROKER.TIMEOUT.QUEUE.

However, you can control the queues that are used by different timeout nodes by creating alternative queues that contain a *QueuePrefix* variable, and by using a Timer configurable service to specify the names of those queues for storing events.

Follow these steps to specify the queue that is used to store event states:

Procedure

1. Create the storage queue to be used by the timeout nodes. The following queue is required:
   - SYSTEM.BROKER.TIMEOUT.*QueuePrefix*.QUEUE

   The *QueuePrefix* variable can contain any characters that are valid in a WebSphere MQ queue name, but must be no longer than eight characters and must not begin or end with a period (.). For example, `SET1` and `SET.1` are valid queue prefixes, but `.SET1` and `SET1.` are invalid.

   If you do not create the storage queue, WebSphere Message Broker creates the queue when the node is deployed; this queue is based on the default queue. If the queue cannot be created, the message flow is not deployed.
2. Use the **mqsicreateconfigurableservice** command to create a Timer configurable service. You can create a configurable service to be used with either specific timeout requests or with all timeout requests in an execution group.
   a. If the configurable service is to be used with specific timeout requests, create the configurable service with the same name as the `Unique identifier` property on the TimeoutNotification and TimeoutControl nodes. If the configurable service is to be used with all timeout requests in an execution group, create the configurable service with the same name as the execution group.
   b. Set the **Queue prefix** property to the required value.

   For example, create a Timer configurable service that uses a queue prefixed with SYSTEM.BROKER.TIMEOUT.SET1:

```
mqsicreateconfigurableservice MB7BROKER -c Timer -o myTimer
-n queuePrefix -v SET1
```

You can use the **mqsideleteconfigurableservice** command to delete the Timer configurable service. However, the storage queue is not deleted automatically when the configurable service is deleted, so you must delete it separately.For more information, see "Configurable services properties" on page 3766.

3. In the TimeoutNotification and TimeoutControl nodes:
   a. Ensure that the name of the Timer configurable service is the same as the name specified in the `Unique Identifier` property on the **Basic** tab; for example, `myTimer`. If there is no Timer configurable service with the same name as the `Unique Identifier`, and if there is a configurable service with the same name as the execution group, that configurable service is used instead.
   b. Optional: Use the **mqsichangeproperties** and **mqsireportproperties** commands to change or view the properties of the configurable service. Alternatively, you can use the WebSphere Message Broker Explorer to view or modify a configurable service. For more information about working with configurable services, see "Using the WebSphere Message Broker Explorer to work with configurable services" on page 644.

What to do next

The properties for the configurable service are not used by the broker until you restart or redeploy the message flow, or restart the broker.

Configuring monitoring event sources using a monitoring profile:

You can create a monitoring profile and use the **mqsichangeflowmonitoring** command to configure your message flows to emit monitoring events.

Before you begin

Before you start:

Read the following topics:

- "Business-level monitoring" on page 3319
- "Monitoring basics" on page 3320

You must have a message flow that contains a node to which you want to add a monitoring event.

You can use XPath 1.0 expressions to configure a monitoring event.

Creating a monitoring profile:
About this task

First create a monitoring profile XML file. This is a file that lists the event sources in the message flow that will emit events, and defines the properties of each event.

Procedure

Follow the guidance at "Monitoring profile" on page 6768 to create your monitoring profile XML file.

Applying a monitoring profile:
About this task

When you have created a monitoring profile XML file, follow these steps to apply it.

Procedure

1. Use the **mqsicreateconfigurableservice** command to create a configurable service for the monitoring profile. In the following command example, replace *myBroker* with the name of your broker, and *myMonitoringProfile* with the name of your monitoring profile.

   ```
   mqsicreateconfigurableservice myBroker -c MonitoringProfiles
        -o myMonitoringProfile
   ```

2. Use the **mqsichangeproperties** command to associate your monitoring profile XML file with the configurable service. In the following command example, replace *myBroker* with the name of your broker, *myMonitoringProfile* with the name of your monitoring profile, and *myMonitoringProfile.xml* with the name of the monitoring profile XML file.

   ```
   mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
        -n profileProperties -p myMonitoringProfile.xml
   ```

   Set the `useParserNameInMonitoringPayload` property to TRUE to force the `wmb:applicationData/wmb:complexContent/wmb:elementName` attribute to hold the name of the input node parser, if present. See "MonitoringProfiles configurable service" on page 3781 for details.

   ```
   mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
        -n useParserNameInMonitoringPayload -v TRUE
   ```

3. Use the **mqsichangeflowmonitoring** command to apply a monitoring profile configurable service to one or more message flows.

   - Apply a monitoring profile to a single message flow *messageflow1* in execution group *EG1*:

     ```
     mqsichangeflowmonitoring myBroker -e EG1
          -f messageflow1 -m myMonitoringProfile
     ```

   - Apply a monitoring profile to all message flows in all execution groups:

     ```
     mqsichangeflowmonitoring myBroker -g -j -m myMonitoringProfile
     ```

   Monitoring for the flow is inactive; applying the monitoring profile does not activate it.

4. Alternatively, use the broker archive editor to apply a monitoring profile configurable service to one or more message flows, by setting message flow property **Monitoring Profile Name**.

   a. In the WebSphere Message Broker Toolkit, switch to the Broker Application Development perspective.

   b. In the Broker Development view, right-click the BAR file, then click **Open with** > **Broker Archive Editor**.

   c. Click the **Manage and Configure** tab.

   d. Click the message flow on which you want to set the monitoring profile configurable service. The properties that you can configure for the message flow are displayed in the **Properties** view.

   e. In the **Monitoring Profile Name** field, enter the name of a monitoring profile.

   f. Save the BAR file.

   g. Deploy the BAR file.

   Monitoring for the flow is inactive; deploying the BAR file does not activate it.

5. Activate monitoring for the flow using the `mqsichangeflowmonitoring -c` command.

   - Activate monitoring for a single message flow *messageflow1* in execution group *EG1*:

```
mqsichangeflowmonitoring myBroker -e EG1
     -f messageflow1 -c active
```

- Activate monitoring for all message flows in all execution groups:

```
mqsichangeflowmonitoring myBroker -g -j -c active
```

Updating a monitoring profile:

Procedure

1. Follow the guidance at "Monitoring profile" on page 6768 to update your monitoring profile XML file.
2. Use the **mqsichangeproperties** command to update the configurable service to use the new XML file. For example:

```
mqsichangeproperties myBroker -c MonitoringProfiles -o myMonitoringProfile
     -n profileProperties -p myMonitoringProfile.xml
```

Related concepts:

"Monitoring basics" on page 3320
Message flows can be configured to emit events. The events can be read and used by other applications for transaction monitoring, transaction auditing, and business process monitoring.

"Configurable services" on page 1296
Configurable services are typically runtime properties. You can use them to define properties that are related to external services on which the broker relies; for example, an SMTP server or a JMS provider.

Related tasks:

"Business-level monitoring" on page 3319
You can configure your message flow to emit event messages that can be used to support transaction monitoring and auditing, and business process monitoring.

"Activating monitoring" on page 3334
Use the **mqsichangeflowmonitoring** command to activate monitoring after you have configured monitoring event sources.

Use the **mqsichangeflowmonitoring** command to enable monitoring of message flows.

"**mqsireportflowmonitoring** command" on page 3924
Use the **mqsireportflowmonitoring** command to display the current options for monitoring that have been set using the **mqsichangeflowmonitoring** command.

"Example XPath expressions for event filtering" on page 6781
Use numeric, string, or Boolean expressions when configuring an event source, to determine whether the event is emitted.

Configuring the XPath cache:

The XPath cache has a default size of 100 elements. However, this default size might become a performance bottleneck for customers who use many XPath expressions with a single flow invocation completely invalidating the cache. Altering the size of the XPath cache might improve message flow performance.

An Execution Group keeps a cache of compiled XPath expressions to help reduce the processor usage of parsing and re-creating XPath expressions that are used repeatedly during Message Flow execution. This cache is shared by all Message Flows within an Execution Group. The default size of this cache is 100.

It might be necessary to alter the size of this cache for optimal message flow performance if many XPath expressions are created for each Message Flow invocation. In a highly multi-threaded environment where many XPath expressions are evaluated on each Message Flow invocation, it might be necessary to disable the cache to remove thread contention on the cache.

The property can be set by running the following **mqsichangeproperties** command:

```
mqsichangeproperties <broker> -e <eg> -o ExecutionGroup -n compiledXPathCacheSizeEntries -v <value
```

where *<value>* is the size of the cache to be set. The size can be set to any value greater than or equal to 100. A value of 0 means that the cache is disabled. The default value is 100.

The configured value can be reported by running the following **mqsireportproperties** command:

```
mqsireportproperties <broker> -e <eg> -o ExecutionGroup -n compiledXPathCacheSizeEntries
```

and can also be reported as part of the other ExecutionGroup level properties:

```
mqsireportproperties <broker> -e <eg> -o ExecutionGroup -a
```

To disable the cache for broker *BRK1* and execution group *EG1*, run the following command:

```
mqsichangeproperties BRK1 -e EG1 -o ExecutionGroup -n compiledXPathCacheSizeEntries -v 0
```

Related concepts:

"XPath overview" on page 1507
The XML Path Language (XPath) is used to uniquely identify or address parts of an XML document. An XPath expression can be used to search through an XML document, and extract information from any part of the document, such as an element or attribute (referred to as a *node* in XML) in it. XPath can be used alone or in conjunction with XSLT.

Related tasks:

"Using XPath" on page 1506
XPath provides an alternative method to ESQL for entering expressions in the property fields of specific built-in nodes.

WS-Security

Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

WS-Security is a message-level standard that is based on securing SOAP messages through XML digital signature, confidentiality through XML encryption, and credential propagation through security tokens. The Web services security specification defines the facilities for protecting the integrity and confidentiality of a message and provides mechanisms for associating security-related claims with the message.

WS-Security provides a general-purpose mechanism for associating security tokens with messages. No specific type of security token is required by WS-Security. It is designed to be extensible, for example, to support multiple security token formats.

WS-Security also describes how to encode binary security tokens and attach them to SOAP messages. Specifically, the WS-Security profile specifications describe how to encode the following tokens:

- Username tokens
- X.509 certificates
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

With WS-Security, the domain of these mechanisms can be extended by carrying authentication information in Web services requests. WS-Security also includes extensibility mechanisms that can be used to further describe the credentials that are included with a message. WS-Security is a building block that can be used in conjunction with other Web service protocols to address a wide variety of application security requirements.

There are numerous advantages to using WS-Security.

- Different parts of a message can be secured in a variety of ways. For example, you can use integrity on the security token (user ID and password) and confidentiality on the SOAP message body.
- Intermediaries can be used and end-to-end message-level security can be provided through any number of intermediaries.
- WS-Security works across multiple transports and is independent of the underlying transport protocol.
- Authentication of both individual users and multiple party identities is possible.

Traditional Web security mechanisms, such as HTTPS, might be insufficient to manage the security requirements of all Web service scenarios. For example, when an application sends a SOAP message using HTTPS, the message is secured only for the HTTPS connection, meaning during the transport of the message between the service requester (the client) and the service. However, the application might require that the message data be secured beyond the HTTPS connection, or even beyond the transport layer. By securing Web services at the message level, message-level security is capable of meeting these expanded requirements.

Message-level security, or securing Web services at the message level, addresses the same security requirements as for traditional Web security. These security requirements include: identity, authentication, authorization, integrity, confidentiality, nonrepudiation, and basic message exchange. Both traditional Web and message-level security share many of the same mechanisms for handling security, including digital certificates, encryption, and digital signatures.

With message-level security, the SOAP message itself either contains the information needed to secure the message or it contains information about where to get that information to handle security needs. The SOAP message also contains information relevant to the protocols and procedures for processing the specified message-level security. However, message-level security is not tied to any particular transport mechanism. Because the security information is part of the message, it is independent of a transport protocol, such as HTTPS.

The client adds to the SOAP message header security information that applies to that particular message. When the message is received, the Web service endpoint, using the security information in the header, verifies the secured message and validates it against the policy. For example, the service endpoint might verify the message signature and check that the message has not been tampered with. It is possible to add signature and encryption information to the SOAP message headers, as well as other information such as security tokens for identity (for example, an X.509 certificate) that are bound to the SOAP message content.

Without message-level security, the SOAP message is sent in clear text, and personal information such as a user ID or an account number is not protected. Without applying message-level security, there is only a SOAP body under the SOAP envelope in the SOAP message. By applying features from the WS-Security specification, the SOAP security header is inserted under the SOAP envelope in the SOAP message when the SOAP body is signed and encrypted.

To keep the integrity or confidentiality of the message, digital signatures and encryption are typically applied.

- Confidentiality specifies the confidentiality constraints that are applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.
- Integrity is provided by applying a digital signature to a SOAP message. Confidentiality is applied by SOAP message encryption.

You can add an authentication mechanism by inserting various types of security tokens, such as the Username token (element). When the Username token is received by the Web service server, the user name and password are extracted and verified. Only when the user name and password combination is valid, will the message be accepted and processed at the server. Using the Username token is just one of the ways of implementing authentication. This mechanism is also known as basic authentication.

The OASIS Web Services Security Specification provides a set of mechanisms to help developers of Web Services secure SOAP message exchanges. For details of the OASIS Web Services Security Specification, see OASIS Standard for WS-Security Specification.

WS-Security mechanisms

The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

Authentication

This mechanism uses a security token to validate the user and determine whether a client is valid in a particular context. A client can be a user, computer, or application. Without authentication, an attacker can use spoofing techniques to send a modified SOAP message to the service provider.

In authentication, a security token is inserted in the request message. Depending on the type of security token that is being used, the security token can also be inserted in the response message. The following types of security token are supported for authentication:

- Username tokens
- X.509 certificates
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

Username tokens are used to validate user names and passwords. When a Web service server receives a username token, the user name and password are extracted and passed to a user registry for verification. If the user name and password combination is valid, the result is returned to the server and the message is accepted and processed. When used in authentication, username tokens are typically passed only in the request message, not the response message.

X.509 tokens are validated by using a certificate path.

The broker support for SAML assertions is restricted to passing the token to a WS-Trust security token server (STS) for validation.

Kerberos tickets are validated against the host's Kerberos `keytab` file.

The broker support for LTPA binary tokens is restricted to passing the token to a WS-Trust STS for validation.

All types of token must be protected. For this reason, if you send them over an untrusted network, take one of the following precautions:
- Use HTTPS
- Configure the policy set to protect the appropriate elements in the SOAP header

Integrity

This mechanism uses message signing to ensure that information is not changed, altered, or lost accidentally. When integrity is implemented, an XML digital signature is generated on the contents of a SOAP message. If unauthorized changes are made to the message data, the signature is not validated. Without integrity, an attacker can use tampering techniques to intercept a SOAP message between the Web service client and server, and modify it.

Confidentiality

This mechanism uses message encryption to ensure that no party or process can access or disclose the information in the message. When a SOAP message is encrypted, only a service that knows the appropriate key can decrypt and read the message.

Related concepts:

"WS-Security" on page 765
Web Services Security (WS-Security) describes enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. WS-Security mechanisms can be used to accommodate a wide variety of security models and encryption technologies.

Implementing WS-Security

Configure authentication, XML encryption, XML signature, and message expiration by using the Policy Sets and Policy Set Bindings editor.

About this task

You use the Policy Sets and Policy Set Bindings editor in the WebSphere Message Broker Explorer to configure the following aspects of WS-Security:

"Authentication"

"Confidentiality" on page 771

"Integrity" on page 772

"Expiration" on page 773

Authentication:
About this task

The following tokens are supported:

- Username
- X.509
- SAML assertions
- Kerberos tickets
- LTPA binary tokens

Configuring authentication with username tokens:

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Policy Sets**.
3. Create a policy set and add UserName authentication tokens to it; see "Policy Sets and Policy Set Bindings editor: Authentication tokens panel" on page 6843.
4. Further configure any X.509 authentication tokens defined in the associated policy set; see "Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854.
5. Configure a security profile; see "Message flow security and security profiles" on page 788.
6. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.

Configuring authentication with X.509 tokens:

1. If you are using the broker's truststore to hold the trusted certificate, you must configure it; see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780 or "Viewing and setting keystore and truststore runtime properties at execution group level" on page 783 depending on where you want to set keystore and truststore runtime properties.
2. Create a policy set and add UserName and X.509 authentication tokens to it; see "Policy Sets and Policy Set Bindings editor: Authentication tokens panel" on page 6843.
3. Configure the certificate mode for either broker truststore or an external security provider; see "Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854.
4. If you are using an external security provider, configure a security profile; see "Message flow security and security profiles" on page 788.
5. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785

Configuring authentication with SAML assertions:

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Policy Sets**.
3. Create a policy set and add SAML pass-through 1.1 or SAML pass-through 2.0 tokens to it; see "Policy Sets and Policy Set Bindings editor: Authentication tokens panel" on page 6843. SAML pass-though does not enforce subject confirmation, but the assertion is simply provided as a token to be processed in the external Security Token Server specified in the security profile that is associated with the node.
4. Configure a security profile. The security profile must be configured to use a WS-Trust v1.3 STS. For more information, see "Message flow security and security profiles" on page 788.
5. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.

Configuring authentication with Kerberos tickets:

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Policy Sets**.
3. Create a policy set and add your Kerberos token type as symmetric tokens; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845.
4. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.
5. Configure the host's Kerberos `keytab` file. For more information about Kerberos configuration, see the documentation for your broker's host system. For example, for Windows, see the "Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability", which you can access at `http://technet.microsoft.com/en-us/library/`.

Configuring authentication with LTPA binary tokens:

1. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
2. In the Properties window, select the Security tab, and click **Policy Sets**.
3. Create a policy set and add LTPA tokens to it; see "Policy Sets and Policy Set Bindings editor: Authentication tokens panel" on page 6843. The LTPA binary token is passed through to the external Security Token Server (STS) specified in the security profile that is associated with the node.
4. Configure a security profile. The security profile must be configured to use a WS-Trust v1.3 STS. For more information, see "Message flow security and security profiles" on page 788.
5. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.

Confidentiality:
About this task

Confidentiality is provided by XML encryption, and requires either X.509 tokens or Kerberos tickets.

Configuring XML encryption with X.509 tokens:

1. If you are using the broker's truststore to hold the trusted certificate, you must configure it; see "Viewing and setting keystore and truststore

runtime properties at broker level" on page 780 or "Viewing and setting keystore and truststore runtime properties at execution group level" on page 783, depending on where you want to set keystore and truststore runtime properties.

2. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
3. In the Properties window, select the **Security** tab, and click **Policy Sets**.
4. Create a policy set, enable XML encryption, create encryption tokens, and select the encryption algorithms that you will use; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845.
5. Define which parts of a message are to be encrypted; see "Policy Sets and Policy Set Bindings editor: Message Part Protection panel" on page 6849.
6. Further configure message part encryption; see "Policy Sets and Policy Set Bindings editor: Message Part Policies panel" on page 6856.
7. Further configure the keystore and truststore; see "Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858.
8. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.

Configuring XML encryption with Kerberos tickets:

1. Configure your host for Kerberos, providing a `krb.conf` configuration file. This step is required on all operating systems, including Windows.
2. Provide the broker with the Kerberos client credentials for accessing the Kerberos Key Distribution Center (KDC). These credentials (which are required for SOAPRequest nodes) can be provided in the Broker properties tree, or by using the **`mqsisetdbparms`** command. The credentials are taken in order of priority:
   - The node has a security profile with the **`propagation`** property set to *True* and the Properties tree username and password token is present. If no Username and password token exists, an exception in thrown.
   - mqsisetdbparms kerberos::<realm>::<execution group name>
   - mqsisetdbparms kerberos::<realm>
   - mqsisetdbparms kerberos::kerberos
3. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
4. In the Properties window, select the **Security** tab, and click **Policy Sets**.
5. Create a policy set and add the required Kerberos token type as Symmetric Tokens; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845.

Integrity:
About this task

Integrity is provided by XML signature, and requires either X.509 tokens or Kerberos tickets.

Configuring XML signature with X.509 tokens:

1. If you are using the broker's truststore to hold the trusted certificate, you must configure it; see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780 or "Viewing and

setting keystore and truststore runtime properties at execution group level" on page 783 depending on where you want to set keystore and truststore runtime properties.

2. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
3. In the Properties window, select the Security tab, and click **Policy Sets**.
4. Create a policy set, enable XML signature, and create signature tokens; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845.
5. Define which parts of a message are to be signed; see "Policy Sets and Policy Set Bindings editor: Message Part Protection panel" on page 6849.
6. Further configure message part signature; see "Policy Sets and Policy Set Bindings editor: Message Part Policies panel" on page 6856.
7. Further configure the keystore and truststore; see "Policy Sets and Policy Set Bindings editor: Key Information panel" on page 6858.
8. Associate the policy set with a message flow or node; see "Associating policy sets and bindings with message flows and nodes" on page 785.

Configuring XML signature with Kerberos tickets:

1. Configure your host for Kerberos, providing a `krb.conf` configuration file. This step is required on all operating systems, including Windows.
2. Provide the broker with the Kerberos client credentials for accessing the Kerberos Key Distribution Center (KDC). These credentials (which are required for SOAPRequest nodes) can be provided in the Broker properties tree, or by using the **mqsisetdbparms** command. The credentials are taken in the following order of priority:
   - The node has a security profile with the **propagation** property set to *True* and the Properties tree username and password token is present. If no Username and password token exists, an exception in thrown.
   - mqsisetdbparms kerberos::<realm>::<execution group name>
   - mqsisetdbparms kerberos::<realm>
   - mqsisetdbparms kerberos::kerberos
3. In the WebSphere Message Broker Explorer, right-click on the broker with which you want to work, and click **Properties**.
4. In the Properties window, select the **Security** tab, and click **Policy Sets**.
5. Create a policy set and add the required Kerberos token type as Symmetric Tokens; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845.

Expiration:
Procedure

To configure message expiration, see "Policy Sets and Policy Set Bindings editor: Message Expiration panel" on page 6862.

Related concepts:

"Policy sets" on page 774
Policy sets and bindings define and configure your WS-Security requirements, supported by WebSphere Message Broker, for the SOAPInput, SOAPReply, SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes.

"Viewing and setting keystore and truststore runtime properties at broker level" on page 780
Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

"Viewing and setting keystore and truststore runtime properties at execution group level" on page 783
Configure an execution group to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

"Associating policy sets and bindings with message flows and nodes" on page 785
Use the Broker Archive editor to associate policy sets and bindings with message flows and nodes, so that they are available to the broker at run time.

Related reference:

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Policy sets

Policy sets and bindings define and configure your WS-Security requirements, supported by WebSphere Message Broker, for the SOAPInput, SOAPReply, SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes.

A *policy set* is a container for the WS-Security policy type.

A policy set *binding* is associated with a policy set and contains information that is specific to the environment and platform, such as information about keys.

Use policy sets and bindings to define the following items for both request and response SOAP messages:

- Authentication for the following tokens:
  - Username tokens (requires a security profile to specify the external security provider)
  - X.509 certificates (requires the broker keystore and truststore, or a security profile to specify the external security provider)
  - SAML assertions, using SAML 1.1 or 2.0 pass-through (requires a security profile to specify the external security provider)
  - LTPA tokens, using LTPA pass-through (requires a security profile to specify the external security provider)
- Asymmetric encryption (confidentiality) using X.509 certificates (requires the broker keystore and truststore)
- Symmetric encryption (confidentiality) using Kerberos tokens (requires the host to be configured for Kerberos)
- Asymmetric signature (integrity) (requires the broker keystore and truststore)

Either the whole SOAP message body, or specific parts of the SOAP message header and body can be encrypted and signed.

You administer policy sets and bindings from WebSphere Message Broker Explorer, which can add, delete, display and edit policy sets and bindings. Any changes to

policy sets or bindings in the toolkit are saved directly to the associated broker. You must stop and then restart the message flow for the new configuration information to take effect.

You can also export and import policy sets and bindings from a broker.

- "Exporting a policy set and policy binding" on page 786
- "Importing a policy set and policy set binding" on page 752

Policy sets and their associated bindings must be saved and restored together.

Policy sets are associated with a message flow, a node or both in the Broker Archive editor. For convenience, you can specify settings for *provider* and *consumer* at the message flow level. The provider setting applies to all SOAPInput and SOAPReply nodes in the message flow. The consumer setting applies to all SOAPRequest, SOAPAsyncRequest, and SOAPAsyncResponse nodes. Individual policy set and binding assignments can be applied at the node level in the Broker Archive editor, and these take precedence over the flow-level provider and consumer settings. The default setting is *none*, meaning that no policy set and bindings are to be used.

Several nodes in the same message flow can refer to the same policy set and bindings. It is the responsibility of the administrator to ensure that the required policy sets are available to the broker at run time. An error is reported if the broker cannot find the associated policy set or bindings.

The rest of this topic describes some of the terms that you will meet when configuring policy sets and bindings.

Default policy set and bindings

When a broker is created, a default policy set and bindings are created called WSS10Default. This default contains a limited security policy which specifies that a Username token is present in request messages (inbound) to SOAPInput nodes in the associated message flow.

The default policy set binding refers to the default WSS10Default policy set. They are not editable.

Consumer and provider nodes

Nodes are either consumers or providers.

Consumer nodes

SOAPRequest
SOAPAsyncRequest
SOAPAsyncResponse

Provider nodes

SOAPInput
SOAPReply

Request and response

Request and response is a message exchange pattern (MEP). It describes a client that sends a SOAP Request message to a Web services server, which in turn sends a Response SOAP message back to the client. The Request message is always the

SOAP message from the client to the server, and the Response message is always the SOAP message reply from server to the client. The following table describes this pattern in relation to the WebSphere Message Broker SOAP nodes:

Node	Broker viewpoint	Request	Response
SOAPInput	SOAP message inbound	Inbound message	Not applicable
SOAPReply	SOAP message outbound	Not applicable	Outbound message
SOAPRequest	SOAP message outbound followed by a SOAP message inbound	Outbound message	Inbound message
SOAPAsyncRequest	SOAP message outbound	Outbound message	Not applicable
SOAPAsyncResponse	SOAP message inbound	Not applicable	Inbound message

Initiator and recipient

Initiator and recipient are roles defined in the exchange of SOAP messages.

Initiator
The role that sends the initial message in a message exchange.

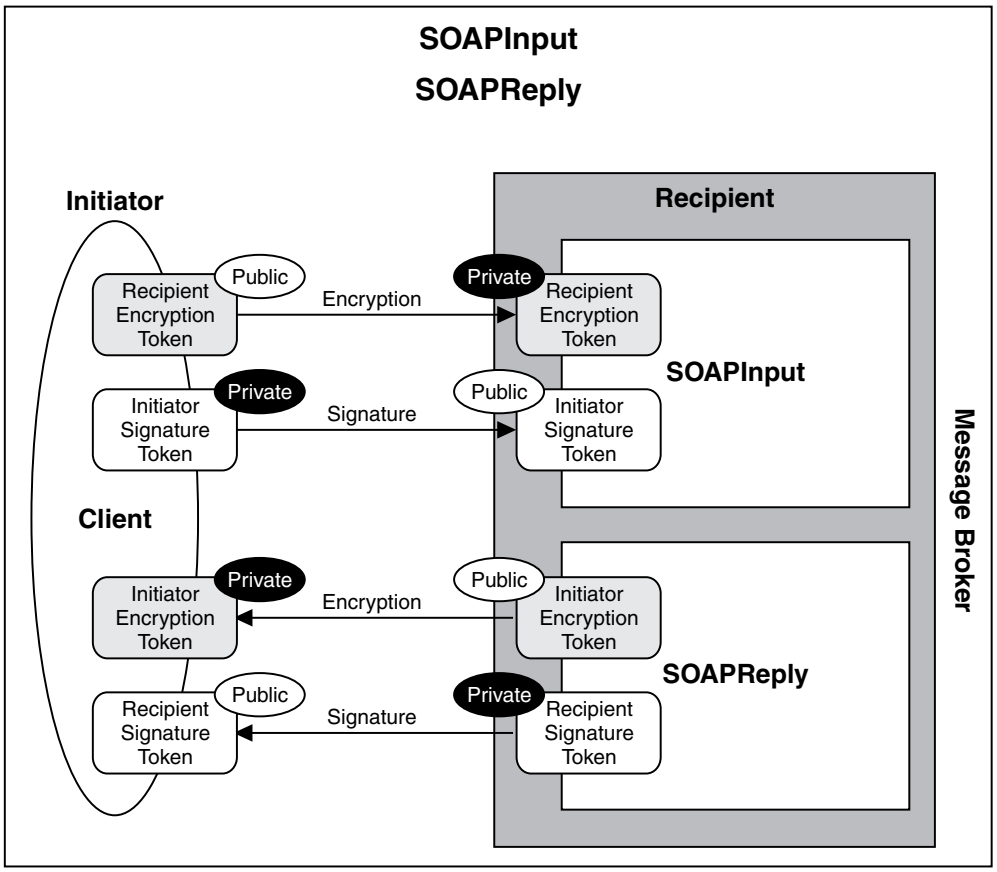
Recipient
The targeted role to process the initial message in a message exchange.

The following table describes these roles in relation to the Message Broker SOAP nodes:

Node	Broker viewpoint	Initiator	Recipient
SOAPInput	SOAP message inbound	External client sending SOAP message to the broker.	SOAPInput node
SOAPReply	SOAP message outbound	External client that sent the original SOAP message to the broker.	SOAPReply node
SOAPRequest (outbound)	SOAP message outbound followed by a SOAP message inbound	SOAPRequest node	External provider receiving the SOAP message
SOAPRequest (inbound)	SOAP message outbound followed by a SOAP message inbound	SOAPRequest node	External provider receiving the SOAP message
SOAPAsyncRequest	SOAP message outbound	SOAPAsyncRequest node	External provider receiving the SOAP message
SOAPAsyncResponse	SOAP message inbound	SOAPAsyncRequest node	External provider receiving the SOAP message

SOAPInput and SOAPReply nodes

In this diagram, the broker acts as recipient. A SOAPInput node receives a message from a client (initiator). A SOAPReply node replies. Inbound and outbound messages are signed and encrypted.



In the request:

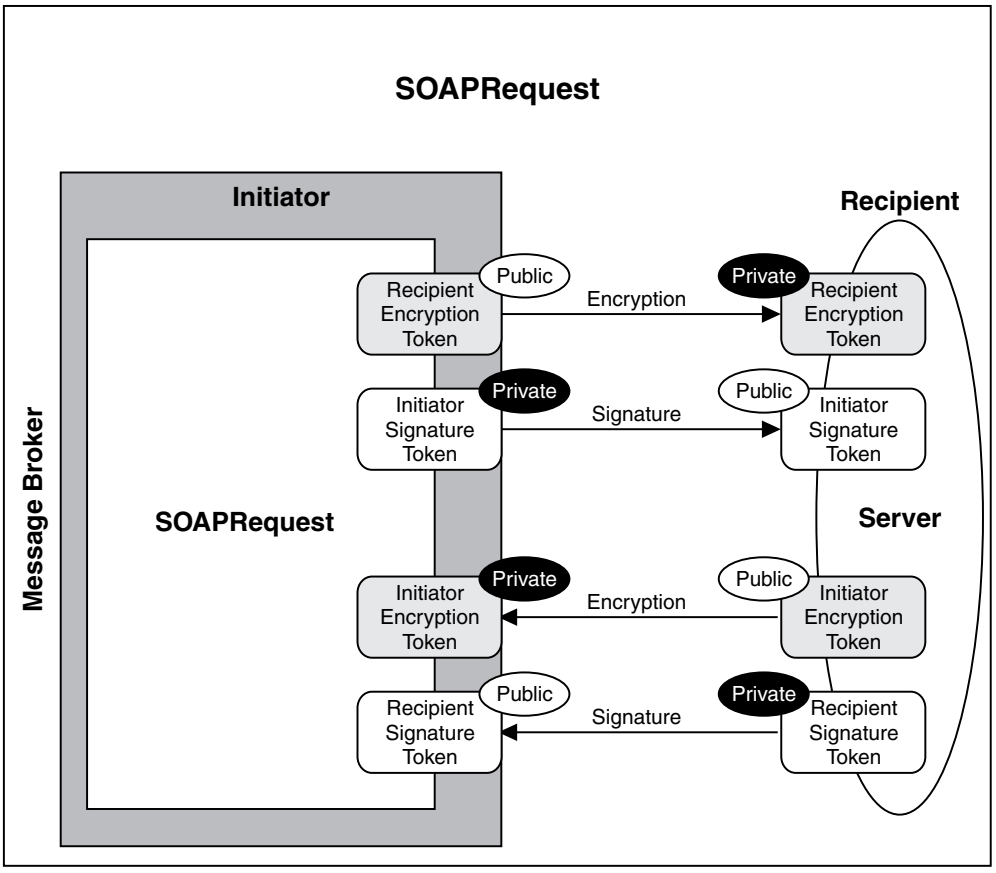
- The initiator uses the broker's public encryption token to encrypt the message, and its own private signature token to sign it.
- The broker uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

In the response:

- The broker uses the initiator's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The initiator uses its own private encryption token to decrypt the message, and the broker's public signature token to verify the signature.

SOAPRequest node

This diagram shows the broker acting as an initiator. It uses the SOAPRequest node to make a synchronous request to an external provider (the recipient). Inbound and outbound messages are signed and encrypted. Use of tokens is similar to the example of the asynchronous SOAP nodes, shown earlier.



In the request:

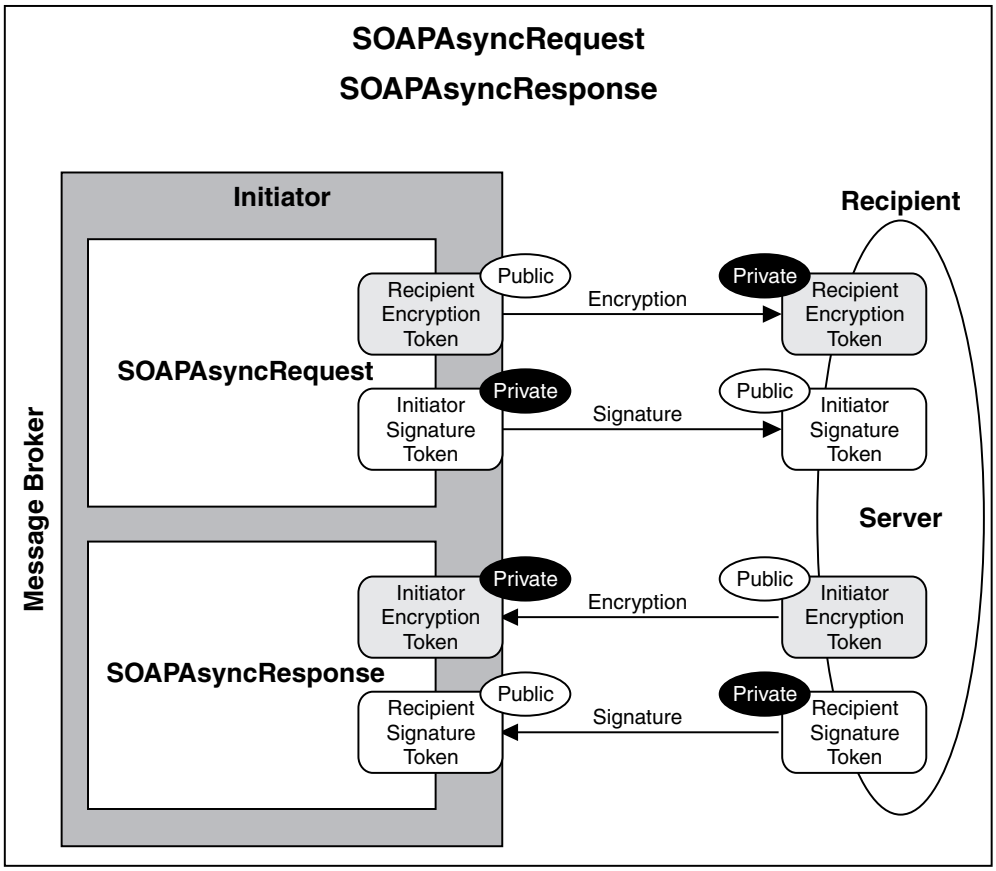
- The broker uses the recipient's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The recipient uses its own private encryption token to decrypt the message, and the broker's public signature token to verify the signature.

In the response:

- The recipient uses the broker's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The broker uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

Asynchronous SOAP nodes

This diagram shows the broker acting as an initiator. It uses the asynchronous SOAP nodes to make a request to an external provider (the recipient). Inbound and outbound messages are signed and encrypted.



In the request:

- The broker uses the recipient's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The recipient uses its own private encryption token to decrypt the message, and the broker's public signature token to verify the signature.

In the response:

- The recipient uses the broker's public encryption token to encrypt the message, and its own private signature token to sign the message.
- The broker uses its own private encryption token to decrypt the message, and the initiator's public signature token to verify the signature.

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Viewing and setting keystore and truststore runtime properties at broker level:

Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

About this task

Keystores and truststores are both keystores. They differ only in the way they are used.

Put all private keys and public key certificates (PKC) in the keystore.

Put all trusted root certificate authority (CA) certificates in the truststore. These certificates are used to establish the trust of any inbound public key certificates.

The only supported type of store is Java keystore (JKS).

Each instance of a broker can be configured to refer to one keystore and one truststore.

The following properties of the broker registry component must be defined correctly for policy sets and bindings:

brokerKeystoreFile
The directory and file location of the keystore.

brokerTruststoreFile
The directory and file location of the truststore.

Listing existing broker registry entries:
About this task

To display all broker registry values, run the command:

```
mqsireportproperties broker_name -o BrokerRegistry -a
```

This returns entries like these:

```
BrokerRegistry=''
  uuid='BrokerRegistry'
  brokerKeystoreType='JKS'
  brokerKeystoreFile=''
  brokerKeystorePass='brokerKeystore::password'
  brokerTruststoreType='JKS'
  brokerTruststoreFile=''
  brokerTruststorePass='brokerTruststore::password'
  httpConnectorPortRange=''
  httpsConnectorPortRange=''
```

Updating the broker reference to a keystore:
About this task

To update the broker reference to a keystore, use the following command:

```
mqsichangeproperties broker_name -o BrokerRegistry
  –n  brokerKeystoreFile
  -v c:\keystore\server.keystore
```

Where `c:\keystore\server.keystore` is the keystore to be referenced.

Updating the broker reference to a truststore:
About this task

To update the broker reference to a truststore, use the following command:

```
mqsichangeproperties broker_name -o BrokerRegistry
  –n  brokerTruststoreFile
  -v c:\truststore\server.truststore
```

Where `c:\truststore\server.truststore` is the truststore to be referenced.

Updating the broker with the keystore password:
About this task

Keystores and truststores normally require passwords for access. Use the **mqsisetdbparms** command to add these passwords to the broker runtime component.

```
mqsisetdbparms broker_name
  -n brokerKeystore::password
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Updating the broker with the truststore password:
About this task

To update the broker with the truststore password, use the following command:

```
mqsisetdbparms broker_name
  -n brokerTruststore::password
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Updating the broker with a private key password:
About this task

Private keys in the keystore might have their own individual passwords. These can be configured based on the alias name that is specified for the key in the Policy sets and bindings editor. If a key password based on the alias is not found, the keystore password is used. The following command updates the broker with the private key password for the key whose alias is *encKey*.

```
mqsisetdbparms broker_name
  -n brokerTruststore::keypass::encKey
  -u temp -p pa55word
```

The user ID, which can be any value, is not required to access the keystore.

Configure an execution group to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

Related reference:

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Viewing and setting keystore and truststore runtime properties at execution group level:

Configure an execution group to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

About this task

An execution group is a named grouping of message flows that have been assigned to a broker. The broker enforces a degree of isolation between message flows in distinct execution groups by ensuring that they run in separate address spaces, or as unique processes. For more information about execution groups, see "Execution groups" on page 53.

Execution group keystore and truststore runtime property values override equivalent property values on the broker, if any are set.

Keystores can contain two kinds of entries: key entries and trusted certificate entries. If a keystore is used to contain trusted certificates, it is typically referred to as a truststore. WebSphere Message Broker can refer to a keystore and a truststore per execution group. When the broker is encrypting or decrypting, it uses entries in its keystore; if the broker is verifying a signature or performing X.509 authentication, it uses entries in its truststore.

The following sample demonstrates the use of viewing and setting keystore and truststore runtime properties at execution group level:

- Address Book

You can view information about samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit or the online information center. You can run samples only when you use the information center that is integrated with the WebSphere Message Broker Toolkit.

Displaying execution group level properties:
About this task

To display execution group level properties, run the command:

```
mqsireportproperties broker_name -o ComIbmJVMManager -a -e execution_group
```

Updating the execution group reference to a keystore:
About this task

To update the broker reference to a keystore at an execution group level, use the following command:

```
mqsichangeproperties broker_name -e execution_group -o ComIbmJVMManager
  -n  keystoreFile
  -v c:\keystore\server.keystore,JKS
```

where `c:\keystore\server.keystore,JKS` is a Java keystore (JKS).

Updating the execution group reference to a truststore:
About this task

To update the broker reference to a truststore at an execution group level, use the following command:

```
mqsichangeproperties broker_name -e execution_group -o ComIbmJVMManager
  –n  truststoreFile
  -v c:\truststore\server.truststore
```

where `c:\truststore\server.truststore` is the truststore to be referenced.

Updating the keystore and truststore passwords:
About this task

The commands used to update the keystore and truststore passwords at execution group level are the same as those used when setting keystore and truststore runtime properties at broker level.

- To update the broker with the keystore password; see "Updating the broker with the keystore password" on page 782.
- To update the broker with the truststore password; see "Updating the broker with the truststore password" on page 782.
- To update the broker with a private key password; see "Updating the broker with a private key password" on page 782.

To use the default broker password for the keystore, the keystorePass parameter must be blank, or it must be set to `brokerKeystore::password`. To use a password other than the default broker password, use the following commands:

```
mqsichangeproperties broker_name -e execution_group -o ComIbmJVMManager -n keystorePass
-v execution_group::keystorePass

mqsisetdbparms broker_name -n execution_group::keystorePass -u na -p password
```

To use the default broker password for the truststore, the truststorePass parameter must be blank, or it must be set to `brokerTruststore::password`. To use a password other than the default broker password, use the following commands:

```
mqsichangeproperties broker_name -e execution_group -o ComIbmJVMManager -n truststorePass
-v execution_group::truststorePass

mqsisetdbparms broker_name -n execution_group::truststorePass -u na -p password
```

Adding new certificates to a keystore or truststore:
About this task

If you add new certificates to a keystore or truststore, to ensure that the new certificates are picked up, you must reload the Java virtual machine (JVM). You can reload the JVM by restarting the execution group.

Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

"Stopping an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 944
You can stop all the message flows in an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

"Starting an execution group using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer" on page 941
You can start an execution group and all the deployed message flows in an execution group by using the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer.

Related reference:

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Associating policy sets and bindings with message flows and nodes:

Use the Broker Archive editor to associate policy sets and bindings with message flows and nodes, so that they are available to the broker at run time.

Before you begin

Before you start

Use the Policy Sets and Policy Set Bindings editor to create and configure policy sets and bindings.

About this task

Associations can be made between policy sets and message flow, or specific nodes. Associations made with a flow apply to all nodes described in the Policy Set and Bindings file. Associations at the flow level are defined as being either for consumer or provider nodes.

An association at the node level overrides any association made at the flow level. You do not enter information about consumer or provider for an association at node level.

Procedure

1. In the WebSphere Message Broker Toolkit or WebSphere Message Broker Explorer, open the BAR file in the Broker Archive editor.
2. Click the **Manage and Configure** tab.
3. Click the message flow or node that you want to associate with a policy set and binding. The properties that you can configure for the message flow or for the node are displayed in the **Properties** view.

4. If you are configuring a message flow, enter values in the following fields in the **Properties** view, as appropriate:

   Provider Policy Set Bindings

   Provider Policy Set

   Consumer Policy Set Bindings

   Consumer Policy Set

5. If you are configuring a node, enter values in the following fields in the **Properties** view:

   Policy Set

   Policy Set Bindings

Example

What to do next

For new associations to take effect, the BAR file must be redeployed and the message flows stopped and restarted.

Related reference:

"Policy Sets and Policy Set Bindings editor" on page 6841
The Policy Sets and Policy Set Bindings editor is the default editor for editing, saving, importing, and exporting a policy set or binding. You can define all the WS-Security policies for a single node, or a set of nodes. The policy set can be associated by the administrator with either a message flow or a node.

Exporting a policy set and policy binding:

Use the **mqsireportproperties** command to export a policy set and associated binding to a file.

About this task

This topic shows how to export policy set *myPolicySet* from broker *myBroker* to a file called *myPolicySet.xml*. The associated binding is *myPolicySetBinding*, which you export to *myPolicySetBinding.xml*.

Procedure

1. Export the policy set to a file:

   ```
   mqsireportproperties myBroker -c PolicySets -o myPolicySet -n ws-security -p myPolicySet.xml
   ```

2. Export the policy set binding to a file:

   ```
   mqsireportproperties myBroker -c PolicySetBindings -o myPolicySetBinding
      -n ws-security -p myPolicySetBinding.xml
   ```

What to do next

Make a note of the policy set that is associated to the binding; you will need this information when you import the policy set and binding. This command displays the policy set associated with a binding:

```
mqsireportproperties myBroker -c PolicySetBindings -o myPolicySetBinding -n associatedPolicySet
```

This displays:

```
PolicySetBindings   myPolicySetBinding     associatedPolicySet='myPolicySet'
BIP8071I: Successful command completion.
```

Importing a policy set and policy set binding:

Use the **mqsichangeproperties** command to import a policy set and associated binding.

About this task

This topic shows how to import policy set *myPolicySet* to broker *myBroker* from a file called *myPolicySet.xml*. The associated binding is *myPolicySetBinding*, which you import from *myPolicySetBinding.xml*.

Procedure

1. Create a configurable service for the policy set, if one does not already exist.

   ```
   mqsicreateconfigurableservice myBroker -c PolicySets -o myPolicySet
   BIP8071I: Successful command completion.
   ```

2. Create a configurable service for the policy set binding, if one does not already exist.

   ```
   mqsicreateconfigurableservice myBroker -c PolicySetBindings -o myPolicySetBinding
   BIP8071I: Successful command completion.
   ```

3. Import the policy set.

   ```
   mqsichangeproperties myBroker -c PolicySets -o myPolicySet -n ws-security -p myPolicySet.xml
   ```

4. Import the policy set binding.

   ```
   mqsichangeproperties myBroker -c PolicySetBindings -o myPolicySetBinding
      -n ws-security -p myPolicySetBinding.xml
   ```

5. Change the value of the associatedPolicySet attribute. Set it to the name of the policy set with which this policy set binding was originally associated.

   ```
   mqsichangeproperties myBroker -c PolicySetBindings -o myPolicySetBinding
      -n associatedPolicySet -v myPolicySet
   ```

Message flow security and security profiles

WebSphere Message Broker provides a security manager for implementing message flow security, so that end-to-end processing of a message through a message flow is secured based on an identity carried in that message instance.

For details of the supported external providers and the operation of the message flow security manager, see "Message flow security overview" on page 383. For information about the token types that are supported by the SOAP nodes and by external security providers, see "Identity" on page 390.

When the message flow is a Web service implemented by using "SOAP nodes" on page 1609 and the identity is to be taken from the "WS-Security" on page 765 SOAP headers, the SOAP nodes are the Policy Enforcement Point (PEP) and the external provider defined by the "Security profiles" on page 387 is the Policy Decision Point (PDP).

The following configuration is required to implement message flow security based on an identity carried in `WS_Security` tokens.

- "Policy sets" on page 774 define the type of tokens used for the identity.
  - To work with a Username and Password identity, configure the policy and binding for Username token "Authentication" on page 770.
  - To work with a X.509 Certificate identity, configure the policy and binding for X.509 certificate token "Authentication" on page 770.

    In the Policy Set Binding, set the X.509 certificate Authentication Token `certificates` mode to `Trust Any`. You set it this way (and not to `Trust Store`) so that the certificate is passed to the security provider defined by the Security Profile. Setting it to `Trust Store` will cause the certificate to

be validated in the local Broker Trust Store. For more details, see "Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854.

  - To work with a SAML assertion token, configure the policy and binding for SAML token "Authentication" on page 770.
- The message flow security operation and external provider are defined by the "Security profiles" on page 387

As an alternative to message flow security and an external PDP, the broker's truststore can be used as a local PDP for X.509 certificate authentication. For WS-Security signing and encryption using only the local broker capability, you must configure the broker's truststore. For details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780, or "Viewing and setting keystore and truststore runtime properties at execution group level" on page 783.

Kerberos based WS-Security is supported in the SOAP nodes. When you use Kerberos for security, the SOAP node's WS-Security processing links directly with the host's Kerberos infrastructure. The broker host must be configured for Kerberos, providing a `krb.conf` file to define the Kerberos Key Distribution Center (KDC) and default realm. A Kerberos `keytab` file must also be configured. For more information about configuring Kerberos, see your host's Kerberos documentation.

To work with Kerberos WS-Security in SOAP nodes, create a policy set and bindings specifying Kerberos symmetric encryption tokens on the Message Level Protection panel; see "Policy Sets and Policy Set Bindings editor: Message Level Protection panel" on page 6845. Also configure the required settings on the Kerberos settings panel, as described in "Policy Sets and Policy Set Bindings editor: Kerberos settings panel" on page 6860, and then associate this policy set and bindings with the SOAP node. You can also associate SOAP nodes with a security profile that sets only propagation, so that Kerberos can be used to:

- Extract the service principal as a Username token from SOAP input nodes
- Propagate the Kerberos Key Distribution Center (KDC) credentials as a Username and password to SOAP request nodes.

"Broker component security" on page 497
You must consider several security aspects when you are setting up brokers running on Windows, Linux, or UNIX platforms.

"Creating a security profile" on page 433
You can create a security profile for use with Lightweight Directory Access Protocol (LDAP) or a WS-Trust V1.3 compliant security token server (STS), such as Tivoli Federated Identity Manager (TFIM) V6.2. Support is also provided for TFIM V6.1, for compatibility with previous versions of WebSphere Message Broker. You can create the security profile by using either the **mqsicreateconfigurableservice** command or an editor in the WebSphere Message Broker Explorer.

"Viewing and setting keystore and truststore runtime properties at broker level" on page 780
Configure the message broker to refer to a keystore, a truststore, or both, before deploying any message flows that require policy set or bindings for signature, encryption, or X.509 Authentication.

Related reference:

"Policy Sets and Policy Set Bindings editor: Authentication and Protection Tokens panel" on page 6854
Use this panel, which is in the Policy Set Bindings section of the editor, to further configure any X.509 authentication tokens defined in the associated policy set.

WS-Security capabilities

Web service security capabilities are supported by the broker.

Web service security mechanisms are defined by OASIS standards. See OASIS Standard for WS-Security Specification

For information about the token profile standards, see:

- OASIS Web Services Security Username Token Profile
- OASIS Web Services Security X.509 Certificate Token Profile
- OASIS Web Services Security Kerberos Token Profile

SAML pass-through support is provided, which enables interoperability with WS-Security SAML profiles, without performing subject confirmation processing. This means that it does not provide validation of the trust relationship between the SAML subject and message content signatures. For information about the SAML token profile standards, see:

- OASIS Web Services Security SAML Token Profile 1.1
- SAML V2 Specification

LTPA pass-through support is also provided, which enables LTPA binary tokens to be passed to an external security token server (STS) for processing.

For more information about using the token profiles, see the following topics:

- "Username token capabilities" on page 791
- "X.509 certificate token capabilities" on page 795

- "SAML token capabilities" on page 804
- "Kerberos token capabilities" on page 809
- "LTPA token capabilities" on page 813

"Username token capabilities for extraction and propagation" on page 794
This topic describes broker capability for extraction, propagation, or both using a username token in Web services.

Username token capabilities for authentication and authorization:

For Web services, you can complete authentication and authorization by using a Web Services Security username token.

For authentication, the Web Services Security username token must include both the username and the optional password.

The Web Services Security username token "Authentication" on page 768 and "Authorization" on page 401 is supported only in the following configuration:

Capability
- Authenticate
- Authorize

Policy Enforcement Point (PEP) and direction
- In (provider)

  "SOAPInput node" on page 4795

  Configured with a security policy and binding that defines that a Web Services Security username token is present for authentication; see "Authentication" on page 770. You can use the default policy and binding WSS10Default; see "Default policy set and bindings" on page 775.

  Configured with a security profile defining the Policy Decision Point (PDP); see the PDP section that follows.

Trust Store or PDP
- LDAP

  Configured by using an LDAP security profile specifying authentication, authorization, or both; see "Creating a security profile for LDAP" on page 435. For authentication, both a username and password are required.
- WS-Trust v1.3 STS

  Configured by using a WS-Trust v1.3 STS security profile specifying authentication, authorization or both; see "Creating a security profile for WS-Trust V1.3 (TFIM V6.2)" on page 440. For authentication, both a username and password are required.
- TFIM V6.1

  Configured by using a TFIM security profile specifying authentication, authorization or both; see "Creating a security profile for TFIM V6.1" on page 444. For authentication, both a username and password are required.

X.509 certificate token capabilities for encryption:

For Web services, you can complete encryption by using an X.509 certificate token.

X.509 certificate token encryption for providing message "Confidentiality" on page 769 on outgoing SOAP messages from the broker is supported in the following configurations:

Capability

- Encrypt (by using a partner public key)

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncRequest node" on page 4750
- Out (provider)

  "SOAPReply node" on page 4819

  Configured with a policy set and binding defining the message "Confidentiality" on page 771.

Trust Store or Policy Decision Point (PDP)

- Broker Truststore; for more details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780.

Encryption is not supported with external PDPs such as TFIM or LDAP.

Related concepts:

"WS-Security mechanisms" on page 768
The WS-Security specification provides three mechanisms for securing Web services at the message level: authentication, integrity, and confidentiality.

"X.509 certificate token capabilities" on page 795
Various WS-Services Security X.509 certificate token profile standards are supported by WebSphere Message Broker.

Related tasks:

"Implementing WS-Security" on page 769
Configure authentication, XML encryption, XML signature, and message expiration by using the Policy Sets and Policy Set Bindings editor.

Related reference:

"X.509 certificate token capabilities for decryption" on page 797
For Web services, you can complete decryption by using an X.509 certificate token.

"X.509 certificate token capabilities for signing" on page 798
For Web services, you can use an X.509 certificate token for signing.

"X.509 certificate token capabilities for verifying" on page 799
For Web services, you can verify a signing by using an X.509 certificate token profile.

"X.509 certificate token capabilities for authentication" on page 800
For Web services, you can complete authentication by using an X.509 certificate token.

"X.509 certificate token capabilities for authorization" on page 801
The X.509 certificate token is not supported for authorization in any configuration or direction.

"X.509 certificate token capabilities for identity mapping" on page 802
For Web services, you can map an identity by using an X.509 certificate token.

"X.509 certificate token capabilities for extraction and propagation" on page 803
This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for decryption:

For Web services, you can complete decryption by using an X.509 certificate token.

X.509 certificate token decryption for incoming SOAP message "Confidentiality" on page 769 is supported in the following configurations:

Capability

- Decrypt (by using a broker private key)

Policy Enforcement Point (PEP) and direction.

- In (provider)

  "SOAPInput node" on page 4795
- In (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncResponse node" on page 4777

  Configured with a policy set and binding defining the message "Confidentiality" on page 771.

Trust Store or Policy Decision Point (PDP).

- Broker Truststore; for details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780.

Decryption is not supported with external PDPs such as TFIM or LDAP.

"X.509 certificate token capabilities for authorization" on page 801
The X.509 certificate token is not supported for authorization in any configuration or direction.

"X.509 certificate token capabilities for identity mapping" on page 802
For Web services, you can map an identity by using an X.509 certificate token.

"X.509 certificate token capabilities for extraction and propagation" on page 803
This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for signing:

For Web services, you can use an X.509 certificate token for signing.

X.509 certificate token signing for outgoing SOAP message "Integrity" on page 769 is supported in the following configurations:

Capability

- Sign (by using a broker private key)

Policy Enforcement Point (PEP) and direction

- Out (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncRequest node" on page 4750
- Out (provider)

  "SOAPReply node" on page 4819

  Configured with a policy set and binding defining the message "Integrity" on page 772.

Trust Store or Policy Decision Point (PDP)

- Broker Truststore; for details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780.

Signing is not supported with an external PDP such as TFIM or LDAP.

This topic describes broker Web services capability for extraction and propagation X.509 certificate token.

X.509 certificate token capabilities for verifying:

For Web services, you can verify a signing by using an X.509 certificate token profile.

X.509 certificate token verification of the "Integrity" on page 769 of a signed incoming SOAP message is supported in the following configurations:

Capability

- Verify signature (by using a partner public key)

Policy Enforcement Point (PEP) and direction

- In (provider)

  "SOAPInput node" on page 4795
- In (consumer)

  "SOAPRequest node" on page 4828

  "SOAPAsyncResponse node" on page 4777

  Configured with a policy set and binding defining the message "Integrity" on page 772

Trust Store or Policy Decision Point (PDP)

- Broker Trust store; for details, see "Viewing and setting keystore and truststore runtime properties at broker level" on page 780.

  Signature verification is not supported with an external PDP, such as TFIM or LDAP.
