Command sets comparison

The tables in this section compare the facilities available for AIX, Linux, and Windows from the different administration command sets, and also show whether you can perform each function by using the IBM MQ Explorer or REST API.

Note:  These comparison tables do not apply to IBM MQ for z/OS®. For information on how to use MQSC commands and PCF commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

 These comparison tables do not apply to IBM MQ for IBM i. For information on how to use MQSC commands and PCF commands on IBM i, see [Alternative ways of administering IBM MQ for IBM i](#).

Queue manager commands

A table of queue manager commands, showing equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Table 1. Queue manager commands					
Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Change Queue Manager	Change Queue Manager	ALTER QMGR	No equivalent	Use “/admin/action/qmgr/{qmgrName}/mqsc” on page 2357 to run MQSC command	Yes
Create Queue Manager	No equivalent	No equivalent	crtmqm	No equivalent	Yes
Delete Queue Manager	No equivalent	No equivalent	dlmqm	No equivalent	Yes
Inquire Queue Manager	Inquire Queue Manager	DISPLAY QMGR	No equivalent	Use “/admin/action/qmgr/{qmgrName}/mqsc” on page 2357 to run MQSC command	Yes
Inquire Queue Manager Status	Inquire Queue Manager Status	DISPLAY QMSTATUS	dspmq	GET /admin/installation GET /admin/qmgr	Yes
Ping Queue Manager	Ping Queue Manager	PING QMGR	No equivalent	Use “/admin/action/qmgr/{qmgrName}/mqsc” on page 2357 to run MQSC command	No
Refresh Queue Manager	Refresh Queue Manager	REFRESH QMGR	No equivalent	Use “/admin/action/qmgr/{qmgrName}/mqsc” on page 2357 to run MQSC command	Yes
Reset Queue Manager	Reset Queue Manager	RESET QMGR	No equivalent	Use “/admin/action/qmgr/{qmgrName}/mqsc” on page 2357 to run MQSC command	No
Start Queue Manager	No equivalent	No equivalent	strmqm	No equivalent	Yes

Table 1. Queue manager commands (continued)					
Description	PCF command	MQSC command	Control command	REST API resource and HTTP method	IBM MQ Explorer equivalent?
Stop Queue Manager	No equivalent	No equivalent	endmqm	No equivalent	Yes

How to read syntax diagrams

The syntax for a command and its options is presented in the form of a syntax diagram, also known as a railroad diagram. A syntax diagram is a visual format suitable for sighted users. It tells you what options you can supply with the command, and how to enter them. It indicates relationships between different options, and sometimes different values for an option.

Each syntax diagram begins with a double right arrow and ends with a right and left arrow pair. Lines beginning with a single right arrow are continuation lines. You read a syntax diagram from left to right and from top to bottom, following the direction of the arrows.

Other conventions used in syntax diagrams are shown in [Table 13](#) on page 20.

Table 13. How to read syntax diagrams	
Convention	Meaning
	You must specify values A, B, and C. Required values are shown on the main line of a syntax diagram.
	You may specify value A. Optional values are shown below the main line of a syntax diagram.
	Values A, B, and C are alternatives, one of which you must specify.
	Values A, B, and C are alternatives, one of which you might specify.
	This shows that a value (for example, A, or B, or C) must be selected, and if another is to be selected then a comma must be used between the values.
	You might specify value A multiple times. The separator in this example is optional.
	Values A, B, and C are alternatives, one of which you might specify. If you specify none of the values shown, the default A (the value shown above the main line) is used.
	The syntax fragment Name is shown separately from the main syntax diagram.
Punctuation and uppercase values	Specify exactly as shown.

IBM MQ control commands reference

Reference information about the IBM MQ control commands.

For information about running these commands on Multiplatforms, see [Administering IBM MQ for Multiplatforms using control commands](#).

Table 14. IBM MQ control commands and their purpose	
Command name	Purpose
“addmqinf (add configuration information)” on page 26	Add IBM MQ configuration information on AIX, Linux, and Windows only.
“amqmdain (services control)” on page 28	amqmdain is used to configure or control some Windows specific administrative tasks.
“amqmfsc (file system check)” on page 34	amqmfsc checks whether a shared file system on IBM i, AIX and Linux systems meets the requirements for storing the queue manager data of a multi-instance queue manager.
“crtmqcvx (create data conversion code)” on page 36	Use the crtmqcvx command to create a fragment of code that performs data conversion on data type structures. The command generates a C function that can be used in an exit to convert C structures.
“crtmqdir (create IBM MQ directories)” on page 37	Use the crtmqdir command to check that the necessary directories and files used by IBM MQ exist and have the appropriate ownership and permissions. The command can optionally create any missing directories or files, and correct any inconsistent ownership or permissions.
“crtmqenv (create IBM MQ environment)” on page 39	Create a list of environment variables for an installation of IBM MQ, on AIX, Linux, and Windows.
“crtmqinst (create IBM MQ installation)” on page 42	Create installation entries in <code>mqinst.ini</code> on AIX and Linux systems.
“crtmqm (create queue manager)” on page 43	Use the crtmqm command to create a queue manager and define the default and system objects.
“dlmqinst (delete IBM MQ installation)” on page 58	Delete installation entries from <code>mqinst.ini</code> on AIX and Linux systems.
“dlmqm (delete queue manager)” on page 59	Use the dlmqm command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the endmqm command.
“dmpmqaut (dump MQ authorizations)” on page 61	Dump a list of current authorizations for a range of IBM MQ object types and profiles.
“dmpmqcfg (dump queue manager configuration)” on page 65	Use the dmpmqcfg command to dump the configuration of an IBM MQ queue manager.
“dmpmqlog (dump MQ formatted log)” on page 70	Display and format a portion of the IBM MQ system log.
“dmpmqmsg (queue load and unload)” on page 72	Use the dmpmqmsg utility to copy or move the contents of a queue, or its messages, to a file. Formerly the IBM MQ qload utility.
“dspmqp (display AMQP server properties)” on page 81	Use the dspmqp command to display the configured AMQP server properties.
“dspmq (display queue managers)” on page 82	Use the dspmq command to display names and details of the queue managers on a Multiplatforms system.
“dspmqaut (display object authorization)” on page 90	Use the dspmqaut command to display the current authorizations of a specific IBM MQ object.
“dspmqcert (display IBM MQ certificates)” on page 95	Use the dspmqcert command to show information about TLS certificates for IBM MQ queue managers.
“dspmqcsv (display command server)” on page 99	Use the dspmqcsv command to display the status of the command server for the specified queue manager.

Table 14. IBM MQ control commands and their purpose (continued)

Command name	Purpose
“dspmqfls (display file names)” on page 100	Use the dspmqfls command to display the real file system name for all IBM MQ objects that match a specified criterion. You can use this command to identify the files associated with a particular object. This command is useful for backing up specific objects.
“dspmqinf (display configuration information)” on page 102	Use the dspmqinf command to display IBM MQ configuration information (AIX, Linux, and Windows only).
“dspmqinst (display IBM MQ installation)” on page 104	Display installation entries from mqinst.ini and license entitlement information on AIX, Linux, and Windows, and license entitlement information on IBM i.
“dspmqlic (display IBM MQ license)” on page 107	On Linux (excluding IBM MQ Appliance) use the dspmqlic command to display the IBM MQ license in the appropriate language for the environment.
“dspmqrtc (display route information)” on page 108	Determine the route that a message has taken through a queue manager network.
“dspmqspl (display security policy)” on page 115	Use the dspmqspl command to display a list of all policies and details of a named policy.  On z/OS you use the command with the CSQOUTIL utility.
“dspmqtrc (display formatted trace)” on page 117	Use the dspmqtrc command to format and display IBM MQ trace.
“dspmqtrn (display incomplete transactions)” on page 118	Use the dspmqtrn command to display details of transactions. This command includes transactions coordinated by IBM MQ and by an external transaction manager.
“dspmqver (display version information)” on page 120	By default, the dspmqver command displays version and build information for the installation from which it was started. A note is displayed if other installations exist; use the -i parameter to display their details.
“dspmqweb properties (display mqweb server configuration properties)” on page 124	Display information about the configurable properties of the mqweb server that is used to support the IBM MQ Console and REST API. That is, the command displays properties that are configurable by the user and the properties that have been modified. The mqweb server does not need to be running.
“dspmqweb remote (display mqweb server remote queue manager configuration)” on page 130	Use the dspmqweb remote command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.
“dspmqweb status (display mqweb server status)” on page 133	Display information about the status of the mqweb server that is used to support the IBM MQ Console and REST API.
“dspmqxr (display MQTT server properties)” on page 135	Use the dspmqxr command to display the configured MQTT server properties.
“endmqcsv (end command server)” on page 136	Use the endmqscv command to stop the command server on the specified queue manager.
“endmqdnm (stop .NET monitor)” on page 138	Stop the .NET monitor for a queue (Windows only).
“endmqlsr (end listener)” on page 138	The endmqlsr command ends all listener processes for the specified queue manager.
“endmqm (end queue manager)” on page 139	Stop a queue manager. or switch to a standby queue manager or replica queue manager.
“endmqsvc (end IBM MQ service)” on page 145	End the IBM MQ service on Windows.
“endmqtrc (end trace)” on page 146	Use the endmqtrc command to end tracing for the specified entity or all entities. The endmqtrc command ends only the trace that is described by its parameters. Using endmqtrc with no parameters ends early tracing of all processes.
“endmqweb (end mqweb server)” on page 148	Use the endmqweb command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

Table 14. IBM MQ control commands and their purpose (continued)	
Command name	Purpose
“migmqlog (migrate IBM MQ logs)” on page 149	The migmqlog command migrates logs, and can also change the type of your queue manager logs from linear to circular or from circular to linear.
“mqcertck (certify TLS setup)” on page 150	Use the mqcertck command to diagnose potential TLS problems with your queue managers.
“mqconfig (check system configuration)” on page 152	Checks that the system configuration meets the requirements to run IBM MQ (AIX and Linux platforms only).
“MQExplorer (launch IBM MQ Explorer)” on page 153	You can start IBM MQ Explorer by using the MQExplorer command in the installation directory. (Windows and Linux x86-64 platforms only).
“mqlicense (accept license after installation)” on page 154	On Linux (excluding IBM MQ Appliance) use the mqlicense command to accept the IBM MQ license after installation.
“mqperfck (MQ performance check)” on page 155	Use the mqperfck command to help understand the performance of your queue manager.
“mqrc (display return code and AMQ message information)” on page 158	Use the mqrc command to display information about symbols, return codes, and AMQ messages. You can specify a range of return codes or AMQ messages, as well as specifying specific return codes or AMQ messages.
“rcdmqimg (record media image)” on page 160	Use the rcdmqimg command to write an image of an object, or group of objects, to the log for use in media recovery. This command can be used only when using linear logging.
“rcrmqobj (re-create object)” on page 163	Use the rcrmqobj command to re-create an object, or group of objects, from their images contained in the log.
“rdqmadm (administer replicated data queue manager cluster)” on page 166	Use the rdqmadm command to administer the Pacemaker cluster used in RDQM high availability configurations. This command is not required for disaster recovery RDQM configurations.
“rdqmclean (clear failed resource actions)” on page 167	Use the rdqmclean command to clear failed resource actions from RDQM HA configurations.
“rdqmdr (manage DR RDQM instances)” on page 167	Change a primary disaster recovery replicated data queue manager (DR RDQM) to a secondary instance, or change a secondary instance to a primary.
“rdqmint (add or delete floating IP address for RDQM)” on page 168	Use the rdqmint command to add or delete the floating IP address that is used to connect to a high availability replicated data queue manager (HA RDQM), regardless of which node in the high availability (HA) group is actually running the RDQM. This command is not applicable to disaster recovery RDQM configurations.
“rdqmstatus (display RDQM status)” on page 169	Use the rdqmstatus command on its own to view a summary of the status of all replicated data queue managers (RDQMs) on a node. You can specify a queue manager name to view detailed status for that RDQM, including details of failed resource actions. You can also view the availability status of all nodes in an HA group.
“rmvmqinf (remove configuration information)” on page 169	Remove IBM MQ configuration information (AIX, Linux, and Windows only).
“rsvmqtrn (resolve transactions)” on page 171	Resolve in-doubt and heuristically completed transactions.
“runamscred (protect passwords in AMS configuration files)” on page 173	Advanced Message Security (AMS) clients might require access to a key repository that contains the private keys that are used to protect messages. To access these key repositories, you set a password in the AMS configuration file <code>keystore.conf</code> . You use the runamscred command to protect the AMS configuration files.
“runmqakm -cert (manage certificates)” on page 175	Use the runmqakm -cert command to manage certificates. runmqakm provides the same functions as the GSKit gskitcapicmd command.
“runmqakm -certreq (manage certificate requests)” on page 188	Use the runmqakm -certreq command to manage certificate requests. runmqakm provides the same functions as the GSKit gskitcapicmd command.

Table 14. IBM MQ control commands and their purpose (continued)	
Command name	Purpose
“runmqakm -keydb (manage key repositories)” on page 199	Use the runmqakm -keydb command to manage key repositories. runmqakm provides the same functions as the GSKit gskitcapicmd command.
“runmqakm -secretkey (manage keys)” on page 209	Use the runmqakm -secretkey command to manage secret keys. runmqakm provides the same functions as the GSKit gskitcapicmd command.
“runmqccred (obfuscate passwords for mqccred exit)” on page 218	Use the runmqccred command to process the mqccred exit .ini file to change all plain text passwords into an obfuscated form. This command should be run before using the .ini with the exit to ensure the exit runs successfully.
“runmqchi (run channel initiator)” on page 219	Run a channel initiator process to automate starting channels.
“runmqchl (run channel)” on page 220	Use the runmqchl command to run either a sender (SDR) or a requester (RQSTR) channel. The channel runs synchronously.
“runmqdlq (run dead-letter queue handler)” on page 221	Use the runmqdlq command to start the dead-letter queue (DLQ) handler, which monitors and handles messages on a DLQ.
“runmqdnm (run .NET monitor)” on page 223	Use the runmqdnm control command to start processing messages on an application queue with a .NET monitor (Windows only). runmqdnm can be run from the command line, or as a triggered application.
“runmqicred (protect IBM MQ client passwords)” on page 225	The runmqicred command protects passwords that are used by the IBM MQ client libraries. For example, the TLS keystore password. It is also used to protect passwords that are used to protect log replication traffic for Native HA configurations.
“runmqktool (manage keys, certificates, and certificate requests)” on page 227	Use the runmqktool command to manage keys, certificates, and certificate requests in key repositories that IBM MQ uses. runmqktool provides the same functions as the Java keytool certificate management utility.
“runmqlsr (run listener)” on page 229	Run a listener process to listen for remote requests on various communication protocols. This command is run synchronously and waits until the listener process has finished before returning to the caller.
“runmqras (collect IBM MQ troubleshooting information)” on page 231	Use the runmqras command to gather IBM MQ troubleshooting information (MustGather data) together into a single archive, for example to submit to IBM Support.
“runmqsc (run MQSC commands)” on page 236	On AIX, Linux, and Windows, the runmqsc command is used to open a command prompt from which you can issue MQSC commands. MQSC commands enable you to perform administration tasks. For example, you can define, alter, or delete a local queue object.
“runmqtmc (start client trigger monitor)” on page 239	Use the runmqtmc command to start a trigger monitor for a client. When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends. While the client trigger monitor is running it keeps the dead-letter queue open.
“runmqtrm (start trigger monitor)” on page 240	Use the runmqtrm command to start a trigger monitor on a server. When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends. While the trigger monitor is running it keeps the dead-letter queue open.
“runp11cred (protect PKCS #11 cryptographic hardware passwords)” on page 241	The runp11cred command protects passwords that are contained in PKCS #11 cryptographic hardware configuration strings. The cryptographic hardware configuration strings are supplied to IBM MQ clients by using either the MQSSLCRYP environment variable, or the SSLCryptoHardware attribute in the SSL stanza of the client configuration file.

Table 14. IBM MQ control commands and their purpose (continued)

Command name	Purpose
“runqmcrcd (protect authentication token keystore password)” on page 242	Use the runqmcrcd command to encrypt the password for the queue manager key repository that contains the trusted authentication token issuer's public key certificates or symmetric keys.
“runswchl (switch cluster channel)” on page 244	On AIX, Linux, and Windows, the runswchl command switches or queries the cluster transmission queues associated with cluster-sender channels.
“setamqp (set AMQP server properties)” on page 245	Use the setamqp properties command to configure AMQP server properties.
“setmqaut (grant or revoke authority)” on page 248	Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.
“setmqcrl (set CRL LDAP server definitions)” on page 260	Use the setmqcrl command to configure and administer support for publishing certificate revocation list (CRL) LDAP definitions in an Active Directory (Windows only).
“setmqenv (set IBM MQ environment)” on page 261	Use the setmqenv command to set up automatically the IBM MQ environment on AIX, Linux, and Windows.
“setmqinst (set IBM MQ installation)” on page 264	Set IBM MQ installations on Multiplatforms. You can use the setmqinst command to change the installation description of an installation, to set or unset an installation as the primary installation, or to set the entitlement of the installation.
“setmqm (set queue manager)” on page 267	Use the setmqm command to set the associated IBM MQ installation of a queue manager. The queue manager can then be administered using only the commands of the associated installation. For example, when a queue manager is started with strmqm , it must be the strmqm command of the installation that was specified by the setmqm command.
“setmqprd (enroll production license)” on page 269	Enroll an IBM MQ production license. A license is normally enrolled as part of the installation process.
“setmqscp (set service connection points)” on page 269	Use the setmqscp command to configure and administer support for publishing client connection channel definitions in an Active Directory. (Windows only).
“setmqspl (set security policy)” on page 271	Use the setmqspl command to define a new security policy, replace an already existing one, or remove an existing policy.  On z/OS you use the command with the CSQ0UTIL utility.
“setmqweb pid (set mqweb server product ID)” on page 275	Use the setmqweb pid command to change the product ID (PID) that the mqweb server runs under on z/OS.
“setmqweb properties (set mqweb server configuration properties)” on page 278	Use the setmqweb properties command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.
“setmqweb remote (set mqweb server remote queue manager configuration)” on page 286	Use the setmqweb remote command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.
“setmqxacred (add XA credentials)” on page 291	Use the setmqxacred command to add, modify or delete credentials in the IBM MQ XA credentials store.
“setmqxr (set MQTT server properties)” on page 292	Use the setmqxr properties command to configure MQTT server properties.
“strmqcsv (start command server)” on page 294	Use the strmqcsv command to start the command server for the specified queue manager. This enables IBM MQ to process commands sent to the command queue.

Table 14. IBM MQ control commands and their purpose (continued)	
Command name	Purpose
“strmqsvc (start IBM MQ service)” on page 296	Use the strmqsvc command to start the IBM MQ service on Windows systems. Run the command to start the service if it has not been started automatically, or if the service has ended. Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.
“strmqm (start queue manager)” on page 296	Use the strmqm command to start a queue manager or ready it for standby operation. If the queue manager startup takes more than a few seconds, IBM MQ shows intermittent messages detailing the startup progress.
“strmqtrc (start trace)” on page 301	Use the strmqtrc command to enable tracing at a specified level of detail, or report the current level of tracing.
“strmqweb (start mqweb server)” on page 309	Use the strmqweb command to start the mqweb server that is used to support the IBM MQ Console and REST API.

Multi **addmqinf (add configuration information)**

Add IBM MQ configuration information on AIX, Linux, and Windows only.

Purpose

Use the **addmqinf** command to add information to the IBM MQ configuration data.

For example, use **dspmqlinf** to display and **addmqinf** to copy configuration data from the system where a queue manager was created, to other systems where the same multi-instance queue manager is also to be started.

Syntax

Usage notes

Use **dspmqlinf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the mqm group.

Required parameters

-v Attribute = Value

The name and value of the stanza attributes to be placed in the stanza specified in the command.

[Table 15 on page 26](#) lists the QueueManager stanza attribute values. The queue manager stanza is the only stanza that is currently supported.

Table 15. QueueManager stanza attributes		
Attribute	Value	Required or optional
Name	The name of the queue manager. You must provide a different name from any other queue manager stanza on the system.	Required

Table 15. QueueManager stanza attributes (continued)		
Attribute	Value	Required or optional
Prefix	The directory path under which this queue manager data directory is stored by default. You can use Prefix to modify the location of the queue manager data directories. The value of Directory is automatically appended to this path.	Required
Directory	The name of the queue manager data directory. Sometimes the name must be provided (as in “Example” on page 28), because it is different from the queue manager name. Copy the directory name from the value returned by dspmqlnf . The rules for transforming queue manager names into directory names are described in Understanding IBM MQ file names .	Required
DataPath	The directory path where the queue manager data files are placed. The value of Directory is not automatically appended to this path and you must provide the transformed queue manager name as part of DataPath . Linux AIX If the DataPath attribute is omitted on AIX and Linux, the queue manager data directory path is defined as Prefix / Directory .	Linux AIX Windows On AIX and Linux: Optional On Windows: Required
EphemeralPrefix	Specifies the path to the directory, within which the queue manager ephemeral data is kept, such as IPC sockets. If the EphemeralPrefix attribute is omitted, the queue manager ephemeral prefix is defined as Prefix .	Optional

Optional parameters

-s *StanzaType*

A stanza of the type *StanzaType* is added to the IBM MQ configuration.

The default value of *StanzaType* is *QueueManager*.

The only supported value of *StanzaType* is *QueueManager*.

Return codes

Table 16. Return code identifiers and descriptions

Return code	Description
0	Successful operation
1	Queue manager location is invalid (either Prefix or DataPath)
39	Bad command-line parameters
45	Stanza already exists
46	Required configuration attribute is missing
58	Inconsistent use of installations detected
69	Storage is not available

Table 16. Return code identifiers and descriptions (continued)

Return code	Description
71	Unexpected error
72	Queue manager name error
100	Log location is invalid

Example

```
addmqinf -v DataPath=/MQHA/qmgrs/QM!NAME +
-v Prefix=/var/mqm +
-v Directory=QM!NAME +
-v Name=QM.NAME
```

Creates the following stanza in mqs.ini:

```
QueueManager:
  Name=QM.NAME
  Prefix=/var/mqm
  Directory=QM!NAME
  DataPath=/MQHA/qmgrs/QM!NAME
```

Related commands

Table 17. Related commands and their descriptions

Command	Description
“dspmqinf (display configuration information)” on page 102	Display IBM MQ configuration information
“rmvmqinf (remove configuration information)” on page 169	Remove IBM MQ configuration information

Related reference

[“dspmqinf \(display configuration information\)” on page 102](#)

Use the **dspmqinf** command to display IBM MQ configuration information (AIX, Linux, and Windows only).

[“rmvmqinf \(remove configuration information\)” on page 169](#)

Remove IBM MQ configuration information (AIX, Linux, and Windows only).

amqmdain (services control)

amqmdain is used to configure or control some Windows specific administrative tasks.

Purpose

The **amqmdain** command applies to IBM MQ for Windows only.

You can use **amqmdain** to perform some Windows specific administrative tasks.

Starting a queue manager with **amqmdain** is equivalent to using the **strmqm** command with the option -ss. **amqmdain** makes the queue manager run in a non-interactive session under a different user account. However, to ensure that all queue manager startup feedback is returned to the command line, use the **strmqm -ss** command rather than **amqmdain**.

You must use the **amqmdain** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq** command as follows:

```
dspmq -o installation
```

To administer and define IBM MQ service and listener objects, use MQSC commands, PCF commands, or the IBM MQ Explorer.

The **amqmdain** command has been updated to modify either the .ini files or the registry as appropriate.

Syntax

Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

qmgr start *QMgrName*

Starts a queue manager.

This parameter can also be written in the form *start QMgrName*.

If you start your queue manager as a service and need the queue manager to continue to run after logoff, use `strmqm -ss qmgr` instead of `amqmdain start qmgr`.

qmgr end QMgrName

Ends a queue manager.

This parameter can also be written in the form **end QMgrName**.

For consistency across platforms, use `endmqm qmgr` instead of `amqmdain end qmgr`.

For fuller descriptions of the options, see [“endmqm \(end queue manager\)”](#) on page 139.

-c

Controlled (or quiesced) shutdown.

-w

Wait shutdown.

-i

Immediate shut down.

-p

Pre-emptive shut down.

-r

Reconnect clients.

-s

Switch over to a standby queue manager instance.

-x

End the standby instance of the queue manager without ending the active instance.

qmgr alter QMgrName

Alters a queue manager.

-i Initiation

Specifies the initiation type. Possible values are:

Table 18. Initiation command parameters.	
Value	Description
auto	Sets the queue manager to automatic startup (when the machine starts, or more precisely when the IBM MQ service starts). The syntax is: <pre>amqmdain qmgr alter QmgrName -i auto</pre>
interactive	Sets the queue manager to manual startup that then runs under the logged on (interactive) user. The syntax is: <pre>amqmdain qmgr alter QmgrName -i interactive</pre>
service	Sets the queue manager to manual startup that then runs as a service. The syntax is: <pre>amqmdain qmgr alter QmgrName -i service</pre>

-x Multi-instance

Specifies if auto queue manager start by the IBM MQ service permits multiple instances. Equivalent to the `-sax` option on the **crtmqm** command. Also specifies if the **amqmdain start qmgr** command permits standby instances. Possible values are:

Table 19. Multi-instance command parameters.	
Value	Description
set	Sets automatic queue manager startup to permit multiple instances. Issues strmqm -x . The set option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: amqmdain qmgr alter QmgrName -x set
unset	Sets automatic queue manager startup to single instance. Issues strmqm . The unset option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: amqmdain qmgr alter QmgrName -x unset

refresh

Refreshes or checks the status of a queue manager. You will not see anything returned on the screen after executing this command.

auto *QMgrName*

Sets a queue manager to automatic startup.

manual *QMgrName*

Sets a queue manager to manual startup.

status *QMgrName* | all

These parameters are optional.

Table 20. Status command parameters.	
Header	Header
If no parameter is supplied:	Displays the status of the IBM MQ services.
If a <i>QMgrName</i> is supplied:	Displays the status of the named queue manager.
If the parameter <i>all</i> is supplied:	Displays the status of the IBM MQ services and all queue managers.

regsec

Ensures that the security permissions assigned to the Registry keys containing installation information are correct.

spn *QMgrName* set | unset

You can set or unset the service principal name for a queue manager.

reg *QMgrName* | * *RegParams*

Parameters *QMgrName*, and * are optional.

Table 21. Reg command parameters.	
Value	Description
If <i>RegParams</i> is specified alone:	Modifies queue manager configuration information related to the default queue manager.
If <i>QMgrName</i> and <i>RegParams</i> are specified:	Modifies queue manager configuration information related to the queue manager specified by <i>QMgrName</i> .
If * and <i>RegParams</i> are specified:	Modifies IBM MQ configuration information.

The parameter, *RegParams*, specifies the stanzas to change, and the changes that are to be made. *RegParams* takes one of the following forms:

- -c add -s *stanza* -v attribute= *value*
- -c remove -s *stanza* -v [attribute|*]
- -c display -s *stanza* -v [attribute|*]

If you are specifying queue manager configuration information, the valid values for *stanza* are:

```
ApiExitLocal\name
Broker
Channels
Connection
DiagnosticMessages\name
ExitPath
ExitPropertiesLocal
InstanceData
Log
LU62
NetBios
QMErrorLog
QueueManagerStartup
SPX
SSL
TCP
XAResourceManager\name
```

If you are modifying IBM MQ configuration information, the valid values for *stanza* are:

```
ApiExitCommon\name
ApiExitTemplate\name
ACPI
AllQueueManagers
Channels
DefaultQueueManager
DiagnosticMessagesTemplate\name
DiagnosticSystemMessages\name
LogDefaults
ExitProperties
```

Note the following usage considerations:

- **amqmdain** does not validate the values you specify for *name*, *attribute*, or *value*.
- Where the *stanza* name is of the form A\B, then A is the real stanza name, and B is the value automatically inserted into the stanza as Name=B. See the following examples.
- When you specify add, and an attribute exists, it is modified.
- If a stanza does not exist, **amqmdain** creates it.
- When you specify remove, you can use the value * to remove all attributes.
- When you specify display, you can use the value * to display all attributes which have been defined. This value only displays the attributes which have been defined and not the complete list of valid attributes.
- If you use remove to delete the only attribute in a stanza, the stanza itself is deleted.
- Any modification you make to the Registry re-secures all IBM MQ Registry entries.

Examples

The following example adds an XAResourceManager to queue manager TEST. The commands issued are:

```
amqmdain reg TEST -c add -s XAResourceManager\Sample -v SwitchFile=sf1
amqmdain reg TEST -c add -s XAResourceManager\Sample -v ThreadOfControl=THREAD
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XAOpenString=openit
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XACloseString=closeit
```

The resulting lines in the queue manager configuration file look something like the following. Notice that the stanza name `XAResourceManager\Sample` is interpreted as stanza `XAResourceManager`, with attribute `Name=Sample`.

```
XAResourceManager:
  Name=Sample
  SwitchFile=sf1
  ThreadOfControl=THREAD
  XAOpenString=openit
  XACloseString=closeit
```

To display the values set by the commands, use:

```
amqmdain reg TEST -c display -s XAResourceManager\Sample -v *
```

The display looks something like the following:

```
Displaying registry value for Queue Manager 'TEST'
  Attribute = Name, Value = Sample
  Attribute = SwitchFile, Value = sf1
  Attribute = ThreadOfControl, Value = THREAD
  Attribute = XAOpenString, Value = openit
  Attribute = XACloseString, Value = closeit
```

To remove the `XAResourceManager` stanza from queue manager `TEST`, use:

```
amqmdain reg TEST -c remove -s XAResourceManager\Sample -v *
```

The following example adds a `DiagnosticMessages` stanza to the configuration for queue manager `TEST`. It causes the queue manager error messages to be written in JSON format into files with names that follow this pattern: `[filename_prefix][99].json`. For example, `MyPrefix01.json`. The commands issued are:

```
amqmdain reg TEST -c add -s DiagnosticMessages\MyName -v Service=File
amqmdain reg TEST -c add -s DiagnosticMessages\MyName -v FilePrefix=MyPrefix
amqmdain reg TEST -c add -s DiagnosticMessages\MyName -v Format=json
```

The resulting lines in the queue manager configuration file look something like the following. Notice that the stanza name `DiagnosticMessages\MyName` is interpreted as stanza `DiagnosticMessages`, with attribute `Name=MyName`.

```
DiagnosticMessages:
  Name=MyName
  Service=File
  FilePrefix=MyPrefix
  Format=json
```

Return codes

Table 22. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
-2	Syntax error
-3	Failed to initialize MFC
-6	Feature no longer supported
-7	Configuration failed
-9	Unexpected Registry error
-16	Failed to configure service principal name
-29	Inconsistent use of installations detected

Table 22. Return code identifiers and descriptions (continued)

Return code	Description
62	The queue manager is associated with a different installation
71	Unexpected error
119	Permission denied

Note:

1. If the **qmgr start QMgrName** command is issued, all return codes that can be returned with **strmqm**, can be returned here also. For a list of these return codes, see “[strmqm \(start queue manager\)](#)” on page 296.
2. If the **qmgr end QMgrName** command is issued, all return codes that can be returned with **endmqm**, can be returned here also. For a list of these return codes, see “[endmqm \(end queue manager\)](#)” on page 139.

IBM i Linux AIX amqmfscck (file system check)

amqmfscck checks whether a shared file system on IBM i, AIX and Linux systems meets the requirements for storing the queue manager data of a multi-instance queue manager.

Purpose

The **amqmfscck** command applies only to IBM i, AIX and Linux systems. You do not need to check the network drive on Windows. **amqmfscck** tests that a file system correctly handles concurrent writes to a file and the waiting for and releasing of locks.

Syntax

Required parameters

DirectoryName

The name of the directory to check.

Optional parameters

-a

Perform the second phase of the data integrity test.

Run this on two machines at the same time. You must have formatted the test file using the `-f` option previously

- c**
Test writing to a file in the directory concurrently.
- f**
Perform the first phase of the data integrity test.
Formats a file in the directory in preparation for data integrity testing.
- i**
Perform the third phase of the data integrity test.
Checks the integrity of the file after the failure to discover whether the test worked.
- p**
Specifies the size of the test file used in the data integrity test in pages. .
The size is rounded up to the nearest multiple of 16 pages. The file is formatted with *PageCount* pages of 4 KB.
The optimum size of the file depends on the speed of the filesystem and the nature of the test you perform. If this parameter is omitted, the test file is 262144 pages, or 1 GB.
The size is automatically reduced so that the formatting completes in about 60 seconds even on a very slow filesystem.
- v**
Verbose output.
- w**
Test waiting for and releasing locks.
- x**
Deletes any files created by **amqmfsc** during the testing of the directory.
Do not use this option until you have completed the testing, or if you need to change the number of pages used in the integrity test.

Usage

You must be an IBM MQ Administrator to run the command. You must have read/write access to the directory being checked.

 On IBM i, use QSH to run the program. There is no CL command.

The task, [Verifying shared file system behavior](#), describes how to use **amqmfsc** to check the whether of a file system is suitable for multi-instance queue managers.

Interpreting your results

If the check fails, the file system is not capable of being used by IBM MQ queue managers. If the tests fail, choose verbose mode to help you to interpret the errors. The output from the verbose option helps you understand why the command failed, and if the problem can be solved by reconfiguring the file system.

Sometimes the failure might be an access control problem that can be fixed by changing directory ownership or permissions. Sometimes the failure can be fixed by reconfiguring the file system to behave in a different way. For example, some file systems have performance options that might need to be changed. It is also possible that the file system protocol does not support concurrency sufficiently robustly, and you must use a different file system. For example, you must use NFSv4 rather than NFSv3.

If the check succeeds, the command reports `The tests on the directory completed successfully`. If your environment is not listed as supported in the [Testing statement for IBM MQ multi-instance queue manager file systems](#), this result does not necessarily mean that you can run IBM MQ multi-instance queue managers successfully.

You must plan and run a variety of tests to satisfy yourself that you have covered all foreseeable circumstances. Some failures are intermittent, and there is a better chance of discovering them if you run the tests more than once.

Return codes

Table 23. Return code identifiers and descriptions

Return code	Description
0	Successful operation
20	Unsuccessful operation

Related tasks

[Verifying shared file system behavior](#)

crtmqcvx (create data conversion code)

Use the **crtmqcvx** command to create a fragment of code that performs data conversion on data type structures. The command generates a C function that can be used in an exit to convert C structures.

Purpose

The command reads an input file containing structures to be converted, and writes an output file containing code fragments to convert those structures.

For information about using this command, see [Utility for creating conversion-exit code](#).

Syntax

```
➤ crtmqcvx — SourceFile — TargetFile ➤
```

Required parameters

SourceFile

The input file containing the C structures to convert.

TargetFile

The output file containing the code fragments generated to convert the structures.

Return codes

Table 24. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following example shows the results of using the data conversion command against a source C structure. The command issued is:

```
crtmqcvx source.tmp target.c
```

The input file, `source.tmp`, looks like this:

```
/* This is a test C structure which can be converted by the */
/* crtmqcvx utility                                         */

struct my_structure
{
    int    code;
    MQLONG value;
};
```

The output file, `target.c`, produced by the command, looks like this:

```
MQLONG Convertmy_structure(
    PMQDXP  pExitParms,
    PMQBYTE *in_cursor,
    PMQBYTE *out_cursor,
    PMQBYTE in_lastbyte,
    PMQBYTE out_lastbyte,
    MQHCONN hConn,
    MQLONG  opts,
    MQLONG  MsgEncoding,
    MQLONG  ReqEncoding,
    MQLONG  MsgCCSID,
    MQLONG  ReqCCSID,
    MQLONG  CompCode,
    MQLONG  Reason)
{
    MQLONG ReturnCode = MQRC_NONE;

    ConvertLong(1); /* code */

    AlignLong();
    ConvertLong(1); /* value */

Fail:
    return(ReturnCode);
}
```

You can use these code fragments in your applications to convert data structures. However, if you do so, the fragment uses macros supplied in the header file `amqsvmha.h`.

crtmqdir (create IBM MQ directories)

Use the **crtmqdir** command to check that the necessary directories and files used by IBM MQ exist and have the appropriate ownership and permissions. The command can optionally create any missing directories or files, and correct any inconsistent ownership or permissions.

Attention: The scope of this command is `<MQ_DATA_PATH>` which, for example, is `/var/mqm` on Linux. This command does not affect `<MQ_INSTALLATION_PATH>`, which is `/opt/mqm` on Linux.

The system-wide directories and files are created as part of the IBM MQ installation procedure. The tool can subsequently be run to check or ensure that the necessary IBM MQ directories and files continue to have appropriate ownership and permissions.

Important:

1. You must have sufficient permission to determine whether the configuration is correct and, optionally, correct that configuration.
2. When you use the **-a** parameter, no queue managers can be running.
3. When you use the **-m** parameter, the queue manager you specified must be stopped.

4. You must not create, delete, or start any queue managers while **crtmqdir** is running.

Linux **AIX** On AIX and Linux, this typically means that you are the mqm user. This is necessary when using the **-a** or **-m** parameters, together with the **-f** parameter.

Depending on the configuration, the **crtmqdir** command might require you to be an operating system administrator, or superuser.

Note: **Linux** **AIX** The security of *data path/log/qm*, on AIX and Linux, is set to 2770.

Windows On Windows, this typically means that you are a member of the IBM MQ administration group. This is necessary when using the **-a** or **-m** parameters.

IBM i On IBM i, you must run the command as a member of the IBM MQ administrative group. This is necessary when using the **-a** or **-m** parameters, together with the **-f** parameter.

Syntax

Required parameters

Specify one of the following parameters only:

-a

Check all directories; that is, system-wide directories and all the queue managers.

Attention: The queue manager must be associated with the current installation.

-m

Check directories for the specified queue manager name.

Attention: The queue manager must be associated with the current installation.

-s

Check the system-wide directories; that is, directories that are not queue manager specific.

Optional parameters

-f

This option causes directories or files to be created if they are missing, and on AIX and Linux only, ownership or permissions to be corrected if they are inappropriately set.

If **-a** or **-m** is specified on AIX and Linux, as a minimum, the program attempts to correct ownership or permissions on files that were created at the time of queue manager creation.

-x level of permissions

Specify one of the following values only:

standard

By default, directories and files get a standard set of permissions, but a high level of permissions can be requested.

high

This option applies to the following platforms:

- **AIX** AIX
- **Linux** Linux

It ensures that files in the following directories can be deleted only by the owner:

- errors
- trace
- webui

Return codes

Table 25. Return code identifiers and descriptions

Return code	Description
0	Successful completion
10	A warning occurred
20	An error occurred

Examples

- The following command checks and fixes the system-wide directories:

```
crtmqdir -s -f
```

- The following command checks (but does not fix) queue manager QM1:

```
crtmqdir -m Qm1
```

crtmqenv (create IBM MQ environment)

Create a list of environment variables for an installation of IBM MQ, on AIX, Linux, and Windows.

Purpose

You can use the **crtmqenv** command to create a list of environment variables with the appropriate values for an installation of IBM MQ. The list of environment variables is displayed on the command line, and any variables that exist on the system have the IBM MQ values added to them. This command does not set the environment variables for you, but gives you the appropriate strings to set the variables yourself, for example, within your own scripts.

If you want the environment variables set for you in a shell environment, you can use the **setmqenv** command instead of using the **crtmqenv** command.

You can specify which installation the environment is created for by specifying a queue manager name, an installation name, or an installation path. You can also create the environment for the installation that issues the **crtmqenv** command by issuing the command with the **-s** parameter.

This command lists the following environment variables, and their values, appropriate to your system:

- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ_DATA_PATH
- MQ_ENV_MODE
- MQ_FILE_PATH
- MQ_INSTALLATION_NAME
- MQ_INSTALLATION_PATH

- MQ_JAVA_INSTALL_PATH
- MQ_JAVA_DATA_PATH
- MQ_JAVA_LIB_PATH
- MQ_JAVA_JVM_FLAG
- MQ_JRE_PATH
- PATH

Syntax

Usage notes

The **crtmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **crtmqenv** command. For example, if you want to add `MQ_INSTALLATION_PATH/java/lib` to `LD_LIBRARY_PATH`, you must do so after running **crtmqenv**.

Required Parameters

-m *QMGrName*

Create the environment for the installation associated with the queue manager *QMGrName*.

-n *InstallationName*

Create the environment for the installation named *InstallationName*.

-p *InstallationPath*

Create the environment for the installation in the path *InstallationPath*.

-r

Remove all installations from the environment.

-s

Create the environment for the installation that issued the command.

Optional Parameters

Linux AIX -k

Applies to AIX and Linux only. If the **-k** flag is specified:

- **AIX** On AIX, the `LIBPATH` environment variable is set.
- **Linux** On Linux, the `LD_LIBRARY_PATH` environment variable is set.

Include the `LD_LIBRARY_PATH`, or `LIBPATH`, environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current `LD_LIBRARY_PATH`, or `LIBPATH`, variable.

Linux AIX -l

Applies to AIX and Linux only. If the **-l** flag is specified:

-  On AIX, the `LIBPATH` environment variable is set.
-  On Linux, the `LD_LIBRARY_PATH` environment variable is set.

Include the `LD_LIBRARY_PATH`, or `LIBPATH`, environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current `LD_LIBRARY_PATH`, or `LIBPATH`, variable.

-x Mode

`Mode` can take the value 32, or 64.

Create a 32-bit or 64-bit environment:

- If you specify `-x 32`, the `PATH` environment variable is changed to add a prefix to the binary path for 32 bit executables.
- If you specify `-x 64`, the `PATH` environment variable is changed to add a prefix to the binary path for 64 bit executables.

If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.

Any attempt to display a 64-bit environment with a 32-bit installation fails.

-j Version

`Version` can take the value 2.0, or 3.0.

-  If you specify `-j 2.0` the `CLASSPATH` environment variable is changed to include the JAR files necessary to run JMS 2.0 applications. This is the default if `-j` is not specified.
-  If you specify `-j 3.0` the `CLASSPATH` environment variable is changed to include the JAR files necessary to run Jakarta Messaging 3.0 applications.

IBM MQ 9.3.0 introduced support for [Jakarta Messaging 3.0](#). JMS 2.0 is still fully supported.

-i

List only the additions to the environment.

When this parameter is specified, the environment variables set for previous installations remain in the environment variable path and must be manually removed.

Return codes

Table 26. Return code identifiers and descriptions

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

Examples

The following examples assume that a copy of IBM MQ is installed in `/opt/mqm` on a Linux or AIX system.

1. This command creates a list of environment variables for an installation installed in `/opt/mqm`:

```
/opt/mqm/bin/crtmqenv -s
```

2. This command creates a list of environment variables for an installation installed in `/opt/mqm2`, and includes the path to the installation at the end of the current value of the `LD_LIBRARY_PATH` variable:

```
/opt/mqm/bin/crtmqenv -p /opt/mqm2 -l
```

3. This command creates a list of environment variables for the queue manager QM1, in a 32-bit environment:

```
/opt/mqm/bin/crtmqenv -m QM1 -x 32
```

The following example assumes that a copy of IBM MQ is installed in C:\Program Files\IBM\MQ on a Windows system.

1. This command creates a list of environment variables for an installation called installation1:

```
"C:\Program Files\IBM\MQ\crtmqenv" -n installation1
```

Related concepts

[Multiple installations](#)

Related tasks

[Choosing a primary installation](#)

Related reference

“setmqenv (set IBM MQ environment)” on page 261

Use the **setmqenv** command to set up automatically the IBM MQ environment on AIX, Linux, and Windows.

crtmqinst (create IBM MQ installation)

Create installation entries in `mqinst.ini` on AIX and Linux systems.

Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see [Installation configuration file, mqinst.ini](#).

The first IBM MQ installation is automatically given an installation name of `Installation1` because the **crtmqinst** command is not available until an installation of IBM MQ is on the system. Subsequent installations can have an installation name set before installation occurs, by using the **crtmqinst** command. The installation name cannot be changed after installation. For more information about installation names, see [Choosing an installation name](#).

Syntax

►► crtmqinst ►►

Notes:

- ¹ When specified together, the installation name and installation path must refer to the same installation.

Parameters

-d

Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use quotation marks around the text if it contains spaces.

-n *InstallationName*

The name of the installation.

The name can contain up to 16 single-byte characters and must be a combination of alphabetic and numeric characters in the ranges a-z, A-Z, and 0-9. The installation name must be unique, regardless of whether uppercase or lowercase characters are used. For example, the names `INSTALLATIONNAME` and `InstallationName` are not unique.

If you do not supply the installation name, the next available name in the series `Installation1`, `Installation2...` is used.

-p *InstallationPath*

The installation path. If you do not supply the installation path, `/opt/mqm` is used on AIX and Linux systems, and `/usr/mqm` is used on AIX.

Return codes

Table 27. Return code identifiers and descriptions

Return code	Description
0	Entry created without error
10	Invalid installation level
36	Invalid arguments supplied
37	Descriptive text was in error
45	Entry already exists
59	Invalid installation specified
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
98	Insufficient authority to access .ini file
131	Resource problem

Example

1. This command creates an entry with an installation name of `myInstallation`, an installation path of `/opt/myInstallation`, and a description "My IBM MQ installation":

```
crtmqinst -n MyInstallation -p /opt/myInstallation -d "My IBM MQ installation"
```

Quotation marks are needed because the descriptive text contains spaces.

Note: On AIX and Linux, the **crtmqinst** command must be run by the root user because full access permissions are required to write to the `mqinst.ini` configuration file.

crtmqm (create queue manager)

Use the **crtmqm** command to create a queue manager and define the default and system objects.

The objects created by the **crtmqm** command are listed in [System and default objects](#). When you have created a queue manager, use the **strmqm** command to start it.

The queue manager is automatically associated with the installation from which the **crtmqm** command was issued. To change the associated installation, use the **setmqm** command.

Windows Note that the Windows installer does not automatically add the user that performs the installation to the mqm group. For more details, see [Authority to administer IBM MQ on AIX, Linux, and Windows systems](#).

Usage notes

Linux

You can use the environment variable **MQLICENSE** to accept or view the license.

The options you can set the **MQLICENSE** environment variable to are 'accept' or 'view'. Other values are treated as if the environment variable is not set.

You can also set the **MQLICENSE** environment variable on the **addmqinf** and **dspmqlinf** commands. However, you cannot set this environment variable directly on the **setmqprid** command.

Note: You can use this environment variable only when the licence has not already been accepted in the normal way (that is, by running **mqlicense**). If the license has already been accepted, this environment variable is ignored regardless of the value.

Syntax

crtmqm

Location Options

HA RDQM Options

DR RDQM Options

DR/HA RDQM Options

Logging Options

Journal Options

►►

Notes:

- ¹ Required by RDQM
- ² Not IBM i
- ³ IBM i only
- ⁴ Windows only
- ⁵ AIX and Linux only
- ⁶ Appliance only
- ⁷ CP4I, MQ Advanced

Required parameters

QMgrName

The name of the queue manager that you want to create. The name can contain up to 48 characters. This parameter must be the last item in the command.

Note: The *QMgrName* is used by IBM MQ applications, other IBM MQ queue managers, and IBM MQ control commands to identify this queue manager.

No other queue manager with the same name can exist on this machine. Where this queue manager is going to connect to other queue managers you must ensure that queue manager names are unique within that group of queue managers.

The *QMgrName* is also used to name the directories created on disk for the queue manager. Due to filesystem limitations the name of the directories created might not be identical to the *QMgrName* supplied on the **crtmqm** command.

In these cases the directories created will be based upon the supplied *QMgrName*, but might be modified, or have a suffix such as .000 or .001, and so on, added to the queue manager name.

Optional parameters

Windows

-a AccessGroup or **-ar AccessGroup**

Use the access group parameter to specify a Windows security group, members of which will be granted full access to all queue manager data files. The group can either be a local or global group, depending on the syntax used.

Valid syntax for the group name is as follows:

LocalGroup

Domain name\GlobalGroup name

GlobalGroup name @ Domain name

You must define the additional access group before running the **crtmqm** command with the **-a** or the **-ar** option.

If you specify the group using **-ar** instead of **-a**, the local mqm group is not granted access to the queue manager data files. Use this option if the file system hosting the queue manager data files does not support access control entries for locally defined groups.

The group is typically a global security group, which is used to provide multi-instance queue managers with access to a shared queue manager data and logs folder. Use the additional security access group to set read and write permissions on the folder or to share containing queue manager data and log files.

The additional security access group is an alternative to using the local group named mqm to set permissions on the folder containing queue manager data and logs. Unlike the local group mqm, you can make the additional security access group a local or a global group. It must be a global group to set permissions on the shared folders that contain the data and log files used by multi-instance queue managers.

The Windows operating system checks the access permissions to read and write queue manager data and log files. It checks the permissions of the user ID that is running queue manager processes. The user ID that is checked depends on whether you started the queue manager as a service or you started it interactively. If you started the queue manager as a service, the user ID checked by the Windows system is the user ID you configured with the **Prepare IBM MQ** wizard. If you started the queue manager interactively, the user ID checked by the Windows system is the user ID that ran the **strmqm** command.

The user ID must be a member of the local mqm group to start the queue manager. If the user ID is a member of the additional security access group, the queue manager can read and write files that are given permissions by using the group.

Restriction: You can specify an additional security access group only on Windows operating system. If you specify an additional security access group on other operating systems, the **crtmqm** command returns an error.

-c Text

Descriptive text for this queue manager. You can use up to 64 characters; the default is all blanks.

If you include special characters, enclose the description in single quotation marks. The maximum number of characters is reduced if the system is using a double-byte character set (DBCS).

-d DefaultTransmissionQueue

The name of the local transmission queue where remote messages are put if a transmission queue is not explicitly defined for their destination. There is no default.

-fe

Specifies that the file system for the queue manager is encrypted. You can optionally specify the encryption passphrase by using the **-fp** parameter, otherwise you are prompted for the passphrase when you run the command.

-fp Passphrase

Used in conjunction with the **-fe** parameter, optionally specifies the encryption passphrase. If you specify **-fe** but omit **-fp** you are prompted for the passphrase when you run the command. The passphrase can be between 1 and 512 characters. You should store a copy of the passphrase somewhere safe.

-g ApplicationGroup

On AIX and Linux, the name of the group that contains members that are allowed to perform the following actions:

- Run MQI applications
- Update all IPCC resources
- Change the contents of some queue manager directories

The default value is **-g all**, which allows unrestricted access.

The **-g ApplicationGroup** value is recorded in the queue manager configuration file, `qm.ini`.

The `mqm` user ID and the user running the command must belong to the specified Application Group. For further details of the operation of restricted mode, see [Restricted mode](#).

-h MaximumHandleLimit

The maximum number of handles that an application can open at the same time.

Specify a value in the range 1 - 999999999. The default value is 256.

-ic FilePath

Automatic configuration of MQSC attributes.

Specify the location containing MQSC commands to be automatically applied to the queue manager on every queue manager restart. This can be a filename, or a directory where each file `*.mqsc` is automatically processed. See [automatic configuration from an MQSC script at startup](#) for more details.

-ii FilePath

Automatic configuration of `qm.ini` file attributes.

Specify a configuration to be automatically applied to the `qm.ini` file on every queue manager restart. This can be a filename containing INI format information, or a directory where `*.ini` is automatically processed. See [automatic configuration from an INI script at startup](#) for more details.

Multi **-iv VARIABLE=VALUE[;VARIABLE=VALUE]**

Configuration variable for use with automatic uniform clusters.

Specify a name and associated value for use as an insert during MQSC definitions. This parameter is only used for CONNAME fields in defining cluster receivers for automatic uniform clusters. For example:

```
-iv CONNAME=QMA.host.name(1414)
```

The next set of parameter descriptions relate to logging, which is described in [Using the log for recovery](#).

Note: Choose the logging arrangements with care, because some cannot be changed after they are committed. The defaults for the logging options to **crtmqm** can be overridden by attributes in the mqs.ini file.

If you specify the logging attributes in the mqs.ini file, those attributes override the default values of the logging command line parameters to **crtmqm**.

IBM i **-lb BufferSize**

The journal buffer size. This is a number in the range 32000 - 15761440. The default is 32000.

-lc

Use circular logging. This method is the default logging method.

-ld LogPath

The directory used to store log files. The default directory to store log paths is defined when you install IBM MQ.

If the volume containing the log file directory supports file security, the log file directory must have access permissions. The permissions allow the user IDs, under whose authority the queue manager runs, read and write access to the directory and its subdirectories. When you install IBM MQ, you grant permissions to the user IDs and to the mqm group on the default log directory. If you set the *LogPath* parameter to write the log file to a different directory, you must grant the user IDs permission to read and write to the directory. The user ID and permissions for AIX and Linux are different from those for the Windows system:

Linux AIX and Linux

The directory and its subdirectories must be owned by the user mqm in the group mqm.

If the log file is shared between different instances of the queue manager, the security identifiers (sid) that are used must be the same for the different instances. You must have set the user mqm to the same sid on the different servers running instances of the queue manager. Likewise for the group mqm.

Windows Windows

If the directory is accessed by only one instance of the queue manager, you must give read and write access permission to the directory for the following groups and users:

- The local group mqm
- The local group Administrators
- The SYSTEM user ID

To give different instances of a queue manager access to the shared log directory, the queue manager must access the log directory using a global user. Give the global group, which contains the global user, read and write access permission to the log directory. The global group is the additional security access group specified in the **-a** parameter.

Windows

In IBM MQ for Windows systems, the default directory is C:\ProgramData\IBM\MQ\log (assuming that C: is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and mqm group must be granted read/write access to the directory.

In IBM MQ for AIX or Linux systems, the default directory is /var/mqm/log. User ID mqm and group mqm must have full authorities to the log files.

If you change the locations of these files, you must give these authorities yourself. If these authorities are set automatically, then the log files are in their default locations.

On IBM i the *logpath* directory is the queue manager library.

-lf LogFilePages

The log data is held in a series of files called log files. The log file size is specified in units of 4 KB pages.

In IBM MQ for AIX or Linux systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 64 and the maximum is 65535.

In IBM MQ for Windows systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 32 and the maximum is 65535.

Note: The size of the log files for a queue manager specified during creation of that queue manager cannot be changed, so the value that the queue manager starts out with is fixed for the lifetime of the queue manager.

On IBM i this parameter is used to specify the journal receiver threshold.

Note: Each recovery log file additionally has an extend header that is two times 4KB in size.

Multi -ll LinearLogging

Use linear logging.

On Multiplatforms, if you create a queue manager using the existing **-ll** option, you need to carry out manual management of log extents as previously (**LogManagement=Manual**).

Multi -lla

Use linear logging with automatic management of log extents (**LogManagement=Automatic**).

Multi -lln

Use linear logging with archive management of log extents (**LogManagement=Archive**).

CP4I MQ Adv. -lr InstanceName

Use log replication. Specify this option when configuring a Native HA group. The *InstanceName* provided is used by Native HA to identify this copy of log data and must be unique. The *InstanceName* can contain up to 48 characters. Valid characters in an *InstanceName* are:

- Uppercase or lowercase alphabetics (A-Z, a-z)
- Numeric characters (0-9)
- Dash (-), the leading character is not permitted to be a dash

- Period (.)
- Underscore (_)

Leading or embedded blanks are not permitted.

-lp LogPrimaryFiles

The log files allocated when the queue manager is created.

Windows

On a Windows system:

- The minimum number of primary log files that you can have is 2 and the maximum is 254.
- The total number of primary and secondary log files must not exceed 255 and must not be less than 3.

Linux AIX

On AIX and Linux systems:

- The minimum number of primary log files you can have is 2 and the maximum is 510. The default is 3.
- The total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is created or started. You can change it after the queue manager has been created. However, a change in the value is not effective until the queue manager is restarted, and the effect might not be immediate.

For more information about primary log files, see [What logs look like](#).

To calculate the size of the primary log files, see [Calculating the size of the log](#).

-ls LogSecondaryFiles

The log files allocated when the primary files are exhausted.

Windows

On a Windows system:

- The minimum number of secondary log files that you can have is 1 and the maximum is 253.
- The total number of primary and secondary log files must not exceed 255 and must not be less than 3.

Linux AIX

On AIX and Linux systems:

- The minimum number of secondary log files that you can have is 2 and the maximum is 509. The default is 2.
- The total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is started. You can change this value, but changes do not become effective until the queue manager is restarted, and even then the effect might not be immediate.

For more information about the use of secondary log files, see [What logs look like](#).

To calculate the size of the secondary log files, see [Calculating the size of the log](#).

▶ IBM i -l_z *ASPInfo*

Specify an auxiliary storage pool number (1-32, default 1) or an auxiliary storage pool device name for the IBM i journal.

-md *DataPath*

▶ Linux

The directory used to hold the data files for a queue manager.

▶ Windows

In IBM MQ for Windows systems, the default is C:\ProgramData\IBM\MQ\qmgrs (assuming that C: is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and mqm group must be granted read/write access to the directory.

▶ Linux ▶ AIX

In IBM MQ for AIX or Linux systems, the default is /var/mqm/qmgrs. User ID mqm and group must have full authorities to the log files.

mqm

▶ Linux

For RDQM on Linux systems, the default is /var/mqm/vols/*qmgrname*/qmgr/.

The **DataPath** parameter is provided to assist in the configuration of multi-instance queue managers. For example, on AIX and Linux systems: if the /var/mqm directory is located on a local file system, use the **DataPath** parameter and the **LogPath** parameter to point to the shared file systems accessible to multiple queue managers.

-oa *group|user|UserExternal*

▶ Linux ▶ AIX

On AIX and Linux systems, you can specify whether group or user authorization is to be used. If you do not set this parameter, group authorization is used. You can change the authorization model later by setting the **SecurityPolicy** parameter in the Service stanza of the *qm.ini* file (see [Service stanza of the qm.ini file](#)).

From IBM MQ 9.3.0, you can use the additional option of *UserExternal* when creating new queue managers. If you select this option, you can create a non-operating system user name, with a maximum of 12 characters, that:

- Must conform to the [Rules for naming IBM MQ objects](#)
- Is not known to the system
- Can be used both for checking and setting authorizations

If you create a non-operating system user name, that user is considered to belong to no groups, except the nobody group. See [Principals and groups on AIX, Linux, and Windows](#) for more information.

For further information, see [Object authority manager \(OAM\)](#).

-p *PortNumber*

Create a managed TCP listener on the specified port.

Specify a valid port value in the range 1-65535, to create a TCP listener object that uses the specified port. The new listener is called SYSTEM.LISTENER.TCP.1. This listener is under queue manager control, and is started and stopped along with the queue manager.

-q

Makes this queue manager the default queue manager. The new queue manager replaces any existing default queue manager.

If you accidentally use this flag and you want to revert to an existing queue manager as the default queue manager, change the default queue manager as described in [Making an existing queue manager the default](#).

-re

Secure all the replication links for an RDQM configuration with TLS. This option secures the HA replication connections for an HA configuration, the DR replication connection for a DR configuration, and both the HA and DR replication connections for an HA/DR configuration.

-red

Secure the DR replication link of an RDQM HA/DR configuration with TLS. The HA replication links are not secured.

-reh

Secure the HA replication links of an RDQM HA/DR configuration with TLS. The DR replication link is not secured.

-rr InstanceType

Create a disaster recovery replicated data queue manager (DR RDQM). Specify **-rr p** to create the primary instance of the queue manager or specify **-rr s** to create the secondary instance. You must be `root` or a user in the `mqm` group with `sudo` privileges to use this command.

Use **-rr** with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM.

-rt ReplicationType

Optionally specify whether your DR RDQM configuration uses synchronous or asynchronous replication. Specify **-rt s** for synchronous and **-rt a** for asynchronous. Asynchronous is the default.

-rl LocalIP

Specify the local IP address used for replication of data between primary and secondary instances of a DR RDQM.

Use **-rl LocalIP,LocalIP,LocalIP** with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM and specify the three IP addresses used for DR replication on the local HA group.

-ri RemoteIP

Specify the remote IP address used for replication of data between primary and secondary instances of a DR RDQM.

Use **-ri RemoteIP,RemoteIP,RemoteIP** with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM and specify the three IP addresses used for DR replication on the remote HA group. You must specify either the **-ri** or the **-rn** parameter when creating a DR/HA RDQM.

-rn RemoteName

Specifies the name of the system that is hosting the other instance of the queue manager. The name is the value that is returned if you run `uname -n` on that server.

Use **-rn GroupName** with the **-sx** or the **-sxs** parameter to create a DR/HA RDQM and specify name of the remote HA group. The *GroupName* refers to the group defined in the `DRGroup` stanza in the `rdqm.ini` file. You must specify either the **-rn** or the **-ri** parameter when creating a DR/HA RDQM.

Note: You should not use **-rn** in conjunction with the **-re** or **-red** parameters to create a DR/HA RDQM.

Linux **-rp DRPortx**

Specifies the port to use for DR replication.

MQ Appliance **-sa**

Automatic queue manager startup, for the appliance. The queue manager is configured to start automatically when the appliance restarts. This argument is mutually exclusive with **-sx**.

Windows **-sa**

Automatic queue manager startup. For Windows systems.

The queue manager is configured to start automatically when the IBM MQ Service starts.

This is the default option if you create a queue manager from IBM MQ Explorer.

Windows **-sax**

Automatic queue manager startup, permitting multiple instances. For Windows systems only.

The queue manager is configured to start automatically when the IBM MQ Service starts.

If an instance of the queue manager is not already running the queue manager starts, the instance becomes active, and standby instances are permitted elsewhere. If a queue manager instance that permits standbys is already active on a different server, the new instance becomes a standby instance.

Only one instance of a queue manager can run on a server.

Linux **-san SubjectAltName**

Specifies the group DNS name that is used in the Subject Alternative Name (SAN) of the certificates that are used to secure the replication links in a RDQM DR/HA configuration.

If either the **-re** or **-red** option is used to specify that the DR replication link in an RDQM DR/HA configuration is secured with TLS, the SAN in the certificates that are configured for each HA group must contain both the hostname of the RDQM node and a group DNS name. The group DNS name defaults to the value `encrypted.remote`. Use the **-san** option to specify a different group DNS name, if the certificates are created with a SAN that contains a group DNS name other than the default value.

If both HA groups are configured with certificates that contain the same group DNS name, specify the group DNS name as a single value for the **-san** parameter.

If the two HA groups are configured with certificates that contain a different group DNS name, specify two values separated by a comma. The first value is the group DNS name for the local HA group, and the second value is the group DNS name for the remote HA group.

For more information about the certificate requirements when secure replication links are used in a RDQM DR/HA configuration, see [Secure replication for DR/HA RDQM](#).

-si

Interactive (manual) queue manager startup.

The queue manager is configured to start only when you manually request startup by using the **strmqm** command. The queue manager runs under the (interactive) user when that user is logged-on. Queue managers configured with interactive startup end when the user who started them logs off.

-ss

Service (manual) queue manager startup.

A queue manager configured to start only when manually requested by using the **strmqm** command. The queue manager then runs as a child process of the service when the IBM MQ Service starts.

Queue managers configured with service startup continue to run even after the interactive user has logged off.

This is the default option if you create a queue manager from the command line.

-sx [-fs FilesystemSize] [DR parameters] [secure replication parameters]

Create a high availability replicated data queue manager (HA RDQM) on the primary node for that queue manager (do not specify DR parameters). RDQM is a high availability solution that is available on Linux only. See [Creating an HA RDQM](#) for more details about creating an RDQM. You must be root or a user in the mqm group with sudo privileges to use this command. The default size for file system size is 3 GB. You can specify a different file system size using the -fs option. The default unit is GB (so -fs 8 creates an 8 GB file system size). You can specify a different unit, for example, specify -fs 1024M to create a 1024 MB file system size. The queue manager is started automatically.

Specify DR parameters to create a DR/HA RDQM on the primary node for that queue manager. See [Creating DR/HA RDQMs](#) for details. The DR parameters are **-rr**, **-ri**, **-rl**, **-rn**, **-rp**.

 Specify the secure replication parameters to secure the replication links in an RDQM configuration with TLS. The secure replication parameters are **-re**, **-red**, and **-reh**.

-sxs [DR parameters] [-fs FilesystemSize] [secure replication parameters]

Create a replicated data queue manager (RDQM) on a secondary node (do not specify DR parameters). RDQM is a high availability solution that is available on Linux only. See [Creating an HA RDQM](#) for more details about creating an RDQM. You must be the root user to use this command. The default size for file system size is 3 GB. The default size for file system size is 3 GB. You can specify a different file system size using the -fs option. The default unit is GB (so -fs 8 creates an 8 GB file system size). You can specify a different unit, for example, specify -fs 1024M to create a 1024 MB file system size.

Specify DR parameters to create a DR/HA RDQM on a secondary node. See [Creating DR/HA RDQMs](#) for details. The DR parameters are **-rr**, **-ri**, **-rl**, **-rn**, **-rp**.

 Specify the secure replication parameters to secure the replication links in an RDQM configuration with TLS. The secure replication parameters are **-re**, **-red**, and **-reh**.

-t IntervalValue

The trigger time interval in milliseconds for all queues controlled by this queue manager. This value specifies the length of time triggering is suspended, after the queue manager receives a trigger-generating message. That is, if the arrival of a message on a queue causes a trigger message to be put on the initiation queue, any message arriving on the same queue within the specified interval does not generate another trigger message.

You can use the trigger time interval to ensure that your application is allowed sufficient time to deal with a trigger condition before it is alerted to deal with another trigger condition on the same queue. You might choose to see all trigger events that happen; if so, set a low or zero value in this field.

Specify a value in the range 0 - 999999999. The default is 999999999 milliseconds; a time of more than 11 days. Allowing the default to be used effectively means that triggering is disabled after the first trigger message. However, an application can enable triggering again by servicing the queue using a command to alter the queue to reset the trigger attribute.

-u DeadLetterQueue

The name of the local queue that is to be used as the dead-letter (undelivered-message) queue. Messages are put on this queue if they cannot be routed to their correct destination.

The default is no dead-letter queue.

-x MaximumUncommittedMessages

The maximum number of uncommitted messages under any one sync point. The uncommitted messages are the sum of:

- The number of messages that can be retrieved from queues

- The number of messages that can be put on queues
- Any trigger messages generated within this unit of work

This limit does not apply to messages that are retrieved or put outside a sync point.

Specify a value in the range 1 - 999999999. The default value is 10000 uncommitted messages.

-Z

Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted error messages. Do not use this flag when using a command line. Using this flag can result in a loss of information.

Return codes

Table 28. Return code identifiers and descriptions

Return code	Description
0	Queue manager created
8	Queue manager exists
18	Invalid trigger interval
19	Invalid dead letter queue
20	Invalid default transmit queue
21	Invalid max handles value
22	Invalid max uncommitted messages value
25	Error creating the queue manager directory structure
37	Invalid queue manager description
38	The access group specified cannot be found
39	Invalid parameter specified
49	Queue manager stopping
58	Inconsistent use of installations detected
63	Invalid Native HA instance name
69	Storage unavailable
70	Queue space unavailable
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started
 CP4I	Log replication is unavailable on this platform
 MQ Adv.	
93	
95	Log replication is incompatible with RDQM
100	Log location invalid
105	The queue manager was created but could not be set as the default queue manager

Table 28. Return code identifiers and descriptions (continued)

Return code	Description
111	Queue manager created. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect
115	Invalid log size
119	Permission denied
155	The group ID specified is not valid
156	The owning group ID can only be changed on AIX and Linux systems
157	The group ID chosen is invalid

Examples

- The following command creates a default queue manager called `Paint.queue.manager`, with a description of `Paint shop`, and creates the system and default objects. It also specifies that linear logging is to be used:

```
crtmqm -c "Paint shop" -ll -q Paint.queue.manager
```

- The following command creates a default queue manager called `Paint.queue.manager`, creates the system and default objects, and requests two primary and three secondary log files:

```
crtmqm -c "Paint shop" -ll -lp 2 -ls 3 -q Paint.queue.manager
```

- The following command creates a queue manager called `travel`, creates the system and default objects, sets the trigger interval to 5000 milliseconds (5 seconds), and specifies `SYSTEM.DEAD.LETTER.QUEUE` as its dead-letter queue.

```
crtmqm -t 5000 -u SYSTEM.DEAD.LETTER.QUEUE travel
```

-   The following command creates a queue manager called `QM1` on AIX and Linux systems, which has log and queue manager data folders in a common parent directory. The parent directory is to be shared on highly available networked storage to create a multi-instance queue manager. Before issuing the command, create other parameters `/MQHA`, `/MQHA/logs` and `/MQHA/qmgrs` owned by the user and group `mqm`, and with permissions `rxwxrwxr-x`.

```
crtmqm -ld /MQHA/logs -md /MQHA/qmgrs QM1
```

Related concepts

[Working with dead-letter queues](#)

Related reference

[strmqm \(start queue manager\)](#)

Use the **strmqm** command to start a queue manager or ready it for standby operation. If the queue manager startup takes more than a few seconds, IBM MQ shows intermittent messages detailing the startup progress.

[endmqm \(end queue manager\)](#)

Stop a queue manager. or switch to a standby queue manager or replica queue manager.

[dlmqm \(delete queue manager\)](#)

Use the **dlmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

[setmqm \(set the associated installation of a queue manager\)](#)

Use the **setmqm** command to set the associated IBM MQ installation of a queue manager. The queue manager can then be administered using only the commands of the associated installation. For example, when a queue manager is started with **strmqm**, it must be the **strmqm** command of the installation that was specified by the **setmqm** command.

Linux AIX dltmqinst (delete IBM MQ installation)

Delete installation entries from `mqinst.ini` on AIX and Linux systems.

Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see [Installation configuration file, mqinst.ini](#).

Before you run this command, you must first uninstall the installation that you are removing from `mqinst.ini`. See [Uninstalling or modifying IBM MQ on Linux](#) and [Uninstalling or modifying IBM MQ on AIX](#).

Attention: Only the user `root` can run this command.

Syntax

Notes:

¹ When specified together, the installation name and installation path must refer to the same installation.

Parameters

-n InstallationName

The name of the installation.

-p InstallationPath

The installation path is the location where IBM MQ is installed.

Return codes

Table 29. Return code identifiers and descriptions

Return code	Description
0	Entry deleted without error
5	Entry still active
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file

Table 29. Return code identifiers and descriptions (continued)

Return code	Description
98	Insufficient authority to access ini file
131	Resource problem

Example

1. This command deletes an entry with an installation name of myInstallation, and an installation path of /opt/myInstallation:

```
dltmqinst -n MyInstallation -p /opt/myInstallation
```

Note: You can only use the **dltmqinst** command on another installation from the one it runs from. If you only have one IBM MQ installation, the command will not work.

Multi **dltmqm (delete queue manager)**

Use the **dltmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

You must use the **dltmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmqr -o installation** command.

Usage notes

Windows On Windows, it is an error to delete a queue manager when queue manager files are open. If you get this error, close the files and reissue the command.

Deleting a cluster queue manager does not remove it from the cluster. To check whether the queue manager you want to delete is part of a cluster, issue the command **DIS CLUSQMGR(*)**. Then check whether this queue manager is listed in the output. If it is listed as a cluster queue manager you must remove the queue manager from the cluster before deleting it. See the related link for instructions.

If you do delete a cluster queue manager without first removing it from the cluster, the cluster continues to regard the deleted queue manager as a member of the cluster for at least 30 days. You can remove it from the cluster using the command **RESET CLUSTER** on a full repository queue manager. Re-creating a queue manager with an identical name and then trying to remove that queue manager from the cluster does not result in the cluster queue manager being removed from the cluster. This is because the newly created queue manager, although having the same name, does not have the same queue manager ID (QMID). Therefore it is treated as a different queue manager by the cluster.

Syntax

```
➤ dltmqm QMGrName ➤
    -z
```

Required parameters

QMGrName

The name of the queue manager to delete.

Optional parameters

-z

Suppresses error messages.

Return codes

Table 30. Return code identifiers and descriptions

Return code	Description
0	Queue manager deleted
3	Queue manager being created
5	Queue manager running
16	Queue manager does not exist
24	Process using the previous instance of the queue manager was not disconnected
25	Error while creating or checking the directory structure for the queue manager
26	Queue manager running as a standby instance
27	Queue manager could not obtain data lock
29	Deleted queue manager available in Active Directory
33	Error while deleting the queue manager directory structure
39	Invalid parameter specified
49	Queue manager stopping
58	Inconsistent use of installations detected
62	Queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started.
100	Invalid log location
112	Queue manager deleted. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect.
119	Permission denied

Examples

1. The following command deletes the queue manager `saturn.queue.manager`.

```
dltmqm saturn.queue.manager
```

2. The following command deletes the queue manager `travel` and also suppresses any messages caused by the command.

```
dltmqm -z travel
```

Related reference

[crtmqm \(create queue manager\)](#)

Use the **crtmqm** command to create a queue manager and define the default and system objects.

[strmqm \(start queue manager\)](#)

Use the **strmqm** command to start a queue manager or ready it for standby operation. If the queue manager startup takes more than a few seconds, IBM MQ shows intermittent messages detailing the startup progress.

[endmqm \(end queue manager\)](#)

Stop a queue manager, or switch to a standby queue manager or replica queue manager.

Multi **dmpmqaut (dump MQ authorizations)**

Dump a list of current authorizations for a range of IBM MQ object types and profiles.

Purpose

Use the **dmpmqaut** command to dump the current authorizations to a specified object.

Syntax

Optional parameters

-m QMgrName

Dump authority records only for the queue manager specified. If you omit this parameter, only authority records for the default queue manager are dumped.

-n Profile

The name of the profile for which to dump authorizations. The profile name can be generic, using wildcard characters to specify a range of names as explained in [Using OAM generic profiles on AIX, Linux, and Windows systems](#).

-l

Dump only the profile name and type. Use this option to generate a *terse* list of all defined profile names and types.

-a

Generate set authority commands.

-t ObjectType

The type of object for which to dump authorizations. Possible values are:

A table showing possible values, and descriptions, for the -t flag.

Value	Description
authinfo	An authentication information object, for use with TLS channel security
channel or chl	A channel
clntconn or clcn	A client connection channel
listener or lstr	A listener
namelist or nl	A namelist
process or prcs	A process
queue or q	A queue or queues matching the object name parameter
qmgr	A queue manager
rqmname or rqmn	A remote queue manager name
service or srvc	A service
topic or top	A topic

-s ServiceComponent

If installable authorization services are supported, specifies the name of the authorization service for which to dump authorizations. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

Windows

-p PrincipalName

This parameter applies to Windows only; AIX and Linux systems keep only group authority records.

The name of a user for whom to dump authorizations to the specified object. The name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see [Principals and groups](#).

-g GroupName

The name of the user group for which to dump authorizations. You can specify only one name, which must be the name of an existing user group.

Windows

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain  
domain\GroupName
```

-e

Display all profiles used to calculate the cumulative authority that the entity has to the object specified in -n *Profile*. The variable *Profile* must not contain any wildcard characters.

The following parameters must also be specified:

- -m *QMgrName*
- -n *Profile*
- -t *ObjectType*

and either -p *PrincipalName*, or -g *GroupName*.

-x

Display all profiles with the same name as specified in **-n Profile**. This option does not apply to the QMGR object, so a dump request of the form `dmpmqaut -m QM -t QMGR ... -x` is not valid.

Examples

The following examples show the use of **dmpmqaut** to dump authority records for generic profiles:

1. This example dumps all authority records with a profile that matches queue a.b.c for principal user1.

```
dmpmqaut -m qm1 -n a.b.c -t q -p user1
```

The resulting dump would look something like this:

```
profile:      a.b.*
object type:  queue
entity:       user1
type:         principal
authority:    get, browse, put, inq
```

Note:   On AIX and Linux, you cannot use the `-p` option. You must use `-g groupname` instead.

2. This example dumps all authority records with a profile that matches queue a.b.c.

```
dmpmqaut -m qmgr1 -n a.b.c -t q
```

The resulting dump would look something like this:

```
profile:      a.b.c
object type:  queue
entity:       Administrator
type:         principal
authority:    all
- - - - -
profile:      a.b.*
object type:  queue
entity:       user1
type:         principal
authority:    get, browse, put, inq
- - - - -
profile:      a.**
object type:  queue
entity:       group1
type:         group
authority:    get
```

3. This example dumps all authority records for profile a.b.*, of type queue.

```
dmpmqaut -m qmgr1 -n a.b.* -t q
```

The resulting dump would look something like this:

```
profile:      a.b.*
object type:  queue
entity:       user1
type:         principal
authority:    get, browse, put, inq
```

4. This example dumps all authority records for queue manager qmX.

```
dmpmqaut -m qmX
```

The resulting dump would look something like this:

```
profile:      q1
object type:  queue
entity:       Administrator
```

```

type:      principal
authority:  all
- - - - -
profile:    q*
object type: queue
entity:     user1
type:      principal
authority:  get, browse
- - - - -
profile:    name.*
object type: namelist
entity:     user2
type:      principal
authority:  get
- - - - -
profile:    pr1
object type: process
entity:     group1
type:      group
authority:  get

```

5. This example dumps all profile names and object types for queue manager qmX.

```
dmpmqaut -m qmX -l
```

The resulting dump would look something like this:

```

profile: q1, type: queue
profile: q*, type: queue
profile: name.*, type: namelist
profile: pr1, type: process

```

Note:

1.  For Windows only, all principals displayed include domain information, for example:

```

profile:    a.b.*
object type: queue
entity:     user1@domain1
type:      principal
authority:  get, browse, put, inq

```

2. Each class of object has authority records for each group or principal. These records have the profile name @CLASS and track the crt (create) authority common to all objects of that class. If the crt authority for any object of that class is changed then this record is updated. For example:

```

profile:    @class
object type: queue
entity:     test
entity type: principal
authority:  crt

```

This shows that members of the group test have crt authority to the class queue.

Attention: You cannot delete the @CLASS entries (the system is working as designed)

3.  For Windows only, members of the "Administrators" group are by default given full authority. This authority, however, is given automatically by the OAM, and is not defined by the authority records. The **dmpmqaut** command displays authority defined only by the authority records. Unless an authority record has been explicitly defined, therefore, running the **dmpmqaut** command against the "Administrators" group displays no authority record for that group.

Related reference

[“setmqaut \(grant or revoke authority\)” on page 248](#)

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

[“DISPLAY AUTHREC \(display authority records\) on Multiplatforms” on page 735](#)

Use the MQSC command **DISPLAY AUTHREC** to display the authority records associated with a profile name.

[“SET AUTHREC \(set authority records\) on Multiplatforms” on page 1035](#)

Use the MQSC command **SET AUTHREC** to set authority records associated with a profile name.

dmpmqcfg (dump queue manager configuration)

Use the **dmpmqcfg** command to dump the configuration of an IBM MQ queue manager.

If any default object has been edited, the **-a** option must be used if the dumped configuration will be used to restore the configuration.

CAUTION: When moving a queue manager from one operating system to another, you use **dmpmqcfg** to save the configuration information of the queue manager that you want to move, and then copy the object definitions across to the new queue manager that you create on the new operating system. You must take great care with copying the object definitions, because some manual modification of the definitions might be needed. For more information, see [Moving a queue manager to a different operating system](#).

The **dmpmqcfg** utility dumps only subscriptions of type MQSUBTYPE_ADMIN, that is, only subscriptions that are created using the MQSC command **DEFINE SUB** or its PCF equivalent. The output from **dmpmqcfg** is a **runmqsc** command to enable the administration subscription to be re-created. Subscriptions that are created by applications using the MQSUB MQI call of type MQSUBTYPE_API are not part of the queue manager configuration, even if durable, and so are not dumped by **dmpmqcfg**. MQTT channels will only be returned for types -t all and -t mqttchl if the telemetry (MQXR) service is running. For instructions on how to start the telemetry service, see [Administering IBM MQ Telemetry](#).

From IBM MQ 8.0, the output of the **dmpmqcfg** is changed to ensure that password fields are commented out in the generated commands. This change brings the **dmpmqcfg** command in line with the **DISPLAY** commands, that show password fields as **PASSWORD(*****)**.

Note: The **dmpmqcfg** command does not make a backup of the Advanced Message Security policies. If you want to export the Advanced Message Security policies, ensure that you run **dspmqspl** with the **-export** flag. This command exports the policies for Advanced Message Security into a text file, which can be used for restoration purposes. For more information see [“dspmqspl \(display security policy\)” on page 115](#).

Attention: The inquiries used by **dmpmqcfg** inquire only QSGDISP(QMGR) definitions by default. You can inquire additional definitions by using the environment variable **AMQ_DMPMQCFG_QSGDISP_DEFAULT**. For more information about the values that you can set with this environment variable, see [AMQ_DMPMQCFG_QSGDISP_DEFAULT](#).

For example, you could use **AMQ_DMPMQCFG_QSGDISP_DEFAULT** to query a z/OS queue manager in a queue sharing group from an IBM MQ for Multiplatforms installation. Using the environment variable allows you to include shared objects that would otherwise not be included in the results.

Optional parameters

-?

Inquire the usage message for dmpmqcfg.

-c

Force a client mode connection. If the **-c** parameter is qualified with the option `default`, the default client connection process is used. If **-c** is omitted, the default is to attempt to connect to the queue manager first by using server bindings and then if this fails by using client bindings.

If the option is qualified with an MQSC `DEFINE CHANNEL CHLTYPE(CLNTCONN)` string then this is parsed and if successful, used to create a temporary connection to the queue manager.

-x [all|object|authrec|chlauth|sub|policy]

Filter the definition procedure to show object definitions, authority records, channel authentication records, durable subscriptions or policy. The default value `all` is that all types are returned.

Note that when you specify an export type of `policy`, the security policies for the queue manager are reported in the configuration information dumped.

-a

Return object definitions to show all attributes. The default is to return only attributes which differ from the defaults for the object type.

-s SeqNumber

Reset channel sequence number for sender, server and cluster sender channel types to the numeric value specified. The value SeqNumber must be in the range 1 - 999999999.

-z

Activate silent mode in which warnings, such as those which appear when inquiring attributes from a queue manager of a higher command level are suppressed.

-n [*|ObjectName]

Filter the definitions produced by object or profile name, the object/profile name can contain a single asterisk. The * option can be placed only at the end of the entered filter string.

@class authority records are included in **dmpmqcfig** output regardless of the object or profile filter specified.

Attention: You cannot delete the @CLASS entries (the system is working as designed)

-t

Choose a single type of object to export. The following table shows the possible values:

Table 31. Possible values for -t parameter	
Value	Description
all	All object types
authinfo	An authentication information object
channel or chl	A channel
comminfo	A communications information object
lstr or listener	A listener
mqttchl	An MQTT channel
namelist or nl	A namelist
process or prcs	A process
queue or q	A queue
qmgr	A queue manager
srvc or service	A service
topic or top	A topic

-o [mqsc|1line|2line|setmqaut|grtmqaut|setmqsp1]

The following table shows the possible values:

Table 32. Possible values for -o parameter options	
Value	Description
mqsc	Multi-line MQSC that can be used as direct input to runmqsc
1line	MQSC with all attributes on a single line for line diffing
2line	MQSC with output on two lines. The first line is an MQSC command string and the second is a commented version with immutable values.
 ALW setmqaut	setmqaut statements for AIX, Linux, and Windows queue managers; valid only when -x authrec is specified.

Table 32. Possible values for -o parameter options (continued)	
Value	Description
 Linux grtmqmaut	Linux only; generates iSeries syntax for granting access to the objects.
setmqspl	The security policies for the queue manager are reported in the format of setmqspl command lines. This format can be used to generate scripts to restore policy configuration to a queue manager. Note that the setmqspl command lines produced by this format includes parameters (-m) that specify the queue manager from which the definition was backed up. This implies that the definitions need to be replayed against the same queue manager. If you need to back up policy definitions from one queue manager, and restore them to a different queue manager, consider using the default MQSC format where the queue manager name is not explicitly specified.

-q

The name of the reply-to queue used when getting configuration information.

-r

The name of the remote queue manager/transmit queue when using queued mode. If this parameter is omitted the configuration for the directly connected queue manager (specified with the **-m** parameter) is dumped.

-m

The name of the queue manager to connect to. If omitted the default queue manager name is used.

-w WaitTime

The time, in seconds, that **dmpmqcfig** waits for each reply message from the command server.

Any replies received after a timeout are discarded, but the MQSC commands still run.

Specify a time in the range 1 through 999999. The default value is 60 seconds.

Timed-out failure is indicated by:

- Nonzero return code to the calling shell or environment.
- Error message to stdout or stderr.

-u UserId

The ID of the user authorized to dump the configuration of queue managers.

Authorizations

You must have MQZAO_OUTPUT (+put) authority to access the command input queue (SYSTEM.ADMIN.COMMAND.QUEUE).

You must have MQZAO_DISPLAY (+dsp) authority and MQZAO_INPUT (+get) authority to access the default model queue (SYSTEM.DEFAULT.MODEL.QUEUE), to be able to create a temporary dynamic queue if using the default reply queue.

You must also have MQZAO_CONNECT (+connect) and MQZAO_INQUIRE (+inq) authority for the queue manager, and MQZAO_DISPLAY (+dsp) authority for every object that is requested.

No authority is required on the object type (RQMNAME) to limit, or restrict the use of, the **dmpmqcfig** command to display details about any OBJTYPE(RQMNAME).

Return code

If a failure occurs **dmpmqcfcfg** returns an error code. Otherwise, the command outputs a footer, an example of which follows:

```
*****
* Script ended on 2016-01-05   at 05.10.09
* Number of Inquiry commands issued: 14
* Number of Inquiry commands completed: 14
* Number of Inquiry responses processed: 273
* QueueManager count: 1
* Queue count: 55
* Namelist count: 3
* Process count: 1
* Channel count: 10
* AuthInfo count: 4
* Listener count: 1
* Service count: 1
* CommInfo count: 1
* Topic count: 5
* Subscription count: 1
* ChlAuthRec count: 3
* Policy count: 1
* AuthRec count: 186
* Number of objects/records: 273
*****
```

Examples

To make these examples work you need to ensure that your system is set up for remote MQSC operation. See [Configuring queue managers for remote administration](#).

The following example dumps all the configuration information from remote queue manager *MYQMGR* in MQSC format and creates an ad-hoc client connection to the queue manager using a client channel called *SYSTEM.ADMIN.SVRCONN*.

```
dmpmqcfcfg -m MYQMGR -c "DEFINE CHANNEL(SYSTEM.ADMIN.SVRCONN) CHLTYPE(CLNTCONN)
CONNAME('myhost.mycorp.com(1414)')"
```

Note: You need to ensure that a server-connection channel with the same name exists.

```
dmpmqcfcfg -m LOCALQM -i MYQMGR
```

The following examples dump all configuration information from remote queue manager *MYQMGR*, in MQSC format, connects initially to local queue manager *LOCALQM*, and sends inquiry messages through this local queue manager.

-  On Windows:

```
dmpmqcfcfg -m LOCALQM -o lline | findstr /V '('SYSTEM"
```

-   On UNIX and Linux:

```
dmpmqcfcfg -m LOCALQM -o lline | grep -v '('SYSTEM"
```

The following example dumps all configuration information from local queue manager *LOCALQM*, in MQSC format, and filters out lines containing “(‘SYSTEM”, even if the string is in a description or in another field. To filter out SYSTEM.* objects only, you can use multiple filters as shown in the following example:

```
dmpmqcfcfg -m LOCALQM -o lline | grep -v " CHANNEL('SYSTEM" | grep -v " QLOCAL('SYSTEM" | grep -v
" QALIAS('SYSTEM"
```

or

```
dmpmqcfcfg -m LOCALQM -o lline | grep -v " CHANNEL('SYSTEM" | grep -v " QLOCAL('SYSTEM" |
grep -v " QREMOTE('SYSTEM" | grep -v " QMODEL('SYSTEM" | grep -v " QALIAS('SYSTEM" | grep
```

-b

Start dumping from the base LSN. The base LSN identifies the start of the log extent that contains the start of the active portion of the log.

-s StartLSN

Start dumping from the specified LSN. The LSN is specified in the format *nnnn:nnnn:nnnn:nnnn*.

If you are using a circular log, the LSN value must be equal to or greater than the base LSN value of the log.

-n ExtentNumber

Start dumping from the specified extent number. The extent number must be in the range 0 - 9999999.

This parameter is valid only for queue managers using linear logging.

-e EndLSN

End dumping at the specified LSN. The LSN is specified in the format *nnnn:nnnn:nnnn:nnnn*.

-f LogFilePath

The absolute (rather than relative) directory path name to the log files. The specified directory must contain the log header file (*amqh1ctl1.lfh*) and a subdirectory called *active*. The *active* subdirectory must contain the log files. By default, log files are assumed to be in the directories specified in the IBM MQ configuration information. If you use this option, queue names associated with queue identifiers are shown in the dump only if you use the *-m* option to name a queue manager name that has the object catalog file in its directory path.

On a system that supports long file names this file is called *qmqmobjcat* and, to map the queue identifiers to queue names, it must be the file used when the log files were created. For example, for a queue manager named *qm1*, the object catalog file is located in the directory *.. \mqmrs\qm1\qmanager*. To achieve this mapping, you might need to create a temporary queue manager, for example named *tmpq*, replace its object catalog with the one associated with the specific log files, and then start **dmpmqlog**, specifying *-m tmpq* and *-f* with the absolute directory path name to the log files.

-m QMgrName

The name of the queue manager. If you omit this parameter, the name of the default queue manager is used.

Note: Do not dump the log while the queue manager is running, and do not start the queue manager while **dmpmqlog** is running.

-d

Do not include log data (only information about the log is output).

-Z

Normalize the format log output to make it easier to pass into other commands.

- All timestamps are output in ISO 8601 format, rather than in local time, enabling use of *-t* and *-u* options.
- XIDs are reformatted, enabling them to be processed by the *-r* XID option.

-t StartTime

Start dumping from the specified time. The time is specified in ISO 8601 format. Cannot be specified at the same time as *-b*, *-s*, or *-n* parameters. The base LSN value of the log is used as the starting search point for records.

 This parameter is not valid on IBM i.

-u EndTime

End dumping from the specified time. The time is specified in ISO 8601 format. Cannot be specified at the same time as *-b*, *-s*, or *-n* parameters. The base LSN value of the log is used as the starting search point for records.

IBM i This parameter is not valid on IBM i.

V 10.00 -r Filter

Filter the output from the **dmpmqlog**. Multiple filters can be specified simultaneously, and a log record is displayed if it matches any of the specified filters. The possible filters are:

Data=hexadecimal_string

Display log records containing or associated with the data string in hexadecimal. The string can consist of 2 through 48 hexadecimal symbols (0-9, A-F) (24 bytes), and must have an even number of characters.

LogRecdType=log_record_type

Display log records with the specified numeric type. For example, `-r LogRecdType=1025` displays ALM Start Checkpoint records.

ObjectName=object_name

Display log records associated with the specified object name.

TranNum=transaction_number

Display log records associated with the specified MQI transaction number in the format High.Low or High,Low.

XID=XA_transaction_identifier

Display log records with the specified XA transaction identifier in the format XA_FORMATID[a], XA_GTRID[b], XA_BQUAL[c] where [a] represents a signed 32-bit integer, and [b] and [c] represent a series of hexadecimal symbols (0-9, A-F). See the `-z` option.

dmpmqmsg (queue load and unload)

Use the **dmpmqmsg** utility to copy or move the contents of a queue, or its messages, to a file. Formerly the IBM MQ **qload** utility.

Purpose

ALW From IBM MQ 8.0, the **qload** utility, that previously shipped in IBM MQ Supportpac MO03, has been integrated into IBM MQ as the **dmpmqmsg** utility.

- On AIX and Linux platforms the utility is available in `<installdir>./bin`.
- On Windows platforms the utility is available in `<installdir>./bin64` as part of the server fileset.

For more information, see [Using the dmpmqmsg utility](#).

z/OS On z/OS the utility is available as an executable module CSQUDMSG in the SCSQLOAD library, with an alias of QLOAD for compatibility. Sample JCL is provided as member CSQ4QLOD in SCSQPROC. You can also reload messages as described in [“Restoring messages from a data set to a queue \(LOAD\) on z/OS” on page 2971](#) and [“Restoring messages from a data set to a queue \(SLOAD\) on z/OS” on page 2973](#).

Syntax

Mode options

Context options

Display options

Optional parameters

-m *QueueManagerName*

The name of the queue manager on which the queue, or queues, exist.

-i or **-I** *Input queue name*

The name of the input queue.

Note: Using **-i** browses the queue (non-destructive get), whereas using **-I** deletes messages from the queue (destructive get).

-f or **-F** *Filename*

Specifies either the source or target file name.

Note:

- Using `-F` on a target file forces output to a file if it already exists. The program does not ask you if the file should be overwritten.
- Take care to ensure that appropriate access controls are set on the output file, as users who are not permitted to access messages on the queue might have access to read the output file.

 **Linux**  **AIX** On AIX and Linux, permissions for new files are set according to the current umask when the utility is run.

 **Windows** On Windows, permissions for new files are inherited from the parent directory ACL.

-o *Output queue name*

Specifies the name of the output queue.

-a

Controls whether the file is opened in append or binary mode, by adding one of the following values to the keyword:

a

Append mode

b

Binary mode

-b

Sets the initial buffer size (in kilobytes) used when reading messages.

-c

Connect in client mode.

If you do not select this flag, the utility runs in local mode, which is the default.

 **z/OS** This option is not available on z/OS.

-P

Controls whether messages taken from a queue are converted.

Use the command

```
-P CCSID [ : X 'Encoding' ]
```

For example `-P850:111`

-C

Controls the context option, by adding one of the following values to the keyword:

A

Set all context. This is the default value.

I

Set identity context.

a

Pass all context.

p

Pass identity context.

Use of the *pass* options is not applicable if the source messages are browsed on a queue.

d

Default context.

n

No context.

-d

Controls the display option or options, by adding one or more of the following values to the keyword.
For example `-dsCM`:

- a** Add ASCII columns to the hexadecimal output in the file to aid readability.
- A** Write ASCII lines of data wherever possible.
-  On EBCDIC platforms, data is instead written in EBCDIC.
- c** Output *ApplicationOriginData* and *ApplicationIdentityData* as characters
- C** Display the *Correlation Identifier* in the queue summary.
- H** Do not write the file header.

Files created with this option are not loadable by the program as the program does not recognize the file format. However, if necessary you can use an editor to add an appropriate header manually, to make the file loadable.
- i** Include the message index in the output.
- p** Printable character output format.

This format is not code page safe. Loading a file written in this format, while running in a new code page does not guarantee to produce the same message.
- s** Write a simple summary of the messages found on input.
- M** Display the *Message Identifier* in the queue summary.
- N** Do not write out the message descriptor content, only the message payload.
- t** Text line output format.

This format is not code page safe. Loading a file written in this format, while running in a new code page does not guarantee to produce the same message.
- T** Display the time the message has been on the queue.
- w Length** Set the data width for the output.
- D** Add a delay, expressed in milliseconds, before writing a message to the output destination, by adding one of the following values to the keyword. For example:
 - Dpositive_value** Add a fixed delay before putting a message. For example, -D500 puts each message half a second apart.
 - Dnegative_value** Add a random delay, up to the specified value before putting a message. For example, -D-10000 adds a random delay of up to 10 seconds before putting a message.
 - rvalue** Replays the messages at a percentage of their original put speed. For example:
 - r** Replays messages at their original speed.

r50

Replays messages at half their original speed.

r200

Replays messages at twice their original speed.

-g

Filter by Message identifier, Correlation identifier, or Group identifier, by adding one of the following values to the keyword.

cvalue

Get by character Correlation identifier.

mvalue

Get by character Message identifier.

gvalue

Get by character Group identifier.

xcvalue

Get by hexadecimal Correlation identifier.

xmvalue

Get by hexadecimal Message identifier.

xgvalue

Get by hexadecimal Group identifier.

-h

Strip headers.

Any Dead Letter Queue header (MQDLH) or Transmission Queue header (MQXQH) is removed from the message before the message is written.

-o

Output queue name.

-p

Causes the source queue to be purged of messages as they are copied to the target destination.

-q

Sets quiet mode. When set, the program does not output its usual summary of activity.

-r

Note: If the **dmpmqmsg** command runs with the **-r** option set to 0, the command copies all messages to the destination, whether that destination is a file or queue.

Sets the applicable message range by adding one of the following values to the keyword.

x

Only message x, for example, **-r10**. If **r** is 0, copies all messages to the destination.

x..y

From message x to message y. For example, **-r 10..20**. **-r0..9** copies one to nine messages to the destination.

x#y

Output y messages starting at message x. For example, **-r 100#10**, **-r0#4** copies one to four messages to the destination.

#x

Output the first x messages, for example, **-r #100**. **-r \#0** copies all messages to the destination.

-t

Sets the transaction message limit. The **dmpmqmsg** utility uses transactions to copy messages. Each transaction contains multiple messages, up to a maximum number that is set by the **-t** parameter. The default value is 200.

0

Transactions are not used, so messages are copied individually. If a failure occurs before the application completes its work, nothing is rolled back.

-1

All messages are copied in a single transaction. Use this value with caution because the number of messages on the queue might exceed either the MAXUMSGS parameter of the queue manager (which sets the maximum number of uncommitted messages within a unit of work), or the available log size.

n

The maximum number of messages in each transaction. For example, `-t1000` specifies that the **dmpmqmsg** utility copies up to 1000 messages in each transaction. Ensure that this number does not exceed the MAXUMSGS parameter of the queue manager. You can use the MQSC **DISPLAY QMGR** command to show the value of the MAXUMSGS parameter.

-T

Allows message selection based on message age.

See [“Using message age” on page 79](#) for information on selection using message age.

Attention: The age is based on the **PutDate** and **PutTime** fields in the Message Descriptor (MQMD), compared to UTC for the system where the utility is running.

-s or -e

Allows message selection based on message content.

On ASCII platforms (AIX, Linux, and Windows) use the **-s** option to search for a natively encoded string.

On EBCDIC platforms (z/OS) use the **-e** option to search for a natively encoded string.

See [“Using message content” on page 80](#) for information on selection using message content.

-S or -E

Allows message selection based on message content.

On ASCII platforms (AIX, Linux, and Windows) use the **-S** option to search for messages that DO NOT contain the specified search string.

On EBCDIC platforms (z/OS) use the **-E** option to search for or messages that DO NOT contain the specified search string.

See [“Using message content” on page 80](#) for information on selection using message content.

-x

Use this option to search for messages that contain the specified hexadecimal string.

-X

Use this option to search for messages that DO NOT contain the specified hexadecimal string.

-u

If you use the `-u` parameter to supply a user ID, you are prompted for a matching password.

If you have configured the CONNAUTH AUTHINFO record with CHCKLOCL(REQUIRED) or CHCKLOCL(REQDADM), you must use the `-u` parameter otherwise you will not be able to copy or move the contents of a queue.

If you specify this parameter and redirect stdin, a prompt will not be displayed and the first line of redirected input should contain the password.

-w

Wait interval, in seconds, for consuming messages. If specified the program waits for messages to arrive, for the specified period, before ending.

For examples of using the utility, see [Examples of using the dmpmqmsg utility](#). If you store the output of the command in a file, see [“Meaning of three letter codes in dmpmqmsg output file” on page 80](#) for the meaning of the codes in the second column of the information in that file.

Table 33. IBM MQ MQSC commands and their purpose	
Command name	Purpose
“Message selection for dmpmqmsg” on page 79	Message selection for the dmpmqmsg command can be based on message age or message content.
“Meaning of three letter codes in dmpmqmsg output file” on page 80	The mapping between the codes from dmpmqmsg and the attribute names from amqsbcg .

Return codes

Table 34. Return code identifiers and descriptions

Return code	Description
0	Successful command completion
39	Invalid arguments provided
40	Queue manager not available
49	Queue manager stopped
71	Unexpected error
72	Queue manager unknown
133	Unknown object name
119	User not authorized

Related concepts

[“Restoring messages from a data set to a queue \(LOAD\) on z/OS” on page 2971](#)

The LOAD function of CSQUTIL is complementary to the COPY or SCOPY function. LOAD restores messages from the destination data set of an earlier COPY or SCOPY operation. The queue manager must be running.

[“Restoring messages from a data set to a queue \(SLOAD\) on z/OS” on page 2973](#)

The SLOAD function of CSQUTIL is complementary to the COPY or SCOPY function. SLOAD restores messages from the destination data set of an earlier COPY or SCOPY operation. SLOAD processes a single queue.

 [The IBM MQ for z/OS utilities](#)

Message selection for dmpmqmsg

Message selection for the **dmpmqmsg** command can be based on message age or message content.

Using message age

You can choose to process only messages older than a certain time interval using the -T flag.

Time interval can be specified in Days, Hours and Minutes. The general format being [days:]hours:]minutes.

The parameter can take one or two times, -T [OlderThanTime] [, YoungerThanTime].

For example:

- Display messages older than five minutes

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T5
```

- Display messages younger than five minutes

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T,5
```

- Display messages older than one day but younger than two days.

```
dmpmqmsg -m QM1 -i Q1 -fstdout -T1440,2880
```

- The following command copies messages older than one hour from Q1 to Q2.

```
dmpmqmsg -m QM1 -i Q1 -o Q2 -T1:0
```

- The following command moves messages older than one week from Q1 to Q2

```
dmpmqmsg -m QM1 -I Q1 -o Q2 -T7:0:0
```

Using message content

You can specify a maximum of three of each search string. If multiple strings are used, they are treated as follows:

Positive search strings

When multiple positive strings are used, then all the strings must be present for the search to match. For example, the command

```
dmpmqmsg -iMATCH -s LIVERPOOL -s CHELSEA
```

only returns messages that contain both strings.

Negative search strings

When multiple negative strings are used, then none of the strings must be present for the search to match. For example, the command

```
dmpmqmsg -iMATCH -S HOME -S DRAW
```

only returns messages that contain neither string.

Multi **Meaning of three letter codes in dmpmqmsg output file**

The mapping between the codes from **dmpmqmsg** and the attribute names from amqsbcbg.

The order of the attributes in the following table is not alphabetical. Instead, the order reflects the sequence of the attribute names from amqsbcbg.

<i>Table 35. Mapping between the three letter codes in the output file from dmpmqmsg and the representation from amqsbcbg</i>	
File format attribute name (from dmpmqmsg)	Representation (from amqsbcbg)
VER	Version
RPT	Report
MST	MsgType
EXP	Expiry
FDB	Feedback
ENC	Encoding
CCS	CodedCharSetId
FMT	Format PRI Priority

Table 35. Mapping between the three letter codes in the output file from **dmpmqmsg** and the representation from **amqsbcg** (continued)

File format attribute name (from dmpmqmsg)	Representation (from amqsbcg)
PER	Persistence
MSI	MsgId
COI	CorrelId
BOC	BackoutCount
RTQ	ReplyToQ
RTM	ReplyToQMgr
USR	UserIdentifier
ACC	AccountingToken
AIX	ApplIdentityData
PAT	PutApplType
PAN	PutApplName
PTD	PutDate
PTT	PutTime
AOX	ApplOriginData
GRP	GroupId
MSQ	MsgSeqNumber
OFF	Offset
MSF	MsgFlags
ORL	OriginalLength

Related concepts

The Browser sample program

Multi **dspamqp (display AMQP server properties)**

Use the **dspamqp** command to display the configured AMQP server properties.

The command allows you to display the properties that are configured in the following properties files:

- amqptraceOn.properties
- amqptraceOff.properties
- amqp_java.properties
- amqp_unix.properties
- amqp_win.properties

Syntax

Required parameters

-m QMgrName

The queue manager you are displaying AMQP server properties for.

Optional parameters

-o format

Specifies the format that the information is output in. One of the following values:

text

Format the output in name/value pairs. This is the default value if the parameter is not specified.

cmd

Format the output as command text (this can then be used as input to the **setamqp** command).

-l

Enable verbose logging. Diagnostic information is written to a log file.

Return codes

Table 36. Return code identifiers and descriptions

Return code	Description
0	Command successful
>0	Command not successful

Examples

The following command displays the configured AMQP server properties for the queue manager QM1, formatting the output in name/value pairs:

```
dspamqp -m QM1 -o text
```

The following command displays the configured AMQP server properties for the queue manager QM1, formatting the output as input for the **setamqp** command:

```
dspamqp -m QM1 -o cmd
```

Related reference

[“setamqp \(set AMQP server properties\)” on page 245](#)

Use the **setamqp properties** command to configure AMQP server properties.

dspmq (display queue managers)

Use the **dspmq** command to display names and details of the queue managers on a Multiplatforms system.

 The equivalent utility to **dspmq** on z/OS is [CSQUDSPM](#).

Syntax

Required parameters

None

Optional parameters

-a

Displays information about the active queue managers only.

A queue manager is active if it is associated with the installation from which the **dspmq** command was issued and one or more of the following statements are true:

- The queue manager is running
- A listener for the queue manager is running
- A process is connected to the queue manager

Success for **dspmq -a** is indicated by the return code 5.

-m *QMgrName*

The queue manager for which to display details. If you give no name, all queue manager names are displayed.

-n

Suppresses translation of output strings.

-s

The operational status of the queue managers is displayed. This parameter is the default status setting.

The parameter *-o status* is equivalent to *-s*.

-o all

The operational status of the queue managers is displayed, and whether any are the default queue manager.

ALW On AIX, Linux, and Windows, the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with is also displayed.

CP4I **MQ Adv.** **Linux** On Native HA configurations, the current HA role (ROLE), the name of this instance (INSTANCE), readiness to take over active role (INSYNC) and quorum status (QUORUM) are also displayed.

-o default

Displays whether any of the queue managers are the default queue manager.

ALW -o installation

AIX, Linux, and Windows only.

Displays the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with.

-o status

The operational status of the queue managers is displayed.

-o standby

Displays whether a queue manager currently permits starting a standby instance. The possible values are shown in [Table 37 on page 84](#).

Table 37. Standby values	
Value	Description
Permitted	The queue manager is running and is permitting standby instances.
Not permitted	The queue manager is running and is not permitting standby instances.
Not applicable	The queue manager is not running. You can start the queue manager and this instance becomes active if it starts successfully.

-o ha | HA

Indicates whether a queue manager is an HA RDQM (high availability replicated data queue manager) or not. If the queue manager is an HA RDQM, one of the following responses is displayed:

HA(Replicated)

Indicates that the queue manager is an HA RDQM.

HA()

Indicates that the queue manager is not an HA RDQM.

For example:

```
dspmqr -o ha
QMNAME(RDQM8)           HA(Replicated)
QMNAME(RDQM9)           HA(Replicated)
QMNAME(RDQM7)           HA(Replicated)
QMNAME(QM7)             HA()
```

-o dr | DR

Indicates whether a queue manager is a DR RDQM (disaster recovery replicated data queue manager) or not. One of the following responses is displayed:

DRROLE()

Indicates that the queue manager is not configured for disaster recovery.

DRROLE(Primary)

Indicates that the queue manager is configured as the DR primary.

DRROLE(Secondary)

Indicates that the queue manager is configured as the DR secondary.

For example:

```
dspmqr -o dr
```

```
QMNAME(RDQM13)
QMNAME(RDQM14)
QMNAME(RDQM15)
QMNAME(QM27)
```

```
DRROLE(Primary)
DRROLE(Primary)
DRROLE(Secondary)
DRROLE()
```

CP4I MQ Adv. Linux -o nativeha | NATIVEHA

Displays operational information for an instance in a Native HA configuration. Used on its own, displays ROLE, INSTANCE, INSYNC, QUORUM, GRPLSN, GRPNAME, and GRPROLE fields. (see Table 38 on page 85). Combine with the -x parameter to view additional information on all the instances in the Native HA configuration (see Table 40 on page 86). Combine with the -g parameter to view information about Native HA groups (see Table 41 on page 87).

Table 38. Native HA instance values

Name	Description
ROLE	Specifies the current role of the instance and is one of Active, Replica, Unknown, Leader, or Not configured.
INSTANCE	The name provided for this instance of the queue manager when it was created using the -lr option of the crtmqm command.
INSYNC	Indicates whether the instance is able to take over as the active instance if required.
QUORUM	Reports the quorum status in the form <i>number_of_instances_in-sync/number_of_instances_configured</i> .
 GRPLSN	Specifies the log sequence number (LSN) that has been replicated between a quorum of instances in the HA group, in <i>nnnnn:nnnnn:nnnnn:nnnnn</i> format. Blank if the LSN is not known.
 GRPNAME	Specifies the name of the HA group. Blank if a name has not been configured.
 GRPROLE	Specifies the current role of the HA group and is one of: Live - A live group Recovery - A recovery group Pending live - A group waiting to become Live Pending recovery - A group waiting to become Recovery Unknown - The current role cannot be determined Not configured - Native HA has not been configured

For examples of **dspmqr** output for Native HA instances, see [Viewing the status of Native HA queue managers for IBM MQ containers](#).

-x

Information about multi-instance queue manager instances is displayed.

   Displays information about Native HA queue manager instances if combined with the `-o nativeha` parameter.

The possible values for multi-instance queue manager instances are shown in [Table 39 on page 86](#).

Table 39. Instance values	
Value	Description
Active	The instance is the active instance.
Standby	The instance is a standby instance.

   The possible values for Native HA queue manager instances are shown in [Table 40 on page 86](#).

Table 40. Native HA instance values when -x specified	
Name	Description
REPLADDR	The replication address of the queue manager instance.
CONNACTV	Indicates whether the instance is connected to the active instance.
BACKLOG	Indicates the number of KB that the instance is behind the active instance.
CONNINST	Indicates whether the named instance is connected to this instance.
ALTDATE	Indicates the date on which this information was last updated. Blank if it has never been updated.
ALTTIME	Indicates the time at which this information was last updated. Blank if it has never been updated.
 ACKLSN	Indicates the LSN that the instance has acknowledged as having been written to the recovery log, in <code>nnnnn:nnnnn:nnnnn:nnnnn</code> format. Blank if the LSN value is not known.
 HASTATUS	Indicates the operational status of this instance and is one of the following values: Normal - the instance is operating normally. Checking - the instance is being checked to ensure the consistency of the recovery log. Synchronizing - the instance is being sent data to bring it in-sync. Rebasing - a new recovery log is being sent to the instance. Disk full - the instance has a full disk. Disconnected - cannot communicate with the instance. Unknown - the instance status is unknown.

Table 40. Native HA instance values when -x specified (continued)	
Name	Description
V 10.0.0 SYNCTIME	Indicates the time when this instance was last in-sync with the active queue manager, in ISO 8601 format. Blank if the time is not known, or if this instance has not been in-sync with the active queue manager.

V 10.0.0 -g

Displays information about Native HA groups if combined with the -o nativeha parameter. One line is output for each configured group. If Native HA is not configured, there is no output.

Table 41. Native HA instance values when -g specified	
Name	Description
V 10.0.0 GRPNAME	Specifies the name of the HA group. Blank if a name has not been configured.
V 10.0.0 GRPROLE	Specifies the current role of the HA group and is one of: Live - A live group Recovery - A recovery group Pending live - A group waiting to become Live Pending recovery - A group waiting to become Recovery Unknown - The current role cannot be determined Not configured - Native HA has not been configured
V 10.0.0 GRPADDR	The IP address of the group. The IP address is Unknown if the group has not received a connection.
V 10.0.0 GRPVER	Indicates the version of the current group leader.
V 10.0.0 CONNGRP	This attribute is displayed only for groups other than the local group. Indicates whether the group is connected to the local group and is one of: yes - the group is connected. no - the group is disconnected. unknown - the connection status is unknown. suspended - the group is connected, but the group cannot replicate data until a configuration incompatibility between the groups is resolved. (This can occur if there is a version incompatibility, for example.)

Table 41. Native HA instance values when -g specified (continued)

Name	Description
V1000 INSYNC	Indicates whether the group could become Live with no loss of data if a failover occurred. (Note that a Recovery group might not be in-sync with the Live group very often because the log is replicated asynchronously. Use the RCOVLSN and RCOVTIME values to indicate if data loss might occur on an unplanned failover). Only displayed for a group when GRPROLE is Unknown, Recovery, or Pending live.
V1000 SYNCTIME	Indicates the time when this group was last in-sync with the Live group, in ISO 8601 format. Blank if the time is not known, or if the group has not been in-sync with the Live group. (Note that a Recovery group might not be in-sync with the Live group very often because the log is replicated asynchronously. Use the RCOVLSN and RCOVTIME values to indicate if data loss might occur on an unplanned failover.)
V1000 BACKLOG	Indicates the number of KB that the group is behind the Live group. This is only displayed when GRPROLE is Recovery or Pending live.
V1000 GRSTATUS	Indicates the operational status of this group and is one of the following values: Normal - the group is operating normally. Checking - the group is being checked to ensure the consistency of the recovery log. Synchronizing - the group is being sent data to bring it in-sync. Rebasing - the group is being sent a new recovery log. Waiting for connection - the group is waiting for a connection from a group with the role Live or Pending Recovery. Disconnected - cannot communicate with the group. Partitioned - two groups believe they are the Live group (that is, a 'split brain' status). V1000 V1000 Sync failed - a Live group is configured to use synchronous replication, but is currently not in-sync. Unknown - the group status is unknown.

Table 41. Native HA instance values when -g specified (continued)	
Name	Description
 RCOVLSN	A log sequence number (LSN) that the group could recover to, in <i>nnnnn:nnnnn:nnnnn:nnnnn</i> format. Any data written to the recovery log after this point might be lost if an unplanned failover occurs. This value can be passed into the -s option of the dmpmqlog command.
 RCOVTIME	A time that the group could recover to, in ISO 8601 format. Any data written to the recovery log after this time might be lost if an unplanned failover occurs. This value can be passed into the -t or -u options of the dmpmqlog command.
 INITLSN	The log sequence number (LSN) of the last log record recovered when the Native HA group initially became live, in the format <i>nnnnn:nnnnn:nnnnn:nnnnn</i> . Only displayed when GRPROLE is Live or Pending recovery.
 INITTIME	The time of the last log record recovered when the Native HA group initially became live, in ISO 8601 format. Blank, if the group is not live or not known. Only displayed when GRPROLE is Live or Pending recovery.
 LIVETIME	The time the group first became the live group, in ISO 8601 format. Only displayed when GRPROLE is Live or Pending recovery.
 ALTDATE	Indicates the date when this information was last updated or blank if never updated.
 ALTTIME	Indicates the time when this information was last updated or blank if never updated.

-c

Shows the list of processes currently connected to the IPCC, QMGR, and PERSISTENT subpools for a queue manager.

For example, this list typically includes:

- Queue manager processes
- Applications, including those that are inhibiting shutdown
- Listeners

Queue manager states

The different states that a queue manager can be in are as follows:

- Starting
- Running
- Running as standby
- Running elsewhere
- Recovery group leader

- Quiescing
- Ending immediately
- Ending pre-emptively
- Ended normally
- Ended immediately
- Ended unexpectedly
- Ended pre-emptively
- Status not available

Return codes

Table 42. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
5	Queue manager running
36	Invalid arguments supplied
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error

Examples

1. The following command displays queue managers on this server:

```
dspmqr -o all
```

2. The following command displays standby information for queue managers on this server that have ended immediately:

```
dspmqr -o standby
```

3. The following command displays standby information and instance information for queue managers on this server:

```
dspmqr -o standby -x
```

dspmqa (display object authorization)

Use the **dspmqa** command to display the current authorizations of a specific IBM MQ object.

Purpose

If a user ID is a member of more than one group, this command displays the combined authorizations of all the groups.

Only one group or principal can be specified.

For more information about authorization service components, see [Installable services](#), [Service components](#), and [Authorization service interface](#).

Syntax

Required parameters

-n *Profile*

The name of the profile for which to display authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified.

This parameter is required, unless you are displaying the authorizations of a queue manager. In this case you must not include it and instead specify the queue manager name using the **-m** parameter.

-t *ObjectType*

The type of object on which to make the inquiry. Possible values are:

Table 43. The object type on which to make the inquiry.	
Object Type	Description
authinfo	An authentication information object, for use with TLS channel security
channel or chl	A channel
clntconn or clcn	A client connection channel
listener or lstr	A Listener
namelist or nl	A namelist
process or prcs	A process
queue or q	A queue or queues matching the object name parameter
qmgr	A queue manager
rqmname or rqmn	A remote queue manager name
service or srvc	A service
topic or top	A topic

Optional parameters

-m *QMgrName*

The name of the queue manager on which to make the inquiry. This parameter is optional if you are displaying the authorizations of your default queue manager.

-g *GroupName*

The name of the user group on which to make the inquiry. You can specify only one name, which must be the name of an existing user group.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

-p *PrincipalName*

The name of a user for whom to display authorizations to the specified object.

Windows For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see [Principals and groups](#).

-s *ServiceComponent*

If installable authorization services are supported, specifies the name of the authorization service to which the authorizations apply. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

Returned parameters

Returns an authorization list, which can contain none, one, or more authorization values. Each authorization value returned means that any user ID in the specified group or principal has the authority to perform the operation defined by that value.

Table 44 on page 92 shows the authorities that can be given to the different object types.

Table 44. Specifying authorities for different object types											
Authority	Queue	Process	Queue manager	Remote queue manager name	Namelist	Topic	Auth info	Clntcon n	Channel	Listener	Service
all	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
alladm	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
allmqi	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No	No
none	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
altusr	No	No	Yes	No	No	No	No	No	No	No	No
browse	Yes	No	No	No	No	No	No	No	No	No	No
chg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
clr	Yes	No	No	No	No	Yes	No	No	No	No	No
connect	No	No	Yes	No	No	No	No	No	No	No	No
crt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
ctrl	No	No	No	No	No	Yes	No	No	Yes	Yes	Yes
ctrlx	No	No	No	No	No	No	No	No	Yes	No	No
dlt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
dsp	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
get	Yes	No	No	No	No	No	No	No	No	No	No

Table 44. Specifying authorities for different object types (continued)											
Authority	Queue	Process	Queue manager	Remote queue manager name	Namelist	Topic	Auth info	Clntcon n	Channel	Listener	Service
pub	No	No	No	No	No	Yes	No	No	No	No	No
put	Yes	No	No	Yes	No	Yes	No	No	No	No	No
inq	Yes	Yes	Yes	No	Yes	No	Yes	No	No	No	No
passall	Yes	No	No	No	No	Yes	No	No	No	No	No
passid	Yes	No	No	No	No	Yes	No	No	No	No	No
resume	No	No	No	No	No	Yes	No	No	No	No	No
set	Yes	Yes	Yes	No	No	No	No	No	No	No	No
setall	Yes	No	Yes	No	No	Yes	No	No	No	No	No
setid	Yes	No	Yes	No	No	Yes	No	No	No	No	No
sub	No	No	No	No	No	Yes	No	No	No	No	No
system	No	No	Yes	No	No	No	No	No	No	No	No

The following list defines the authorizations associated with each value:

Table 45. Authorizations associated with each value.	
Value	Description
all	Use all operations relevant to the object. all authority is equivalent to the union of the authorities alladm, allmqi, and system appropriate to the object type.
alladm	Perform all administration operations relevant to the object
allmqi	Use all MQI calls relevant to the object
altusr	Specify an alternative user ID on an MQI call
browse	Retrieve a message from a queue by issuing an MQGET call with the BROWSE option
chg	Change the attributes of the specified object, using the appropriate command set
clr	Clear a queue (PCF command Clear queue only) or a topic
ctrl	Start, and stop the specified channel, listener, or service, and ping the specified channel.
ctrlx	Reset or resolve the specified channel
connect	Connect the application to the specified queue manager by issuing an MQCONN call
crt	Create objects of the specified type using the appropriate command set
dlt	Delete the specified object using the appropriate command set

<i>Table 45. Authorizations associated with each value. (continued)</i>	
Value	Description
dsp	Display the attributes of the specified object using the appropriate command set
get	Retrieve a message from a queue by issuing an MQGET call
inq	Make an inquiry on a specific queue by issuing an MQINQ call
passall	Pass all context
passid	Pass the identity context
pub	Publish a message on a topic using the MQPUT call.
put	Put a message on a specific queue by issuing an MQPUT call
resume	Resume a subscription using the MQSUB call.
set	Set attributes on a queue from the MQI by issuing an MQSET call
setall	Set all context
setid	Set the identity context
sub	Create, alter, or resume a subscription to a topic using the MQSUB call.
system	Use queue manager for internal system operations

The authorizations for administration operations, where supported, apply to these command sets:

- Control commands
- MQSC commands
- PCF commands

Return codes

Table 46. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error

Table 46. Return code identifiers and descriptions (continued)

Return code	Description
133	Unknown object name
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing

Examples

- The following example shows a command to display the authorizations on queue manager `saturn.queue.manager` associated with user group `staff`:

```
dspmqaut -m saturn.queue.manager -t qmgr -g staff
```

The results from this command are:

```
Entity staff has the following authorizations for object:
  get
  browse
  put
  inq
  set
  connect
  altusr
  passid
  passall
  setid
```

- The following example displays the authorities user1 has for queue `a.b.c`:

```
dspmqaut -m qmgr1 -n a.b.c -t q -p user1
```

The results from this command are:

```
Entity user1 has the following authorizations for object:
  get
  put
```

Related reference

[“setmqaut \(grant or revoke authority\)” on page 248](#)

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

dspmqcert (display IBM MQ certificates)

Use the **dspmqcert** command to show information about TLS certificates for IBM MQ queue managers.

Purpose

The **dspmqcert** program provides an easy way to query TLS certificates for queue managers.

A typical use for **dspmqcert** is to check the validity of TLS certificate dates. Checking TLS certificate dates is crucial because they expire and must be renewed to meet current security standards. Failure to renew before expiry disrupts TLS communication between applications.

Information output from the program can be in plain text, JSON or CSV depending on the intended use.

Syntax

Description

Run without parameters, the program iterates through the available queue managers and reads the keystore in the default location. If present, then the keystore is queried using the stash file credentials, if available. Then the certificates within the store are listed in textual format. Both CMS (key . kdb) and PKCS#12 (key . p12) keystores are supported.

Optional parameters

-h | ?

Print this help.

-o *style*

Output style, json, csv, or text. The default is text.

-d *days*

Show certificates due to expire within this number of days.

-m *pattern*

Queue manager name or pattern such as QM1, 'QM?', 'ERR*', 'Q*PROD'. Enclose patterns in quotation marks so they are not interpreted by the shell.

-f *path*

 Path to the INI file if not in the default location of \$HOME/.mqm/dspmqcert.ini.

 Path to the INI file if not in the default location of <DATA_DIR>/.mqm/dspmqcert.ini.

-e

If **-d** is specified, request the program exit with return code 127 if one or more certificates are due to expire. If you are using this option, do not pipe the output to other programs or the exit code will be lost.

-a

Include CA and intermediate certificates if present in keystore. CA certificates are identified by the Basic Constraints extension where CA=TRUE.

Note: Not all certificates include this extension, specifically, old Verisign certificates. If present in the keystore, they are included in the output.

Keystore passwords

Keystores require a password. There are a few ways to provide the password:

- By using environment variables
- By using the INI file
- By using a stash file

Environment variables

Firstly, **dspmqcert** checks the environment variables. They must be in the format:

```
KBPASS_QM_NAME
```

Where KBPASS_ is the prefix and QM_NAME is the name of the queue manager that the keystore is defined for. For example, the following command tells the program to use passwd0rd for the keystore defined for queue manager QM1.

```
KBPASS_QM1=passwd0rd dspmqcert -m QM1
```

Passwords that are provided in environment variables are encrypted and written to the configuration file and used in subsequent calls.

Provided in the INI file

If no environment variable(s) exist then the program looks at the configuration file. Passwords may be stored within the INI file as an attribute. For example:

```
#
# Example file to demonstrate alternative keystore locations
# for queue managers QM1 and ERRL
#
QM1:
  path=/path/to/keystore.kdb # if keystore not default name/location
  passwd=passwd0rd           # may be specified in plain text
ERRL:
  path=/path/to/keystore.kdb
  passwd=<QM>!2!7DF+zWm6E5qj0jv1JrX3s7DDnnqMgW30JSP1zsFfimk==
```

- When the program runs, any plain-text passwords are encrypted in-place using PBE encryption.
- If passwords are supplied in the environment, they too are written to the configuration file (possibly overwriting an existing password). Passwords in the environment therefore only need to be supplied once. For more information, see [“Protecting keystore passwords” on page 97](#).

Provided through a stash file

If you are using a stash file, you do not need to supply a password. **dspmqcert** opens the keystore using the credentials stored in the stash file.

Protecting keystore passwords

The IBM MQ PBE system ensures passwords are encrypted at rest. If the program discovers a plain text password in one of the mechanisms above, it is treated as follows:

1. If an initial keyfile called “.dspmqcert_passkey” that should exist next to the configuration file does not exist, a new one is created with a random initial key generated in the configuration directory with 0400 permissions.
2. The plain text password is encrypted using the initial key and the QM component for the fixed salt.
3. The encrypted password is then be written to the configuration file, overlaying the plain text password, or adding in the password field if it was provided using an environment variable.

Migrating passwords

If you then wish to migrate the configuration file, you also need to copy the configuration directory to the new environment:

-  \$HOME/.mqm/.dspmqcert_passkey
-  <DATA_DIR>/.mqm/.dspmqcert_passkey

Password failure

If the keystore password is missing, incorrect or not in the stash file, the program exits with error AMQ3066: Unable to find a password.

The encryption key

The program automatically generates a key file called `.dspmqcert_passkey`. This file is located the configuration directory and contains a 36-character key used to encrypt and decrypt passwords in the config file. It is created for the current user with read-only (0400) permissions. Each IBM MQ user has their own configuration and key and must provide the password separately.

Note: The program exits with error AMQ3059 if the key is group or world readable.

Return codes

On successful completion, a zero value is returned. If an error occurs, an error message is printed to STDERR and a non-zero exit code is returned.

Table 47. Information		
IBM MQ error code	Value	Description (EN_US)
OK	0	Exit successful
AMQ3058	12376	Usage statement
AMQ3060	12384	No queue managers found
AMQ3065	12389	Unable to find keystore

Table 48. Errors		
IBM MQ	Value	Description (EN_US)
AMQ3059	536883289	File has incorrect permissions
AMQ3061	536883297	Error getting certificates from keystore
AMQ3062	536883298	Unable to query details of certificate
AMQ3063	536883299	Unable to open file for read/write operations
AMQ3064	536883300	Unexpected error occurred
AMQ3066	536883302	Unable to find a password
AMQ3067	536883303	Error creating config directory
AMQ3068	536883304	Variable not in the environment

The configuration file

 This is created by default with the path `$HOME/.mqm/dspmcert.ini` on UNIX platforms or `%USERPROFILE%\mqm\dspmcert.ini` on Windows.

 This is created by default with the path `<DATA_DIR>/mqm/dspmcert.ini`.

An alternative path may be used with the `-f` option.

The purpose of this file is to associate queue managers with keystore locations and passwords. The file may be edited by the user or automatically by the program.

The format of the `.ini` file is the queue manager name followed by a colon and newline. Indented underneath are optional lines for keystore path and password.

A hash (`#`) including text to the end of the line is treated as a comment and ignored.

Any unrecognized keys or superfluous text will output a warning to stderr.

Examples

- Show the help and exit:

```
dspmqcrt -h
```

- Show all self-signed or CA issued user certificates:

```
dspmqcrt
```

- Show all certificates, including CA intermediate and root certificates due to expire in the next 30 days:

```
dspmqcrt -a -d 30
```

- Show certificates for queue manager QM1 with CSV output:

```
dspmqcrt -m QM1 -o csv
```

- Show certificates for queue managers beginning with “QMPROD” (enclose the query in quotes to prevent globbing):

```
dspmqcrt -m "QMPROD*"
```

- Show the certificates for queue manager QM1, use the password “passw0rd” and write it to the config file

```
KBPASS_QM1=passw0rd dspmqcrt -m QM1
```

Multi **dspmqcsv (display command server)**

Use the **dspmqcsv** command to display the status of the command server for the specified queue manager.

The status can be one of the following:

- Starting
- Running
- Running with SYSTEM.ADMIN.COMMAND.QUEUE not enabled for gets
- Ending
- Stopped

You must use the **dspmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

Syntax

Required parameters

None

Required parameters

GenericObjName

The name of the object. The name is a string with no flag and is a required parameter. Omitting the name returns an error.

This parameter supports an asterisk (*) as a wildcard at the end of the string.

Optional parameters

-m QMgrName

The name of the queue manager for which to examine files. If you omit this name, the command operates on the default queue manager.

-t ObjType

The object type. The following list shows the valid object types. The abbreviated name is shown first followed by the full name.

Table 51. Valid object types.	
Object Type	Description
* or all	All object types; this parameter is the default
authinfo	Authentication information object, for use with TLS channel security
channel or chl	A channel
clntconn or clcn	A client connection channel
catalog or ctlg	An object catalog
namelist or nl	A namelist
listener or lstr	A listener
process or prcs	A process
queue or q	A queue or queues matching the object name parameter
qalias or qa	An alias queue
qlocal or ql	A local queue
qmodel or qm	A model queue
qremote or qr	A remote queue
qmgr	A queue manager object
service or srvc	A service

Note:

1. The **dspmqfls** command displays the name of the directory containing the queue, not the name of the queue itself.
2.   On AIX and Linux, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). The way you do this depends on the shell you are using. It may involve the use of single quotation marks, double quotation marks, or a backslash.

Return codes

Table 52. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed but not entirely as expected
20	An error occurred during processing

Examples

1. The following command displays the details of all objects with names beginning `SYSTEM.ADMIN` defined on the default queue manager.

```
dspmqrfls SYSTEM.ADMIN*
```

2. The following command displays file details for all processes with names beginning `PROC` defined on queue manager `RADIUS`.

```
dspmqrfls -m RADIUS -t prcs PROC*
```

dspmqrinf (display configuration information)

Use the **dspmqrinf** command to display IBM MQ configuration information (AIX, Linux, and Windows only).

Usage notes

Use **dspmqrinf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

Syntax

Required parameters

StanzaName

The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

Optional parameters

-s *StanzaType*

The type of stanza to display. If omitted, the `QueueManager` stanza is displayed.

The only supported value of *StanzaType* is `QueueManager`.

-o *stanza*

Displays the configuration information in stanza format as it is shown in the `.ini` files. This format is the default output format.

Use this format to display stanza information in a format that is easy to read.

-o command

Displays the configuration information as an **addmqinf** command.

Information about the installation associated with the queue manager is not displayed using this parameter. The **addmqinf** command does not require information about the installation.

Use this format to paste into a command shell.

Return codes

Table 53. Return code identifiers and descriptions

Return code	Description
0	Successful operation
39	Bad command-line parameters
44	Stanza does not exist
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error

Examples

```
dspmqinf QM.NAME
```

The command defaults to searching for a QueueManager stanza named QM.NAME and displays it in stanza format.

```
QueueManager:
  Name=QM.NAME
  Prefix=/var/mqm
  Directory=QM!NAME
  DataPath=/MQHA/qmgrs/QM!NAME
  InstallationName=Installation1
```

The following command gives the same result:

```
dspmqinf -s QueueManager -o stanza QM.NAME
```

The next example displays the output in **addmqinf** format.

```
dspmqinf -o command QM.NAME
```

The output is on one line:

```
addmqinf -s QueueManager -v Name=QM.NAME -v Prefix=/var/mqm -v Directory=QM!NAME
-v DataPath=/MQHA/qmgrs/QM!NAME
```

Related commands

Table 54. Related command names and descriptions

Command	Description
“addmqinf (add configuration information)” on page 26	Add queue manager configuration information

Table 54. Related command names and descriptions (continued)

Command	Description
“rmvmqinf (remove configuration information)” on page 169	Remove queue manager configuration information

Related reference

[“addmqinf \(add configuration information\)” on page 26](#)
Add IBM MQ configuration information on AIX, Linux, and Windows only.

[“rmvmqinf \(remove configuration information\)” on page 169](#)
Remove IBM MQ configuration information (AIX, Linux, and Windows only).

Multi dspmquist (display IBM MQ installation)

Display installation entries from `mqinst.ini` and license entitlement information on AIX, Linux, and Windows, and license entitlement information on IBM i.

Purpose

The `mqinst.ini` file contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see [Installation configuration file, mqinst.ini](#).

ULW On AIX, Linux, and Windows, you can use the **dspmquist** command to display `mqinst.ini` information from all installations on the system, or about specific installations (see [“Examples for AIX, Linux, and Windows” on page 105](#)).

dspmquist also displays information about license entitlement for each installation. The command displays the license type (Production, Trial, Beta, or Developer) and the licensed entitlement required for the IBM MQ installation. The required entitlement is reported based on the components that are installed and the usage information that has been specified using the **setmqinst** command (see [“setmqinst \(set IBM MQ installation\)” on page 264](#)). For more information about license types and entitlement, see [IBM MQ license information](#).

IBM i From IBM MQ 9.3.0, the **dspmquist** command is supported on IBM MQ for IBM i without any options to display the license entitlement required for an IBM MQ installation. The required entitlement is reported based on the components that are installed and usage information that has been specified using the **setmqinst** command (see [“Examples for IBM i” on page 106](#)).

Syntax

Notes:

¹ When specified together, the installation name and installation path must refer to the same installation.

Required parameters

None

Optional parameters

-n *InstallationName*

The name of the installation.

-p *InstallationPath*

The installation path.

?

Display usage information.

Return codes

Table 55. Return code identifiers and descriptions

Return code	Description
0	Entry displayed without error
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
131	Resource problem

Examples for AIX, Linux, and Windows

1. Display details of all IBM MQ installations on the system:

```
dspmquist
```

2. Query the entry for the installation named `Installation3`:

```
dspmquist -n Installation3
```

3. Query the entry with an installation path of `/opt/mqm`:

```
dspmquist -p /opt/mqm
```

4. Query the entry for the installation named `Installation3`. Its expected installation path is `/opt/mqm`:

```
dspmquist -n Installation3 -p /opt/mqm
```

5. The following examples show the output of **dspmquist** for different license types and entitlements:

- Output for an IBM MQ client installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ Client
```

- Output for a standard IBM MQ server installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ
```

- Output for an IBM MQ server installation that has been identified as a High Availability Replica:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ High Availability Replica
```

- Output for an IBM MQ Advanced Advanced server installation:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ Advanced
```

- Output for an IBM MQ Advanced server installation that has High Availability Replica entitlement:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ Advanced High Availability Replica
```

- Output for an IBM MQ Advanced server installation that has Non-Production entitlement:

```
InstName:      Installation1
InstDesc:      My installation
Identifier:    1
InstPath:      /opt/mqm
Version:       9.3.0.0
Primary:       No
State:         Available
License:       Production
Entitlement:    IBM MQ Advanced (Non-production)
```

Examples for IBM i

From IBM MQ 9.3.0, the **dspmqinst** command is supported to be run without any options. In /QIBM/ProdData/mqm/bin, running **dspmqinst** displays the **InstName**, **InstPath** **Version**, **LicenseType**, and **Entitlement**.

The following examples shows the output of **dspmqinst** for an IBM MQ Advanced server installation that has been identified as a High Availability Replica:

```
dspmqinst
```

InstName: Installation1
InstPath: /QIBM/ProdData/mqm
Version: 9.3.0.0
LicenseType: Production
Entitlement: IBM MQ Advanced High Availability Replica

 dspmqlc (display IBM MQ license)

On Linux (excluding IBM MQ Appliance) use the **dspmqlc** command to display the IBM MQ license in the appropriate language for the environment.

Usage notes

You can change the language can by setting the **LANG** environment variable. Note that you might need to install the necessary operating system language pack to obtain the required information in a language other than English.

Syntax

►► dspmqlc ◄◄

Required parameters

None

Optional parameters

None

Return codes

Table 56. Return code identifiers and descriptions

Return code	Description
0	The license file is displayed in some language
20	An error occurred

Related concepts

[Accepting the license on IBM MQ for Linux](#)

Related reference

[MQLICENSE](#)

[“mqlicense \(accept license after installation\)” on page 154](#)

On Linux (excluding IBM MQ Appliance) use the **mqlicense** command to accept the IBM MQ license after installation.

[strmqm \(start queue manager\)](#)

Use the **strmqm** command to start a queue manager or ready it for standby operation. If the queue manager startup takes more than a few seconds, IBM MQ shows intermittent messages detailing the startup progress.

Multi **dspmqrte (display route information)**

Determine the route that a message has taken through a queue manager network.

Purpose

The IBM MQ display route application (**dspmqrte**) command can be run on all platforms except z/OS. You can run the IBM MQ display route application as a client to an IBM MQ for z/OS queue manager by specifying the **-c** parameter when issuing the **dspmqrte** command.

The IBM MQ display route application generates and puts a trace-route message into a queue manager network. As the trace-route message travels through the queue manager network, activity information is recorded. When the trace-route message reaches its target queue, the activity information is collected by the IBM MQ display route application and displayed. For more information, and examples of using the IBM MQ display route application, see [IBM MQ display route application](#).

Syntax

Required parameters

-q TargetQName

If the IBM MQ display route application is being used to send a trace-route message into a queue manager network, *TargetQName* specifies the name of the target queue.

If the IBM MQ display route application is being used to view previously gathered activity information, *TargetQName* specifies the name of the queue where the activity information is stored.

Optional parameters

-c

Specifies that the IBM MQ display route application connects as a client application. For more information about how to set up client machines, see:

-  [Installing an IBM MQ client on an AIX workstation](#)
-  [Installing an IBM MQ client on a Linux workstation](#)
-  [Installing an IBM MQ client on a Windows workstation](#)
-  [Installing an IBM MQ client on an IBM i workstation](#)

This parameter can be used only if the client component is installed.

-i *CorrelId*

This parameter is used when the IBM MQ display route application is used to display previously accumulated activity information only. There can be many activity reports and trace-route reply messages on the queue specified by -q *TargetQName*. *CorrelId* is used to identify the activity reports, or a trace-route reply message, related to a trace-route message. Specify the message identifier of the original trace-route message in *CorrelId*.

The format of *CorrelId* is a 48 character hexadecimal string.

-m *QMgrName*

The name of the queue manager to which the IBM MQ display route application connects. The name can contain up to 48 characters.

If you do not specify this parameter, the default queue manager is used.

Generation options

The following parameters are used when the IBM MQ display route application is used to put a trace-route message into a queue manager network.

-ac

Specifies that activity information is to be accumulated within the trace-route message.

If you do not specify this parameter, activity information is not accumulated within the trace-route message.

-ar

Requests that a trace-route reply message containing all accumulated activity information is generated when the number of activities performed on the trace-route message exceeds the value of specified in -s *Activities*

For more information about trace-route reply messages, see [Trace-route reply message reference](#).

If you do not specify this parameter, a trace-route reply message is not requested.

-d *Deliver*

Specifies whether the trace-route message is to be delivered to the target queue on arrival. Possible values for *Deliver* are:

Table 57. Delivery parameter values.	
Value	Description
yes	On arrival, the trace-route message is put to the target queue, even if the queue manager does not support trace-route messaging.
no	On arrival, the trace-route message is not put to the target queue.

If you do not specify this parameter, the trace-route message is not put to the target queue.

-f Forward

Specifies the type of queue manager that the trace-route message can be forwarded to. Queue managers use an algorithm when determining whether to forward a message to a remote queue manager. For details of this algorithm, see [The cluster workload management algorithm](#). The possible values for *Forward* are:

Table 58. *Forward parameter values.*

Value	Description
all	The trace-route message is forwarded to any queue manager.
supported	The trace-route message is only forwarded to a queue manager that honors the <i>Deliver</i> parameter from the <i>TraceRoute</i> PCF group.

If you do not specify this parameter, the trace-route message is only forwarded to a queue manager that honors the *Deliver* parameter.

-l Persistence

Specifies the persistence of the generated trace-route message. Possible values for *Persistence* are:

Table 59. *Persistence parameter values.*

Value	Description
yes	The generated trace-route message is persistent. (MQPER_PERSISTENT).
no	The generated trace-route message is not persistent. (MQPER_NOT_PERSISTENT).
q	The generated trace-route message inherits its persistence value from the queue specified by -q <i>TargetQName</i> . (MQPER_PERSISTENCE_AS_Q_DEF).

A trace-route reply message, or any report messages, returned shares the same persistence value as the original trace-route message.

If *Persistence* is specified as yes, you must specify the parameter -rq *ReplyToQ*. The reply-to queue must not resolve to a temporary dynamic queue.

If you do not specify this parameter, the generated trace-route message is not persistent.

-o

Specifies that the target queue is not bound to a specific destination. Typically this parameter is used when the trace-route message is to be put across a cluster. The target queue is opened with option MQOO_BIND_NOT_FIXED.

If you do not specify this parameter, the target queue is bound to a specific destination.

-p Priority

Specifies the priority of the trace-route message. The value of *Priority* is either greater than or equal to 0, or MQPRI_PRIORITY_AS_Q_DEF. MQPRI_PRIORITY_AS_Q_DEF specifies that the priority value is taken from the queue specified by -q *TargetQName*.

If you do not specify this parameter, the priority value is taken from the queue specified by -q *TargetQName*.

-qm TargetQMName

Qualifies the target queue name; normal queue manager name resolution applies. The target queue is specified with -q *TargetQName*.

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

-ro none | ReportOption

Table 60. ReportOption parameter values.	
Value	Description
none	Specifies no report options are set.
ReportOption	Specifies report options for the trace-route message. Multiple report options can be specified using a comma as a separator. Possible values for <i>ReportOption</i> are: activity The report option MQRO_ACTIVITY is set. coa The report option MQRO_COA_WITH_FULL_DATA is set. cod The report option MQRO_COD_WITH_FULL_DATA is set. exception The report option MQRO_EXCEPTION_WITH_FULL_DATA is set. expiration The report option MQRO_EXPIRATION_WITH_FULL_DATA is set. discard The report option MQRO_DISCARD_MSG is set.

If `-ro ReportOption` or `-ro none` are not specified, then the MQRO_ACTIVITY and MQRO_DISCARD_MSG report options are specified.

-rq ReplyToQ

Specifies the name of the reply-to queue that all responses to the trace-route message are sent to. If the trace-route message is persistent, or if the **-n** parameter is specified, a reply-to queue must be specified that is not a temporary dynamic queue.

If you do not specify this parameter, the system default model queue, SYSTEM.DEFAULT.MODEL.QUEUE is used as the reply-to queue. Using this model queue causes a temporary dynamic queue, for the IBM MQ display route application, to be created.

-rqm ReplyToQMGr

Specifies the name of the queue manager where the reply-to queue is located. The name can contain up to 48 characters.

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

-s Activities

Specifies the maximum number of recorded activities that can be performed on behalf of the trace-route message before it is discarded. This parameter prevents the trace-route message from being forwarded indefinitely if caught in an infinite loop. The value of *Activities* is either greater than or equal to 1, or MQROUTE_UNLIMITED_ACTIVITIES. MQROUTE_UNLIMITED_ACTIVITIES specifies that an unlimited number of activities can be performed on behalf of the trace-route message.

If you do not specify this parameter, an unlimited number of activities can be performed on behalf of the trace-route message.

-t Detail

Specifies the activities that are recorded. The possible values for *Detail* are:

Table 61. Detail parameter values.	
Value	Description
low	Activities performed by user-defined application are recorded only.

Table 61. Detail parameter values. (continued)	
Value	Description
medium	Activities specified in low are recorded. Additionally, activities performed by MCAs are recorded.
high	Activities specified in low, and medium are recorded. MCAs do not expose any further activity information at this level of detail. This option is available to user-defined applications that are to expose further activity information only. For example, if a user-defined application determines the route a message takes by considering certain message characteristics, the routing logic can be included with this level of detail.

If you do not specify this parameter, medium level activities are recorded.

-ts TopicString

Specifies a topic string to which the IBM MQ display route application is to publish a trace-route message, and puts this application into topic mode. In this mode, the application traces all of the messages that result from the publish request.

-xp PassExpiry

Specifies whether the report option MQRO_DISCARD_MSG and the remaining expiry time from the trace-route message is passed on to the trace-route reply message. Possible values for *PassExpiry* are:

Table 62. PassExpiry parameter values.	
Value	Description
yes	The report option MQRO_PASS_DISCARD_AND_EXPIRY is specified in the message descriptor of the trace-route message. If a trace-route reply message, or activity reports, are generated for the trace-route message, the MQRO_DISCARD_MSG report option (if specified), and the remaining expiry time are passed on. This parameter is the default value.
no	The report option MQRO_PASS_DISCARD_AND_EXPIRY is not specified. If a trace-route reply message is generated for the trace-route message, the discard option and remaining expiry time from the trace-route message are not passed on.

If you do not specify this parameter, the MQRO_PASS_DISCARD_AND_EXPIRY report option is not specified in the trace-route message.

-xs Expiry

Specifies the expiry time for the trace-route message, in seconds.

If you do not specify this parameter, the expiry time is specified as 60 seconds.

-n

Specifies that activity information returned for the trace-route message is not to be displayed.

If this parameter is accompanied by a request for a trace-route reply message (-ar), or any of the report generating options from (-ro *ReportOption*), then a specific (non-model) reply-to queue must be specified using -rq *ReplyToQ*. By default, activity report messages are requested.

After the trace-route message is put to the specified target queue, a 48 character hexadecimal string is returned containing the message identifier of the trace-route message. The message identifier can be used by the IBM MQ display route application to display the activity information for the trace-route message at a later time. This can be done using the -i *CorrelId* parameter.

If you do not specify this parameter, activity information returned for the trace-route message is displayed in the form specified by the **-v** parameter.

Display options

The following parameters are used when the IBM MQ display route application is used to display collected activity information.

-b

Specifies that the IBM MQ display route application only browses activity reports or a trace-route reply message related to a message. This parameter allows activity information to be displayed again at a later time.

If you do not specify this parameter, the IBM MQ display route application gets activity reports and deletes them, or a trace-route reply message related to a message.

-v **summary** | **all** | **none** | **outline DisplayOption**

Table 63. DisplayOption parameter values.	
Value	Description
summary	The queues that the trace-route message was routed through are displayed.
all	All available information is displayed.
none	No information is displayed.
outline DisplayOption	Specifies display options for the trace-route message. Multiple display options can be specified using a comma as a separator. If no values are supplied the subsequent information is displayed: • The application name • The type of each operation • Any operation-specific parameters Possible values for <i>DisplayOption</i> are: activity All non-PCF group parameters in <i>Activity</i> PCF groups are displayed. identifiers Values with parameter identifiers MQBACF_MSG_ID or MQBACF_CORREL_ID are displayed. This overrides <i>msgdelta</i>. message All non-PCF group parameters in <i>Message</i> PCF groups are displayed. When this value is specified, you cannot specify <i>msgdelta</i>. msgdelta All non-PCF group parameters in <i>Message</i> PCF groups, that have changed since the last operation, are displayed. When this value is specified, you cannot specify <i>message</i>. operation All non-PCF group parameters in <i>Operation</i> PCF groups are displayed. traceroute All non-PCF group parameters in <i>TraceRoute</i> PCF groups are displayed.

If you do not specify this parameter, a summary of the message route is displayed.

-w **WaitTime**

Specifies the time, in seconds, that the IBM MQ display route application waits for activity reports, or a trace-route reply message, to return to the specified reply-to queue.

If you do not specify this parameter, the wait time is specified as the expiry time of the trace-route message, plus 60 seconds.

-u *UserId*

The ID of the user authorized to determine the route that a message has taken through a queue manager network.

Return codes

Table 64. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Invalid arguments supplied
20	An error occurred during processing

Examples

1. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Providing queue managers on route are enabled for activity recording, activity reports are generated. Depending on the queue manager attribute, ACTIVREC, activity reports are either delivered to the reply-to queue ACT.REPORT.REPLY.Q, or are delivered to a system queue. The trace-route message is discarded on arrival at the target queue.

```
dspmqrte -q TARGET.Q -rq ACT.REPORT.REPLY.Q
```

Providing one or more activity reports are delivered to the reply-to queue, ACT.REPORT.REPLY.Q, the IBM MQ display route application orders and displays the activity information.

2. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Activity information is accumulated within the trace-route message, but activity reports are not generated. On arrival at the target queue, the trace-route message is discarded. Depending on the value of the target queue manager attribute, ROUTEREC, a trace-route reply message can be generated and delivered to either the reply-to queue, TRR.REPLY.TO.Q, or to a system queue.

```
dspmqrte -ac -ar -ro discard -rq TRR.REPLY.TO.Q -q TARGET.Q
```

Providing a trace-route reply message is generated, and delivered to the reply-to queue TRR.REPLY.TO.Q, the IBM MQ display route application orders and displays the activity information that was accumulated in the trace-route message.

For more examples of using the IBM MQ display route application and its output, see [IBM MQ display route application examples](#).

dspmqspl (display security policy)

Use the **dspmqspl** command to display a list of all policies and details of a named policy.  On z/OS you use the command with the CSQOUTIL utility.

Before you begin

The queue manager on which you want to operate must be running.

 You must grant the necessary +connect, +inq and +chg authorities, using the [setmqaut](#) command, to connect to the queue manager and create a security policy.

► **z/OS** For more information on the authorities needed to run this command on z/OS see “[Specific security information](#)” on page 3014 in the CSQOUTIL topic.

For more information about configuring security see [Setting up security](#).

Syntax

►► dspmqspl — -m — QMgrName — -p — PolicyName — -export —►

Table 65. dspmqspl command flags

Command flag	Explanation
-m	Queue manager name (mandatory).
-p	Policy name.
-export	Adding this flag generates output which can easily be applied to a different queue manager. ► z/OS The output is written to a DD named EXPORT

Examples

The **dspmqspl** command shows the key reuse count for all policies. The following example is the output you receive on [Multiplatforms](#):

```
Policy Details:
Policy name: PROT
Quality of protection: PRIVACY
Signature algorithm: SHA256
Encryption algorithm: AES256
Signer DNS: -
Recipient DNS:
  CN=Name, O=Organization, C=Country
Toleration: 0
Key Reuse Count: 0
-----
Policy Details:
Policy name: PROT2
Quality of protection: CONFIDENTIALITY
Signature algorithm: NONE
Encryption algorithm: AES256
Signer DNS: -
Recipient DNS:
  CN=Name, O=Organization, C=Country
Toleration: 0
Key Reuse Count: 100
```

Related reference

“[SET POLICY \(set security policy\) on Multiplatforms](#)” on page 1054

Use the MQSC command **SET POLICY** to set a security policy.

“[DISPLAY POLICY \(display a security policy\) on Multiplatforms](#)” on page 850

Use the MQSC command **DISPLAY POLICY** to display a security policy.

“[setmqspl \(set security policy\)](#)” on page 271

Use the **setmqsp1** command to define a new security policy, replace an already existing one, or remove an existing policy.  On z/OS you use the command with the CSQOUTIL utility.

dspmqtrc (display formatted trace)

Use the **dspmqtrc** command to format and display IBM MQ trace.

The **dspmqtrc** command is supported on AIX and Linux systems only.

The runtime TLS trace files have the names AMQ.SSL.TRC and AMQ.SSL.TRC.1. You cannot format any of the TLS trace files. The TLS trace files are binary files and, if they are transferred to IBM Support by FTP, they must be transferred in binary transfer mode.

Syntax

Required parameters

InputFileName

The name of the file containing the unformatted trace, for example:

```
/var/mqm/trace/AMQ12345.01.TRC
```

If you provide one input file, **dspmqtrc** formats it to the output file you name. If you provide more than one input file, any output file you name is ignored, and formatted files are named AMQ *yyyyyy*.
zz.FMT, based on the PID of the trace file.

Optional parameters

-t *FormatTemplate*

The name of the template file containing details of how to display the trace. If this parameter is not supplied, the default template file location is used:

 For AIX systems, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc2.fmt
```

 For Linux, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc.fmt
```

MQ_INSTALLATION_PATH represents the high-level directory in which IBM MQ is installed.

-h

Omit header information from the report.

-s

Extract trace header and put to stdout.

-o *output_filename*

The name of the file into which to write formatted data.

[Command sets comparison: Other commands](#)

A table of other commands, showing the command description, and the equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Multi dspmqtrn (display incomplete transactions)

Use the **dspmqtrn** command to display details of transactions. This command includes transactions coordinated by IBM MQ and by an external transaction manager.

Syntax

Optional parameters

-e

Requests details of externally coordinated, in-doubt XA transactions. Such transactions are those for which the queue manager (RM) has been asked to prepare to commit, but has not yet been informed by the TM of the transaction outcome (commit or rollback).

-h

Requests details of externally coordinated transactions that were resolved by the **rsvmqtrn** command, and the external transaction coordinator has yet to acknowledge with an **xa-forget** command. This transaction state is termed *heuristically completed* by X/Open.

Note: If you do not specify **-e**, **-h**, or **-i**, details of both internally and externally coordinated in-doubt transactions are displayed, but details of externally coordinated, heuristically completed transactions are not displayed.

-i

Requests details of internally coordinated, in-doubt XA transactions. Such transactions are those for which the queue manager (TM) has asked each resource manager (RM) to prepare to commit, but

an error was reported by one of the resource managers (for example, a network connection broke). In this state, the queue manager (TM) has yet to inform all resource managers of the transaction outcome (commit or rollback), but stands ready to do so. For more information, see [Displaying outstanding units of work with the dspmqtrn command](#).

Information about the state of the transaction in each of its participating resource managers is displayed. This information can help you assess the affects of failure in a particular resource manager.

Note: If you do not specify **-e** or **-i**, details of both internally and externally coordinated in-doubt transactions are displayed.

-a

Requests a list of all transactions known to the queue manager . The returned data includes transaction details for all transactions known to the queue manager. If a transaction is currently associated with an IBM MQ application connection, information related to that IBM MQ application connection is also returned. The data returned by this command might typically be correlated with the output of a runmqsc [“DISPLAY CONN \(display application connection information\)”](#) on page 819 command, and the output fields have the same meaning as in that command.

Not all of the fields are appropriate for all transactions. When the fields are not meaningful, they are displayed as blank. For example: The UOWLOG value when the command is issued against a circular logging queue manager.

-q

Specifying this parameter on its own is the same as specifying **-a -q**.

Displays all the data from the **-a** parameter and a list of up to 100 unique objects updated within the transaction. If more than 100 objects are updated in the same transaction, only the first 100 distinct objects are listed for each transaction.

-m QMgrName

The name of the queue manager for which to display transactions. If you omit the name, the transaction of the default queue manager are displayed.

Return codes

Table 68. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
102	No transactions found

Example

Here is a typical use of the command, showing the form that is usually requested by IBM MQ Support:

```
dspmqtrn -m <qmgrname> -q -a
```

The output generated would be long. As an illustration, here is what one XA transaction might look like in the output:

```
TranNum(0,12294)
TRANSTATE(ACTIVE)
UOWLOGDA(2024-11-04)
UOWLOGTI(14.58.32)
UOWSTDA(2024-11-04)
UOWSTTI(14.58.32)
UOWLOG( )
EXTURID(XA_FORMATID[40]
XA_GTRID[7378717467323134000000000000000000000000
000000000000000000000000000004D8CF5C2E29D80014751A]
XA_BQUAL[0000002800000000100000003])
OBJECT(TEST.Q)
```

Related tasks

Displaying outstanding units of work with the dspmqtrn command

Related reference

“rsvmqtrn (resolve transactions)” on page 171

Resolve in-doubt and heuristically completed transactions.

Multi **dspmqver (display version information)**

By default, the **dspmqr** command displays version and build information for the installation from which it was started. A note is displayed if other installations exist; use the **-i** parameter to display their details.

Syntax

Optional parameters

-a

Display information about all fields and components.

-p Components

Display information for the components specified by *component*. Either a single component or multiple components can be specified. Enter either the value of a single component or the sum of the values of all the required components. Available components and related values are as follows:

Value	Description
1	IBM MQ server, or client.
2	IBM MQ classes for Java.
4	IBM MQ classes for Java Message Service  and IBM MQ classes for Jakarta Messaging.
8	WebScale Distribution Hub
16 “1” on page 121	 IBM MQ custom channel for Windows Communication Foundation.

Value	Description
32	 IBM MQ Message Service Client (XMS) for .NET (XMS .NET) - this component is only available on Windows.
64	IBM Global Security Kit (GSKit)
128	Advanced Message Security
256	IBM MQ AMQP Service
512	IBM MQ Telemetry Service
1024	Other bundled components that are used by IBM MQ
2048	WebSphere® Liberty profile
4096	IBM MQ Java runtime environment
8192	IBM MQ Replicated Data Queue Managers (RDQM)

Notes:

1.  Supported by IBM MQ for Windows only. If you have not installed Microsoft.NET 3 or later, the following error message is displayed:

Title: WMQWCFCustomChannelLevel.exe - Application Error

The application failed to initialize properly (0x0000135).

The default value is 1.

-f Fields

Display information for the fields specified by *field*. Specify either a single field or multiple fields. Enter either the value of a single field or the sum of the values of all the required fields. Available fields and related values are as follows:

Value	Description
1	Name
2	Version, in the form V . R . M . F: Where V =Version, R =Release, M =Modification, and F =Fix pack
4	Level
8	Build type
16	Platform
32	Addressing mode
64	Operating system
128	Installation path
256	Installation description
512	Installation name
1024	Maximum command level
2048	Primary installation
4096	Data Path

Value	Description
8192	License type
16384	Release type, can be: • Long Term Support (LTS) and Continuous Delivery (CD) if the Modification and Fix pack is zero • Long Term Support (LTS) if the Modification is zero and Fix pack is not zero. • Continuous Delivery (CD) otherwise See IBM MQ release types and versioning .

Information for each selected field is displayed on a separate line when the **dspmqr** command is run.

The default value is 65535. This displays information for all fields.

-b

Omit header information from the report.

-v

Display verbose output.

-i

Display information about all installations. You cannot use this option with other options. The installation from which the **dspmqr** command was issued is displayed first. For any other installations, only the following fields are displayed: Name, Version, Installation name, Installation description, Installation path, and Primary installation.

Return codes

Table 69. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following command displays IBM MQ version and build information, using the default settings for **-p** and **-f**:

```
dspmqr
```

The following command displays information about all fields and components and is the equivalent of specifying `dspmqr -p 63 -f 4095`:

```
dspmqr -a
```

The following command displays version and build information for the IBM MQ classes for Java:

```
dspmqr -p 2
```

The following command displays the Common Services for Java Platform Standard Edition, IBM MQ, Java Message Service Client, IBM MQ classes for Java Message Service, and **JM 3.0** IBM MQ classes for Jakarta Messaging:

```
dspmqrver -p 4
```

The following command displays the build level of the WebScale Distribution Hub:

```
dspmqrver -p 8 -f 4
```

Windows The following command displays the name and build type for IBM MQ custom channel for Windows Communication Foundation:

```
dspmqrver -p 16 -f 9
```

The following command displays information about installations of IBM MQ.

```
dspmqrver -i
```

Example output for MQ.NET Standard classes:

```
Name:      IBM Message Service Client for .NET Standard
Version:    9.1.1.0
Level:      p911-LXXXX
Build Type: Production
```

Command failure

Failure when viewing the IBM MQ classes for Java

The **dspmqrver** command can fail if you try to view version or build information for the IBM MQ classes for Java, and you have not correctly configured your environment, or if the IBM MQ JRE component is not installed, and an alternative JRE could not be located.

For example, you might see the following message:

```
[root@blade883 ~]# dspmqrver -p 2
AMQ8351: IBM MQ Java environment has not been configured
correctly, or the IBM MQ JRE feature has not been installed.
```

To resolve this problem, consider installing the IBM MQ JRE component if it is not already installed, or ensure that the path is configured to include the JRE, and that the correct environment variables are set.

> Linux **> AIX** For example, on AIX and Linux, you can use one of the following scripts to resolve this problem:

- **> JMS 2.0** For JMS 2.0, use `setjmsenv` or `setjmsenv64`. For example:

```
export PATH=$PATH:/opt/mqm/java/jre/bin
cd /opt/mqm/java/bin/
. ./setjmsenv64
```

```
[root@blade883 bin]# dspmqrver -p 2
Name:      IBM MQ classes for Java
Version:    8.0.0.0
Level:      k000-L110908
Build Type: Production
```

- **> JM 3.0** For Jakarta Messaging 3.0, use `setjms30env` or `setjms30env64`. For example:

```
export PATH=$PATH:/opt/mqm/java/jre/bin
cd /opt/mqm/java/bin/
. ./setjms30env64
```

```
[root@blade883 bin]# dspmqrver -p 2
Name:      IBM MQ classes for Java
```

Version: 8.0.0.0
Level: k000-L110908
Build Type: Production

Notes:

-   The **setjmsenv** and **setjms30env** scripts apply to AIX and Linux only.
-  On Windows, the **runjms** scripts provide similar functionality to that provided by the **setjmsenv** and **setjms30env** scripts on AIX and Linux.
-  For the IBM MQ classes for Java on Windows, if the IBM MQ JRE component is installed, you need to issue the **setmqenv** command to resolve error [AMQ8351](#).

[Setting environment variables for IBM MQ classes for JMS](#)

Related reference

[Scripts provided with IBM MQ classes for JMS](#)

dspmqweb properties (display mqweb server configuration properties)

Display information about the configurable properties of the mqweb server that is used to support the IBM MQ Console and REST API. That is, the command displays properties that are configurable by the user and the properties that have been modified. The mqweb server does not need to be running.

Using the setmqweb and dspmqweb commands on z/OS

Before you issue either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the **WLP_USER_DIR** environment variable so that the variable points to your mqweb server configuration.

To set the **WLP_USER_DIR** environment variable, enter the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory that is passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

For more information, see [Create the mqweb server](#).

You must also set the **JAVA_HOME** environment variable to reference a 64-bit version of Java on your system.

Using the setmqweb and dspmqweb commands in a stand-alone IBM MQ Web Server installation

Before you issue either the **setmqweb** or **dspmqweb** commands in a stand-alone IBM MQ Web Server installation, you must set the **MQ_OVERRIDE_DATA_PATH** environment variable to the IBM MQ Web Server data directory.

The user ID running the command needs write access to the data directory and its subdirectories.

Syntax

➔ **dspmqweb properties**     

Optional parameters

- u**
Displays only the configurable properties that have been modified by the user.
- a**
Displays all available configurable properties, including those properties which have been modified by the user.
- t**
Formats the output as text name-value pairs.
- c**
Formats the output as command text, which can be used as input to the corresponding **setmqweb properties** command.
- l**
Enable verbose logging. Diagnostic information is written to a mqweb server log-file.

Properties that can be returned by the command

The following properties can be returned by the **dspmqweb properties** command on all platforms, including the IBM MQ Appliance. Some of the following properties are not available in a stand-alone IBM MQ Web Server installation.

ltpaExpiration

This configuration property is used to specify the time, in seconds, before the LTPA token expires.

maxTraceFiles

This configuration property is used to specify the maximum number of mqweb server log files that are generated by the mqweb server.

maxTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each mqweb server log file can reach.

mqConsoleEnableDashboardBrowse

This configuration property is used to enable or disable queue browsing that is used by the IBM MQ Console to obtain some of the information that is displayed in the [MQ Console dashboard](#).

mqConsoleEnableSystemTopicMonitoring

This configuration property is used to enable or disable system topic monitoring that is used to display system information in the IBM MQ Console.

mqConsoleMaxMsgCharsToDisplay

This configuration property is used to specify the maximum characters to retrieve from each message when you browse a queue by using the IBM MQ Console.

mqConsoleMaxMsgRequestSize

This configuration property is used to specify the maximum size, in MB, a browse request can be across all messages when you browse queues by using the IBM MQ Console.

mqConsoleMaxMsgsPerRequest

This configuration property is used to specify the total number of messages to retrieve from a queue when you browse by using the IBM MQ Console.

mqRestCorsAllowedOrigins

This configuration property is used to specify the origins that are allowed to access the REST API. For more information about CORS, see [Configuring CORS for the REST API](#).

mqRestCorsMaxAgeInSeconds

This configuration property is used to specify the time, in seconds, that a web browser can cache the results of any CORS pre-flight checks.

mqRestCsrfValidation

This configuration property is used to specify whether CSRF validation checks are performed. A value of `false` removes the CSRF token validation checks.

mqRestGatewayEnabled

This configuration property is used to specify whether the administrative REST API gateway is enabled.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

mqRestGatewayQmgr

This configuration property is used to specify the name of the queue manager to use as the gateway queue manager. This queue manager must be in the same installation as the mqweb server. A blank value indicates that no queue manager is configured as the gateway queue manager.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

mqRestMessagingAdoptWebUserContext

This configuration property is used to specify the user context that is used for authorization when you send, publish, receive, or browse messages by using the messaging REST API. That is, it specifies which user ID is used for authorization.

If the value is set to `true`, the ID that is used for authorization is the user ID that is logged in to the REST API.

If the value is set to `false`, the ID that is used for authorization is the user ID that is used to start the mqweb server.

mqRestMessagingEnabled

This configuration property is used to specify whether the messaging REST API is enabled.

mqRestMessagingFullPoolBehavior

This configuration property is used to specify the behavior of the messaging REST API when all connections in the connection pool are in use.

If the value is set to `block`, wait for a connection to become available if all the connections in the pool are in use. When this option is used, the wait for a connection is indefinite.

If the value is set to `error`, return an error if all connections in the pool are in use.

If the value is set to `overflow`, create a nonpooled connection to use if all the connections in the pool are in use.

mqRestMessagingMaxPoolSize

This configuration property is used to specify the maximum connection pool size for each queue manager connection pool.

mqRestMftCommandQmgr

This configuration property is used to specify the name of the command queue manager to which create transfer and create, delete, or update resource monitor requests are submitted by the REST API for MFT.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftCoordinationQmgr

This configuration property is used to specify the name of the coordination queue manager from which transfer details are retrieved by the REST API for MFT.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftEnabled

This configuration property is used to specify whether the REST API for MFT is enabled.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftReconnectTimeoutInMinutes

This configuration property is used to specify the length of time, in minutes, after which the REST API for MFT stops trying to connect to the coordination queue manager.

This property is not returned in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestRequestTimeout

This configuration property is used to specify the time, in seconds, before a REST request times out.

traceSpec

This configuration property is used to specify the level of trace that is generated by the mqweb server. For a list of possible values, see [Configuring logging for the IBM MQ Console and REST API](#).

 The following properties are the additional properties that can be returned by the **dspmqweb properties** command on z/OS, AIX, Linux, and Windows. Some of the following properties are not available in a stand-alone IBM MQ Web Server installation.

httpHost

This configuration property is used to specify the HTTP hostname as an IP address, domain name server (DNS) hostname with domain name suffix, or the DNS hostname of the server where IBM MQ is installed.

An asterisk specifies all available network interfaces, and the value `localhost` allows only local connections.

httpPort

This configuration property is used to specify the HTTP port number that is used for HTTP connections.

If the value is set to `-1` the port is disabled.

httpsPort

This configuration property is used to specify the HTTPS port number that is used for HTTPS connections.

If the value is set to `-1` the port is disabled.

ltpaCookieName

This configuration property is used to specify the name of the LTPA token cookie name.

By default, the value of this property is `LtpaToken2_${env.MQWEB_LTPA_SUFFIX}` on AIX, Linux, and Windows, or `LtpaToken2_${httpsPort}` on z/OS. The variable after the `LtpaToken2_` prefix is used by the mqweb server to generate a unique name for the cookie. You cannot set this variable, but you can change the `ltpaCookieName` to a value of your choosing.

maxMsgTraceFiles

This configuration property is used to specify the maximum number of messaging trace files that are generated by the mqweb server for the IBM MQ Console.

maxMsgTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each messaging trace file can reach.

This property applies only to the IBM MQ Console.

mqConsoleAutostart

This configuration property is used to specify whether the IBM MQ Console automatically starts when the mqweb server starts.

mqConsoleFrameAncestors

This configuration property is used to specify the list of origins of web pages that can embed the IBM MQ Console in an IFrame.

mqConsoleRemoteAllowLocal

This configuration property is used to specify whether remote and local queue managers are visible in the IBM MQ Console when remote queue manager connections are allowed. When this property is set to true, both local and remote queue managers are displayed.

This property is not returned in a stand-alone IBM MQ Web Server installation. The IBM MQ Console can be used only with remote queue managers in this environment.

mqConsoleRemotePollTime

This configuration property is used to specify the time, in seconds, before the remote queue manager connections list is refreshed. On refresh, unsuccessful connections are retried.

mqConsoleRemoteSupportEnabled

This configuration property is used to specify whether the IBM MQ Console allows remote queue manager connections. When this property is set to true, remote queue manager connections are allowed.

This property is not returned in a stand-alone IBM MQ Web Server installation. The IBM MQ Console can be used only with remote queue managers in this environment.

mqConsoleRemoteUIAdmin

This configuration property is used to specify whether remote queue managers can be added to the IBM MQ Console by using the Console, or if remote queue managers can be added only by using the **setmqweb remote** command. When this property is set to true, remote queue managers can be added by using the IBM MQ Console.

mqRestAutostart

This configuration property is used to specify whether the REST API automatically starts when the mqweb server starts.

mqRestMessagingConnectionMode

This configuration property is used to specify whether the messaging REST API can send messages to queue managers that are not in the same installation as the mqweb server.

If the value is set to `local`, the messaging REST API can send messages only to queue managers that are in the same installation as the mqweb server.

If the value is set to `remote`, the messaging REST API can send messages to any queue manager that is configured for use by the messaging REST API.

This property is not returned in a stand-alone IBM MQ Web Server installation. The messaging REST API can be used only with remote queue managers in this environment.

remoteKeyfile

This configuration property is used to specify the location of the key file that contains the initial encryption key that is used to decrypt the passwords that are stored in the remote queue manager connection information.

secureLtpa

This configuration property is used to specify whether the LTPA token is secured for all requests. An unsecured LTPA token is required in order to send HTTP requests from a browser.

 The following properties are the additional properties that can be returned by the **dspmqweb properties** command on AIX, Linux, and Windows:

managementMode

This configuration property is used to specify whether queue managers and listeners are able to be created, deleted, started, and stopped by the IBM MQ Console.

If the value is set to `standard`, queue managers and listeners can be created and administered in the IBM MQ Console.

If the value is set to `externallyprovisioned`, queue managers and listeners cannot be created in the IBM MQ Console. Only queue managers and listeners that are created outside of the IBM MQ Console can be administered.

Related commands

Table 71. Related commands and descriptions

Command	Description
dspmqweb status	Display the mqweb server status
dspmqweb remote	Display the mqweb server remote queue manager configuration
strmqweb	Start the mqweb server.
endmqweb	Stop the mqweb server.
 setmqweb pid	Configure the product ID that the mqweb server runs under on z/OS.
“setmqweb properties (set mqweb server configuration properties)” on page 278	Configure the mqweb server properties.
“setmqweb remote (set mqweb server remote queue manager configuration)” on page 286	Configure the mqweb server remote queue manager connections.

Related reference

[“dspmqweb status \(display mqweb server status\)” on page 133](#)

Display information about the status of the mqweb server that is used to support the IBM MQ Console and REST API.

[“dspmqweb remote \(display mqweb server remote queue manager configuration\)” on page 130](#)

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.

[“endmqweb \(end mqweb server\)” on page 148](#)

Use the **endmqweb** command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

[“setmqweb pid \(set mqweb server product ID\)” on page 275](#)

Use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under on z/OS.

[“setmqweb properties \(set mqweb server configuration properties\)” on page 278](#)

Use the **setmqweb properties** command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.

[“setmqweb remote \(set mqweb server remote queue manager configuration\)” on page 286](#)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

[“strmqweb \(start mqweb server\)” on page 309](#)

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

dspmqweb remote (display mqweb server remote queue manager configuration)

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.

Using the setmqweb and dspmqweb commands on z/OS

Before you issue either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the **WLP_USER_DIR** environment variable so that the variable points to your mqweb server configuration.

To set the **WLP_USER_DIR** environment variable, enter the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory that is passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

For more information, see [Create the mqweb server](#).

You must also set the **JAVA_HOME** environment variable to reference a 64-bit version of Java on your system.

Using the setmqweb and dspmqweb commands in a stand-alone IBM MQ Web Server installation

Before you issue either the **setmqweb** or **dspmqweb** commands in a stand-alone IBM MQ Web Server installation, you must set the **MQ_OVERRIDE_DATA_PATH** environment variable to the IBM MQ Web Server data directory.

The user ID running the command needs write access to the data directory and its subdirectories.

Syntax

Optional parameters

-li

Displays all the remote queue manager unique IDs.

-a

Displays all the remote queue manager connection definitions and properties.

-uniqueName uniqueName

Displays the remote queue manager connection definition and properties for the queue manager that is associated with the unique name.

-l

Enable verbose logging. Diagnostic information is written to a mqweb server log-file.

Properties that can be returned by the command

The following global properties can be returned when the **-a** parameter is used:

globalTrustStorePath

The path to the truststore JKS file. This truststore is used for all remote connections unless it is overridden by specific remote queue manager connection information in the **trustStorePath** entry.

globalTrustStorePassword

The password for the global truststore.

This value is encrypted and is displayed as a series of asterisks.

globalKeyStorePath

The path to the keystore JKS file. This keystore is used for all remote connections unless it is overridden by a specific remote queue manager connection information in the **keyStorePath** entry.

globalKeyStorePassword

The password for the global keystore.

This value is encrypted and is displayed as a series of asterisks.

For each remote queue manager connection, the following properties can be returned:

uniqueName

The unique name for the remote queue manager connection.

qmgrName

The name of the queue manager.

ccdtURL

The path to the CCDT file that is associated with the remote queue manager connection.

group

Whether this remote queue manager connection is part of a queue manager group. If the value is **true**, then the **uniqueName** specifies the group name.

This property is valid only for the messaging REST API.

visibility

Whether this remote queue manager connection can be used by the messaging REST API, the IBM MQ Console, or both.

username

The username that is used for the remote queue manager connection.

password

The password that is associated with the username that is used for the remote queue manager connection.

This value is encrypted in the remote queue manager connection information and is displayed as a series of asterisks.

enableMutualTLS

Whether this remote queue manager connection uses mutual TLS.

trustStorePath

The path to the truststore JKS file. This value overrides the global truststore value.

trustStorePassword

The password for the truststore file.

This value is encrypted in the remote queue manager connection information and is displayed as a series of asterisks.

keyStorePath

The path to the keystore JKS file. This value overrides the global keystore value.

keyStorePassword

The password for the keystore file.

This value is encrypted in the remote queue manager connection information and is displayed as a series of asterisks.

Return codes

Use the **endmqweb** command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

[“setmqweb pid \(set mqweb server product ID\)” on page 275](#)

Use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under on z/OS.

[“setmqweb properties \(set mqweb server configuration properties\)” on page 278](#)

Use the **setmqweb properties** command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.

[“setmqweb remote \(set mqweb server remote queue manager configuration\)” on page 286](#)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

[“strmqweb \(start mqweb server\)” on page 309](#)

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

dspmqweb status (display mqweb server status)

Display information about the status of the mqweb server that is used to support the IBM MQ Console and REST API.

The mqweb server must be running to use the IBM MQ Console or the REST API. If the server is running then the available root context URLs and associated ports that are used by the IBM MQ Console and REST API are displayed by the **dspmqweb status** command.

Using the setmqweb and dspmqweb commands on z/OS

Before you issue either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the **WLP_USER_DIR** environment variable so that the variable points to your mqweb server configuration.

To set the **WLP_USER_DIR** environment variable, enter the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory that is passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

For more information, see [Create the mqweb server](#).

You must also set the **JAVA_HOME** environment variable to reference a 64-bit version of Java on your system.

Using the setmqweb and dspmqweb commands in a stand-alone IBM MQ Web Server installation

Before you issue either the **setmqweb** or **dspmqweb** commands in a stand-alone IBM MQ Web Server installation, you must set the **MQ_OVERRIDE_DATA_PATH** environment variable to the IBM MQ Web Server data directory.

The user ID running the command needs write access to the data directory and its subdirectories.

Syntax

➤ **dspmqweb status** A diagram showing a horizontal line with an arrow pointing right. Below the line, there is a bracketed section containing the text "-l".

Optional parameters

-l

Enable verbose logging. Diagnostic information is written to a mqweb server log-file.

Return codes

Table 74. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see [Liberty:server command options](#) in the WebSphere Application Server documentation.

Related commands

Related reference

[“dspmqweb properties \(display mqweb server configuration properties\)” on page 124](#)

Display information about the configurable properties of the mqweb server that is used to support the IBM MQ Console and REST API. That is, the command displays properties that are configurable by the user and the properties that have been modified. The mqweb server does not need to be running.

[“dspmqweb remote \(display mqweb server remote queue manager configuration\)” on page 130](#)

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.

[“endmqweb \(end mqweb server\)” on page 148](#)

Use the **endmqweb** command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

[“setmqweb pid \(set mqweb server product ID\)” on page 275](#)

Use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under on z/OS.

[“setmqweb properties \(set mqweb server configuration properties\)” on page 278](#)

Use the **setmqweb properties** command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.

[“setmqweb remote \(set mqweb server remote queue manager configuration\)” on page 286](#)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

[“strmqweb \(start mqweb server\)” on page 309](#)

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

dspmqxr (display MQTT server properties)

Use the **dspmqxr** command to display the configured MQTT server properties.

The command allows you to display the properties that are configured in the following properties files:

- `mqxrtraceOff.properties`
- `mqxrtraceOn.properties`
- `java.properties`
- `mqxr_unix.properties`
- `mqxr_win.properties`

Syntax

```
➔ dspmqxr properties — -m — QMgrName ————— -o — format — -l ➔
```

Required parameters

-m QMgrName

The queue manager you are viewing MQTT properties for.

Optional parameters

-o format

Specifies the format that the information is output in. One of the following values:

text

Format the output in name/value pairs. This is the default value if the parameter is not specified.

cmd

Format the output as command text (this can then be used as input to the **setmqxr** command).

-l

Enable verbose logging. Diagnostic information is written to a log file.

Return codes

Table 76. Return code identifiers and descriptions

Return code	Description
0	Command successful
>0	Command not successful

Examples

The following command displays the configured MQTT server properties for the queue manager QM1, formatting the output in name/value pairs:

```
dspmqxr -m QM1 -o text
```

The following command displays the configured MQTT server properties for the queue manager QM1, formatting the output as input for the **setmqxr** command:

```
dspmqxr -m QM1 -o cmd
```

Related reference

[“setmqxr \(set MQTT server properties\)” on page 292](#)

Use the **setmqxr properties** command to configure MQTT server properties.

endmqcsv (end command server)

Use the **endmqcsv** command to stop the command server on the specified queue manager.

You must use the **endmqscsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

If the queue manager attribute, SCMDSERV, is specified as QMGR then changing the state of the command server using **endmqscsv** does not effect how the queue manager acts upon the SCMDSERV attribute at the next restart.

Syntax

Required parameters

QMGrName

The name of the queue manager for which to end the command server.

Optional parameters

-c

Stops the command server in a controlled manner. The command server can complete the processing of any command message that it has already started. No new message is read from the command queue.

This parameter is the default.

-i

Stops the command server immediately. Actions associated with a command message currently being processed might not complete.

Return codes

Table 77. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

1. The following command stops the command server on queue manager `saturn.queue.manager`:

```
endmqcsv -c saturn.queue.manager
```

The command server can complete processing any command it has already started before it stops. Any new commands received remain unprocessed in the command queue until the command server is restarted.

2. The following command stops the command server on queue manager `pluto` immediately:

```
endmqcsv -i pluto
```

Related commands

Table 78. Related command names and descriptions

Command	Description
strmqcsv	Start a command server
dspmqcsv	Display the status of a command server

Related reference

[“Command server commands” on page 7](#)

A table of command server commands, showing equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

[“dspmqcsv \(display command server\)” on page 99](#)

Use the **dspmqcsv** command to display the status of the command server for the specified queue manager.

[“strmqcsv \(start command server\)” on page 294](#)

Use the **strmqcsv** command to start the command server for the specified queue manager. This enables IBM MQ to process commands sent to the command queue.

Windows **endmqdnm (stop .NET monitor)**

Stop the .NET monitor for a queue (Windows only).

Syntax

```
➤ endmqdnm — -q — QueueName — -m — QMgrName ➤
```

Required parameters

-q QueueName

The name of the application queue that the .NET monitor is monitoring.

Optional parameters

-m QMgrName

The name of the queue manager that hosts the application queue.

If omitted, the default queue manager is used.

Return codes

Table 79. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

Related tasks

[Using the .NET monitor](#)

Multi **endmqlsr (end listener)**

The **endmqlsr** command ends all listener processes for the specified queue manager.

You must use the **endmqlsr** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmqr -o installation** command.

You do not have to stop the queue manager before issuing the **endmqlsr** command. If any of the listeners are configured to have inbound channels running within the **runmqlsr** listener process, rather than within a pool process, the request to end that listener might fail if channels are still active. In this case a message is written indicating how many listeners were successfully ended and how many listeners are still running.

If the listener attribute, CONTROL, is specified as QMGR then changing the state of the listener using **endmq1sr** does not effect how the queue manager acts upon the CONTROL attribute at the next restart.

Syntax

Optional parameters

-m QMgrName

The name of the queue manager. If you omit this parameter, the command operates on the default queue manager.

-w

Wait before returning control.

Control is returned to you only after all listeners for the specified queue manager have stopped.

Return codes

Table 80. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Multi endmqm (end queue manager)

Stop a queue manager. or switch to a standby queue manager or replica queue manager.

Purpose

Use the **endmqm** command to end (stop) a specified queue manager. This command stops a queue manager in the following modes:

- Controlled or quiesced shutdown
- Immediate shutdown
- Pre-emptive shut down
- Wait shutdown

The **endmqm** command stops all instances of a multi-instance queue manager in the same way as it stops a single instance queue manager. You can issue the **endmqm** on either the active instance, or one of the standby instances of a multi-instance queue manager. You must issue **endmqm** on the active instance to end the queue manager.

If you issue the **endmqm** command on the active instance of a multi-instance queue manager, you can permit a standby instance to switch over to being the new active instance when the current active instance completes its shutdown.

If you issue the **endmqm** command on a standby instance of a multi-instance queue manager, you can end the standby instance by adding the **-x** option, and leave the active instance running. The queue manager reports an error if you issue **endmqm** on the standby instance without the **-x** option.

CP4I You can issue the **endmqm** command on the active or replica nodes of a Native HA group. A check is performed to see if stopping the specified instance breaks the group's quorum, and the command fails if it does. If you issue **endmqm -s** on the active instance, that instance stops and one of the replicas becomes the active instance. If you issue **endmqm -x** on a replica instance, the instance is stopped.

Issuing the **endmqm** command will affect any client application connected through a server-connection channel. The effect varies depending on the parameter used, but it is as though a **STOP CHANNEL** command was issued in one of the three possible modes. See [Stopping MQI channels](#), for information about the effects of **STOP CHANNEL** modes on server-connection channels. The **endmqm** optional parameter descriptions state which STOP CHANNEL mode they will be equivalent to.

If you issue **endmqm** to stop a queue manager, reconnectable clients do not try to reconnect. To override this behavior, specify either the **-r** or **-s** option to enable clients to start trying to reconnect.

Note: If a queue manager or a channel ends unexpectedly, reconnectable clients start trying to reconnect.

Note: The client might not reconnect to this queue manager. Depending on the MQCONNX reconnect option the client has used, and the definition of the queue manager group in the client connection table, the client might reconnect to a different queue manager. You can configure the client to force it to reconnect to the same queue manager.

You must use the **endmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq -o installation** command.

The attributes of the queue manager and the objects associated with it are not affected by the **endmqm** command. You can restart the queue manager using the **strmqm** (Start queue manager) command.

To delete a queue manager, stop it and then use the **dlmqm** (Delete queue manager) command.

Syntax

Required parameters

QMGrName

The name of the message queue manager to be stopped.

Optional parameters

-c

Controlled (or quiesced) shutdown. This parameter is the default.

The queue manager stops, but only after all applications have disconnected. Any MQI calls currently being processed are completed. In the unlikely event that a “[dspmq \(display queue managers\)” on page 82](#) command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the “[dspmq \(display queue managers\)” on page 82](#) command might transiently report the status as `Ending immediately`, even though a controlled shutdown was requested.

Control is returned to you immediately and you are not notified of when the queue manager has stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in QUIESCE mode.

-i

Immediate shutdown. The queue manager stops after it has completed all the MQI calls currently being processed. Any MQI requests issued after the command has been issued fail. Any incomplete units of work are rolled back when the queue manager is next started.

Control is returned after the queue manager has ended.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in FORCE mode.

-p

Pre-emptive shutdown.

Important: Use this type of shutdown only in exceptional circumstances, for example, when a queue manager does not stop as a result of a normal **endmqm** command.

The queue manager might stop without waiting for applications to disconnect or for MQI calls to complete. This can give unpredictable results for IBM MQ applications. The shutdown mode is set to *immediate shutdown*. If the queue manager has not stopped after a few seconds, the shutdown mode is escalated, and all remaining queue manager processes are stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in TERMINATE mode.

-r

Start trying to reconnect reconnectable clients. This parameter has the effect of reestablishing the connectivity of clients to other queue managers in their [queue manager group](#).

-s

For a multi-instance queue manager, switch over to a standby queue manager instance after shutting down. The command checks that there is a standby instance running before ending the active instance. It does not wait for the standby instance to start before ending. Connections to the queue manager are broken by the active instance shutting down. Reconnectable clients start trying to reconnect. You can configure the reconnection options of a client to reconnect only to another instance of the same queue manager, or to reconnect to other queue managers in the queue manager group.

 **CP4I** For the active instance of a Native HA group, switch over to a replica instance after shutting down.

- Specify the `-r` option to help client applications to reconnect to another instance.
- If this instance is not the active instance in the Native HA group then the command fails.

- If ending this active instance would cause the group quorum to fail then the command fails. (If other instances end or become unavailable at the same time as you run this command, the quorum check might not detect this, the Native HA group ends and can only be restarted when enough instances are available.)

-w

Wait shutdown.

This type of shutdown is equivalent to a controlled shutdown except that control is returned to you only after the queue manager has stopped. You receive the message `Waiting for queue manager qmName` to end while shutdown progresses. In the unlikely event that a “[dspmq \(display queue managers\)](#)” on page 82 command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the “[dspmq \(display queue managers\)](#)” on page 82 command might transiently report the status as `Ending immediately`, even though a controlled shutdown was requested.

The effect on any client applications connected through a server-connection channel is equivalent to a **STOP CHANNEL** command issued in QUIESCE mode.

-x

For a multi-instance queue manager, end a standby instance of the queue manager, without ending the active instance of the queue manager.

CP4I For a replica instance of a Native HA group, stop the instance:

- If this instance is the active instance in the Native HA group then the command fails.
- If ending this replica instance would cause the group quorum to fail then the command fails. (If other instances end or become unavailable at the same time as you run this command, the quorum check might not detect this, the Native HA group ends and can only be restarted when enough instances are available.)

-z

Suppresses error messages on the command.

-t interval

The target time in which ending the queue manager within *interval* seconds is attempted, escalating the phases of application disconnection. Non-essential queue manager maintenance tasks are allowed to complete, which might prolong the phase of the queue manager ending. (See [Ending a queue manager within a target time](#) for more details.)

-tp interval

The target time in which ending the queue manager within *interval* seconds is attempted, escalating the phases of application disconnection. Non-essential queue manager maintenance tasks are interrupted if necessary. (See [Ending a queue manager within a target time](#) for more details.)

Return codes

Table 81. Return code identifiers and descriptions

Return code	Description
0	Queue manager ended
3	Queue manager being created
4	Queue Manager is being started
16	Queue manager does not exist
39	Invalid parameter specified

Table 81. Return code identifiers and descriptions (continued)

Return code	Description
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
77	IBM MQ queue manager cannot switch over
79	Active instance of IBM MQ queue manager <i>QmgrName</i> not ended
90	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended
119	Permission denied

Examples

The following examples show commands that stop the specified queue managers.

1. This command ends the queue manager named `mercury.queue.manager` in a controlled way. All applications currently connected are allowed to disconnect.

```
endmqm mercury.queue.manager
```

2. This command ends the queue manager named `saturn.queue.manager` immediately. All current MQI calls complete, but no new ones are allowed.

```
endmqm -i saturn.queue.manager
```

The results of issuing **endmqm** to the local instance of a multi-instance queue manager are shown in the following table. The results of the command depend on whether the `-s` or `-x` switch is used, and on the running status of local and remote instances of the queue manager.

Table 82. endmqm actions					
endmqm option	Local machine	Remote machine	RC	Message	Result
	Active	None	0	-	Queue manager ended.
		Standby			Queue manager ended, including the standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.
-s	Active	None	77	AMQ7276	IBM MQ queue manager cannot switch over.
		Standby	0	-	Queue manager QMNAME ended, permitting switchover to a standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.

Table 82. <i>endmqm</i> actions (continued)					
endmqm option	Local machine	Remote machine	RC	Message	Result
-x	Active	None	79	AMQ8367	Active instance of IBM MQ queue manager <i>QmgrName</i> not ended.
		Standby			
	Standby	Active	0	-	Standby instance of queue manager QMNAME ended.

The following table shows the results of issuing **endmqm** to Native HA instances.

Table 83. <i>endmqm</i> actions					
endmqm option	Local machine	Remote machine	RC	Message	Result
	Active	None	0	-	Queue manager ended.
		Standby			Queue manager ended, including the standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.
CP4I	Native HA Active	-	0	-	Active instance ended. Remaining instances communicate and elect a new Active, if they can find a quorum.
	Native HA Replica	-	0	-	Replica instance ended. Remaining instances continue, if they have quorum.
-s	Active	None	77	AMQ7276	IBM MQ queue manager cannot switch over.
		Standby	0	-	Queue manager QMNAME ended, permitting switchover to a standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.
CP4I -s	Native HA Active	Quorum would remain	0	-	Active instance ended.
	Native HA Active	Quorum would be broken	79	AMQ7275	Instance has not ended because it would cause quorum to be lost.
	Native HA Replica	-	90	AMQ7277	This operation is not valid on a Replica instance.

Table 83. endmqm actions (continued)					
endmqm option	Local machine	Remote machine	RC	Message	Result
-x	Active	None	79	AMQ8367	Active instance of IBM MQ queue manager <i>QmgrName</i> not ended.
		Standby			
	Standby	Active	0	-	Standby instance of queue manager QMNAME ended.
CP4I -x	Native HA Active	-	79	AMQ8367	Active instance of IBM MQ queue manager 'MG' not ended.
	Native HA Replica	Quorum would remain	0	-	Replica instance ended.
	Native HA Replica	Quorum would be broken	90	AMQ7275	Instance has not ended because it would cause quorum to be lost.

[endmqm](#) (end queue manager)

Stop a queue manager. or switch to a standby queue manager or replica queue manager.

[dlmqm](#) (delete queue manager)

Use the **dlmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

endmqsvc (end IBM MQ service)

End the IBM MQ service on Windows.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke **endmqsvc** with elevated privileges. To open an elevated command prompt, right click the command prompt icon and select **Run as administrator** (see [Authority to administer IBM MQ on AIX, Linux, and Windows](#)).

Run the command to end the service, if the service is running.

Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

Syntax

endmqsvc

Parameters

The **endmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **endmqsvc** binary file.

Return codes

Table 84. Return code identifiers and descriptions

Return code	Description
0	Successful command completion
36	Invalid arguments provided
119	User not authorized to stop the service
657	Service could not be stopped

Related reference

“strmqsvc (start IBM MQ service)” on page 296

Use the **strmqsvc** command to start the IBM MQ service on Windows systems. Run the command to start the service if it has not been started automatically, or if the service has ended. Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

Multi **endmqtrc (end trace)**

Use the **endmqtrc** command to end tracing for the specified entity or all entities. The **endmqtrc** command ends only the trace that is described by its parameters. Using **endmqtrc** with no parameters ends early tracing of all processes.

All **endmqtrc** commands set the type of output to *mqm* on **strmqtrc**.

Attention: There can be a slight delay between the **endmqtrc** command ending, and all trace operations actually completing. This is because IBM MQ processes are accessing their own trace files. As each process becomes active at different times, their trace files close independently of one another.

Syntax

The syntax of this command is as follows:

Optional parameters

-m QMgrName

The name of the queue manager for which to end tracing.

The *QMgrName* supplied must match exactly the *QMgrName* supplied on the **strmqtrc** command. If the **strmqtrc** command used wildcards, the **endmqtrc** command must use the same wildcard specification including the escaping of any wildcard characters to prevent them being processed by the command environment.

A maximum of one -m flag and associated queue manager name can be supplied on the command.

-i PidTids

Process identifier (PID) and thread identifier (TID) for which to end tracing. You cannot use the **-i** flag with the **-e** flag. If you try to use the **-i** flag with the **-e** flag, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

-p Apps

The named processes for which to end tracing. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (*) or question mark (?) wildcards are allowed. You cannot use the **-p** flag with the **-e** flag. If you try to use the **-p** flag with the **-e** flag, then an error message is issued.

-e

Ends early tracing of all processes.

Using **endmqtrc** with no parameters has the same effect as **endmqtrc -e**. You cannot specify the **-e** flag with the **-m** flag, the **-i** flag, or the **-p** flag.

-a

Ends all tracing.

Important: This flag must be specified alone.

Return codes

Table 85. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments to the command
119	Not authorized
58	Inconsistent use of installations detected

Examples

This command ends tracing of data for a queue manager called QM1.

```
endmqtrc -m QM1
```

The following examples are a sequence that shows how the **endmqtrc** command ends only the trace that is described by its parameters.

1. The following command enables tracing for queue manager QM1 and process amqxxx.exe:

```
strmqtrc -m QM1 -p amqxxx.exe
```

2. The following command enables tracing for queue manager QM2:

```
strmqtrc -m QM2
```

3. The following command ends tracing for queue manager QM2 only. Tracing of queue manager QM1 and process amqxxx.exe continues:

```
endmqtrc -m QM2
```

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

migmqlog (migrate IBM MQ logs)

The **migmqlog** command migrates logs, and can also change the type of your queue manager logs from linear to circular or from circular to linear.

  **migmqlog** is only supported on Mutliplatforms.

Usage notes

-  On Windows, running **migmqlog** enables you to move your queue manager logs to an Advanced Format disk. For more information, see [Migrating logs to an Advanced Format disk](#).
- migmqlog** can only run when the queue manager is inactive.
- If the running of **migmqlog** is interrupted by, for example, a power failure, you should be rerun the same command until it completes normally.
- A partially migrated log can not be used to start a queue manager, and the result of attempting to do so is not well defined.
- Following any log migration, the log is configured such that all future log writes occur with 4096 byte alignment, at minimum.
- For more information about linear and circular logging, see [Types of logging](#).

Syntax

Required parameters

-m QMgrName

The name of the queue manager on which to migrate logs.

Optional parameters

-ld *New log path*

Specifies the location to move the migrated log file to.

The path that is specified with *New log path* is an absolute file path that specifies the new location for the log file. Do not use a relative file path with the **-ld** parameter.

If you specify **-ld**, the log path in the `qm.ini` file is updated, so when you start your queue manager it uses the migrated log.

When logs are moved to a new log location, no change is made to any existing log files and all valid recovery log files in the old location are migrated to the new location.

-ll

Specifies that the log file uses linear logging.

If the queue manager uses circular logging before the command is run, the queue manager is reconfigured to use linear logging.

-lc

Specifies that the log file uses circular logging.

If the queue manager uses linear logging before the command is run, the queue manager is reconfigured to use circular logging.

[Migrating the log of your queue manager from circular to linear](#)

mqcertck (certify TLS setup)

Use the **mqcertck** command to diagnose potential TLS problems with your queue managers.

The command can be used as a first check to determine why a connection using TLS has been unable to successfully connect to queue managers within your enterprise, and works with multiple certificates.

Syntax

➔ mqcertck — *QmgrName* ➔

Required parameters

QmgrName

Name of the queue manager to check for TLS errors.

Optional parameters

-clientkeyr *client_key_repository*

Required if you supply the **-clientuser**, **-clientlabel**, **-clientchannel**, or **-clientport** parameters.

Location of the client key repository used by a client application connecting to the referenced queue manager.

Important: You must supply the name without the `.kdb` extension.

-clientuser *client_username*

Cannot be used if you supplied the **-clientlabel** parameter.

User running the client application that connects to the referenced queue manager. If supplied, requires **-clientkeyr**.

-clientlabel *client_certlabl*

Cannot be used if you supplied the **-clientuser** parameter.

Certificate label that is given to the client that connects to the referenced queue manager by using one of the IBM MQ MQI client CERTLABL methods. If supplied, requires **-clientkeyr**.

-clientchannel *channel_name*

Name of the channel on the referenced queue manager to check for TLS errors. If supplied, requires **-clientkeyr**.

-clientport *port_number*

Specify a specific port to use when testing the client.

The value must be:

- An integer value between 1 and 65535 inclusive.
- A port number, which must be a free port that **mqcertck** can use during its client checks.
- Not be a port that is in use by the queue manager, or any other process on the machine running **mqcertck**.

If you do not specify a value, port 5857 is used. If supplied, requires **-clientkeyr**.

Examples**Example 1**

After configuring an IBM MQ queue manager for TLS connections, you can use **mqcertck** to verify that no mistakes have been made, before attempting to start your channels.

The information returned in the example shows that no certificate has been found for queue manager **qmgr**.

```
[mqm@mq-host ~]$ mqcertck qmgr
5724-H72 (C) Copyright IBM Corp. 1994, 2026.
+-----+
| IBM MQ TLS Configuration Test tool
+-----+

ERROR:
No Certificate could be found for the Queue Manager qmgr

EXPLANATION:
Queue managers will use a certificate with the label set in the Queue Manager's
CERTLABL attribute. There is no certificate with the label ibmwebsphermqqmgr
in the key repository being used by the queue manager The Key repository being
used is located at /var/mqm/qmgrs/qmgr/ssl/key.kdb.

ACTION:
A valid certificate with the label ibmwebsphermqqmgr needs to be added to the
key repository.

+-----+

This application has ended. See above for any problems found.

If there are problems then resolve these and run this tool again.

+-----+
```

Example 2

After creating a key repository, certificate, and exchanging certificates for a client application, you can use **mqcertck** to verify that a client application is able to connect to a queue manager.

To do this, you need to run **mqcertck** on the machine where the IBM MQ queue manager is running, and have access to the client key repository.

You can do this in a variety of ways, for example, a file system mount. After you have set up your machine, run the following command:

```
mqcertck QmgrName -clientkeyr Location_of_Client_Key_Repository
                  -clientlabel Client_certificate_label
```

For example:

```
mqcertck qmgr -clientkeyr /var/mqm/qmgrs/qmgr/ssl/key
              -clientlabel ibmwebspheremqmgr
```

Check the output for any problems identified with your configuration.

Note that, if you are planning on having your clients connect anonymously, you can run the preceding command without the **-clientlabel** parameter.

mqconfig (check system configuration)

Checks that the system configuration meets the requirements to run IBM MQ (AIX and Linux platforms only).

Purpose

The **mqconfig** command is run to verify the system configuration matches or exceeds that which is required by an IBM MQ queue manager environment. The configuration values are minimum values, and large installations might require values greater than those checked by this command.

For further information about configuring your system for IBM MQ, see the *Operating system configuration and tuning information for IBM MQ* on the platform, or platforms, that your enterprise uses.

Syntax

```
➤ mqconfig -v Version ➤
```

Optional parameters

-v Version

The system requirements vary between different versions of IBM MQ. Specify the version of IBM MQ for which you need to verify the current system configuration.

The default value, if **-v** is not specified, is the current version.

Example

The following output is an example of what the command produces on a Linux system:

```
# mqconfig -v 8.0
mqconfig: V3.7 analyzing Red Hat Enterprise Linux Server release 6.5
(Santiago) settings for IBM MQ V8.0

System V Semaphores
semmsl (sem:1) 500 semaphores IBM>=32 PASS
semmsn (sem:2) 35 of 256000 semaphores (0%) IBM>=4096 PASS
semopm (sem:3) 250 operations IBM>=32 PASS
semnmi (sem:4) 3 of 1024 sets (0%) IBM>=128 PASS

System V Shared Memory
shmmax 68719476736 bytes IBM>=268435456 PASS
shmmni 1549 of 4096 sets (37%) IBM>=4096 PASS
shmall 7464 of 2097152 pages (0%) IBM>=2097152 PASS

System Settings
file-max 4416 of 524288 files (1%) IBM>=524288 PASS

Current User Limits (root)
nofile (-Hn) 10240 files IBM>=10240 PASS
nofile (-Sn) 10240 files IBM>=10240 PASS
```

nproc	(-Hu)	11 of 30501 processes	(0%)	IBM>=4096	PASS
nproc	(-Su)	11 of 4096 processes	(1%)	IBM>=4096	PASS

Note: Any values listed in the Current User Limits section are resource limits for the user who ran **mqconfig**. If you normally start your queue managers as the mqm user, you should switch to mqm and run **mqconfig** there.

If other members of the mqm group (and perhaps root) also start queue managers, all those members should all run **mqconfig**, to ensure that their limits are suitable for IBM MQ.

The limits displayed by **mqconfig** are not applied to queue managers on Linux started with **systemd**.

Prerequisites of mqconfig

mqconfig has the following dependency: bc.

Return codes

Table 89. Return code identifiers and descriptions

Return code	Description
0	Successful operation
1	Warning
2	Failed operation
	Failed due to a syntax error or unexpected condition

Related tasks

[Configuring and tuning the operating system on Linux](#)

Windows Linux MQExplorer (launch IBM MQ Explorer)

You can start IBM MQ Explorer by using the **MQExplorer** command in the installation directory. (Windows and Linux x86-64 platforms only).

The **MQExplorer** command is in `MQ_EXPLORER_INSTALLATION_PATH`, where `MQ_EXPLORER_INSTALLATION_PATH` is the installation path for the stand-alone IBM MQ Explorer. For more information, see [Installing and uninstalling IBM MQ Explorer as a stand-alone application on Linux and Windows](#).

Syntax

MQExplorer.exe (the MQExplorer command) supports standard Eclipse runtime options. The syntax of this command is as follows:

Optional parameters

-clean

Cleans the caches used by the Eclipse runtime to store bundle dependency resolution and eclipse extension registry data. Using this option forces Eclipse to reinitialize these caches.

-initialize

Initializes the configuration being run. All runtime-related data structures and caches are refreshed. Any user/plugin defined configuration data is not purged.

No application is run, any product specifications are ignored and no UI is presented (for example, the splash screen is not drawn).

Related tasks

[Launching IBM MQ Explorer](#)

mqlicense (accept license after installation)

On Linux (excluding IBM MQ Appliance) use the **mqlicense** command to accept the IBM MQ license after installation.

Note: You must have the appropriate privileges to run this command on your system, typically root access on Linux.

The license agreement is displayed in a language appropriate to your environment and you are prompted to accept or decline the terms of the license.

If possible, **mqlicense** opens an X-window to display the license.

If you need the license to be presented as text in the current shell, which can be read by a screen reader, type the following command:

```
mqlicense -text_only
```

Usage notes

Note that running this command, with the environment variable **MWLICENSE=accept**, has the same effect as specifying the **-accept** parameter.

Syntax

Required parameters

None

Optional parameters

-accept

Accept the IBM MQ license without it being displayed.

-check_only

Check whether the IBM MQ license has already been accepted without it being displayed.

-jre

Path to the Java executable used to display the license.

-text_only

Display a text-only version of the license, which can be read by a screen-reader.

Return codes

Table 90. Return code identifiers and descriptions

Return code	Description
0	Successful completion. You can accept or decline the result, depending upon what you chose.
10	A warning occurred
20	An error occurred

[MQLICENSE](#)

“[dspmqlic \(display IBM MQ license\)](#)” on page 107

On Linux (excluding IBM MQ Appliance) use the **dspmqlic** command to display the IBM MQ license in the appropriate language for the environment.

mqperfck (MQ performance check)

Use the **mqperfck** command to help understand the performance of your queue manager.

The command can be used to gather information about the CPU and Log resources being used by a queue manager, and the activity on local queues and sender channels. Run this command when the work being processed by your queue manager is low, and when it is high, to compare the impact of different workloads on the queue manager.

The command produces an HTML report summarizing the workload. You can view the report in a web browser. For more information on how to interpret the report, see [Interpreting the IBM MQ Performance Check Report](#).

Syntax

Notes:

-  Not available on IBM MQ Appliance.

Required parameters

None.

Optional parameters

-h or -?

Display usage help text and exit.

-m QmgrName

The name of queue manager to connect to. If this is not specified, the command will attempt to connect to the default queue manager.

-q QueueName

The name of a local queue to analyze. You can analyze up to 10 queues by repeating this parameter. The queue must exist, it must be a local queue, and the user running the tool must have permission to open the queue for inquire.

-s SenderChannel

The name of a sender channel to analyze. You can analyze up to 10 channels by repeating this parameter. The channel must exist, it must have attribute **CHLTYPE(SDR)**, and the **MONCHL** attribute of the channel must be set to either LOW, MEDIUM, or HIGH. If the channel's **MONCHL** attribute is MQMON_Q_MGR, then the **MONCHL** attribute of the queue manager must be LOW, MEDIUM, or HIGH.

If the channel's transmission queue has not been provided on the command line using the **-q** parameter, and fewer than 10 queues have been requested, then the transmission queue will be automatically added to the list of queues that will be analyzed.

-n Iterations

The number of sampling iterations to perform. The default is 6. A new iteration begins when the queue manager publishes a set of resource statistics which typically happens every 10 seconds.

-d OutputDirectory

The directory to which the output file will be written.

If this parameter is omitted, then output will be written to the current directory.

 This option is not available on the IBM MQ Appliance where output will always be written into the "mqdiag:" file system.

-u User

The user id to be used to authenticate the connection to the queue manager. If this parameter is specified, the command will prompt for a password. The password will not be displayed on the screen.

-N

Suppresses translation of the report.

-C

Specifies that the **mqperfck** command connects to the queue manager as a client application. This parameter can be used only if the client component is installed. If **-c** is omitted, **mqperfck** attempts to connect to the queue manager using server bindings. For more details on how to configure the connection, see [Connecting client applications to queue managers using environment variables](#).

-t Seconds

Specifies the maximum time that the **mqperfck** command will wait for the queue manager to publish statistics. If no publications are received within this time, the command assumes that the queue manager has stopped publishing statistics and the report is terminated. If the **-t** option is not specified the timeout defaults to 120 seconds.

Granting permissions to run the command

To subscribe to the system statistics, the command must be run by a member of the mqm group or a user who has permissions to topics in the \$SYS/MQ branch of the topic tree. For more information, see [System topics for monitoring and activity trace](#).

In addition, the command needs the following permissions to run:

Table 91. Permissions needed for each object type		
Object name	Object type	Permissions
QmgrName	qmgr	+connect +inq +dsp
SYSTEM.DEFAULT.MODEL.QUEUE	queue	+get +dsp
SYSTEM.ADMIN.COMMAND.QUEUE	queue	+put
SYSTEM.ADMIN.TOPIC	topic	+sub

For each queue named on the command line (and any channel's transmission queues which are automatically added by the command) add the following permissions:

Table 92. Additional permissions for queues		
Object name	Object type	Permissions
QueueName	Queue	+inq

For each channel named on command line add the following permissions:

Table 93. Additional permissions for channels		
Object name	Object type	Permissions
ChannelName	Channel	+dsp

Examples

The following command creates a report containing six iterations of CPU and Log statistics for the default queue manager:

```
[mqm@mq-host ~]$ mqperfck
Connected to queue manager DFT.QMGR.
Creating file: mqperfcheck_DFT.QMGR_2024-12-20_132743-0.html
Waiting for messages.
Processing iteration 1 of 6.
Processing iteration 2 of 6.
Processing iteration 3 of 6.
Processing iteration 4 of 6.
Processing iteration 5 of 6.
Processing iteration 6 of 6.
Writing report summary.
```

The following command creates a report with three iterations of statistics for queue manager SENDER.QM, queue TESTQ, and channel TO.RECEIVER.QM. The report includes information about the channel's transmission queue:

```
[mqm@mq-host ~]$ mqperfck -m SENDER.QM -q TESTQ -s TO.RECEIVER.QM -n 3
Connected to queue manager SENDER.QM.
Creating file: mqperfcheck_SENDER.QM_2024-12-20_133202-0.html
Waiting for messages.
Processing iteration 1 of 3.
Processing iteration 2 of 3.
Processing iteration 3 of 3.
```

[Metrics published on the system topics](#)

Multi **mqrc** (display return code and AMQ message information)

Use the **mqrc** command to display information about symbols, return codes, and AMQ messages. You can specify a range of return codes or AMQ messages, as well as specifying specific return codes or AMQ messages.

Numeric arguments are interpreted as decimal if they start with a digit 1 - 9, or hex if prefixed with 0x.

Syntax

Notes:

¹ If there is a problem with a message within a range, an indication is displayed before the message text. ? is displayed if there are no matching return codes for the message. ! is displayed if the message severity is different to the return code severity.

Parameters

returnCode

The return code to display

AMQmessage

The AMQ message to display

symbol

The symbol to display

-a

Try all severities to find message text

-b

Display messages without extended information

-f first

First number in a range

-l last

Last number in a range

-m AMQmessage

The AMQ message to list

-M

Display AMQ messages in a range

-r returnCode

The return code to display

-R

Display all return codes. If used with the **-f** and **-l** parameters, **-R** displays the return codes within a range.

-s symbol

The symbol to display

-

If a - is given as a trailing parameter, it indicates that further input will come from stdin.

 -d language

Display the message in the specified language, for example, `Fr_FR`.

-i format

Determine the message to display from a message in the specified format, which must be one of the following:

text

The textual format of the **QMErrorLog** service, including the Insert attributes.

json

JSON format diagnostic messages, specified in UTF-8.

-o format

Display the message in the specified format, which must be one of the following:

mqrc

The format used by **mqrc** in previous versions of the product.

text

The textual format of the **QMErrorLog** service.

json

The JSON format, described in JSON format diagnostic messages.

 -p

Display the message explanation only. For example:

```
mqrc -p AMQ8118
```

displays

The queue manager *insert_5* does not exist.

 -u

Display the user response only. For example:

```
mqrc -u AMQ8118
```

displays

Either create the queue manager (`crtmqm` command) or correct the queue manager name used in the command and then try the command again.

-x

Display extended message information, including the message severity. For example, the following message has an error (**E**) severity of 30:

```
mqrc -x AMQ8118
536903960 0x20008118 E 30 urcMS_MQCONN_FAILED
536903960 0x20008118 E 30 zrc_CSPRC_Q_MGR_DOES_NOT_EXIST
```

MESSAGE:
IBM MQ queue manager does not exist.

EXPLANATION:
The queue manager *<insert three>* does not exist.

ACTION:

Either create the queue manager (crtmqm command) or correct the queue manager name used in the command and then try the command again.

Examples

1. This command displays AMQ message 5005:

```
mqrc AMQ5005
```

2. This command displays return codes in the range 2505 - 2530:

```
mqrc -R -f 2505 -l 2530
```

3. Running the following command, where AMQERR01.json contains JSON formatted messages in any language, converts all messages into US English in the original textual **QMErrorLog** format:

```
cat AMQERR01.json | mqrc -d En_US -i json -o text -
```

Alternatively, you could take AMQERR01.LOG and convert it to JSON:

```
cat AMQERR01.LOG | mqrc -i text -o json -
```

4. Running the following command, where AMQERR01.LOG contains text formatted messages in any language, converts messages into US English:

```
cat AMQERR01.LOG | mqrc -d En_US -i text -o text -
```

Return codes

Table 94. Return code identifiers and descriptions

Return code	Description
0	Successful operation
10	Invalid arguments provided

rcdmqing (record media image)

Use the **rcdmqing** command to write an image of an object, or group of objects, to the log for use in media recovery. This command can be used only when using linear logging.

See [Types of logging](#) for more information about linear logging. Use the associated command **rcrmqobj** to re-create the object from the image.

Before IBM MQ 9.1.0, or when using **LogManagement=Manual**, the command does not run automatically as it must be run in accordance with, and as determined by, the usage of each individual customer of IBM MQ.

After IBM MQ 9.1.0, when using **LogManagement=Automatic** or **Archive**, the queue manager automatically records media images, however **rcdmqing** can also be run manually as well, if required.

Running **rcdmqing** moves the log sequence number (LSN) forwards and frees up old log files for archival or deletion.

When determining when and how often to run **rcdmqing**, consider these factors:

Disk space

If disk space is limited, regular running of **rcdmqing** releases log files for archive or deletion.

Impact on normal system performance

rcdmqing activity can take a long time if the queues on the system are deep. At this time, other system usage is slower and disk utilization increases because data is being copied from the queue

files to the logs. Therefore, the ideal time to run **rcdmqimg** is when the queues are empty and the system is not being heavily used.

You use this command with an active queue manager. Further activity on the queue manager is logged so that, although the image becomes out of date, the log records reflect any changes to the object.

Syntax

Required parameters

GenericObjName

The name of the object to record. This parameter can have a trailing asterisk to record that any objects with names matching the portion of the name before the asterisk.

This parameter is required unless you are recording a queue manager object or the channel synchronization file. Any object name you specify for the channel synchronization file is ignored.

-t ObjectType

The types of object for which to record images. Valid object types are:

Table 95. Valid object types	
Object Type	Description
all and *	All the object types; ALL for objtype and * for GenericObjName
authinfo	Authentication information object, for use with TLS channel security
channel or chl	Channels
clntconn or clcn	Client connection channels
catalog or ctlg	An object catalog
listener or lstr	Listeners
namelist or nl	Namelists
process or prcs	Processes
queue or q	All types of queue
qalias or qa	Alias queues
qlocal or ql	Local queues
qmodel or qm	Model queues
qremote or qr	Remote queues
qmgr	Queue manager object
service or srvc	Service
syncfile	Channel synchronization file.
topic or top	Topics

Note:   When using IBM MQ for AIX or Linux systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks ("), or a backslash (\).

Optional parameters

-m QMgrName

The name of the queue manager for which to record images. If you omit this parameter, the command operates on the default queue manager.

-z

Suppresses error messages.

-l

Writes messages containing the names of the oldest log files required to restart the queue manager and to perform media recovery. The messages are written to the error log and the standard error destination. (If you specify both the -z and -l parameters, the messages are sent to the error log, but not to the standard error destination.)

When issuing a sequence of **rcdmqimg** commands, include the -l parameter only on the last command in the sequence, so that the log file information is gathered only once.

Return codes

Table 96. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
28	Object not media recoverable.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
131	Resource problem
132	Object damaged
135	Temporary object cannot be recorded

When are log extents deleted

Log extents are only deleted when the queue manager determines that they can be deleted. Note that log extents are not deleted immediately after recording the media image.

For example, if the starting media extent is 04, the queue manager does not delete this extent until the extent number moves forward, and the queue manager might or might not delete extents 01 to 04.

The logger event messages, and the IBM MQ queue manager error logs, show the log extents required for queue manager restart and media recovery.

Examples

The following command records an image of the queue manager object `saturn.queue.manager` in the log.

```
rcdmqimg -t qmgr -m saturn.queue.manager
```

Related commands

Table 97. Related command names and descriptions

Command	Description
<u>rcrmqobj</u>	Re-create a queue manager object

Related reference

[“rcrmqobj \(re-create object\)” on page 163](#)

Use the **rcrmqobj** command to re-create an object, or group of objects, from their images contained in the log.

rcrmqobj (re-create object)

Use the **rcrmqobj** command to re-create an object, or group of objects, from their images contained in the log.

Note: Use this command on a running queue manager.

- With *ObjectType* argument of `clchltab` or `syncfile`, this command re-creates the object files from the internal queue manager state.
- For other *ObjectType* arguments, the command can only be used when the queue manager is configured to use linear logging. Use the associated command, `rcdmqimg`, to record the object images to the log. The object is re-created from images in the log.

All activity on the queue manager after the image was recorded is logged. To re-create an object, replay the log to re-create events that occurred after the object image was captured.

Syntax

Required parameters

GenericObjName

The name of the object to re-create. This parameter can have a trailing asterisk to re-create any objects with names matching the portion of the name before the asterisk.

This parameter is required, unless the object type is the channel synchronization file; any object name supplied for this object type is ignored.

-t *ObjectType*

The types of object to re-create. Valid object types are:

Table 98. Valid object types.	
Object Type	Description
* or all	All object types
authinfo	Authentication information object, for use with TLS channel security
channel or chl	Channels
clntconn or clcn	Client connection channels
clchltab	Client channel table
comminfo	Communication information object
listener or lstr	Listener
namelist or nl	Namelists
process or prcs	Processes
queue or q	All types of queue
qalias or qa	Alias queues
qlocal or ql	Local queues
qmodel or qm	Model queues
qremote or qr	Remote queues
service or srvc	Service
syncfile	Channel synchronization file. You can use this option when circular logs are configured but the syncfile fails if the channel scratchpad files, which are used to rebuild syncfile, are damaged or missing. You might want to do this if your system has reported the error message AMQ7353 (krcE_SYNCFILE_UPDATE_FAILED) .
topic or top	Topics

Note:   When using IBM MQ for AIX or Linux systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks ("), or a backslash (\).

Optional parameters

-m *QMgrName*

The name of the queue manager for which to re-create objects. If omitted, the command operates on the default queue manager.

-z

Suppresses error messages.

Return codes

Table 99. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
28	Object not media recoverable.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
66	Media image not available
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
135	Temporary object cannot be recovered
136	Object in use

Examples

1. The following command re-creates all local queues for the default queue manager:

```
rcrmqobj -t ql *
```

2. The following command re-creates all remote queues associated with queue manager store:

```
rcrmqobj -m store -t qr *
```

Related commands

[“rcdmqimg \(record media image\)” on page 160](#)

Use the **rdmqimg** command to write an image of an object, or group of objects, to the log for use in media recovery. This command can be used only when using linear logging.

Linux **rdmqadm (administer replicated data queue manager cluster)**

Use the **rdmqadm** command to administer the Pacemaker cluster used in RDQM high availability configurations. This command is not required for disaster recovery RDQM configurations.

Syntax

Optional parameters

-c

Initialize the Pacemaker cluster, using the settings specified in the `/var/mqm/rdqm.ini` file. The same command must be run on each of the three nodes by the `root` user. (You can also run this command as a user in the `mqm` group if you have configured `sudo`, see [Requirements for RDQM HA solution](#).) The command fails if the node is already part of a Pacemaker cluster. A node cannot be a member of two Pacemaker clusters.

V1000 -e

Use in conjunction with the `-c` option to optionally specify that heartbeat links are encrypted. See [./configure/config_encrypt_heartbeat.dita](#).

-u

Delete the Pacemaker cluster configuration. The same command must be run on each of the three nodes by the `root` user. (You can also run this command as a user in the `mqm` group if you have configured `sudo`, see [Requirements for RDQM HA solution](#).) The Pacemaker cluster configuration cannot be deleted if any replicated data queue managers (RDQMs) exist.

-s [-n *nodename*]

Suspend the local node (or the specified node if the `-n nodename` argument is supplied). The command can be run on any of the three nodes by a user in the `haclient` group, or by `root`. The node is taken offline. Any replicated data queue managers (RDQMs) running on that node are stopped and restarted on an active node. Queue manager data does not replicate to the offline node. The command fails if the specified node is the last active node.

-r [-n *nodename*]

Resume the local or specified node. The command can be run on any of the three nodes by a user in the haclient group, or by root. The node is brought online. If the node is the preferred location for any replicated data queue managers (RDQMs), the queue managers are stopped and restarted on this node.

-p -m *qmname* [-n *nodename*[,*nodename*]]

Assign the local or specified node as the Preferred Location for the named queue manager. If the Pacemaker cluster is in a normal state and the Preferred Location is not the current primary node, the queue manager is stopped and restarted on the new Preferred Location. You can specify a comma-separated list of two node names to assign a second preference of Preferred Location.

-p -m *qmname* -d

Clear the Preferred Location so that the queue manager does not automatically return to a node when it is restored.

Linux **rdqmclean (clear failed resource actions)**

Use the **rdqmclean** command to clear failed resource actions from RDQM HA configurations.

Failed resource actions arise when the Pacemaker component of an RDQM high availability configuration encounters some problem with a resource on one of the nodes in an HA group. Some failed resource actions prevent the resource from running on one or all nodes and must be cleared before Pacemaker can restart the resource. You must also resolve the cause of the resource failure.

Syntax

```

➔ rdqmclean -m qmname -a ➔

```

Optional parameters**-m *qmname***

Specify the name of the queue manager for which you are clearing failed resource actions.

-a

Clear all failed resource actions in the RDQM HA configuration.

Related concepts

[Failed resource actions](#)

Related tasks

Linux [Viewing RDQM and HA group status](#)

Linux **rdqmdr (manage DR RDQM instances)**

Change a primary disaster recovery replicated data queue manager (DR RDQM) to a secondary instance, or change a secondary instance to a primary.

Use the **rdqmdr** command to control whether an instance of a DR RDQM has the primary or secondary role.

You can also use **rdqmdr** on the node where you created a primary DR RDQM to retrieve the command that you need to create the secondary instance on the recovery node.

You must be root or a user in the mqm group with sudo privileges to use this command.

Syntax

Parameters

-m *qmname*

Specify the name of the DR RDQM that you are issuing the command for.

-s

Specify `-s` to make a DR RDQM that is currently in the primary role into the secondary.

-p

Specify `-p` to make a DR RDQM that is currently in the secondary role into the primary. This command fails if the primary instance of the queue manager is still running and the DR replication link is still functioning.

-d

Specify `-d` to return the **crtmqm** command required to create a secondary instance of the specified DR RDQM.

rdqmint (add or delete floating IP address for RDQM)

Use the **rdqmint** command to add or delete the floating IP address that is used to connect to a high availability replicated data queue manager (HA RDQM), regardless of which node in the high availability (HA) group is actually running the RDQM. This command is not applicable to disaster recovery RDQM configurations.

Syntax

Optional parameters

-m *qmname*

Specify the name of the RDQM for which you are adding or deleting a floating IP address.

-a

Specify this option to add a floating IP address.

-d

Specify this option to delete a floating IP address.

-f *ipv4address*

The IP address in dot decimal format.

The floating IP address must be a valid IPv4 address that is not already defined on any HA node, and it must belong to the same subnet as the static IP addresses defined for the local interface.

-l *interfacename*

The name of the physical interface that the floating IP address is bound to.

Examples

To specify a floating IP address for the queue manager RDQM1, enter the following command:

```
rdqmint -m RDQM1 -a 192.168.7.5 -l MQIF
```

To delete the floating IP address for the queue manager RDQM1, enter the following command:

```
rdqmint -m qmname -d
```

Linux **rdqmstatus (display RDQM status)**

Use the **rdqmstatus** command on its own to view a summary of the status of all replicated data queue managers (RDQMs) on a node. You can specify a queue manager name to view detailed status for that RDQM, including details of failed resource actions. You can also view the availability status of all nodes in an HA group.

You can enter the command on any node in an HA group, or either node in a DR pair, or any node in a DR/HA configuration.

For examples of the output of the **rdqmstatus** command, see [Viewing RDQM and HA group status](#), and [Viewing DR RDQM status](#), and [Viewing DR/HA RDQM and HA group status](#).

Syntax

Optional parameters

-m qmname

Specify the name of the RDQM for which you are requesting status.

-a

Optionally use with **-m qmname** to view failed resource actions associated with the specified queue manager (see [Failed resource actions](#)).

-n

Specify **-n** to list the three nodes in the HA group, and their current online or offline status.

V1000 This option also displays the encryption status of the HA group heartbeat links as Configured or Not Configured. To display the actual encryption status, you must run `rdqmstatus -n` as user root, otherwise the Not Configured status is reported.

ALW **rmvmqinf (remove configuration information)**

Remove IBM MQ configuration information (AIX, Linux, and Windows only).

Use the **rmvmqinf** command to remove IBM MQ configuration information.

You must use the **rmvmqinf** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command.

Syntax

Required parameters

StanzaName

The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

Optional parameters

-s StanzaType

The type of stanza to remove. If omitted, a QueueManager stanza is removed.

The only supported value of *StanzaType* is QueueManager.

Return codes

Table 101. Return code identifiers and descriptions

Return code	Description
0	Successful operation
5	Queue manager is running
26	Queue manager is running as a standby instance
39	Bad command line parameters
44	Stanza does not exist
49	Queue manager is stopping
58	Inconsistent use of installations detected
69	Storage is not available
71	Unexpected error
72	Queue manager name error

Example

```
rmvmqinf QM.NAME
```

Usage notes

Use `rmvmqinf` to remove an instance of a multi-instance queue manager.

To use this command you must be an IBM MQ administrator and a member of the mqm group.

Related commands

Related reference

[“addmqinf \(add configuration information\)” on page 26](#)

Add IBM MQ configuration information on AIX, Linux, and Windows only.

[“dspmqinf \(display configuration information\)” on page 102](#)

Use the **dspmqinf** command to display IBM MQ configuration information (AIX, Linux, and Windows only).

rsvmqtrn (resolve transactions)

Resolve in-doubt and heuristically completed transactions.

Purpose

The **rsvmqtrn** command is used to resolve two different transaction states.

in-doubt transactions

Use the **rsvmqtrn** command to commit or back out internally or externally coordinated in-doubt transactions.

Note: Use this command only when you are certain that transactions cannot be resolved by the normal protocols. Issuing this command might result in the loss of transactional integrity between resource managers for a distributed transaction.

heuristically completed transactions

Use the **rsvmqtrn** command with the **-f** parameter for IBM MQ to remove all information about externally coordinated transactions that were previously resolved manually using the **rsvmqtrn** command, but the resolution has not been acknowledged by the transaction coordinator using the **xa-forget** command. Transactions that are manually resolved by a resource manager and unacknowledged by the transaction manager, are known as *heuristically completed* transactions by X/Open.

Note: Only use the **-f** option if the external transaction coordinator is permanently unavailable. The queue manager, as a resource manager, remembers the transactions that are committed or backed out manually by the **rsvmqtrn** command.

Syntax

Required parameters

-m QMgrName

The name of the queue manager.

Attention: The following parameters are mutually exclusive. You must supply the **-a** parameter on its own, or one of the other parameters together with its transaction number.

Optional parameters

-a

The queue manager resolves all internally coordinated, in-doubt transactions (that is, all global units of work).

-b

Backs out the named transaction. This flag is valid for externally coordinated transactions (that is, for external units of work) only.

-c

Commits the named transaction. This flag is valid for externally coordinated transactions (that is, external units of work) only.

-f

Forgets the named heuristically completed transaction. This flag is valid only for externally coordinated transactions (that is, external units of work) that are resolved, but unacknowledged by the transaction coordinator.

Note: Use only if the external transaction coordinator is never going to be able to acknowledge the heuristically completed transaction. For example, if the transaction coordinator has been deleted.

-r RMID

The participation of the resource manager in the in-doubt transaction can be ignored. This flag is valid for internally coordinated transactions only, and for resource managers that have had their resource manager configuration entries removed from the queue manager configuration information.

Note: The queue manager does not call the resource manager. Instead, it marks the participation of the resource manager in the transaction as being complete.

Transaction

The transaction number of the transaction being committed or backed out. Use the **dspmqtzn** command to find the relevant transaction number. This parameter is required with the **-b**, **-c**, **-f**, and **-r RMID** parameters and must be the last parameter when used.

Return codes

Table 103. Return code identifiers and descriptions

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
32	Transactions could not be resolved
34	Resource manager not recognized
35	Resource manager not permanently unavailable
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping

Table 103. Return code identifiers and descriptions (continued)

Return code	Description
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
85	Transactions not known

Related commands

Table 104. Related command names and descriptions

Command	Description
dspmqtrn	Display list of prepared transactions

Related reference

“[dspmqtrn \(display incomplete transactions\)](#)” on page 118

Use the **dspmqtrn** command to display details of transactions. This command includes transactions coordinated by IBM MQ and by an external transaction manager.

runamscred (protect passwords in AMS configuration files)

Advanced Message Security (AMS) clients might require access to a key repository that contains the private keys that are used to protect messages. To access these key repositories, you set a password in the AMS configuration file `keystore.conf`. You use the **runamscred** command to protect the AMS configuration files.

Usage notes

Note:  On IBM MQ for IBM i, use **runamscri** as the name of this control command.

There are two variants of this command:

- An MQI variant that is located in `<IBM MQ installation root>/bin`.
- A Java variant that is located in `<IBM MQ installation root>/java/bin`.

Use the Java **runamscred** command to protect configuration files that are used with Java AMS clients and the MQI **runamscred** command to protect configuration files for IBM MQ MQI clients that use AMS.

An encryption key, which is known as the initial key, is used to encrypt passwords in the AMS configuration file. You can provide a file that contains the initial key when you run the **runamscred** command. Create the initial key file before you run the command. If you do not provide the initial key, the default initial key is used.

To encrypt the passwords with a specific initial key, use one of the following mechanisms to specify the name of the file that contains the initial key, in order of priority:

1. The **-sf** parameter to the **runamscred** command.
2. The **MQS_AMSCRED_KEYFILE** environment variable.
3. The **amscred.keyfile** parameter in the [keystore.conf](#) configuration file.

CAUTION: The default initial key is the same for all IBM MQ installations. To protect passwords securely, supply an initial key that is unique to your installation when you encrypt passwords.

Syntax

Required parameters

-f config_file

The path to the keystore configuration file to protect.

-sp protection_mode

The password protection mode that is used by the command. One of the following values can be specified:

0

Deprecated Use the deprecated password protection mode that is compatible with Java AMS clients in versions earlier than IBM MQ 9.2.

This value is not applicable to MQI clients

1

Use the IBM MQ 9.2 password protection mode.

2

Use the latest password protection mode. This value is the default value.

Optional parameters

-sf keyfile

The path to the file that contains the initial key that is used to encrypt the password. The file must contain at least one character, and only one line.

If this parameter is not specified, the default initial key is used.

-h

Displays the command syntax.

-sm

Encrypts passwords by using a FIPS compliant cryptographic library.

You cannot use this parameter with the **-sp** parameter set to 0.

This parameter is not available on IBM i or z/OS.

Examples

Linux **AIX** To encrypt a password in the /home/alice/keystore.conf configuration file by using the latest protection mode, issue the following command:

```
runamscred -f /home/alice/keystore.conf
```

Linux **AIX** To encrypt a password in the /home/alice/keystore.conf configuration file, by using the initial key in the /etc/secure/alice_initial.key file and the latest protection mode, issue the following command:

```
runamscred -sf /etc/secure/alice_initial.key -f /home/alice/keystore.conf
```

Windows To encrypt a password in the C:\Users\alice\keystore.conf configuration file by using the latest protection mode, issue the following command:

```
runamscred -f C:\Users\alice\keystore.conf
```

Windows To encrypt a password in the C:\Users\alice\keystore.conf configuration file, that uses the initial key in the C:\secure\alice_initial.key file and the latest protection mode, issue the following command:

```
runamscred -sf C:\secure\alice_initial.key -f C:\Users\alice\keystore.conf
```

Return codes

0

Command completed successfully.

1

Command ended unsuccessfully.

Related tasks

runmqakm -cert (manage certificates)

Use the **runmqakm -cert** command to manage certificates.

Purpose

Use the **runmqakm** command to manage the key repositories, certificates, certificate requests, and secret keys that IBM MQ uses.

The **runmqakm** command is certified as FIPS compliant, and can be configured to operate in a FIPS compliant manner by specifying the **-fips** parameter.

V1000 The **runmqakm** command does not allow the creation of RSA TLS certificates with a keysize less than 2048 while operating in **fips** mode, which is the default.

The **runmqakm** command supports the following file formats for key repositories:

- CMS
- PKCS #12

The **runmqktool** command supports other key repository formats. For more information, see [“runmqktool \(manage keys, certificates, and certificate requests\)”](#) on page 227.

Syntax

-add

-create

-delete

-details

►► -details ►

-export

-extract

►► -extract ►

-import

-list

Actions

-add

Adds a certificate to a key repository.

-create

Creates a certificate.

-delete

Deletes a certificate in a key repository.

-details

Shows details of a certificate in a key repository.

-export

Exports a certificate and private key from a key repository.

-extract

Extracts a certificate from a key repository.

-import

Imports a certificate into a key repository.

-list

Lists all the certificates and secret keys that are stored in a key repository.

-receive

Receives a CA signed certificate into a key repository.

-rename

Renames the label of a certificate in a key repository.

-validate

Validates a certificate in a key repository.

The validation checks that all necessary intermediate and root certificates that are used to validate the certificate are present in the key repository. The validation also checks that the certificates in the chain are not expired.

Parameters**-certpolicy *policy***

Specifies the certificate policy. The certificate policy is a named set of rules that limit the applicability of the certificate.

You can specify multiple values by separating the values with commas.

-crypto *moduleName*

Specifies a PKCS#11 cryptographic device, where *moduleName* is the path to the module to manage the cryptographic device.

If you specify the module name in the properties file, you do not need to specify a value after

-crypto.

-db *keyRepositoryName*

Specifies the fully qualified path name of a key repository.

-dn *distinguishedName*

Specifies the X.500 distinguished name that uniquely identifies the certificate. Enclose the *distinguishedName* value in quotation marks.

You must specify the O and C attributes.

-eku *list*

Specifies an extended key usage property list.

-expire *days*

Specifies the expiration time of the certificate, in days.

The value is a value between 1 to 7300 days (20 years). The default value is 365 days.

-format

Specifies the format of the data.

The value is either **ascii** or **binary**.

The default is Base64 encoded ASCII.

-file *filename*

Specifies the file name of the certificate to add, import, receive, or view details for.

-fips

Specifies whether to force Federal Information Processing Standards (FIPS) mode. In FIPS mode, the underlying cryptographic provider is initialized in FIPS mode so that it uses only algorithms that are FIPS validated.

If **-fips** is set to true and the provider cannot be initialized in FIPS mode, the command fails. If

-fips is set to false and the provider cannot be initialized in FIPS mode, then the utility uses a non-FIPS mode of operation.

Attention: FIPS support is currently not available for Linux s390x. Specifying this attribute will cause the command to fail. Customers on this platform who require FIPS support should remain at a previous version of IBM MQ. Support for FIPS 140-3 will be enabled in a future FixPack once the IBM Crypto for C (ICC) cryptographic module has received its certification on this platform.

-ku *list*

Specifies a key usage property list. This list specifies the valid uses for the certificate.

-label *label*

Specifies the label for the certificate. This label uniquely identifies the certificate.

If the certificate is a personal certificate that is used to identify an IBM MQ client application or queue manager, the label must correspond to the IBM MQ certificate label (CERTLABL) setting, for more information, see [Digital certificate labels, understanding the requirements](#).

-nolabelupdate

By default, if a certificate that exists in the keystore is added again with a different label, the action becomes a rename operation. If this flag is set, then an error is returned if the certificate exists in the keystore so that the label is not changed.

-pw *keyRepositoryPassword*

Specifies the password for the key repository.

-rfc3339

Specifies that the date and time are displayed as Coordinated Universal Time.

-san_dnsname *name*

Specifies the Subject Alternative Name (SAN) names for the entry.

-san_emailaddr *address*

Specifies the Subject Alternative Name (SAN) email addresses for the entry.

You can specify multiple values by separating the values with commas.

-san_ipaddr *address*

Specifies the Subject Alternative Name (SAN) IP addresses for the entry.

-secondaryDB *keyRepositoryName*

Specifies a key repository that is used to support a PKCS#11 device.

-secondaryDBpw *password*

Specifies the password for the secondary key repository.

-showOID

Specifies that a more detailed view of the certificate request is displayed.

-showsizely

Specifies that the secret key value is not displayed.

-sigalg *signatureAlgorithm*

Specifies the hashing algorithm that used during the creation of a certificate request, a self-signed certificate, or the signing of a certificate. This hashing algorithm is used to create the signature that is associated with the newly-created certificate or certificate request.

The value is one of the following values: md5, MD5_WITH_RSA, MD5WithRSA, sha1, SHA_WITH_RSA, SHAWithRSA, SHA1WithRSA, sha224, SHA224_WITH_RSA, SHA224WithRSA, sha256, SHA256_WITH_RSA, SHA256WithRSA, sha3_256, SHA3_256WithRSA, sha384, SHA384_WITH_RSA, SHA384WithRSA, sha3_384, SHA3_384WithRSA, sha512, SHA512_WITH_RSA, SHA512WithRSA, sha3_512, SHA3_512WithRSA, RSASSAPSS, RSASSAPSSPSS, SHA224_WITH_RSASSAPSS, SHA224WithRSASSAPSS, SHA256_WITH_RSASSAPSS, SHA256WithRSASSAPSS, SHA384_WITH_RSASSAPSS, SHA384WithRSASSAPSS, SHA512_WITH_RSASSAPSS, SHA512WithRSASSAPSS, SHA3_256WithRSASSAPSS, SHA3_384WithRSASSAPSS, SHA3_512WithRSASSAPSS, SHA_WITH_DSA, SHA1WithDSA, SHAWithDSA, SHA256WithDSA, SHA1WithECDSA, EC_ecdsa_with_SHA1, SHA224WithECDSA, EC_ecdsa_with_SHA224, SHA256WithECDSA, EC_ecdsa_with_SHA256, SHA384WithECDSA, EC_ecdsa_with_SHA384, SHA512WithECDSA, EC_ecdsa_with_SHA512, SHA3_256WithECDSA, SHA3_384WithECDSA, SHA3_512WithECDSA, DH, Kyber, Dilithium, SHA256WithDilithium, SHA384WithDilithium, SHA512WithDilithium.

The default value is SHA1WithRSA.

-size *keySize*

Specifies the size of the new key pair. This size ranges in value based on the key type:

- For RSA signature algorithms (the default algorithm that is used if no **-sig_alg** is specified), the value can be 512, 1024, 2048, or 4096. An RSA key size of **LTS** 512 **EV mode** less than 2048 bits is not permitted if the **-fips** parameter is enabled. The default RSA key size is 2048 bits.
- For Elliptic Curve algorithms, the value can be 256, 384, or 512. The default Elliptic Curve key size depends upon the signature algorithm. For SHA256, it is 256; for SHA384, it is 384; and for SHA512, it is 512.

-stashed

Specifies that the password for the key repository is stored in a stash file.

-target destinationName

- For **-import**, specifies the file name of the key repository where the certificate is imported to.
- For **-export**, specifies the file name of the key repository or file where the certificate is exported to.
- For **-extract**, specifies the file name of the file where the certificate is extracted to.

-tokenlabel tokenLabel

Specifies the token label that is associated with the PKCS#11 device.

-x509version

Specifies which version of the X.509 certificate to create.

The value is a value from 1 to 3. The default value is 3.

Error codes

Error code	Error message
0	Success
1	Unknown error occurred
2	An ASN.1 encoding/decoding error occurred.
3	An error occurred while initializing the ASN.1 encoder/decoder.

[“runmqakm -secretkey \(manage keys\)” on page 209](#)

Use the **runmqakm -secretkey** command to manage secret keys.

runmqakm -certreq (manage certificate requests)

Use the **runmqakm -certreq** command to manage certificate requests.

Purpose

Use the **runmqakm** command to manage the key repositories, certificates, certificate requests, and secret keys that IBM MQ uses.

The **runmqakm** command is certified as FIPS compliant, and can be configured to operate in a FIPS compliant manner by specifying the **-fips** parameter.

V 10.0.0 The **runmqakm** command does not allow the creation of RSA TLS certificates with a keysize less than 2048 while operating in **fips** mode, which is the default.

The **runmqakm** command supports the following file formats for key repositories:

- CMS
- PKCS #12

The **runmqktool** command supports other key repository formats. For more information, see [“runmqktool \(manage keys, certificates, and certificate requests\)” on page 227](#).

Syntax

-create

-delete

-details

▶ `-showOID` — `-file` — `filename` →

-extract

-list

-recreate

Actions

-create

Creates an RSA private-public key pair and a PKCS10 certificate request in a key repository.

-delete

Deletes a certificate request from a key repository.

-details

Lists the details of the certificate request.

-extract

Extracts an existing certificate request from a key repository.

-list

Lists all certificate request labels in a key repository.

-recreate

Re-creates a certificate request from an existing certificate in a key repository.

Parameters

-certpolicy policy

Specifies the certificate policy. The certificate policy is a named set of rules that limit the applicability of the certificate.

You can specify multiple values by separating the values with commas.

-crypto moduleName

Specifies a PKCS#11 cryptographic device, where *moduleName* is the path to the module to manage the cryptographic device.

If you specify the module name in the properties file, you do not need to specify a value after

-crypto.

-db keyRepositoryName

Specifies the fully qualified path name of a key repository.

-dn distinguishedName

Specifies the X.500 distinguished name that uniquely identifies the certificate. Enclose the *distinguishedName* value in quotation marks.

You must specify the O and C attributes.

-eku list

Specifies an extended key usage property list.

-file filename

Specifies the file name of the certificate to view details for.

-fips

Specifies whether to force Federal Information Processing Standards (FIPS) mode. In FIPS mode, the underlying cryptographic provider is initialized in FIPS mode so that it uses only algorithms that are FIPS validated.

If **-fips** is set to true and the provider cannot be initialized in FIPS mode, the command fails. If **-fips** is set to false and the provider cannot be initialized in FIPS mode, then the utility uses a non-FIPS mode of operation.

Attention: V10.0.0 FIPS support is currently not available for Linux s390x. Specifying this attribute will cause the command to fail. Customers on this platform who require FIPS support should remain at a previous version of IBM MQ. Support for FIPS 140-3 will be enabled in a future FixPack once the IBM Crypto for C (ICC) cryptographic module has received its certification on this platform.

-ku list

Specifies a key usage property list. This list specifies the valid uses for the certificate.

-label label

Specifies the label for the certificate. This label uniquely identifies the certificate.

If the certificate is a personal certificate that is used to identify an IBM MQ client application or queue manager, the label must correspond to the IBM MQ certificate label (CERTLABL) setting, for more information, see [Digital certificate labels, understanding the requirements](#).

-pw keyRepositoryPassword

Specifies the password for the key repository.

-san_dnsname name

Specifies the Subject Alternative Name (SAN) names for the entry.

-san_emailaddr address

Specifies the Subject Alternative Name (SAN) email addresses for the entry.

You can specify multiple values by separating the values with commas.

-san_ipaddr address

Specifies the Subject Alternative Name (SAN) IP addresses for the entry.

-secondaryDB keyRepositoryName

Specifies a key repository that is used to support a PKCS#11 device.

-secondaryDBpw password

Specifies the password for the secondary key repository.

-showOID

Specifies that a more detailed view of the certificate request is displayed.

-sigalg signatureAlgorithm

Specifies the hashing algorithm that used during the creation of a certificate request, a self-signed certificate, or the signing of a certificate. This hashing algorithm is used to create the signature that is associated with the newly-created certificate or certificate request.

The value is one of the following values: md5, MD5_WITH_RSA, MD5WithRSA, sha1, SHA_WITH_RSA, SHAWithRSA, SHA1WithRSA, sha224, SHA224_WITH_RSA, SHA224WithRSA, sha256, SHA256_WITH_RSA, SHA256WithRSA, sha3_256, SHA3_256WithRSA, sha384, SHA384_WITH_RSA, SHA384WithRSA, sha3_384, SHA3_384WithRSA, sha512, SHA512_WITH_RSA, SHA512WithRSA, sha3_512, SHA3_512WithRSA, RSASSAPSS, RSASSAPSSPSS, SHA224_WITH_RSASSAPSS, SHA224WithRSASSAPSS, SHA256_WITH_RSASSAPSS, SHA256WithRSASSAPSS, SHA384_WITH_RSASSAPSS, SHA384WithRSASSAPSS, SHA512_WITH_RSASSAPSS, SHA512WithRSASSAPSS, SHA3_256WithRSASSAPSS, SHA3_384WithRSASSAPSS, SHA3_512WithRSASSAPSS, SHA_WITH_DSA, SHA1WithDSA, SHAWithDSA, SHA256WithDSA, SHA1WithECDSA, EC_ecdsa_with_SHA1, SHA224WithECDSA, EC_ecdsa_with_SHA224, SHA256WithECDSA, EC_ecdsa_with_SHA256, SHA384WithECDSA, EC_ecdsa_with_SHA384, SHA512WithECDSA, EC_ecdsa_with_SHA512, SHA3_256WithECDSA, SHA3_384WithECDSA, SHA3_512WithECDSA, DH, Kyber, Dilithium, SHA256WithDilithium, SHA384WithDilithium, SHA512WithDilithium.

The default value is SHA1WithRSA.

-size *keySize*

Specifies the size of the new key pair. This size ranges in value based on the key type:

- For RSA signature algorithms (the default algorithm that is used if no **-sig_alg** is specified), the value can be 512, 1024, 2048, or 4096. An RSA key size of **LTS** 512 **V1000** less than 2048 bits is not permitted if the **-fips** parameter is enabled. The default RSA key size is 2048 bits.
- For Elliptic Curve algorithms, the value can be 256, 384, or 512. The default Elliptic Curve key size depends upon the signature algorithm. For SHA256, it is 256; for SHA384, it is 384; and for SHA512, it is 512.

-stashed

Specifies that the password for the key repository is stored in a stash file.

-target *targetName*

Specifies the file name that the certificate is extracted to.

-tokenlabel *tokenLabel*

Specifies the token label that is associated with the PKCS#11 device.

-v

Specifies that more information is returned when certificate labels are listed. This information includes the subject and issuer names for the certificate.

Error codes

Error code	Error message
0	Success
1	Unknown error occurred
2	An ASN.1 encoding/decoding error occurred.
3	An error occurred while initializing the ASN.1 encoder/decoder.

Use the **runmqakm -keydb** command to manage key repositories.

[“runmqakm -secretkey \(manage keys\)” on page 209](#)

Use the **runmqakm -secretkey** command to manage secret keys.

▶ **ALW** runmqakm -keydb (manage key repositories)

Use the **runmqakm -keydb** command to manage key repositories.

Purpose

Use the **runmqakm** command to manage the key repositories, certificates, certificate requests, and secret keys that IBM MQ uses.

The **runmqakm** command is certified as FIPS compliant, and can be configured to operate in a FIPS compliant manner by specifying the **-fips** parameter.

V1000 The **runmqakm** command does not allow the creation of RSA TLS certificates with a keysize less than 2048 while operating in **fips** mode, which is the default.

The **runmqakm** command supports the following file formats for key repositories:

- CMS
- PKCS #12

The **runmqktool** command supports other key repository formats. For more information, see [“runmqktool \(manage keys, certificates, and certificate requests\)” on page 227](#).

Syntax

▶▶ runmqakm →

-changepw

Actions

-changepw

Changes the password for a specified key repository.

-convert

Converts the key repository to a different format.

-create

Creates a CMS or PKCS#12 key repository.

-delete

Deletes a specified key repository.

-list

Lists information about key repositories.

-stashpw

Stashes the password for a specified key repository to a specified file.

Parameters

-crypto *moduleName*

Specifies a PKCS#11 cryptographic device, where *moduleName* is the path to the module to manage the cryptographic device.

If you specify the module name in the properties file, you do not need to specify a value after

-crypto.

-db *keyRepositoryName*

Specifies the fully qualified path name of a key repository.

-expire *passwordExpiry*

The number of days until the password for the key repository expires. The value specified must be between 1 and 7300 days (20 years). If this parameter is not specified, the key repository password does not expire.

This parameter is ignored for a PKCS#12 key repository.

-fips

Specifies whether to force Federal Information Processing Standards (FIPS) mode. In FIPS mode, the underlying cryptographic provider is initialized in FIPS mode so that it uses only algorithms that are FIPS validated.

If **-fips** is set to true and the provider cannot be initialized in FIPS mode, the command fails. If

-fips is set to false and the provider cannot be initialized in FIPS mode, then the utility uses a non-FIPS mode of operation.

Attention:  FIPS support is currently not available for Linux s390x. Specifying this attribute will cause the command to fail. Customers on this platform who require FIPS support should remain at a previous version of IBM MQ. Support for FIPS 140-3 will be enabled in a future FixPack once the IBM Crypto for C (ICC) cryptographic module has received its certification on this platform.

-genpw

Specifies that a password is generated for the new key repository.

If you use the **-genpw** parameter, you must also use the **-stash** parameter.

-new_db *keyRepositoryName*

Specifies the fully qualified path name of the new key repository that is created.

-new_format

Specifies the type of the key repository that is created.

The value is either **cms** or **pkcs12**.

-new_pw *newKeyRepositoryPassword*

Specifies a new password for the key repository.

-pqc true(default) | false

When enabled, instructs **runmqakm** to use a stronger keystore protection algorithm. This algorithm might not be available on earlier versions of IBM MQ or Java.

-pw *keyRepositoryPassword*

Specifies the password for the key repository.

-stash

Specifies that the password for the key repository is stashed to a file.

-stashed

Specifies that the password for the key repository is stored in a stash file.

-strong

Specifies that the password meets the following minimum requirements:

- The minimum password length is 14 characters.
- A password must have at least one lowercase character, one uppercase character, and one digit or special character. A space is classified as a special character.
- Each character must not occur more than three times in a password.
- No more than two consecutive characters of the password can be identical.
- All characters are in the standard ASCII printable character set within the range from 0x20 to 0x7E inclusive.

-tokenlabel *tokenLabel*

Specifies the token label that is associated with the PKCS#11 device.

-type

Specifies the type of key repository.

The value is either **cms** or **pkcs12**.

Error codes

Error code	Error message
0	Success
1	Unknown error occurred
2	An ASN.1 encoding/decoding error occurred.
3	An error occurred while initializing the ASN.1 encoder/decoder.
4	An ASN.1 encoding/decoding error occurred because of an out-of-range index or nonexistent optional field.
5	A database error occurred.
6	An error occurred opening the database file, check for file existence and permission.
7	An error occurred re-opening the database file.
8	Database creation failed.
9	The database exists.
10	An error occurred deleting the database file.
11	The database cannot be opened.
12	An error occurred reading the database file.

Error code	Error message
13	An error occurred writing data to the database file.
14	A database validation error occurred.
15	An invalid database version was encountered.
16	An invalid database password was encountered.
17	An invalid database file type was encountered.
18	The specified database is corrupted.
19	An invalid password was provided or the key database has been tampered with or corrupted.
20	A database key entry integrity error occurred.
21	A duplicate certificate exists in the database.
22	A duplicate key exists in the database (Record ID).
23	A certificate with the same label exists in the key database.
24	A duplicate key exists in the database (Signature).
25	A duplicate key exists in the database (Unsigned Certificate).
26	A duplicate key exists in the database (Issuer and Serial Number).
27	A duplicate key exists in the database (Subject Public Key Info).
28	A duplicate key exists in the database (Unsigned CRL).
29	The label has been used in the database.
30	A password encryption error occurred.
31	An LDAP related error occurred. (LDAP is not supported by this program)
32	A cryptographic error occurred.
33	An encryption/decryption error occurred.
34	An invalid cryptographic algorithm was found.
35	An error occurred signing data.
36	An error occurred verifying data.
37	An error occurred computing a digest of data.
38	An invalid cryptographic parameter was found.
39	An unsupported cryptographic algorithm was encountered.
40	The specified input size is greater than the supported modulus size.
41	An unsupported modulus size was found.

Error code	Error message
42	A database validation error occurred.
43	Key entry validation failed.
44	A duplicate extension field exists.
45	The version of the key is wrong.
46	A required extension field does not exist.
47	The validity period does not include today or does not fall within its issuer's validity period
48	The validity period does not include today or does not fall within its issuer's validity period.
49	An error occurred validating the private key usage extension.
50	The issuer of the key was not found.
51	A required certificate extension is missing.
52	An invalid basic constraint extension was found.
53	The key signature validation failed.
54	The root key of the key is not trusted.
55	The key has been revoked.
56	An error occurred validating the authority key identifier extension.
57	An error occurred validating the private key usage extension.
58	An error occurred validating the subject alternative name extension.
59	An error occurred validating the issuer alternative name extension.
60	An error occurred validating the key usage extension.
61	An unknown critical extension was found.
62	An error occurred validating key pair entries.
63	An error occurred validating CRL.
64	A mutex error occurred.
65	An invalid parameter was found.
66	A null parameter or memory allocation error was encountered.
67	Number or size is too large or too small.
68	The old password is invalid.
69	The new password is invalid.
70	The password has expired.

Error code	Error message
71	A thread-related error occurred.
72	An error occurred creating threads.
73	An error occurred while a thread was waiting to exit.
74	An I/O error occurred.
75	An error occurred loading CMS.
76	A cryptography hardware-related error occurred.
77	The library initialization routine was not successfully called.
78	The internal database handle table is corrupted.
79	A memory allocation error occurred.
80	An unrecognized option was found.
81	An error occurred getting time information.
82	Mutex creation error occurred.
83	An error occurred opening message catalog.
84	An error occurred opening error message catalog
85	A null file name was found.
86	An error occurred while opening files, check for file existence and permissions.
87	An error occurred opening files to read.
88	An error occurred opening files to write.
89	No such file.
90	The file cannot be opened because of its permission setting.
91	An error occurred writing data to files.
92	An error occurred deleting files.
93	Invalid Base64-encoded data was found.
94	An invalid Base64 message type was found.
95	An error occurred while encoding data with Base64 encoding rule.
96	An error occurred decoding Base64-encoded data.
97	An error occurred getting a distinguished name tag.
98	The required common name field is empty.
99	The required country or region name field is empty.
100	An invalid database handle was found.
101	The key database does not exist.
102	The request key pair database does not exist.

Error code	Error message
103	The password file does not exist.
104	The new password is identical to the old one.
105	No key was found in the key database.
106	No request key was found.
107	No trusted CA was found.
108	No request key was found for the certificate.
109	There is no private key in the key database.
110	There is no default key in the key database.
111	There is no private key in the key record.
112	There is no certificate in the key record.
113	There is no CRL entry.
114	An invalid key database file name was found.
115	An unrecognized private key type was found.
116	An invalid distinguished name input was found.
117	No key entry was found that has the specified key label.
118	The key label list is corrupted.
119	The input data is not valid PKCS12 data.
120	The password is invalid or the PKCS12 data is corrupted or has been created with later version of PKCS12
121	An unrecognized key export type was found.
122	An unsupported password-based encryption algorithm was found.
123	An error occurred converting the key ring file to a CMS key database.
124	An error occurred converting the CMS key database to a key ring file.
125	An error occurred creating a certificate for the certificate request.
126	A complete issuer chain cannot be built.
127	Invalid WEBDB data was found.
128	There is no data to be written to the key ring file.
129	The number of days that you entered extends beyond the permitted validity period.
130	The password is too short; it must consist of at least {0} characters.
131	A password must contain at least one numeric digit.

Error code	Error message
132	All characters in the password are either alphabetic or numeric characters.
133	An unrecognized or unsupported signature algorithm was specified.
134	An invalid database type was encountered.
135	The specified secondary key database is in use by another PKCS#11 device.
136	No secondary key database was specified.
137	The label does not exist on the PKCS#11 device.
138	Password is required to access the PKCS#11 device.
139	Password is not required to access the PKCS#11 device.
140	Unable to load the cryptographic library.
141	PKCS#11 is not supported for this operation.
142	An operation on a PKCS#11 device failed.
143	The LDAP user is not a valid user. (LDAP is not supported by this program)
144	The LDAP user is not a valid user. (LDAP is not supported by this program)
145	The LDAP query failed. (LDAP is not supported by this program)
146	An invalid certificate chain was found.
147	The root certificate is not trusted.
148	A revoked certificate was encountered.
149	A cryptographic object function failed.
150	There is no certificate revocation list data source available.
151	There is no cryptographic token available.
152	FIPS mode is not available.
153	There is a conflict with the FIPS mode settings.
154	The password does not meet the minimum required strength.
200	There was a failure during initialization of the program.
201	Tokenization of the arguments passed to the runmqakm Program failed.
202	The object that is identified in the command is not a recognized object.
203	The action is not a known -keydb action.

Error code	Error message
204	The action is not a known -cert action.
205	The action is not a known -certreq action.
206	There is a tag missing for the requested command.
207	The value that is passed with the -version tag is not a recognized value.
208	The value that is passed with the -size tag is not a recognized value.
209	The value that is passed in with the -dn tag is not in the correct format.
210	The value that is passed in with the -format tag is not a recognized value.
211	There was an error with opening the file.
212	PKCS12 is not supported at this stage.
213	The cryptographic token that you are trying to change the password for is not password protected.
214	PKCS12 is not supported at this stage.
215	The password does not meet the minimum required strength.
216	FIPS mode is not available.
217	The number of days entered as the expiry date is out of the allowed range.
218	Password strength failed the minimum requirements.
219	No Default certificate was found in the requested key database.
220	An invalid trust status was encountered.
221	An unsupported signature algorithm was encountered. At this stage only Deprecated MD5 and Deprecated SHA1 are supported.
222	PCKS11 is not supported for that particular operation.
223	The action is not a known -random action.
224	A length less than zero is not allowed.
225	When using the -strong tag the minimum length password is 14 characters.
226	When using the -strong tag the maximum length password is 300 characters.
227	The MD5 algorithm is not supported when in FIPS mode.

Error code	Error message
228	The site tag is not supported for the -cert -list command. This attribute is added for backward compatibility and potential future enhancement.
229	The value associated with the -ca tag is not recognized. The value must be either 'true' or 'false'.
230	The value passed in with the -type tag is not valid.
231	The value passed in with the -expire tag is below the allowed range.
232	The encryption algorithm that is used or requested is not supported.
233	The target exists.

[“runmqakm -secretkey \(manage keys\)” on page 209](#)

Use the **runmqakm -secretkey** command to manage secret keys.

runmqakm -secretkey (manage keys)

Use the **runmqakm -secretkey** command to manage secret keys.

Purpose

Use the **runmqakm** command to manage the key repositories, certificates, certificate requests, and secret keys that IBM MQ uses.

The **runmqakm** command is certified as FIPS compliant, and can be configured to operate in a FIPS compliant manner by specifying the **-fips** parameter.

V1000 The **runmqakm** command does not allow the creation of RSA TLS certificates with a keysize less than 2048 while operating in **fips** mode, which is the default.

The **runmqakm** command supports the following file formats for key repositories:

- CMS
- PKCS #12

The **runmqktool** command supports other key repository formats. For more information, see [“runmqktool \(manage keys, certificates, and certificate requests\)” on page 227](#).

Syntax

-add

-create

-extract

Actions

-add

Adds a secret key to a key repository.

-create

Creates a random secret key of a specified length.

-extract

Extracts a secret key from a key repository.

Parameters

-crypto *moduleName*

Specifies a PKCS#11 cryptographic device, where *moduleName* is the path to the module to manage the cryptographic device.

If you specify the module name in the properties file, you do not need to specify a value after

-crypto.

-db *keyRepositoryName*

Specifies the fully qualified path name of a key repository.

-format

Specifies the format of the data.

The value is either **ascii** or **binary**.

The default is Base64 encoded ASCII.

-file *keyFilename*

Specifies the file name of the key to add to the key repository.

-fips

Specifies whether to force Federal Information Processing Standards (FIPS) mode. In FIPS mode, the underlying cryptographic provider is initialized in FIPS mode so that it uses only algorithms that are FIPS validated.

If **-fips** is set to true and the provider cannot be initialized in FIPS mode, the command fails. If **-fips** is set to false and the provider cannot be initialized in FIPS mode, then the utility uses a non-FIPS mode of operation.

Attention: VS000 VS000 FIPS support is currently not available for Linux s390x. Specifying this attribute will cause the command to fail. Customers on this platform who require FIPS support should remain at a previous version of IBM MQ. Support for FIPS 140-3 will be enabled in a future FixPack once the IBM Crypto for C (ICC) cryptographic module has received its certification on this platform.

-label *label*

Specifies the label that is attached to the key.

-pw *keyRepositoryPassword*

Specifies the password for the key repository.

-secondaryDB *keyRepositoryName*

Specifies a key repository that is used to support a PKCS#11 device.

-secondaryDBpw *password*

Specifies the password for the secondary key repository.

-size *keyLength*

Specifies the key length, in bytes.

-stashed

Specifies that the password for the key repository is stored in a stash file.

-target *destinationFilename*

Specifies a fully qualified file name to which the key is extracted.

-tokenlabel *tokenLabel*

Specifies the token label that is associated with the PKCS#11 device.

“runmqakm -keydb (manage key repositories)” on page 199

Use the **runmqakm -keydb** command to manage key repositories.

runmqccred (obfuscate passwords for mqccred exit)

Use the **runmqccred** command to process the **mqccred** exit .ini file to change all plain text passwords into an obfuscated form. This command should be run before using the .ini with the exit to ensure the exit runs successfully.

Usage notes

The **runmqccred** program locates the ini file in the same way as the channel exit. The program also writes console messages saying which file is being modified, and any success or failure status.

Note that the channel exit can work with either **Password** or **OPW** attributes, but the expectation is that you will protect passwords.

Important: The **runmqccred** program works only from IBM MQ 8.0 or later. You must run the program on an IBM MQ 8.0 or later system and then transfer the output .ini file manually to a system running a previous version if you want to use clients there.

By default the exit only works when there are no plain text passwords in the file. You can override this by using the **NOCHECKS SCYDATA** option.

The **runmqccred** program also checks that the .ini file does not have excessive permissions set that allow other users to access it. By default the program fails with an error if the filemode enables others to access it. Use the **-p** flag to continue processing even when the error appears.

The **runmqccred** program is installed in the following folder:

AIX and Linux

The `MQ_INSTALLATION_PATH/usr/mqm/samp/mqccred/`

Windows platforms

The `MQ_INSTALLATION_PATH\Tools\c\Samples\mqccred\`

If the file permissions are not secure enough **runmqccred** produces this message:

```
Configuration file 'C:\Users\User1\mqc\mqccred.ini' is not secure.
Other users may be able to read it. No changes have been made to the file.
Use the -p option for runmqccred to bypass this error.
```

You can bypass this issue with the **-p** flag, but the exit will fail to run when put into production if you have not resolved this issue. When **runmqccred** runs successfully it informs you how many passwords have been obfuscated.

```
File 'C:\Users\User1\.mqsc\mqccred.in' processed successfully.  
Plaintext passwords found: 3
```

Syntax

➤ **runmqccred** 

Optional Parameters

-f

Specify a specific file to edit, other than the default file.

By default, the program locates the `.ini` file in the same way as the channel exit.

-p

By default the program fails with an error, if the filemode enables others to access the file you edited.

Use the **-p** flag to continue processing even when the error appears.

This might be necessary in situations where you might, for example, have mounted a UNIX file system onto your Windows machine using NFS, or some other protocol, and are trying to use the `.ini` file from there (perhaps to share the same `.ini` file across multiple accounts).

Since NFS does not support the Windows NT FS Access Control Lists, the exit would fail unless you bypass the permissions check.

runmqchi (run channel initiator)

Run a channel initiator process to automate starting channels.

You must use the **runmqchi** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq -o installation** command.

The channel initiator is started by default as part of the queue manager.

Syntax

➤ **runmqchi** 

Optional parameters

-q *InitiationQName*

The name of the initiation queue to be processed by this channel initiator. If you omit it, `SYSTEM.CHANNEL.INITQ` is used.

-m *QMGrName*

The name of the queue manager on which the initiation queue exists. If you omit the name, the default queue manager is used.

Return codes

Table 105. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If errors occur that result in return codes of either 10 or 20, review the queue manager error log that the channel is associated with for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager. For more information about error logs, see [Error log directories](#).

runmqchl (run channel)

Use the **runmqchl** command to run either a sender (SDR) or a requester (RQSTR) channel. The channel runs synchronously.

To stop the channel, issue the MQSC command **STOP CHANNEL**.

Syntax

Required parameters

-c ChannelName

The name of the channel to run.

Optional parameters

-m QMgrName

The name of the queue manager with which this channel is associated. If you omit the name, the default queue manager is used.

Return codes

Table 106. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If return codes 10 or 20 are generated, review the error log of the associated queue manager for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager.

Multi **runmqdlq (run dead-letter queue handler)**

Use the **runmqdlq** command to start the dead-letter queue (DLQ) handler, which monitors and handles messages on a DLQ.

Before IBM MQ 9.3.0, this command is used on servers. If you want client mode you should compile **amqsdlq** in client mode. See [The sample DLQ handler amqsdlq](#) for more information.

From IBM MQ 9.3.0, you can use **runmqdlq** with the **-c** parameter to specify that it should connect to a queue manager by using a client connection.

Syntax

Description

Use the dead-letter queue handler to perform various actions on selected messages by specifying a set of rules that can both select a message and define the action to be performed on that message.

The **runmqdlq** command takes its input from `stdin`. When the command is processed, the results and a summary are put into a report that is sent to `stdout`.

By taking `stdin` from the keyboard, you can enter **runmqdlq** rules interactively.

By redirecting the input from a file, you can apply a rules table to the specified queue. The rules table must contain at least one rule.

If you use the DLQ handler without redirecting `stdin` from a file (the rules table), the DLQ handler reads its input from the keyboard:

- **Linux** **AIX** On AIX and Linux, the DLQ handler does not start to process the named queue until it receives an `end_of_file` (Ctrl+D) character.
- **Windows** On Windows, the DLQ handler does not start to process the named queue until you press the following sequence of keys: Ctrl+Z, Enter, Ctrl+Z, Enter.

For more information about rules tables and how to construct them, see [The DLQ handler rules table](#).

Optional parameters

The MQSC command rules for comment lines and for joining lines also apply to the DLQ handler input parameters.

QName

The name of the queue to be processed.

If you omit the name, the dead-letter queue defined for the local queue manager is used. If you enter one or more blanks (' '), the dead-letter queue of the local queue manager is explicitly assigned.

QMGrName

The name of the queue manager that owns the queue to be processed.

If you omit the name, the default queue manager for the installation is used. If you enter one or more blanks (' '), the default queue manager for this installation is explicitly assigned.

-u UserID

If you use the **-u** parameter to supply a user ID, you are prompted for a matching password.

If you have configured the CONNAUTH AUTHINFO record with CHCKLOCL (REQUIRED) or CHCKLOCL (REQDADM), you must use the **-u** parameter otherwise you will not be able to start a dead-letter queue handler for your queue manager with **runmqdlq**.

If you specify this parameter and redirect stdin, a prompt will not be displayed and the first line of redirected input should contain the password.

-c

Modifies the **runmqdlq** command to connect to a queue manager by using a client connection. The client channel definitions used to connect to the queue manager are located using the following environment variables in this order of precedence: **MQSERVER**, **MQCHLLIB**, and **MQCHLTAB**.

This option requires the client to be installed. If it is not installed an error message reporting the missing client libraries is issued.

Attention: From IBM MQ 9.4.0, the default permissions of **runmqdlq** have been changed to remove the setuid bit. When running **runmqdlq**, the tool runs under the context of the user that invokes the command.

Before IBM MQ 9.4.0, **runmqdlq** is a setuid application that runs as the 'mqm' user regardless of which user started the application. If you use a CCDT file, the 'mqm' group must have permission to read the CCDT file as well as 'execute' permission on the directory structure. Failure to grant the correct permissions results in **runmqdlq** failing with an AMQ9516 error.

Return codes

Table 107. Return code identifiers and descriptions

Return code	Description
0	Successful operation
16	Usage / Invalid arguments provided
32	Warning
64	Expected error
95	Unexpected error
151	Unable to load Libraries

Related tasks

[Invoking the dead-letter queue handler](#)

[Undelivered messages troubleshooting](#)

Windows **runmqdnm** (run .NET monitor)

Use the **runmqdnm** control command to start processing messages on an application queue with a .NET monitor (Windows only). **runmqdnm** can be run from the command line, or as a triggered application.

Syntax

Required parameters

-q QueueName

The name of the application queue to monitor.

-a AssemblyName

The name of the .NET assembly.

Optional parameters

-m QMgrName

The name of the queue manager that hosts the application queue.

If omitted, the default queue manager is used.

-c ClassName

The name of the .NET class that implements the IMQObjectTrigger interface. This class must reside in the specified assembly.

If omitted, the specified assembly is searched to identify classes that implement the IMQObjectTrigger interface:

- If one class is found, then *ClassName* takes the name of this class.
- If no classes or multiple classes are found, then the .NET monitor is not started and a message is written to the console.

-u UserData

User-defined data. This data is passed to the Execute method when the .NET monitor calls it. User data must contain ASCII characters only, with no double quotation marks, NULLs, or carriage returns.

If omitted, null is passed to the Execute method.

-s Syncpoint

Specifies whether sync point control is required when messages are retrieved from the application queue. Possible values are:

Table 108. Syncpoint parameter values.	
Value	Description
YES	Messages are retrieved under sync point control (MQGMO_SYNCPOINT).
NO	Messages are not retrieved under sync point control (MQGMO_NO_SYNCPOINT).
PERSISTENT	Persistent messages are retrieved under sync point control (MQGMO_SYNCPOINT_IF_PERSISTENT).

If omitted, the value of *Syncpoint* is dependent on your transactional model:

- If distributed transaction coordination (DTC) is being used, then *Syncpoint* is specified as YES.
- If distributed transaction coordination (DTC) is not being used, then *Syncpoint* is specified as PERSISTENT.

-d Conversion

Specifies whether data conversion is required when messages are retrieved from the application queue. Possible values are:

Table 109. Conversion parameter values.	
Value	Description
YES	Data conversion is required (MQGMO_CONVERT).
NO	Data conversion is not required (no get message option specified).

If omitted, *Conversion* is specified as NO.

-n MaxThreads

The maximum number of active worker threads.

If omitted, *MaxThreads* is specified as 20.

-t Timeout

The time, in seconds, that the .NET monitor waits for further messages to arrive on the application queue. If you specify -1, the .NET monitor waits indefinitely.

If omitted when run from the command line, the .NET monitor waits indefinitely.

If omitted when run as a triggered application, the .NET monitor waits for 10 seconds.

-b BackoutThreshold

Specifies the backout threshold for messages retrieved from the application queue. Possible values are:

Table 110. BackoutThreshold parameter values.	
Value	Description
-1	The backout threshold is taken from the application queue attribute, BOTHRESH.
0	The backout threshold is not set.
1 or more	Explicitly sets the backout threshold.

If omitted, *BackoutThreshold* is specified as -1.

-r QueueName

The queue to which messages, with a backout count exceeding the backout threshold, are put.

If omitted, the value of *QueueName* is dependent on the value of the BOQNAME attribute from the application queue:

- If BOQNAME is non-blank, then *QueueName* takes the value of BOQNAME.
- If BOQNAME is blank, then *QueueName* is specified as the queue manager dead letter queue. If a dead letter queue has not been assigned to the queue manager, then backout processing is not available.

-p ContextOption

Specifies whether context information from a message that is being backed out is passed to the backed out message. Possible values are:

Table 111. ContextOption parameter values.	
Value	Description
NONE	No context information is passed.
IDENTITY	Identity context information is passed only.
ALL	All context information is passed.

If omitted, *ContextOption* is specified as ALL.

Return codes

Table 112. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

Related tasks

[Using the .NET monitor](#)

Multi runmqicred (protect IBM MQ client passwords)

The **runmqicred** command protects passwords that are used by the IBM MQ client libraries, for example, the TLS keystore password. It is also used to protect passwords that are used to protect log replication traffic for Native HA configurations.

Usage notes

The **runmqicred** command prompts for the password to be encrypted to be entered. An encryption key, which is known as the initial key, is used to encrypt the password. You can provide a file that contains the initial key when you run the command. Create the initial key file before you run the command. If you do not provide the initial key, the default initial key is used.

To encrypt the password with a specific initial key, use one of the following mechanisms to specify the name of the file that contains the initial key, in order of priority:

1. The **-sf** parameter to the **runmqicred** command.
2. The `MQS_MQI_KEYFILE` environment variable.

CAUTION: The default initial key is the same for all IBM MQ installations. To protect passwords securely, supply an initial key that is unique to your installation when you encrypt passwords.

After the password is encrypted, **runmqicred** displays the encrypted password string.

Store the encrypted password in the appropriate property.

- For IBM MQ clients, store the encrypted password in either the appropriate property of the `mqclient.ini` file, or the `MQKEYRPWD` environment variable.
- For Native HA configurations, store the encrypted password in the appropriate property of the **NativeHALocalInstance** stanza of the `qm.ini` file.

Syntax

Optional parameters

-sf keyfile

The path to the file that contains the initial key that is used to encrypt the password. If specified, the file must contain at least one character, and only one line.

If this parameter is not specified, the default initial key is used.

-sp protection_mode

The password protection mode that is used by the command. One of the following values can be specified:

1

Use the password protection mode that is compatible with IBM MQ 9.2.

2

Use the latest password protection mode. This mode is the most secure credentials protection mode.

This value is the default.

-sm

Encrypts passwords using a FIPS compliant cryptographic library.

Examples

```
>runmqicred
```

```
5724-H72 (C) Copyright IBM Corp. 1994, 2026.
Credentials are encrypted using the default encryption key. For more secure
protection of stored credentials, use a custom, strong encryption key. Enter password:
*****
<MQI>!2!+uIepF0e70/R7CUCe/46ToTo5MucJCWgLZKCSYwLix4=!+6AG1pYrphCo/dlfSt8N3g===
```

```
>runmqicred -sf InitialKey.file
```

```
5724-H72 (C) Copyright IBM Corp. 1994, 2026.
Enter password:
*****
<MQI>!2!STHVy96FWSEwPkwNQfR2Nuoe6/uWl/EAqqy10jav9qs=!l+2y9yB/SjpszssrpGd+wJw=====
```

Return codes

0

Command completed successfully.

1

Command completed unsuccessfully.

runmqktool (manage keys, certificates, and certificate requests)

Use the **runmqktool** command to manage keys, certificates, and certificate requests in key repositories that IBM MQ uses. **runmqktool** provides the same functions as the Java **keytool** certificate management utility.

The **runmqktool** command supports the following key repository file formats:

- PKCS #12
- JKS
- JCEKS

The **runmqakm** command supports other key repository formats. For more information, see [“runmqakm -keydb \(manage key repositories\)”](#) on page 199.

From IBM MQ 9.4.0, this command replaces the **runmqckm** command that is used to manage certificates in earlier versions of IBM MQ.

The **runmqktool** command requires that the IBM MQ Java runtime environment (JRE) component is installed.

Usage notes

The **runmqktool** command calls the **keytool** certificate management utility in the Java runtime environment that is supplied with IBM MQ.

 From IBM MQ 10.0.0, for more information about the **keytool** command and its usage, see [The keytool Command](#).

Note: Due to a restriction in the IBM Java 8 **keytool** command, **runmqktool** cannot import certificates in printable encoding format (also known as Base64 encoding) as defined by the Internet RFC 1421 if the file contains comments. To import a certificate in printable encoding format, remove all comments from the file. The file must begin with a string that starts with "-----BEGIN", and end with a string that starts with "-----END".

Syntax

Parameters

-certreq

Create a request for a signed certificate to be sent to a certificate authority (CA). You must first create a key pair by using the `-genkeypair` command.

-changealias

Change the label that is associated with an entry in the key repository.

-delete

Delete an entry from the key repository.

-exportcert

Extract the public part of a certificate from the key repository.

-genkeypair

Create a public key and private key pair, and an associated self-signed certificate.

-importcert

Add a certificate to the key repository. Use this command to complete one of the following actions:

- Add a certificate to the key repository as a trusted certificate.
- Receive a certificate that is signed by a certificate authority (CA) into the key repository.

-importkeystore

Import certificates and their associated private keys into the key repository from another key repository.

-keypasswd

Change the password that protects a private key in the key repository.

-list

List the contents of the key repository.

-storepasswd

Change the key repository password.

options

The parameters that are required for the specified command.

All commands and options that are specified are passed unchanged to the Java **keytool** certificate management utility.

 From IBM MQ 10.0.0, for more information about the commands and options that can be specified, see [The keytool Command](#).

Return codes

Table 113. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

Multi runmqtsr (run listener)

Run a listener process to listen for remote requests on various communication protocols. This command is run synchronously and waits until the listener process has finished before returning to the caller.

Syntax

Required parameters

-t
The transmission protocol to be used:

Table 114. Transmission protocol values.	
Value	Description
tcp	Transmission Control Protocol / Internet Protocol (TCP/IP)
lu62	 SNA LU 6.2 (Windows only)
netbios	 NetBIOS (Windows only)
spx	 SPX (Windows only)

Optional parameters

-p Port
The port number for TCP/IP. This flag is valid for TCP only. If you omit the port number, it is taken from the queue manager configuration information, or from defaults in the program. The default value is 1414. It must not exceed 65535.

-i IPAddr

The IP address for the listener, specified in one of the following formats:

- IPv4 dotted decimal
- IPv6 hexadecimal notation
- Alphanumeric format

This flag is valid for TCP/IP only.

On systems that are both IPv4 and IPv6 capable you can split the traffic by running two separate listeners. One listening on all IPv4 addresses and one listening on all IPv6 addresses. If you omit this parameter, the listener listens on all configured IPv4 and IPv6 addresses.

-n TpName

The LU 6.2 transaction program name. This flag is valid only for the LU 6.2 transmission protocol. If you omit the name, it is taken from the queue manager configuration information.

-a Adapter

The adapter number on which NetBIOS listens. By default the listener uses adapter 0.

-l LocalName

The NetBIOS local name that the listener uses. The default is specified in the queue manager configuration information.

-e Names

The number of names that the listener can use. The default value is specified in the queue manager configuration information.

-s Sessions

The number of sessions that the listener can use. The default value is specified in the queue manager configuration information.

-o Commands

The number of commands that the listener can use. The default value is specified in the queue manager configuration information.

-x Socket

The SPX socket on which SPX listens. The default value is hexadecimal 5E86.

-m QMgrName

The name of the queue manager. By default the command operates on the default queue manager.

-b Backlog

The number of concurrent connection requests that the listener supports. See [TCP](#), [LU62](#), [NETBIOS](#), and [SPX](#) for a list of default values and further information.

Return codes

Table 115. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
4	Command completed after being ended by the endmq1sr command
10	Command completed with unexpected results
20	An error occurred during processing: the AMQMSRVN process did not start.

Examples

The following command runs a listener on the default queue manager using the NetBIOS protocol. The listener can use a maximum of five names, five commands, and five sessions. These resources must be within the limits set in the queue manager configuration information.

```
runmqclsr -t netbios -e 5 -s 5 -o 5
```

Related reference

[“Listener commands” on page 12](#)

A table of listener commands, showing equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

runmqras (collect IBM MQ troubleshooting information)

Use the **runmqras** command to gather IBM MQ troubleshooting information (MustGather data) together into a single archive, for example to submit to IBM Support.

The **runmqras** command requires a Java 7, or later, Java runtime environment (JRE) in order to run. If the IBM MQ JRE component (on Linux) or feature (on Windows) is not installed, then **runmqras** searches the system path for an alternative JRE and attempts to use that.

If no alternative could be found, error message AMQ8599 is output. In this case:

1. Install the IBM MQ JRE component, or install an alternative Java 7 JRE
2. Add the JRE to the system path
3. Rerun the command

By default, **runmqras** gathers information such as:

- IBM MQ FDC files
- Error logs (from all queue managers as well as the machine-wide IBM MQ error logs)
- Product versioning, status information, and output from various other operating system commands.

Note, for example, the **runmqras** command does not gather user information that is contained in messages on queues.

Running without requesting more sections is intended as a starting point for general problem diagnosis, however, you can request more *sections* through the command line.

These additional *sections* gather more detailed information, depending on the type of problem being diagnosed. If non-default sections are needed by IBM Support, they will tell you.

The **runmqras** command can be run under any user ID, but the command gathers only information that the user ID can gather manually. In general, when debugging IBM MQ problems, run the command under:

-   The mqm user ID
-  A user ID in the mqm group.

to allow the command to gather queue manager files and command outputs.

  The **runmqras** command retrieves the environment variable information by default. This applies to Linux and AIX.

 The **runmqras** command retrieves a listing of the queue manager's data directory by default. This applies to Multiplatforms. The userdata directory under the data directory is excluded.

Syntax

Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

-application *application*

Collects information about valid applications.

-caseno *caseNo*

A valid Salesforce case number.

Use this option to ensure that the output is prefixed with your case number, so that when the information is sent to IBM, the information is automatically associated with that case number.

Note: If you want to specify a PMR number, use the **-pmrno** parameter, not the **-caseno** parameter.

It is not permitted to supply both the **-caseno** and **-pmrno** parameters together.

-custominput *CustomInputFileName*

Fully qualified name of an additional XML input file

-demo

Run in demonstration mode where no commands are processed, and no files gathered.

By running in demonstration mode, you can see exactly which commands would have been processed, and what files would have been gathered. The output `.zip` file contains a `console.log` file that documents exactly what would have been processed and gathered, should the command be run normally.

-ftp ibm|custom

Allows the collected archive to be sent through basic FTP to a remote destination.

At the end of processing, the resultant archive can be sent through basic FTP to a site of your choosing.

Important: From IBM MQ 9.3.0, the **-ftp IBM** option is no longer available. If you select this option, the following message is generated:

The FTP IBM option will no longer work as the IBM FTP servers have been disabled

-ftpdirectory path

The directory on the FTP server to place the resulting `.zip` file into, used when an FTP custom option is used.

-ftppassword password

The password to log in to the FTP server with, when an FTP custom option is used.

-ftpserver server

An FTP server name to connect to, when an FTP custom option is used.

-ftpusername userid

The user ID to log in to the FTP server with, when an FTP custom option is used.

-help

Provide simple help.

-inputfile InputFileName

Fully qualified name of the XML input file

-noqmdata

From IBM MQ 9.3.0, setting **-noqmdata** captures installation-level diagnostics only, skipping any queue manager-specific diagnostics.

The **-qmlist** parameter and the **-noqmdata** parameter cannot be used together. If both parameters are specified, the following error is returned:

Argument error: At most one of -noqmdata or -qmlist may be supplied

-outputdir path

The directory in which the resulting output file is placed.

By default, the output directory is the same as the work directory.

-pmrno 12345,678,9AB

A valid IBM PMR number (problem record number) against which to associate the documentation.

Use this option to ensure that the output is prefixed with your PMR number, so that when the information is sent to IBM, the information is automatically associated with that problem record.

Note: If you want to specify a Salesforce case number, use the **-caseno** parameter, not the **-pmrno** parameter.

It is not permitted to supply both the **-caseno** and **-pmrno** parameters together.

-qmlist QMA[, QMB]

A list of queue manager names on which the **runmqras** command is to be run.

This parameter does not apply to a client product because there are no queue managers from which to request direct output.

By supplying a comma-separated list, you can restrict the iteration across queue managers to a specific list of queue managers. By default, iteration of commands is across all queue managers.

-section *SectionA,SectionB*

The optional sections about which to gather more specific information. You must use a comma as the separator character between sections, with no spaces. For example:

```
runmqras -qmlist ESBSTGAPPQMVH2 -section defs,trace,cluster -caseno TEST123
```

By default, a generic section of documentation is collected, whereas more specific information can be gathered for a specified problem type; for example, a section name of *trace* gathers all of the contents of the trace directory.

The default collections can be avoided by supplying a section name of *nodefault*.

IBM Support generally supplies you with the sections to use. Example available sections are:

all

Gathers all possible information, including all trace files, and diagnostics for many different types of problems. You must use this option only in certain circumstances and this option is not intended for general use.

cluster

Gathers cluster configuration and queue information.

dap

Gathers transaction and persistence information.

default

IBM MQ logs, FDC files, basic configuration, and status.

Note: Always gathered unless you use the section name **nodefault**. Some information about the current environment (saved in `env.stdout` on Linux, AIX and IBM i, and in `set.stdout` on Windows) and current user limits (saved in `mqconfig.stdout` on AIX and Linux) might be altered by the **runmqras** command. If necessary, run the **env**, **set**, or **mqconfig** commands manually in your environment to check the actual values.

 On the IBM MQ Appliance, any files other than queue manager trace files present in the `mqtrace: filesystem` are now captured in the *default* section.

Note: You should continue to specify the *trace* section if you need to obtain any queue manager trace files present in the `mqtrace: filesystem`.

defs

Gathers the queue manager definitions and status information.

kernel

Gathers queue manager kernel information.

leak

Gathers IBM MQ process resource usage information.

This section applies to Linux and AIX.

logger

Gathers recovery logging information.

mft

Captures the data obtained by the **fteRas** command.

Note: **-section mft** only collects information for the default coordination queue manager topology.

mqweb

Gathers trace and configuration data for the mqweb server.

nativeha

Gathers diagnostic information from a native HA queue manager instance. It is useful to gather information from all instances to view recent history of activity and communication between the instances.

nodefault

Prevents the default collections from occurring, but other explicitly requested sections are still collected.

QMGR

Gathers all queue manager files: queues, logs, and configuration files.

topic

Gathers topic tree information.

trace

Gathers all the trace file information plus the default information.

Note: Does not enable tracing.

For more information, see [Choosing sections to gather](#), in the IBM technote on using the IBM MQ **runmqras** command to collect data.

-sub

Shows the keywords that will be substituted in the xml.

-timeout secs

The default timeout to give an individual command before the command stops waiting for completion.

By default, a timeout of 10 seconds is used. A value of zero means wait indefinitely.

-v

Extends the amount of information that is logged in the console.log file, contained in the output .zip file.

-workdirectory path

The directory that is used for storing the output from commands that are run during the processing of the tool. If supplied, this directory must either not exist, in which case it is created, or must be empty.

If you do not supply the path, a directory whose name starts with **runmqras** and is suffixed by the date and time is used:

-   On AIX and Linux, the directory is under /tmp.
-  On Windows, the directory is under %temp%.

-zipfile ZipFileName

Supply the file name of the resulting archive.

runmqras appends the hostname to the name of the archive file. For example, if you run the following command:

```
runmqras -zipFile diagnostics.zip
```

the resulting archive file is called `diagnostics-hostname.zip`.

By default, the name of the archive file is `runmqras-hostname.zip` where *hostname* is the hostname that **runmqras** appends to the file name.

Examples

This command gathers the default documentation from the IBM MQ installation, and all queue managers on a machine:

```
runmqras
```

This command gathers the default documentation from the IBM MQ installation on a machine into an output file with a name that starts with the appropriate case number:

```
runmqras -caseno TS123456789
```

This command gathers the default documentation from a machine, plus all trace files, the queue manager definitions, and status for all queue managers on the machine:

```
runmqras -section trace,defs
```

For more examples of how to use **runmqras**, see [Collecting troubleshooting information automatically with runmqras](#).

Return codes

[Sending troubleshooting information to IBM](#)

ALW runmqsc (run MQSC commands)

On AIX, Linux, and Windows, the **runmqsc** command is used to open a command prompt from which you can issue MQSC commands. MQSC commands enable you to perform administration tasks. For example, you can define, alter, or delete a local queue object.

How to open, use and close the **runmqsc** command prompt is described in [Running MQSC commands interactively under runmqsc](#). The MQSC commands and their syntax are described in “MQSC commands reference” on page 310.

Syntax

You can use the **-n** parameter on its own, or you can use a number of other parameters in combination:

Description

You can start the **runmqsc** command in three ways:

Verify command

Verify MQSC commands but do not run them. An output report is generated indicating the success or failure of each command. This mode is available on a local queue manager only.

Run command directly

Send MQSC commands directly to a local queue manager.

Run command indirectly

Run MQSC commands on a remote queue manager. These commands are put on the command queue of a remote queue manager and run in the order in which they were queued. Reports from the commands are returned to the local queue manager.

The **runmqsc** command takes its input from stdin. When the commands are processed, the results and a summary are put into a report that is sent to stdout.

By taking stdin from the keyboard, you can enter MQSC commands interactively.

Alternatively, you can redirect stdin from a text file. By redirecting the input from a file, you can run a sequence of frequently used commands contained in the file. You can also redirect the output report to a file.

Note: If you run **runmqsc** in client mode by redirecting stdin from a text file, IBM MQ expects the first line of the input file to be a password.

Optional parameters

-c

Modifies the **runmqsc** command to connect to a queue manager by using a client connection. The client channel definitions used to connect to the queue manager are located using the following environment variables in this order of precedence: **MQSERVER**, **MQCHLLIB**, and **MQCHLTAB**.

This option requires the client to be installed. If it is not installed an error message reporting the missing client libraries is issued.

-e

Prevents source text for the MQSC commands from being copied into a report. This parameter is useful when you enter commands interactively.

-m *LocalQMgrName*

The local queue manager that you want to use to submit commands to the remote queue manager. If you omit this parameter the local default queue manager is used to submit commands to the remote queue manager. The **-w** parameter must also be specified.

-n

Modifies the **runmqsc** command to not connect to a queue manager. If this parameter is specified, all other command parameters must be omitted, otherwise an error message is issued.

This option requires the client libraries to be installed. If they are not installed an error message is issued.

MQSC commands entered in this mode are limited to managing the local channel definition file, which is located through the **MQCHLLIB** and **MQCHLTAB** environment variables, or the default values if not defined.

Note: If you add new entries into the local channel definition file, or alter existing entries, these changes are not reflected inside the queue manager. The queue manager does not read the contents of the local channel definition file. The CCDT file is a write-only file from the perspective of the queue manager. The queue manager does not read the contents of the CCDT file.

Only the following MQSC commands are recognized:

ALTER, DEFINE, DELETE, DISPLAY AUTHINFO (Only of type CRLLDAP or OSCP)

ALTER, DEFINE, DELETE, DISPLAY CHANNEL (Only of type CLNTCONN)

For the AUTHINFO management commands, the names of existing AUTHINFO definitions are mapped and addressed using the names CRLLDAP*n* or OSCP *n* (according to type), where *n* is the numeric

order in which they appear in the channel definition file. New AUTHINFO definitions are appended to the client channel table in order. For example, the the following commands are issued:

```
DEFINE AUTHINFO(XYZ) AUTHTYPE(CRLLDAP) CONNAME('xyz')
DEFINE AUTHINFO(ABC) AUTHTYPE(CRLLDAP) CONNAME('abc')
```

This results in the 'xyz' LDAP server being checked for a CRL first, if that CRL server is unavailable then the 'abc' server is checked.

Using the **DISPLAY AUTHINFO(*) CONNAME** command shows this:

```
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP1)
AUTHTYPE(CRLLDAP)          CONNAME(xyz)
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP2)
AUTHTYPE(CRLLDAP)          CONNAME(abc)
```

Note: The client mode only supports inserting new entries at the end of the client channel table. If you want to change the order of precedence of the CRL LDAP servers, you must remove the existing objects from the list and reinsert them in the correct order at the end.

-u UserID

If you use the **-u** parameter to supply a user ID, you are prompted for a matching password.

If you have configured the CONNAUTH AUTHINFO record with CHCKLOCL (REQUIRED) or CHCKLOCL (REQDADM), you must use the **-u** parameter otherwise you will not be able to administer your queue manager with **runmqsc**.

If you specify this parameter and redirect stdin, a prompt will not be displayed and the first line of redirected input should contain the password.

-v

Verifies the specified commands without performing the actions. This mode is only available locally. The **-w** and **-x** parameters are ignored if they are specified at the same time as **-v**.

Important: The **-v** flag checks the syntax of the command only. Setting the flag does not check if any objects mentioned in the command actually exist.

For example, if the queue Q1 does not exist in the queue manager, the following command is syntactically correct and does not generate any syntax errors: **runmqsc -v Qmgr display q1(Q1)**.

However, if you omit the **-v** flag, you receive error message AMQ8147.

-w WaitTime

Run the MQSC commands on another queue manager. You must have the required channel and transmission queues set up for this. For more information, see [Configuring queue managers for remote administration](#).

This parameter is ignored if the **-v** parameter is specified.

WaitTime

The time, in seconds, that **runmqsc** waits for replies. Any replies received after this are discarded, but the MQSC commands still run. The wait time is set as the expiry time of the PCF command message, and the remaining time is set on the PCF reply messages by the command server. Specify a time in the range 1 through 999999.

Each command is sent as an Escape PCF to the command queue (SYSTEM.ADMIN.COMMAND.QUEUE) of the target queue manager.

The replies are received on queue SYSTEM.MQSC.REPLY.QUEUE and the outcome is added to the report. This can be defined as either a local queue or a model queue.

-x

The target queue manager is running under z/OS. This parameter applies only in indirect mode. The **-w** parameter must also be specified. In indirect mode, the MQSC commands are written in a form suitable for the IBM MQ for z/OS command queue.

QMgrName

The name of the target queue manager on which to run the MQSC commands. If not specified, the default queue manager is used.

-f filename

Read input to be processed from the supplied filename rather than standard input.

Return codes

Table 117. Return code identifiers and descriptions

Return code	Description
0	MQSC command file processed successfully
10	MQSC command file processed with errors; report contains reasons for failing commands
20	Error; MQSC command file not run

Related tasks

Running MQSC commands interactively under [runmqsc](#)

Running MQSC commands from text files

runmqtm (start client trigger monitor)

Use the **runmqtm** command to start a trigger monitor for a client. When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends. While the client trigger monitor is running it keeps the dead-letter queue open.

Purpose

For further information about using trigger monitors, see [Initiation queue processing by trigger monitors](#).

Syntax

Optional parameters

-m QMgrName

The name of the queue manager on which the client trigger monitor operates, by default the default queue manager.

-q InitiationQName

The name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

-r

Specifies that the client trigger monitor automatically reconnects.

-u *UserId*

The ID of the user authorized to get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

Note: As the **runmqtrmc** command makes a standard client connection, you can send a user ID and password, and have the password encrypted, using the mqccred security exit.

Return codes

Table 118. Return code identifiers and descriptions

Return code	Description
0	Not used but reserved as the client trigger monitor is designed to run continuously without ending
10	Trigger monitor interrupted by an error
20	Error; client trigger monitor not run

Examples

For examples of using this command, see [The Triggering sample programs](#).

Multi **runmqtrm (start trigger monitor)**

Use the **runmqtrm** command to start a trigger monitor on a server. When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends. While the trigger monitor is running it keeps the dead-letter queue open.

For more information about using trigger monitors, see [Initiation queue processing by trigger monitors](#).

Syntax

Optional parameters

-m *QMgrName*

The name of the queue manager on which the trigger monitor operates, by default the default queue manager.

-q *InitiationQName*

Specifies the name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

-u *UserId*

The ID of the user authorized to read the initiation queue, and get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

Return codes

Table 119. Return code identifiers and descriptions

Return code	Description
0	Not used but reserved as the client trigger monitor is designed to run continuously without ending

Stop a queue manager. or switch to a standby queue manager or replica queue manager.

runp11cred (protect PKCS #11 cryptographic hardware passwords)

The **runp11cred** command protects passwords that are contained in PKCS #11 cryptographic hardware configuration strings. The cryptographic hardware configuration strings are supplied to IBM MQ clients by using either the **MQSSLCRYP** environment variable, or the **SSLCryptoHardware** attribute in the **SSL** stanza of the client configuration file.

Usage notes

The **runp11cred** command prompts for the password to be encrypted to be entered. An encryption key, which is known as the initial key, is used to encrypt the password. You can provide a file that contains the initial key when you run the **runp11cred** command. Create the initial key file before you run the command. If you do not provide the initial key, the default initial key is used.

To encrypt the password with a specific initial key, use one of the following mechanisms to specify the name of the file that contains the initial key, in order of priority:

1. The **-sf** parameter to the **runp11cred** command.
2. The **MQS_SSLCRYP_KEYFILE** environment variable.

CAUTION: The default initial key is the same for all IBM MQ installations. To protect passwords securely, supply an initial key that is unique to your installation when you encrypt passwords.

After the password is encrypted, **runp11cred** displays the encrypted password string.

Store the encrypted password in the cryptographic hardware configuration string, which is specified either in the appropriate property in the `mqclient.ini` file, or the **MQSSLCRYP** environment variable.

Syntax

➔ **runp11cred** 

Optional parameters

-sf *keyfile*

The path to the file that contains the initial key that is used to encrypt the password. If specified, the file must contain at least one character, and only one line.

If this parameter is not specified, the default initial key is used.

-sp *protection_mode*

The password protection mode that is used by the command. One of the following values can be specified:

1

Use the password protection mode that is compatible with IBM MQ 9.2.

2

Use the latest password protection mode. This mode is the most secure password protection mode.

This value is the default.

-sm

Encrypts passwords using a FIPS compliant cryptographic library.

Examples

```
>runp11cred
```

```
5724-H72 (C) Copyright IBM Corp. 1994, 2026.  
Enter password:  
*****  
Credentials are encrypted using the default encryption key. For more secure  
protection of stored credentials, use a custom, strong encryption key.  
<P11>!2!N5eSuyDco5urE1GXhvpX7Hdk4bo840A08b0ZqyZv9P8=!Wtlg2x2SlYmCvhFtkUM5Ag==
```

```
>runp11cred -sf InitialKey.file
```

```

<P11>!2!8ctSQHBKH0m7cBHBqz11Fx0iVGrlka9340DvIR/Dx7g=!SsvlsLVVZrt/30Dvwcoklw==
```

Return codes

0

Command completed successfully.

1

Command completed unsuccessfully.

runqmc cred (protect authentication token keystore password)

Use the **runqmc cred** command to encrypt the password for the queue manager key repository that contains the trusted authentication token issuer's public key certificates or symmetric keys.

Purpose

The **runqmc cred** command is used to encrypt the queue manager authentication token key repository. The authentication token key repository contains the public key certificates or symmetric keys for trusted authentication token issuers. The path to the key repository and the file that contains the encrypted password are specified in the **AuthToken** stanza in the `qm.ini` file. The queue manager uses the information in the **AuthToken** stanza to verify that the token that an application provides for authentication purposes is issued by a trusted issuer.

The key repository password must be encrypted as it is not secure to store plain text passwords. Copy the encrypted password that is returned by the **runqmcrcd** command into a file, and include the path to the file in the **KeyStorePwdFile** attribute of the **AuthToken** stanza in the `qm.ini` file.

An encryption key, which is known as the initial key, is used to encrypt the password. You can provide a file that contains the initial key when you run the **runqmcrcd** command. Create the initial key file before you run the command. If you do not provide the initial key, the default initial key is used.

CAUTION: The default initial key is the same for all IBM MQ installations. To protect passwords securely, supply an initial key that is unique to your installation when you encrypt passwords.

Important: If you supply an initial key when you encrypt the password, the same initial key must be specified in the queue manager **INITKEY** attribute so that the queue manager can decrypt the password. If the queue manager **INITKEY** attribute is already set, use the same initial key when you run the **runqmcrcd** command. For more information about the queue manager **INITKEY** attribute, see “[UNIX, Linux, Windows, IBM i]INITKEY” on page 432.

Syntax

```
runqmcrcd -sf keyfile -sm
```

Optional parameters

-sf *keyfile*

Path to a file that contains the initial key that is used to encrypt the password. Create this file that contains the initial key before you run the **runqmcrcd** command. The same initial key must be specified in the queue manager **INITKEY** attribute. The file must contain a single line of at least one character.

If this parameter is not specified, the default initial key is used.

-sm

Encrypts passwords using a FIPS compliant cryptographic library.

Examples

The following example encrypts the authentication token key repository password with the initial key that you provide.

Use the **-sf** argument to provide the initial key file path. You are prompted to enter the password to encrypt.

```
runqmcrcd -sf /home/initial.key
```

The command outputs the following text, with the encrypted password on the last line.

```
5724-H72 (C) Copyright IBM Corp. 1994, 2026.  
Enter password:  
*****  
<QM>!2!UnH/9hRXEGA0cenLVSGCW9a0s5A2vHDkTiA7vRv8ogc=!yh1sHFw7MIh48SvaYeTwRQ==
```

The following example encrypts the authentication token keystore password with the default initial key.

```
runqmcrcd
```

The command outputs the following text, with the encrypted password on the last line.

```
5724-H72 (C) Copyright IBM Corp. 1994, 2026.  
Credentials are encrypted using the default encryption key. For more secure  
protection of stored credentials, use a custom, strong encryption key.  
Enter password:  
*****  
<QM>!2!b5rb01sMzFzc1C1ZeQMryruWFM3HSm8DKyEaZK7qzWY=!TrWdU57DCDXM0Qah99I/Lg==
```

Return codes

Table 120. Return code identifiers and descriptions

Return code	Description
0	Command successful
10	Command completed with warnings
20	Command completed with errors

Examples

To display the configuration state of cluster-sender channel T0.QM2:

```
RUNSWCHL -m QM1 -c T0.QM2 -q
```

To switch the transmission queue for cluster-sender channel T0.QM3 without moving the messages on it:

```
RUNSWCHL -m QM1 -c T0.QM3 -n
```

To switch the transmission queue for cluster-sender channel T0.QM3 and move the messages on it:

```
RUNSWCHL -m QM1 -c T0.QM3
```

To display the configuration state of all cluster-sender channels on QM1:

```
RUNSWCHL -m QM1 -c * -q
```

To display the configuration state of all cluster-sender channels with a generic name of T0.*:

```
RUNSWCHL -m QM1 -c T0.* -q
```

[Clustering: Switching cluster transmission queues](#)

setamqp (set AMQP server properties)

Use the **setamqp properties** command to configure AMQP server properties.

The command allows you to individually configure the properties that are specified in the following configuration files:

- amqptraceOn.properties
- amqptraceOff.properties
- amqp_java.properties
- amqp_unix.properties
- amqp_win.properties

Notes:

- From IBM MQ 10.0.0, the AMQP server only supports FIPS 140-3. FIPS 140-2 is no longer supported.
- To enable FIPS 140-3, you need to include two new JVM properties in the amqp_java.properties file. For more information, see [Table 121 on page 246](#).
- FIPS is not supported on Linux s390.

Syntax

```
➤ setamqp properties — -m — QMgrName — -k — name — { -d — | -v — value — | -r — } — -l — ➤
```

Required parameters

-m QMgrName

The queue manager you are setting AMQP properties for.

-k name

The name of the AMQP property that you want to set. You must combine this parameter with one of the following parameters:

-d

Delete the specified AMQP property.

-v value

The value that the property is set to.

-r

Reset the specified property to its default value.

Optional parameters

-l

Enable verbose logging. Diagnostic information is written to a log file.

The following table lists some of the properties can be configured by the **setamqp properties** command on all platforms, including the IBM MQ Appliance. A full list of properties that can be configured using this command can be viewed using the [dspamqp](#) command.

Table 121. AMQP Server Properties and values	
Property	Description
-Dcom.ibm.mq.AMQP.BATCHSZ	Defines the maximum number of acknowledgments to be received before the AMQP service removes messages. The number can be in the range 1 through 9999. If an invalid number is set, or if the specified number is out of range, the default value of 50 is used. See Removing acknowledged AMQP messages from the queue in batches for more information.
-Dcom.ibm.mq.AMQP.BATCHINT	Defines the amount of time, in milliseconds, that the AMQP service keeps acknowledged messages on the queue. The batch is cleared after this duration, even if the batch is not full. You can specify any number of milliseconds, from 1 through 999 999 999. The default value is 50. If you do not specify a value for this attribute, the default value of 50 is used. See Removing acknowledged AMQP messages from the queue in batches for more information.
-Xms<size>	The -Xms option sets the initial and minimum Java heap size. The size is specified in megabytes. For example, -Xms512m. To configure this property, the -v argument must be left empty.

Table 121. AMQP Server Properties and values (continued)	
Property	Description
-Xmx<size>	This option sets the maximum Java heap size. The size is specified in megabytes. For example, -Xmx1024m. To configure this property, the -v argument must be left empty.
handlers	Specifies the log file handler to use. It accepts the values com.ibm.mq.util.logging.MQErrorLogFileHandler, com.ibm.mq.util.logging.MQJSONErrorLogFileHandler, java.util.logging.MemoryHandler, and com.ibm.mq.util.logging.MQCommonServicesHandler. A combination of these can also be used by specifying a comma-separated list.
-Dcom.ibm.mq.MQXR.GenerateHeapDump	Specifies whether or not a Java heap dump is generated when the service encounters a low memory exception. It accepts a value of true and false. If you do not specify a value for this attribute, the default value of false is used.
-Dcom.ibm.mq.MQXR.GenerateJavaDump	Specifies whether or not a Java core dump is generated when an FDC is generated. It accepts a value of true and false. If you do not specify a value for this attribute, the default value of false is used.
com.ibm.mq.MQXR.Workers	The number of server workers the service should use. If not set, the value defaults to the number of processors. See AMQP listener control properties .
com.ibm.mq.MQXR.MQIBindType	The binding type for the service, one of: FASTPATH, SHARED, or ISOLATED. The default is FASTPATH. See AMQP listener control properties .
 -Dsemeru.fips	Specifies that FIPS is enabled when the value is set to TRUE. The default value is FALSE.
 -Dsemeru.customprofile	Defines the cryptographic provider to use with FIPS 140-3. If the AMQP server is running with FIPS 140-3, set this property to OpenJCEPlusFIPS.

Return codes

Table 122. Return code identifiers and descriptions

Return code	Description
0	Command successful
>0	Command not successful

Examples

- The following command enables JSON logging format for the queue manager QM1 by setting the handlers property:

```
setamqp properties -m QM1 -k handlers -v com.ibm.mq.util.logging.MQJSONErrorLogFileHandler
```

- The following command resets the logging format back to its default setting of plain text logs:

```
setamqp properties -m QM1 -k handlers -r
```

- V1000 If **SSLFIPS** is enabled in the queue manager without setting both the **Dsemeru** Java properties, the AMQP service does not start and the following error message is logged:

```
AMQXR2125E: SSLFIPS property is set to YES in the Queue Manager configuration but the FIPS
140-3 JVM system
properties -Dsemeru.fips=true and -Dsemeru.customprofile=OpenJCEPlusFIPS are not set in the
amqp_java.properties file.
```

Related reference

[“dspamqp \(display AMQP server properties\)” on page 81](#)

Use the **dspamqp** command to display the configured AMQP server properties.

setmqaut (grant or revoke authority)

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

For more information about authorization service components, see [Configuring installable services](#), [Service components](#), and [Authorization service interface](#).

For more information about how authorizations work, see [How authorizations work](#).

  On UNIX and Linux systems, the object authority manager (OAM) can use user-based authorization as well as group-based authorization. For more information about user-based authorizations, see [OAM user-based permissions on AIX and Linux systems](#).

  If you specify the **-p** (principal) option, IBM MQ authorization uses groups, instead. This means that if you enter `setmqaut -p username . . .`, the primary group of the specified user is the one that is associated with the authorization being updated.

Note: The previous statement does not apply if you have configured your Object Authority Manager (OAM) to allow users.

Syntax

MQI authorizations

Context authorizations

Administration authorizations

Generic authorizations

Description

Use **setmqaut** both to grant an authorization, that is, give a principal or user group permission to perform an operation, and to revoke an authorization, that is, remove the permission to perform an operation. You can specify a number of parameters:

- Queue manager name
- Principals and user groups
- Object type
- Profile name
- Service component

The authorizations that can be given are categorized as follows:

- Authorizations for issuing MQI calls
- Authorizations for MQI context
- Authorizations for issuing commands for administration tasks
- Generic authorizations

Each authorization to be changed is specified in an authorization list as part of the command. Each item in the list is a string prefixed by a plus sign (+) or a minus sign (-). For example, if you include +put in the authorization list, you grant authority to issue MQPUT calls against a queue. Alternatively, if you include -put in the authorization list, you revoke the authority to issue MQPUT calls.

On AIX, Linux, and Windows, you can use the **SecurityPolicy** attribute to control the queue manager authorization:

-  **Windows** On Windows systems, the **SecurityPolicy** attribute applies only if the service specified is the default authorization service, that is, the OAM. The **SecurityPolicy** attribute allows you to specify the security policy for each queue manager.
-  **Linux**  **AIX** On UNIX and Linux systems, the value of the **SecurityPolicy** attribute specifies whether the queue manager uses user-based or group-based authorization. If you do not include this attribute, the default, which uses group-based authorization, is used.

For more information about the **SecurityPolicy** attribute, see [Service stanza of the qm.ini file](#).

For more information about the effect of user-based authorization as well as group-based authorization, see [OAM user-based permissions on AIX and Linux](#).

You can specify any number of principals, user groups, and authorizations in a single **setmqaut** command, but you must specify at least one principal or user group.

If a principal is a member of more than one user group, the principal effectively has the combined authorities of all those user groups.

 **Windows** On Windows systems, the principal also has all the authorities that are granted to it explicitly using the **setmqaut** command.

 **Linux**  **AIX** On AIX and Linux, if the queue manager uses user-based authorization, the principal has all the authorities that are granted to it explicitly by using the **setmqaut** command. However, if the queue manager uses group-based authorization, all authorities are held by user groups, not by principals. Granting authorities to groups has the following implications:

- If you use the **setmqaut** command to grant an authority to a principal, the authority is granted to the primary user group of the principal. This means that the authority is effectively granted to all members of that user group.
- If you use the **setmqaut** command to revoke an authority from a principal, the authority is revoked from the primary user group of the principal. This means that the authority is effectively revoked from all members of that user group.

Attention: The SYSTEM.AUTH.DATA.QUEUE object contains sensitive authorization data.

Regardless of the broader permissions that are assigned by using the **setmqaut** command, a non mqm user or group is only granted the display (dsp) authority to the SYSTEM.AUTH.DATA.QUEUE queue manager system object. For example, if a non mqm user or group is granted +all authority on system queues, the permission to SYSTEM.AUTH.DATA.QUEUE remains restricted to display only. No additional authorities are granted to this object.

This access behavior is by design, which enforces stricter protection of the SYSTEM.AUTH.DATA.QUEUE object when you apply broader permissions.

To alter authorizations for a cluster sender channel that has been automatically generated by a repository, see [Channel definition commands](#).

Required parameters

-t *ObjectType*

The type of object for which to change authorizations.

Possible values are as follows:

Table 123. <i>ObjectType</i> values.	
Value	Description
authinfo	An authentication information object
channel or chl	A channel
clntconn or clcn	A client connection channel
comminfo	A communication information object
listener or lstr	A listener
namelist or nl	A namelist
process or prcs	A process
queue or q	A queue
qmgr	A queue manager
rqmname or rqmn	A remote queue manager name
service or srvc	A service
topic or top	A topic

-n *Profile*

The name of the profile for which to change authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified. The profile name can be generic, using wildcard characters to specify a range of names as explained in [Using OAM generic profiles on AIX, Linux, and Windows systems](#).

This parameter is required, unless you are changing the authorizations of a queue manager, in which case you must not include it. To change the authorizations of a queue manager use the queue manager name, for example

```
setmqaut -m QMGR -t qmgr -p user1 +connect
```

where *QMGR* is the name of the queue manager and *user1* is the principal for which you are adding or removing permissions.

Each class of object has authority records for each group or principal. These records have the profile name @CLASS and track the crt (create) authority common to all objects of that class. If the crt authority for any object of that class is changed then this record is updated. For example:

```
profile:  @class
object type: queue
entity:   test
entity type: principal
authority: crt
```

This shows that members of the group test have crt authority to the class queue.

Attention: You cannot delete the @CLASS entries (the system is working as designed)

Optional parameters

-m *QMgrName*

The name of the queue manager of the object for which to change authorizations. The name can contain up to 48 characters.

This parameter is optional if you are changing the authorizations of your default queue manager.

-p *PrincipalName*

The name of the principal for which to change authorizations.

Windows For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see [Principals and groups on AIX, Linux, and Windows](#).

You must have at least one principal or group.

-g *GroupName*

The name of the user group for which to change authorizations. You can specify more than one group name, but each name must be prefixed by the -g flag.

Windows For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

The IBM MQ Object Authority Manager validates the users and groups at the domain level, only if you set the **GroupModel** attribute to *GlobalGroups* in the [Securing](#) stanza of the queue manager.

-u *SID*

The SID for which authorities are to be removed. You can specify more than one SID, but each name must be prefixed by the -u flag.

This option must be used with either +remove or -remove.

This parameter is only valid on IBM MQ for Windows.

-s *ServiceComponent*

The name of the authorization service to which the authorizations apply (if your system supports installable authorization services). This parameter is optional; if you omit it, the authorization update is made to the first installable component for the service.

+remove or -remove

Remove all the authorities from IBM MQ objects that match the specified profile.

Authorizations

The authorizations to be granted or revoked. Each item in the list is prefixed by a plus sign (+) or a minus sign (-). The plus sign indicates that authority is to be granted. The minus sign indicates that authority is to be revoked.

For example, to grant authority to issue MQPUT calls, specify +put in the list. To revoke the authority to issue MQPUT calls, specify -put.

Table 124 on page 254 shows the authorities that can be given to the different object types.

Table 124. Specifying authorities for different object types												
Authority	Queue	Process	Queue manager	Remote queue manager name	Name list	Topic	Auth info	Clntconn	Channel	Listener	Service	Commit
all ¹	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
alladm ²	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
allmqi ³	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No	No	No
none	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes
altusr	No	No	Yes	No	No	No	No	No	No	No	No	No
browse	Yes	No	No	No	No	No	No	No	No	No	No	No
chg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
clr	Yes	No	No	No	No	Yes	No	No	No	No	No	No
connect	No	No	Yes	No	No	No	No	No	No	No	No	No
crt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
ctrl ⁴	No	No	Yes	No	No	Yes	No	No	Yes	Yes	Yes	No
ctrlx	No	No	No	No	No	No	No	No	Yes	No	No	No
dlt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
dsp	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
get	Yes	No	No	No	No	No	No	No	No	No	No	No
pub	No	No	No	No	No	Yes	No	No	No	No	No	No
put	Yes	No	No	Yes	No	No	No	No	No	No	No	No
inq	Yes	Yes	Yes	No	Yes	No	Yes	No	No	No	No	No
passall	Yes	No	No	No	No	No	No	No	No	No	No	No
passid	Yes	No	No	No	No	No	No	No	No	No	No	No
resume	No	No	No	No	No	Yes	No	No	No	No	No	No

Table 124. Specifying authorities for different object types (continued)

Autho rity	Queue	Proce ss	Queue manag er	Remot e queue manag er name	Namel ist	Topi c	Auth info	Clntc onn	Chann el	Liste ner	Servi ce	Comm info
set	Yes	Yes	Yes	No	No	No	No	No	No	No	No	No
setal l ⁵	Yes	No	Yes	No	No	No	No	No	No	No	No	No
setid ⁵	Yes	No	Yes	No	No	Yes	No	No	No	No	No	No
sub	No	No	No	No	No	Yes	No	No	No	No	No	No
system	No	No	Yes	No	No	No	No	No	No	No	No	No

Notes:

1. The authority `all` is equivalent to the union of the authorities `alladm`, `allmqi`, and `system` appropriate to the object type.
2. The authority `alladm` is equivalent to the union of the individual authorities `chg`, `clr`, `dlt`, `dsp`, `ctrl`, and `ctrlx` appropriate to the object type. `crt` authority is not included in the subset `alladm`.
3. The authority `allmqi` is equivalent to the union of the individual authorities `altusr`, `browse`, `connect`, `get`, `inq`, `pub`, `put`, `resume`, `set`, and `sub` appropriate to the object type.
4. The authority `ctrl` on the `qmgr` object is included when the you specify `alladm` on the **setmqaut** command.
5. To use `setid` or `setall` authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object. `setid` and `setall` are included in `allmqi`.

Description of specific authorities

You should not grant a user an authority (for example, `set` authority on a queue manager, or `system` authority) that allows the user to access IBM MQ privileged options, unless the required authority is specifically documented, and required to run any IBM MQ command, or IBM MQ API call.

For example, a user requires `system` authority to run the **setmqaut** command.

chg

A user needs `chg` authority to make any authorization changes on the queue manager. The authorization changes include:

- Changing the authorizations to a profile, object, or class of objects
- Creating and modifying channel authentication records, and so on

A user also needs `chg` authority to change or set the attributes of an IBM MQ object, using PCF or MQSC commands.

ctrl

Within CHLAUTH rules it is possible to insist that users connecting are not privileged.

For the channel to check whether a user is privileged, the real user id running the channel process must have `+ctrl` authority on the `qmgr` object.

For example, when the SVRCONN channel is running as a thread in an amqrmppa process and the real uid for this process is a userid named mqadmin (the userid that started the queue manager), then mqadmin must have +ctrl authority on the qmgr object.

crt

If you grant an entity +crt authority to the queue manager, then that entity also gains +crt authority for each object class.

However, when you remove +crt authority against the queue manager object that only removes the authority on the queue manager object class; crt authority for other objects classes are not removed.

Note that crt authority on the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

dlt

Note that the dlt authority against the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

set

A user needs set authority against the queue to change or set the attributes of a queue using the MQSET API call.

set authority on the queue manager is not required for any administrative purpose, or for any application connecting to the queue manager.

However, a user needs set authority against the queue manager to set privileged connection options.

Note that set authority on the process object has no functional use, and is available for backwards-compatibility purposes only.

Important: Privileged connection options are internal to the queue manager and are not available in IBM MQ API calls used by IBM MQ applications.

system

The **setmqaut** command makes a privileged IBM MQ connection to the queue manager.

Any user who runs IBM MQ commands that makes a privileged IBM MQ connection needs system authority on the queue manager.

Return codes

Table 125. Return code identifiers and descriptions

Return code	Explanation
0	Successful operation
26	Queue manager running as a standby instance
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
133	Unknown object name

Table 125. Return code identifiers and descriptions (continued)

Return code	Explanation
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing
150	Authorization specification missing
151	Invalid authorization specification

Examples

Note: When using a name that includes wildcard characters, wrapping the name in single or double quotation marks can be important, depending on how a script is being used and what the parameters are. Single quotation marks, which are used in the code examples, always work for UNIX, AIX, Linux, and Windows on PowerShell. For scripts run from the Windows command prompt, use double quotation marks.

1. This example shows a command that specifies that the object on which authorizations are being given is the queue orange.queue on queue manager saturn.queue.manager.

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue
        -g tango +inq +alladm
```

The authorizations are given to a user group called tango, and the associated authorization list specifies that the user group can:

- Issue MQINQ calls
- Perform all administration operations on that object

2. In this example, the authorization list specifies that a user group called foxy:

- Cannot issue any MQI calls to the specified queue
- Can perform all administration operations on the specified queue

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue
        -g foxy -allmqi +alladm
```

3. This example gives user1 full access to all queues with names beginning a.b. on queue manager qmgr1. The profile applies to any object with a name that matches the profile.

```
setmqaut -m qmgr1 -n 'a.b.*' -t q -p user1 +all
```

4. This example deletes the specified profile.

```
setmqaut -m qmgr1 -n 'a.b.*' -t q -p user1 -remove
```

5. This example creates a profile with no authority.

```
setmqaut -m qmgr1 -n 'a.b.*' -t q -p user1 +none
```

Table 126. IBM MQ MQSC commands and their purpose	
Command name	Purpose

[OAM user-based permissions on AIX and Linux](#)

Authorizations for MQI calls

Available values for authorizing MQI calls

Table 127. Authorizations for MQI calls.

Value	Description
altusr	Use another user's authority for the queue manager. Also required for channel operations where the asserting userid is different from the one associated with the connection handle. (For example, an assigned dedicated profile on the receiver MCA end, or when processing a RESET CHL SEQNUM() request from remote systems.)
browse	Retrieve a message from a queue using an MQGET call with the BROWSE option.
connect	Connect the application to the specified queue manager using an MQCONN call.
get	Retrieve a message from a queue using an MQGET call.
inq	Make an inquiry on a specific queue using an MQINQ call.
pub	Publish a message on a topic using the MQPUT call.
put	Put a message on a specific queue using an MQPUT call.
resume	Resume a subscription using the MQSUB call.
set	Set attributes on a queue from the MQI using an MQSET call.
sub	Create, alter or resume a subscription to a topic using the MQSUB call.

Note: If you open a queue for multiple options, you must be authorized for each option.

Authorizations for context

Available values for authorizing context

Table 128. Authorizations for context.	
Value	Description
passall	Pass all context on the specified queue. All the context fields are copied from the original request.
passid	Pass identity context on the specified queue. The identity context is the same as that of the request.
setall	Set all context on the specified queue. This is used by special system utilities.
setid	Set identity context on the specified queue. This is used by special system utilities. In order to modify any of the message context options, you must have the appropriate authorizations to issue the call. For example, in order to use MQOO_SET_IDENTITY_CONTEXT or MQPMO_SET_IDENTITY_CONTEXT, you must have +setid permission.

Note: To use setid or setall authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object.

Authorizations for commands

Available values for authorizing commands

Table 129. Authorizations for commands.	
Value	Description
chg	Change the attributes of the specified object.
clr	Clear the specified queue or a topic.
crt	Create objects of the specified type.
dlt	Delete the specified object. Note, that the dlt authority has no effect on a queue manager object.
dsp	Display the attributes of the specified object.
ctrl	For listeners and services, start and stop the specified channel, listener, or service. For channels, start, stop, and ping the specified channel. For topics, define, alter, or delete subscriptions.
ctrlx	Reset or resolve the specified channel.

Multi Authorizations for generic operations

Available values for authorizing generic operations

Table 130. Authorizations for generic operations.	
Value	Description
all	Use all operations applicable to the object. all authority is equivalent to the union of the authorities alladm, allmqi, and system appropriate to the object type.
alladm	Use all administration operations applicable to the object.
allmqi	Use all MQI calls applicable to the object.
none	No authority. Use this authorization to create profiles without authority. When an authority is given to an object or group that was previously showing "none", then the authorization changes to the authority just applied. However, when the "none" authorization is added to an object or group with an existing alternative authority, the authority does not change.
system	Use queue manager for internal system operations.

Windows setmqcrl (set CRL LDAP server definitions)

Use the **setmqcrl** command to configure and administer support for publishing certificate revocation list (CRL) LDAP definitions in an Active Directory (Windows only).

A domain administrator must use this command, or **setmqscp**, to prepare the Active Directory for IBM MQ usage, and to grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects. You can also use the **setmqcrl** command to display all the currently configured CRL server definitions available on the Active Directory, that is, those definitions referred to by the queue manager's CRL namelist.

The only types of CRL servers supported are LDAP servers.

Syntax

Optional parameters

You must specify one of -a (add), -r (remove) or -d (display).

-a

Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called CN=IBM-MQClientConnections. Do not delete this folder in any other way than by using the **setmqscp** command.

-d

Displays the IBM MQ CRL server definitions.

-r

Removes the IBM MQ CRL server definitions.

-m [* | qmgr]

Modifies the specified parameter (**-a** or **-x**) so that only the specified queue manager is affected. You must include this option with the **-a** parameter.

*** | qmgr**

* specifies that all queue managers are affected. This enables you to migrate a specific IBM MQ CRL server definitions file from one queue manager alone.

Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently. (In this, it is functionally equivalent to `setmqscp -a`.)

```
setmqcrl -a
```

The following command migrates existing CRL server definitions from a local queue manager, Paint.queue.manager, to the Active Directory.

Note: The command first deletes any other CRL definitions from the Active Directory.

```
setmqcrl -a -m Paint.queue.manager
```

setmqenv (set IBM MQ environment)

Use the **setmqenv** command to set up automatically the IBM MQ environment on AIX, Linux, and Windows.

Alternatively, you can use the **crtmqenv** command to create a list of environment variables and values to manually set each environment variable for your system. See [“crtmqenv \(create IBM MQ environment\)”](#) on page 39.

Note: Any changes you make to the environment are not persistent. If you log out, and log in again, your changes are lost.

You can specify which installation the environment is set up for by specifying a queue manager name, an installation name, or an installation path. You can also set up the environment for the installation that issues the **setmqenv** command by issuing the command with the **-s** parameter.

The **setmqenv** command sets the following environment variables, appropriate to your system:

- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ_DATA_PATH
- MQ_ENV_MODE
- MQ_FILE_PATH
- MQ_INSTALLATION_NAME
- MQ_INSTALLATION_PATH
- MQ_JAVA_INSTALL_PATH
- MQ_JAVA_DATA_PATH
- MQ_JAVA_LIB_PATH

- MQ_JAVA_JVM_FLAG
- MQ_JRE_PATH
- PATH

Usage notes

- The **setmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment for. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **setmqenv** command. For example, if you want to add `MQ_INSTALLATION_PATH/java/lib` to `LD_LIBRARY_PATH`, you must do so after running the **setmqenv** command.
- In some shells, command-line parameters cannot be used with **setmqenv** and any **setmqenv** command issued is assumed to be a `setmqenv -s` command. The command produces an informational message that the command has been run as if a `setmqenv -s` command had been issued. Therefore, in these shells you must ensure that you issue the command from the installation for which you want to set the environment for. In these shells, you must set the `LD_LIBRARY_PATH` variable manually. Use the **crtmqenv** command with the **-l** or **-k** parameter to list the `LD_LIBRARY_PATH` variable and value. Then use this value to set the `LD_LIBRARY_PATH`.

Syntax

Optional Parameters

-m *QMgrName*

Set the environment for the installation associated with the queue manager *QMgrName*.

-n *InstallationName*

Set the environment for the installation named *InstallationName*.

-p *InstallationPath*

Set the environment for the installation in the path *InstallationPath*.

-r

Remove all installations from the environment.

-s

Set the environment for the installation that issued the **setmqenv** command.

Linux AIX -k

Applies to AIX and Linux only. If the **-k** flag is specified:

- **AIX** On AIX, the `LIBPATH` environment variable is set.
- **Linux** On Linux, the `LD_LIBRARY_PATH` environment variable is set.

Include the `LD_LIBRARY_PATH` or `LIBPATH` environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current `LD_LIBRARY_PATH` or `LIBPATH` variable.

Applies to AIX and Linux only. If the **-l** flag is specified:

-  On AIX, the `LIBPATH` environment variable is set.
-  On Linux, the `LD_LIBRARY_PATH` environment variable is set.

Include the `LD_LIBRARY_PATH` or `LIBPATH` environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current `LD_LIBRARY_PATH` or `LIBPATH` variable.

-x Mode

Mode can take the value 32 or 64.

Create a 32-bit or 64-bit environment. If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.

Any attempt to display a 64-bit environment with a 32-bit installation fails.

-j Version

Version can take the value 2.0, or 3.0.

-  If you specify **-j 2.0** the `CLASSPATH` environment variable is changed to include the JAR files necessary to run JMS 2.0 applications. This is the default if **-j** is not specified.
-  If you specify **-j 3.0** the `CLASSPATH` environment variable is changed to include the JAR files necessary to run Jakarta Messaging 3.0 applications.

IBM MQ 9.3.0 introduced support for [Jakarta Messaging 3.0](#). JMS 2.0 is still fully supported.

Return codes

Table 131. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following examples assume that a copy of IBM MQ is installed in the `/opt/mqm` directory on AIX and Linux systems.

Notes:

- The period character (`.`) used at the beginning of each command makes the **setmqenv** script run in the current shell. Therefore, the environment changes made by the **setmqenv** script are applied to the current shell. Without the period character (`.`), the environment variables are changed in another shell, and the changes are not applied to the shell from which the command is issued.
- Some shells, for example the Ubuntu 18.04 default shell, do not pass parameters when you use the period character at the beginning of a command. If you are using such a shell, the following warning is issued and any parameters to the command are ignored:

```
$ . /opt/mqm/bin/setmqenv -sAMQ8588W: No parameter was detected.
```

The environment has been set for the installation from which the **setmqenv** command was issued.

To pass parameters into **setmqenv** for such shells, you must use the following environment variable:
MQ_ENV_OPTIONS=*<your options>*.

For example, to remove IBM MQ from the environment, issue the command:

```
$ MQ_ENV_OPTIONS=-x . /opt/mqm/bin/setmqenv
```

- The following command sets up the environment for an installation installed in the /opt/mqm directory:

```
. /opt/mqm/bin/setmqenv -s
```

- The following command sets up the environment for an installation installed in the /opt/mqm2 directory, and includes the path to the installation at the end of the current value of the `LD_LIBRARY_PATH` variable:

```
. /opt/mqm/bin/setmqenv -p /opt/mqm2 -l
```

- The following command sets up the environment for queue manager QM1 in a 32-bit environment:

```
. /opt/mqm/bin/setmqenv -m QM1 -x 32
```

Windows The following example assumes that a copy of IBM MQ is installed in C:\Program Files\IBM\MQ on a Windows system. This command sets up the environment for an installation called Installation1:

```
"C:\Program Files\IBM\MQ\bin\setmqenv.cmd" -n Installation1
```

Related concepts

[Multiple installations](#)

Related tasks

[Choosing a primary installation](#)

Related reference

[“crtmqenv \(create IBM MQ environment\)” on page 39](#)

Create a list of environment variables for an installation of IBM MQ, on AIX, Linux, and Windows.

Multi **setmqinst** (set IBM MQ installation)

Set IBM MQ installations on Multiplatforms. You can use the **setmqinst** command to change the installation description of an installation, to set or unset an installation as the primary installation, or to set the entitlement of the installation.

To change the primary installation, you must unset the current primary installation before you can set a new primary installation. This command updates information contained in the `mqinst.ini` file.

After unsetting the primary installation, the **setmqinst** command is not available unless you specify the full path or have an appropriate installation directory on your PATH (or equivalent). The default path in a system standard location will have been deleted.

You can use the **dspmqinst** command to display the installations.

Linux **AIX** On AIX and Linux, you should not assume that the current directory is in the path. If you are in /opt/mqm/bin and want to run, for example, /opt/mqm/bin/dspmqver, you need to enter **"/opt/mqm/bin/dspmqver"** or **"./dspmqver"**.

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see [Installation configuration file, mqinst.ini](#).

ALW On AIX and Linux, you must run this command as root. On Windows, you must run this command as a member of the Administrators group. The command does not have to be run from the installation you are modifying.

Note: By default, user mqm does not have sufficient authority to use this command.

IBM i From IBM MQ 9.3.0, this command is supported on IBM i to set and unset HA Replica and Non-Production IBM License Metric Tool (ILMT) tags for an installation.

Syntax

Action

Installation

Entitlement

Parameters

-d *DescriptiveText*

Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use double quotation marks around the text if it contains spaces.

-i

Set this installation as the primary installation.

-x

Unset this installation as the primary installation.

-n *InstallationName*

The name of the installation to modify.

-p *InstallationPath*

The path of the installation to modify, for example, opt/mqm. You must use double quotation marks around the path if it contains spaces.

-l *entitlement* -e y|yes|n|no

Set or unset the entitlement of the installation.

The entitlement can be set only if an applicable component is installed and entitlement is not already set to IBM MQ Advanced for Developers. *entitlement* is one of the following values:

hareplica

Sets the entitlement to High Availability Replica.

The hareplica entitlement cannot be set with the IBM MQ Advanced (Non-production) entitlement.

V1000 This setting is mutually exclusive with nha.

V1000 nha

Sets the entitlement for the chargeable system in a Native High Availability (Native HA) group. Add this if you have IBM MQ Server or IBM MQ for Non-Production installed and have purchased the Native HA add-on.

One of the systems in a Native HA group must be entitled using either this Add-On or as IBM MQ Advanced.

This setting is mutually exclusive with `hareplica` and `nhareplica`.

nhareplica

Sets the entitlement to Native HA Replica. Add this to mark the installation as a Native HA replica if you have IBM MQ Advanced, IBM MQ Advanced (Non-production), IBM MQ Server, or IBM MQ for Non-Production entitlement set.

This setting is mutually exclusive with `nha` and `hareplica`.

advanced

Sets the entitlement to IBM MQ Advanced.

nonprod

From IBM MQ 9.4.0, sets the entitlement to IBM MQ (Non-Production) or IBM MQ Advanced (Non-Production), depending on whether the installation is IBM MQ Advanced or not.

The `nonprod` entitlement cannot be set with the High Availability Replica entitlement. The server component must be installed to set this entitlement.

 From IBM MQ 9.3.0, you can set the options of `hareplica` and `nonprod` for *entitlement* on IBM i.

The entitlement is picked up automatically by the IBM License Metric Tool (ILMT) after it is set. See [IBM MQ license information](#).

Use **-e y** or **-e yes** to set the entitlement.

Use **-e n** or **-e no** to unset the entitlement.

Return codes

Table 132. Return code identifiers and descriptions

Return code	Description
0	Entry set without error
36	Invalid arguments supplied
37	Descriptive text was in error
 39	Licensed entitlement not valid for installation
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file
98	Insufficient authority to access ini file
131	Resource problem

Examples

1. This command sets the installation with the name of `myInstallation` as the primary installation:

```
setmqinst -i -n myInstallation
```

2. This command sets the installation with an installation path of `/opt/myInstallation` as the primary installation:

```
setmqinst -i -p /opt/myInstallation
```

3. This command unsets the installation named `myInstallation` as the primary installation:

```
setmqinst -x -n myInstallation
```

4. This command unsets the installation with an installation path of /opt/myInstallation as the primary installation:

```
setmqinst -x -p /opt/myInstallation
```

5. This command sets the descriptive text for the installation named myInstallation:

```
setmqinst -d "My installation" -n myInstallation
```

The descriptive text is enclosed in quotation marks as it contains spaces.

6. This command specifies that the installation at /opt/myInstallation has High Availability Replica entitlement:

```
setmqinst -l hareplica -e yes -p /opt/myInstallation
```

7. This command specifies that the installation myInstallation does not have High Availability Replica entitlement:

```
setmqinst -l hareplica -e no -n myInstallation
```

8. This command specifies that the installation myInstallation has non-production entitlement:

```
setmqinst -l nonprod -e y -n myInstallation
```

9. This command specifies that the installation at /opt/myInstallation does not have non-production entitlement:

```
setmqinst -l nonprod -e n -p /opt/myInstallation
```

10.  This command specifies that the installation at /opt/myInstallation has Native HA entitlement:

```
setmqinst -l nha -e y -p /opt/myInstallation
```

11.  This command specifies that the installation at /opt/myInstallation does not have Native HA entitlement:

```
setmqinst -l nha -e n -p /opt/myInstallation
```

[Choosing a primary installation](#)

[Changing the primary installation](#)

setmqm (set queue manager)

Use the **setmqm** command to set the associated IBM MQ installation of a queue manager. The queue manager can then be administered using only the commands of the associated installation. For example, when a queue manager is started with **strmqm**, it must be the **strmqm** command of the installation that was specified by the **setmqm** command.

For more information about using this command, including information about when to use it, see [Associating a queue manager with an installation](#).

This command is only applicable to AIX, Linux, and Windows.

Usage notes

- You must use the **setmqm** command from the installation you want to associate the queue manager with.

- The installation name specified by the **setmqm** command must match the installation from which the **setmqm** command is issued.
- You must stop the queue manager before executing the **setmqm** command. The command fails if the queue manager is still running.
- Once you have set the associated installation of a queue manager using the **setmqm** command, migration of the queue manager's data occurs when you start the queue manager using the **strmqm** command.
- Once you have started the queue manager on an installation, you cannot then use **setmqm** to set the associated installation to an earlier version of IBM MQ, as it is not possible to migrate back to earlier versions of IBM MQ.
- You can find out which installation is associated with a queue manager by using the **dspmq** command. See [“dspmq \(display queue managers\)”](#) on page 82 for more information.

Syntax

➤ **setmqm** — **-m** — *QMgrName* — **-n** — *InstallationName* ➤

Required Parameters

-m *QMgrName*

The name of the queue manager to set the associated installation for.

-n *InstallationName*

The name of the installation that the queue manager is to be associated with. The installation name is not case-sensitive.

Return codes

Table 133. Return code identifiers and descriptions

Return code	Description
0	Queue manager set to an installation without error
5	Queue manager running
36	Invalid arguments supplied
59	Invalid installation specified
60	Command not executed from the installation named by the -n parameter
61	Invalid installation name for this queue manager
69	Resource problem
71	Unexpected error
72	Queue manager name error
119	User not authorized

Examples

1. This command associates a queue manager QMGR1, with an installation with the installation name of myInstallation.

```
MQ_INSTALLATION_PATH/bin/setmqm -m QMGR1 -n myInstallation
```

Multi **setmqprd (enroll production license)**

Enroll an IBM MQ production license. A license is normally enrolled as part of the installation process.

Note: You must have the appropriate privileges to run this command on your system. AIX and Linux require root access, and Windows with UAC (User Account Control) requires Administrator access to run this command.

Syntax

```
➤ setmqprd — LicenseFile ➤
```

Required parameters

LicenseFile

Specifies the fully-qualified name of the production license certificate file.

The full license file is `amqpcert.lic`:

- **Linux** **AIX** On AIX and Linux, it is in the `/MediaRoot/licenses` directory on the installation media.
- **Windows** On Windows it is in the `\MediaRoot\licenses` directory on the installation media. It is installed into the `bin` directory on the IBM MQ installation path.
- **IBM i** On IBM i, issue the command

```
CALL PGM(QMQM/SETMQPRD) PARM('LICENSE_PATH/amqpcert.lic')
```

where `LICENSE_PATH` is the path to the `amqpcert.lic` file that you obtained.

Trial license conversion

A trial license installation is identical to a production license installation, except for the "count-down" message that is displayed when you start a queue manager on an installation with a trial license. Parts of IBM MQ that are not installed on the server, such as the IBM MQ MQI client, continue to work after the expiry of the trial license. You do not need to run **setmqprd** to enroll them with a production license.

When a trial license expires, you can still uninstall IBM MQ. You can also reinstall IBM MQ with a full production license.

Run **setmqprd** to enroll a production license after installing and using a installation with a trial license.

Related tasks

- **AIX** [Converting a trial license on AIX](#)
- **IBM i** [Converting a trial license on IBM i](#)
- **Linux** [Converting a trial license on Linux](#)
- **Windows** [Converting a trial license on Windows](#)

Windows setmqscp (set service connection points)

Use the **setmqscp** command to configure and administer support for publishing client connection channel definitions in an Active Directory. (Windows only).

Initially, this command is used by a domain administrator to:

- Prepare the Active Directory for IBM MQ use

- Grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects

You can also use the **setmqscp** command to display all the currently configured client connection channel definitions available on the Active Directory.

Syntax

Optional parameters

You must specify one of -a (add), -r (remove) or -d (display).

-a

Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called CN=IBM-MQClientConnections. Do not delete this folder in any other way than by using the `setmqscp -r` command.

-d

Displays the service connection points.

-r

Removes the service connection points. If you omit **-m**, and no client connection definitions exist in the IBM-MQClientConnections folder, the folder itself is removed from the Active Directory.

-m [* | qmgr]

Modifies the specified parameter (-a or -r) so that only the specified queue manager is affected.

* | qmgr

* specifies that all queue managers are affected. This enables you to migrate a specific client connection table file from one queue manager alone, if required.

Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently:

```
setmqscp -a
```

The following command migrates existing client connection definitions from a local queue manager, Paint.queue.manager, to the Active Directory:

```
setmqscp -a -m Paint.queue.manager
```

The following command migrates all client connection definitions on the local server to the Active Directory:

```
setmqscp -a -m *
```

Return codes

Table 134. Return code identifiers and descriptions

Return code	Description
0	Successful operation

setmqspl (set security policy)

Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.  On z/OS you use the command with the CSQOUTIL utility.

Before you begin

The queue manager on which you want to operate must be running.

 You must grant the necessary +connect, +inq and +chg authorities, using the [setmqaut](#) command, to connect to the queue manager and create a security policy.

 For more information on the authorities needed to run this command on z/OS see “Specific security information” on page 3014 in the CSQOUTIL topic.

For more information about configuring security see [Setting up security](#).

Syntax

¹ If an encryption algorithm is selected, a recipient DN must also be provided.

² If an author DN is provided, a signing algorithm must also be selected.

Table 135. *setmqspl* command flags

Command flag	Explanation
-m	Queue manager name. This flag is mandatory for all actions on security policies.
-p	Policy name. Set the policy name to the name of the queue you want the policy to apply to.
-e	Digital encryption algorithm. Advanced Message Security supports the following encryption algorithms: •  RC2 V 10.0.0 “1” on page 274 •  DES V 10.0.0 “1” on page 274 •  3DES V 10.0.0 “1” on page 274 • AES128 • AES256 The default value is NONE. Important: • The name of the encryption algorithm must be provided in uppercase •  z/OS On z/OS encryption algorithm  RC2 is not supported for confidentiality policies.
-r	The distinguished name (DN) of the message recipient (if provided, the certificate pertaining to the DN is used to encrypt a given message). Recipients can be specified, only if the encryption algorithm is different from NONE. Multiple recipients can be included for a message. Each DN must be provided with a separate -r flag. Important: • DN attribute names must be in uppercase. • Commas must be used as a name separators. • To avoid command interpreter errors, place quotation marks around the DNs. For example: <pre>-r "CN=alice, O=ibm, C=US"</pre>

Table 135. *setmqspl* command flags (continued)

Command flag	Explanation
-a	Signature DN that is validated during message retrieval. Only messages signed by a user with a provided DN are accepted during the retrieval. Signature DNs can be specified only if the signature algorithm is different from NONE. Multiple authorized signers can be specified, each authorized signer needs to have a separate -a flag. Important: The attribute in the DN name must be in uppercase. Specify CN= rather than cn=. The attribute values in the DN are case sensitive so, for example, CN=USERID1 is different from CN=userid1.
-s	Digital signature algorithm. Advanced Message Security supports the following values: •  MD5 VS18000 “1” on page 274 •  SHA-1 • SHA-2 family: – SHA256 – SHA384 (minimum key length acceptable - 768 bits) – SHA512 (minimum key length acceptable - 768 bits) All must be in uppercase. The default value is NONE. Important: • For the SHA384 and SHA512 cryptographic hash functions, keys used for signing must be longer than 768 bits. • The name of the signature algorithm must be provided in uppercase. • From IBM MQ 9.0, with the Confidentiality policy, the signature algorithm must be NONE. For more information about the Confidentiality policy, see Qualities of protection available with AMS.

Table 135. *setmqspl* command flags (continued)

Command flag	Explanation
-t	The toleration flag indicates whether messages that do not meet the requirements of the policy can still be successfully browsed or retrieved by an application. Toleration may be useful for example when introducing a policy to a queue which already contains unprotected messages. Valid values include: • 0 (default) Toleration flag off. • 1 Toleration flag on. Toleration is optional and facilitates staged implementation, where policies were applied to queues but those queues may already contain messages that have no policy, or still receive messages from remote systems that do not have the security policy set.
-c	The key reuse count can be provided as an integer from 1 through 9,999,999. Special values are: • 0 Keys are not reused. • * Allows applications to reuse an encryption key an unlimited number of times. If you omit the -c parameter when defining a policy, a key reuse count of 0 is assumed for backwards compatibility with previous versions of Advanced Message Security and IBM WebSphere MQ Extended Security Edition. Note that a non-zero key reuse count is only valid for a confidentiality policy. If you attempt to create or modify an integrity or privacy policy, with a non-zero key reuse count, you receive error message AMQ9091: Key reuse is not valid for policy and the policy operation fails.
-remove	Delete policy. Only the policy name flag, -p is valid for use in combination with this flag.

Notes:

1.  Not available when queue manager is configured for FIPS. Attempting to set it results in an AMQ9111 error. For more information see [FIPS mode in AMS](#).

Examples

The following list shows examples of some valid **setmqsp1** commands on [Multiplatforms](#):

```
setmqsp1 -m QMGR -p PROT -s SHA256
setmqsp1 -m QMGR -p PROT -s SHA256 -a "CN=Alice, O=IBM, C=US"
setmqsp1 -m QMGR -p PROT -s SHA256 -e AES128 -a "CN=Alice, O=IBM, C=US" -r "CN=Bob, O=IBM, C=GB"
setmqsp1 -m QMGR -p PROT -e AES128 -r "CN=Bob, O=IBM, C=GB" -c 50
```

The following list shows examples of **setmqsp1** commands that are not valid:

- No recipients specified:

```
setmqsp1 -m QMGR -p PROT -e AES128
```

- Key reuse not valid for an Integrity policy:

```
setmqsp1 -m QMGR -p PROT -s SHA256 -c 1
```

- Key reuse is not valid for a Privacy policy:

```
setmqsp1 -m QMGR -p PROT -s SHA256 -e AES128 -r "CN=Bob, O=IBM, C=GB" -c 1
```

Related reference

[“SET POLICY \(set security policy\) on Multiplatforms” on page 1054](#)

Use the MQSC command **SET POLICY** to set a security policy.

[“DISPLAY POLICY \(display a security policy\) on Multiplatforms” on page 850](#)

Use the MQSC command **DISPLAY POLICY** to display a security policy.

[“dspmqsp1 \(display security policy\)” on page 115](#)

Use the **dspmqsp1** command to display a list of all policies and details of a named policy.  On z/OS you use the command with the CSQOUTIL utility.

setmqweb pid (set mqweb server product ID)

Use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under on z/OS.

By default, on z/OS, the mqweb server runs under the PID that is chosen when you use the **crtmqweb** command.

Before using **setmqweb pid**, ensure that the mqweb server has been stopped by using the MVS **STOP** command on the mqweb server started task.

For more information on PIDs and how they are used on z/OS, see [Product usage recording with IBM MQ for z/OS products](#).

Using the **setmqweb pid** command on z/OS

Before you issue either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the **WLP_USER_DIR** environment variable so that the variable points to your mqweb server configuration.

To set the **WLP_USER_DIR** environment variable, enter the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory that is passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

For more information, see [Create the mqweb server](#).

You must also set the **JAVA_HOME** environment variable to reference a 64-bit version of Java on your system.

The user ID running the command needs write access to the following directories:

- *WLP_user_directory* and its subdirectories.
- /tmp or to another directory that is referenced by the *TMPDIR* variable. If you do not have access to /tmp, the command fails with message FSUMF315 Cannot define temporary file. If you need to set the *TMPDIR* variable, issue the following command in the z/OS UNIX shell: `export TMPDIR=user_directory`

Syntax

➤ `setmqweb` — `pid` — `-p` — `pid_name` — `-l`

Parameters

Before using **setmqweb pid**, ensure that the mqweb server has been stopped by using the MVS **STOP** command on the mqweb server started task.

-p *pid_name*

Specifies the PID that the mqweb server runs under. *pid_name* is one of the following values:

MQ

The mqweb server runs under IBM MQ for z/OS (5656-MQA)

VUE

The mqweb server runs under IBM MQ for z/OS Value Unit Edition (5656-VUA)

ADVANCEDVUE

The mqweb server runs under IBM MQ Advanced for z/OS VUE (5656-AVA)

-l

Enable verbose logging. Diagnostic information is written to an mqweb server log file.

Return codes

Table 136. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see [Liberty:server command options](#) in the WebSphere Application Server documentation.

Related reference

[“dspmqweb properties \(display mqweb server configuration properties\)” on page 124](#)

Display information about the configurable properties of the mqweb server that is used to support the IBM MQ Console and REST API. That is, the command displays properties that are configurable by the user and the properties that have been modified. The mqweb server does not need to be running.

[“dspmqweb remote \(display mqweb server remote queue manager configuration\)” on page 130](#)

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.

[“dspmqweb status \(display mqweb server status\)” on page 133](#)

Display information about the status of the mqweb server that is used to support the IBM MQ Console and REST API.

[“endmqweb \(end mqweb server\)” on page 148](#)

Use the **endmqweb** command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

[“setmqweb properties \(set mqweb server configuration properties\)” on page 278](#)

Use the **setmqweb properties** command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.

[“setmqweb remote \(set mqweb server remote queue manager configuration\)” on page 286](#)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

[“strmqweb \(start mqweb server\)” on page 309](#)

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

Related information

[crtmqweb \(creating the mqweb server\)](#)

Parameters

-r

Reset to default values. This parameter removes all user-modified configuration properties from the `mqwebuser.xml` file.

-k *name*

The name of the configuration property to add, update, or remove to or from the `mqwebuser.xml` file. The following values are the valid values for *name* on all platforms, including the IBM MQ Appliance. Some of the following properties are not available in a stand-alone IBM MQ Web Server installation.

ltpaExpiration

This configuration property is used to specify the time, in minutes, before the LTPA token expires.

The value for this property is an integer value. The default value is 120 minutes.

maxTraceFiles

This configuration property is used to specify the maximum number of mqweb server log files that are generated by the mqweb server.

The value for this property is an integer value. The default value is 2.

maxTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each mqweb server log file can reach.

The value for this property is an integer value. The default value is 200.

mqConsoleEnableDashboardBrowse

Some aspects of the [MQ Console dashboard](#) contains information that is only available by browsing queues. This queue browsing is enabled by default in the IBM MQ Console. If a particular user does not have the correct authority to browse queues, many log entries can be generated, recording the failed access. To reduce the load on the logs, you can disable this queue browsing by setting this property to the string value `"false"`.

mqConsoleEnableSystemTopicMonitoring

This configuration property is used to enable or disable system topic monitoring that is used to display system information in the IBM MQ Console (see [Metrics published on the system topics](#)). If system topic monitoring is enabled, more information is available to display in the queue manager **Overview** tab in the IBM MQ Console. See [Quick tour of the MQ Console](#).

The value for this property is a string value and is set to `"true"` to enable system topic monitoring or `"false"` to disable it.

mqConsoleMaxMsgCharsToDisplay

This configuration property is used to specify the maximum characters to retrieve from each message when you browse a queue by using the IBM MQ Console.

The value for this property is an integer. The default value is 1024.

mqConsoleMaxMsgRequestSize

This configuration property is used to specify the maximum size, in MB, a browse request can be across all messages when you browse queues by using the IBM MQ Console.

The value for this property is an integer. The default value is 1.

mqConsoleMaxMsgsPerRequest

This configuration property is used to specify the total number of messages to retrieve from a queue when you browse by using the IBM MQ Console.

The value for this property is an integer. The default value is 1000.

mqRestCorsAllowedOrigins

This configuration property is used to specify the origins that are allowed to access the REST API. For more information about CORS, see [Configuring CORS for the REST API](#).

The value for this property is a string value.

mqRestCorsMaxAgeInSeconds

This configuration property is used to specify the time, in seconds, that a web browser can cache the results of any CORS pre-flight checks.

The value for this property is an integer value. The default value is 0.

mqRestCsrfValidation

This configuration property is used to specify whether CSRF validation checks are performed. A value of `false` removes the CSRF token validation checks.

The value for this property is a Boolean value. The default value is `true`.

mqRestGatewayEnabled

This configuration property is used to specify whether the administrative REST API gateway is enabled.

The value for this property is a Boolean value. The default value is `true`.

This property is not valid in a stand-alone IBM MQ Web Server installation. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

mqRestGatewayQmgr

This configuration property is used to specify the name of the queue manager to use as the gateway queue manager. This queue manager must be in the same installation as the mqweb server. A blank value indicates that no queue manager is configured as the gateway queue manager.

The value for this property is a string value. If this value can be interpreted as number or a Boolean value, it must be enclosed in double quotation marks.

This property is not valid in a stand-alone IBM MQ Web Server installation. You cannot use the administrative REST API with the stand-alone IBM MQ Web Server.

mqRestMessagingAdoptWebUserContext

This configuration property is used to specify the user context that is used for authorization when you send, publish, receive, or browse messages by using the messaging REST API. That is, it specifies which user ID is used for authorization.

The value can be one of the following values:

true

The ID that is used for authorization is the user ID that is logged in to the REST API.

MQMD.UserIdentifier is set to the user ID that is logged in to the REST API, and the

MQMD.AppIdentityData is set to the user ID that is logged in to the REST API.

See [MQMD](#) for more information about the message descriptor parts of the IBM MQ message.

false

The ID that is used for authorization is the user ID that is used to start the mqweb server. The **MQMD.UserIdentifier** is left blank, and the **MQMD.AppIdentityData** is set to the user ID that is logged in to the REST API.

The value for this property is a Boolean value. The default value is `true`.

mqRestMessagingEnabled

This configuration property is used to specify whether the messaging REST API is enabled.

The value for this property is a Boolean value. The default value is `true`.

mqRestMessagingFullPoolBehavior

This configuration property is used to specify the behavior of the messaging REST API when all connections in the connection pool are in use.

The value can be one of the following values:

block

When all the connections in the pool are in use, wait for a connection to become available.

When this option is used, the wait for a connection is indefinite.

Inactive connections are closed and removed from a queue manager pool automatically. The state of each queue manager pool is interrogated every 2 minutes, and any connections that have been inactive for the last 30 seconds are closed and removed from the associated pool.

error

When all the connections in the pool are in use, return an error.

overflow

When all the connections in the pool are in use, create a nonpooled connection to use. This connection is deleted after it is used.

The value for this property is a string value. The default value is overflow.

mqRestMessagingMaxPoolSize

This configuration property is used to specify the maximum connection pool size for each queue manager connection pool.

The value for this property is an integer value. The default value is 20.

mqRestMftCommandQmgr

This configuration property is used to specify the name of the command queue manager to which create transfer and create, delete, or update resource monitor requests are submitted by the REST API for MFT.

The value for this property is a string value. If this value can be interpreted as number or a Boolean value, it must be enclosed in double quotation marks.

Changes to the value of this property take effect when the mqweb server is next started.

This property is not valid in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftCoordinationQmgr

This configuration property is used to specify the name of the coordination queue manager from which transfer details are retrieved by the REST API for MFT.

The value for this property is a string value. If this value can be interpreted as number or a Boolean value, it must be enclosed in double quotation marks.

Changes to the value of this property take effect when the mqweb server is next started.

This property is not valid in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftEnabled

This configuration property is used to specify whether the REST API for MFT is enabled.

The value for this property is a Boolean value. The default value is false.

Changes to the value of this property take effect when the mqweb server is next started.

This property is not valid in a stand-alone IBM MQ Web Server installation. You cannot use the REST API for MFT with the stand-alone IBM MQ Web Server.

mqRestMftReconnectTimeoutInMinutes

This configuration property is used to specify the length of time, in minutes, after which the REST API for MFT stops trying to connect to the coordination queue manager.

The value for this property is an integer value. The default value is 30.

Changes to the value of this property take effect when the mqweb server is next started.

This property is not valid in a stand-alone IBM MQ Web Server installation as the REST API for MFT is not available in this environment.

mqRestRequestTimeout

This configuration property is used to specify the time, in seconds, before a REST request times out.

The value for this property is an integer value. The default value is 30.

traceSpec

This configuration property is used to specify the level of trace that is generated by the mqweb server. For a list of possible values, see [Configuring logging for the IBM MQ Console and REST API](#).

The value for this property is a string value. The default value is `*=info`.

The following values are the additional valid values for *name* on z/OS, UNIX, Linux, and Windows. Some of the following properties are not available in a stand-alone IBM MQ Web Server installation.

httpHost

This configuration property is used to specify the HTTP hostname as an IP address, domain name server (DNS) hostname with domain name suffix, or the DNS hostname of the server where IBM MQ is installed.

You can use an asterisk in double quotation marks to specify all available network interfaces.

You can use the value `localhost` to allow only local connections.

The value for this property is a string value. The default value is `localhost`.

httpPort

This configuration property is used to specify the HTTP port number that is used for HTTP connections.

You can use a value of `-1` to disable the port.

The value for this property is an integer value. The default value is `-1`.

httpsPort

This configuration property is used to specify the HTTPS port number that is used for HTTPS connections.

You can use a value of `-1` to disable the port.

The value for this property is an integer value. The default value is `9443`.

ltpaCookieName

This configuration property is used to specify the name of the LTPA token cookie name.

By default, the value of this property is `LtpaToken2_${env.MQWEB_LTPA_SUFFIX}` on AIX, Linux, and Windows, or `LtpaToken2_${httpsPort}` on z/OS. The variable after the `LtpaToken2_` prefix is used by the mqweb server to generate a unique name for the cookie. You cannot set this variable, but you can change the `ltpaCookieName` to a value of your choosing.

The value for this property is a string value.

maxMsgTraceFiles

This configuration property is used to specify the maximum number of messaging trace files that are generated by the mqweb server for the IBM MQ Console.

The value for this property is an integer value. The default value is `5`.

maxMsgTraceFileSize

This configuration property is used to specify the maximum size, in MB, that each messaging trace file can reach.

This property applies only to the IBM MQ Console.

The value for this property is an integer value. The default value is `20`.

mqConsoleAutostart

This configuration property is used to specify whether the IBM MQ Console automatically starts when the mqweb server starts.

The value for this property is a Boolean value. The default value is `true`.

mqConsoleFrameAncestors

This configuration property is used to specify the list of origins of web pages that can embed the IBM MQ Console in an IFrame. For more information about this property, see [embedding the IBM MQ Console in an IFrame](#).

The value for this property is a string.

mqConsoleRemoteSupportEnabled

This configuration property is used to specify whether the IBM MQ Console allows remote queue manager connections. When this property is set to true, remote queue manager connections are allowed.

The value for this property is a Boolean value. The default value is true.

This property is not valid in a stand-alone IBM MQ Web Server installation. The IBM MQ Console can be used only with remote queue managers in a stand-alone IBM MQ Web Server installation.

mqConsoleRemoteAllowLocal

This configuration property is used to specify whether remote and local queue managers are visible in the IBM MQ Console when remote queue manager connections are allowed. When this property is set to true, both local and remote queue managers are displayed.

The value for this property is a Boolean. The default value is true.

This property is not valid in a stand-alone IBM MQ Web Server installation. The IBM MQ Console can be used only with remote queue managers in a stand-alone IBM MQ Web Server installation.

mqConsoleRemotePollTime

This configuration property is used to specify the time, in seconds, before the remote queue manager connections list is refreshed. On refresh, unsuccessful connections are retried.

The value for this property is an integer. The default value is 300.

mqConsoleRemoteUIAdmin

This configuration property is used to specify whether remote queue managers can be added to the IBM MQ Console by using the Console, or if remote queue managers can be added only by using the **setmqweb remote** command. When this property is set to true, remote queue managers can be added by using the IBM MQ Console.

The value for this property is a Boolean. The default value is false.

mqRestAutostart

This configuration property is used to specify whether the REST API automatically starts when the mqweb server starts.

The value for this property is a Boolean value. The default value is true.

mqRestMessagingConnectionMode

This configuration property is used to specify whether the messaging REST API can send messages to queue managers that are not in the same installation as the mqweb server.

The value can be one of the following values:

local

The messaging REST API can send messages only to queue managers that are in the same installation as the mqweb server.

remote

The messaging REST API can send messages to any queue manager that is configured for use by the messaging REST API. If the queue manager is in the same installation as the mqweb server, no configuration is required. For all other queue managers, a remote queue manager definition must exist. For more information about creating a remote queue manager definition to use with the messaging REST API, see [Setting up a remote queue manager to use with the messaging REST API](#).

The value is a string value. The default value is local.

The mqweb server must be restarted after this value is set.

This property is not valid in a stand-alone IBM MQ Web Server installation. The messaging REST API can be used only with remote queue managers in a stand-alone IBM MQ Web Server installation.

remoteKeyfile

This configuration property is used to specify the location of the key file that contains the initial encryption key that is used to decrypt the passwords that are stored in the remote queue manager connection information.

The initial key is a file that must contain a single line of at least one character. However, you should use a key that is at least 16 characters. For example, your initial key file might contain the following encryption key:

```
Th1sIs@n3Ncrypt|onK$y
```

Ensure that your key file is adequately protected by using the operating system permissions, and that the encryption key is unique to the key file.

If you do not provide a key file, a default key is used.

You can also provide the path to the key file by using the **MQS_WEBUI_REMOTE_KEYFILE** environment variable.

The key file that is provided here must match the same key file that is used to encrypt the password using the **-sf** parameter.

The mqweb server must be restarted after this value is set.

secureLtpa

This configuration property is used to specify whether the LTPA token is secured for all requests. An unsecured LTPA token is required in order to send HTTP requests from a browser.

The value for this property is a Boolean value. The default value is true.

The following values are the additional valid values for *name* on AIX, Linux, and Windows:

managementMode

This configuration property is used to specify whether queue managers and listeners are able to be created, deleted, started, and stopped by the IBM MQ Console.

The value for this property is a string value and can be one of the following values:

standard

Queue managers and listeners can be created and administered in the IBM MQ Console.

externallyprovisioned

Queue managers and listeners cannot be created in the IBM MQ Console. Only queue managers and listeners that are created outside of the IBM MQ Console can be administered.

The default value is standard.

-d

Deletes the specified configuration property from the mqwebuser.xml file.

-v value

The value of the configuration property to add to, or update in, the mqwebuser.xml file. Any existing configuration properties of the same *name* are overwritten. Duplicate configuration properties are removed.

The value is case-sensitive. To specify an asterisk, multiple tokens, or an empty value, enclose the value in double quotation marks.

The *value* that is specified is not validated. If incorrect values are specified a subsequent attempt to start the mqweb server might fail.

Note: The value that is provided for a configuration property is converted into a Java Object, and some heuristic parsing is applied:

Numbers

If the value is numeric, it is parsed as a Java Number object, such as Integer or Double. A prefix of 0 indicates an octal value, 0x a hexadecimal one, and so on. For example, 0101 becomes an Integer with the decimal value 65.

Booleans

If the value matches `true` or `false`, it is parsed as a Boolean object.

Quoted values

If the value is enclosed in double quotation marks, it is parsed as a String object. If a single character is enclosed in single quotation marks, it is parsed as a Character object.

Other values

If none of the previous rules apply, then the value is parsed without change as a String object.

These rules are important when you provide string values. If such a value can be interpreted as a number or Boolean then you must ensure that it is specified to the `setmqweb` command in double quotation marks. For example, if you give a queue manager a numeric name or call it `TRUE`, you must enclose the name in double quotation marks.

You must escape double quotation marks on the command line. For example, you might specify

```
setmqweb properties -k mqRestGatewayQmgr - v "\"0101\""
```

to set a gateway queue manager name that resembles a number.

-l

Enable verbose logging. Diagnostic information is written to an mqweb server log file.

Return codes

Table 138. Return code identifiers and descriptions

Return code	Description
0	Command successful
>0	Command not successful

For a full list of server command exit codes, see [Liberty:server command options](#) in the WebSphere Application Server documentation.

Related commands

Table 139. Related commands and descriptions

Command	Description
 “setmqweb pid (set mqweb server product ID)” on page 275	Configure the product ID that the mqweb server runs under on z/OS
“setmqweb remote (set mqweb server remote queue manager configuration)” on page 286	Configure the mqweb server remote queue manager connections.
strmqweb	Start the mqweb server.
endmqweb	Stop the mqweb server.
dspmqweb status	Display the status of the mqweb server.
dspmqweb properties	Display the mqweb server configuration properties.
dspmqweb remote	Display the mqweb server remote queue manager configuration.

Related reference

[“dspmqweb properties \(display mqweb server configuration properties\)” on page 124](#)

Display information about the configurable properties of the mqweb server that is used to support the IBM MQ Console and REST API. That is, the command displays properties that are configurable by the user and the properties that have been modified. The mqweb server does not need to be running.

[“dspmqweb remote \(display mqweb server remote queue manager configuration\)” on page 130](#)

Use the **dspmqweb remote** command to view details of the remote queue manager connections that are configured for use with the IBM MQ Console and the messaging REST API.

[“dspmqweb status \(display mqweb server status\)” on page 133](#)

Display information about the status of the mqweb server that is used to support the IBM MQ Console and REST API.

[“endmqweb \(end mqweb server\)” on page 148](#)

Use the **endmqweb** command to stop the mqweb server. If you stop the mqweb server, you cannot use the IBM MQ Console or the REST API.

[“setmqweb pid \(set mqweb server product ID\)” on page 275](#)

Use the **setmqweb pid** command to change the product ID (PID) that the mqweb server runs under on z/OS.

[“setmqweb remote \(set mqweb server remote queue manager configuration\)” on page 286](#)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

[“strmqweb \(start mqweb server\)” on page 309](#)

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

setmqweb remote (set mqweb server remote queue manager configuration)

Use the **setmqweb remote** command to set up remote queue manager connections for the mqweb server. The remote queue manager connection information is used for the IBM MQ Console and the messaging REST API to connect to remote queue managers.

Using the setmqweb and dspmqweb commands on z/OS

Before you issue either the **setmqweb** or **dspmqweb** commands on z/OS, you must set the **WLP_USER_DIR** environment variable so that the variable points to your mqweb server configuration.

To set the **WLP_USER_DIR** environment variable, enter the following command:

```
export WLP_USER_DIR=WLP_user_directory
```

where *WLP_user_directory* is the name of the directory that is passed to **crtmqweb**. For example:

```
export WLP_USER_DIR=/var/mqm/web/installation1
```

For more information, see [Create the mqweb server](#).

Also set the **JAVA_HOME** environment variable to reference a 64-bit version of Java on your system.

The user ID running the command needs write access to the following directories:

- *WLP_user_directory* and its subdirectories.
- /tmp or to another directory that is referenced by the *TMPDIR* variable. If you do not have access to /tmp, the command fails with message FSUMF315 Cannot define temporary file. If you need to set the *TMPDIR* variable, issue the following command in the z/OS UNIX shell: `export TMPDIR=user_directory`

Using the **setmqweb** and **dspmqweb** commands in a stand-alone IBM MQ Web Server installation

Before you issue either the **setmqweb** or **dspmqweb** commands in a stand-alone IBM MQ Web Server installation, you must set the **MQ_OVERRIDE_DATA_PATH** environment variable to the IBM MQ Web Server data directory.

The user ID running the command needs write access to the data directory and its subdirectories.

Syntax

➔ **setmqweb** — remote ➔

Parameters

add

Add an entry to the remote queue manager connection information instead of editing an existing entry.

-group

Whether this remote queue manager connection is part of a queue manager group.

This option can be used only when you add a new remote queue manager connection, and is valid only for the messaging REST API.

-uniqueName *uniqueID*

A unique name for the remote queue manager connection. This name is the name that appears in the IBM MQ Console.

Use a name that makes it clear that the queue manager is remote. For example, if you are specifying a unique name for remote connections to queue manager QM2, you might specify the remote name "remote-QM2".

The unique name must be specified in the following cases:

- To add a new remote queue manager connection when a queue manager with the same name might already exist in the remote queue manager connection information. In this case, you must also specify the **-qmgrName** parameter to specify the queue manager that you are creating a unique name for.
- To delete a remote queue manager connection that has a unique name.
- To modify a remote queue manager connection that has a unique name.

-qmgrName *qmgrName*

The name of the queue manager to add or update.

This parameter must be specified to add a new remote queue manager connection. The name appears as *remote_qmgrName* in the IBM MQ Console.

-sf *keyfilePath*

The location of the key file that contains the initial encryption key that is used to encrypt the passwords that are stored in the remote queue manager connection information.

The initial key is a file that must contain a single line of at least one character. However, you should use a key that is at least 16 characters. For example, your initial key file might contain the following encryption key:

```
Th1sIs@n3Ncrypt|onK$y
```

Ensure that your key file is adequately protected by using the operating system permissions, and that the encryption key is unique to the key file.

If you do not provide a key file, a default key is used.

You can also provide the path to the key file by using the **MQS_REMOTE_KEYFILE** environment variable.

-jsonkey *value*|-d|-i***jsonkey***

The name of the property to add, update, or remove. To add or update a value, specify the value after the *jsonkey* property. To delete a value, specify the **-d** flag after the *jsonkey* property.

You can add, update, or remove two types of properties. The first type are global properties that you can set with the **setmqweb remote** command without specifying a queue manager name or unique name. The second type are properties that are specific to a single remote queue manager connection. These properties can be set with the **setmqweb remote** command only if you also specify a queue manager name, a unique name, or both.

The following values are valid *jsonkey* values that you must specify without a queue manager name or unique name in the **setmqweb remote** command:

globalTrustStorePath

The path to the truststore PKCS#12 or JKS file. This truststore is used for all remote connections unless it is overridden by specific remote queue manager connection information in the **trustStorePath** entry.

The value for this jsonkey is a string value.

globalTrustStorePassword

The password for the global truststore.

The value for this jsonkey is a string value, and it is encrypted in the remote queue manager connection information.

globalKeyStorePath

The path to the keystore PKCS#12 or JKS file. This keystore is used for all remote connections unless it is overridden by a specific remote queue manager connection information in the **keyStorePath** entry.

globalKeyStorePassword

The password for the global keystore.

The value for this jsonkey is a string value, and it is encrypted in the remote queue manager connection information.

This password is used to access both the keystore and the keys in the keystore.

The following values are valid *jsonkey* values that require you to specify a queue manager name or unique name in the **setmqweb remote** command:

ccdtURL

The path to the CCDT file that is associated with the remote queue manager.

The value for this jsonkey is a string value.

username

The username that is used for the remote queue manager connection.

The value for this jsonkey is a string value.

password

The password that is associated with the username that is used for the remote queue manager connection.

The value for this jsonkey is a string value, and it is encrypted in the remote queue manager connection information.

enableMutualTLS

Whether this remote queue manager connection adds a keystore to enable mutual TLS.

The value for this jsonkey is a Boolean value.

keyStorePath

The path to the keystore PKCS#12 or JKS file.

The value for this jsonkey is a string value, and it overrides the global keystore value.

keyStorePassword

The password for the keystore file.

The value for this jsonkey is a string value, and it is encrypted in the remote queue manager connection information.

This password is used to access both the keystore and the keys in the keystore.

trustStorePath

The path to the truststore PKCS#12 or JKS file.

The value for this jsonkey is a string value, and it overrides the global truststore value.

trustStorePassword

The password for the truststore file.

The value for this jsonkey is a string value, and it is encrypted in the remote queue manager connection information.

visibility

Whether this remote queue manager connection can be used by the messaging REST API, the IBM MQ Console, or both.

The value for this jsonkey can be one of the following values:

messaging

The queue manager connection can be used only by the messaging REST API.

console

The queue manager connection can be used only by the IBM MQ Console.

messaging,console

The queue manager connection can be used by either the messaging REST API or the IBM MQ Console.

The value for this jsonkey is a string value. The default value is **messaging,console**.

value

The value of the JSON key entry to add or update.

The values are case-sensitive and must be enclosed in double quotation marks.

-d

Delete the specified property from the remote connection information.

-i

Enable interactive mode for the specified JSON key entry. You are then prompted for the JSON key value as the command runs.

-d

Delete the connection information for the queue manager with the specified unique name.

-r

Reset and remove all remote connection information.

-l

Enable verbose logging. Diagnostic information is written to an mqweb server log file.

-sm

Encrypts passwords using a FIPS compliant cryptographic library.

This parameter is not available on IBM i or z/OS.

Return codes

Table 140. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see [Liberty:server command options](#) in the WebSphere Application Server documentation.

Examples

The following example sets the path to the global keystore for remote queue manager connections:

```
setmqweb remote -globalTrustStorePath "c:\supersecure\keys.jks"
```

The following example creates a new entry for a queue manager, QM2, in the remote queue manager connection information. The example sets the CCDT URL, a username and password to use with the connection, and a keystore path:

```
setmqweb remote add -qmgrName "QM2" -ccdtURL "c:\myccdt\cdt.json" -username "user" -password "password" -keyStorePath "c:\supersecure\keys.jks"
```

The following example creates a new entry for a different queue manager that is also named QM2, and specifies a unique name to differentiate between the two QM2 queue managers. The example sets the CCDT URL, a username, and a password. The example uses the **-i** option to interactively enter the password that is associated with the username when the command runs:

```
setmqweb remote add -uniqueName qm2remote -qmgrName "QM2" -ccdtURL "c:\myccdt\cdt.json" -username "mqadmin" -password -i
```

“setmqweb properties (set mqweb server configuration properties)” on page 278 Use the setmqweb properties command to configure the mqweb server. Changes to properties take effect dynamically, within a few seconds, unless otherwise stated.	
“strmqweb (start mqweb server)” on page 309 Use the strmqweb command to start the mqweb server that is used to support the IBM MQ Console and REST API.	

ALW **setmqxacred (add XA credentials)**

Use the **setmqxacred** command to add, modify or delete credentials in the IBM MQ XA credentials store.

Syntax

➔ **setmqxacred** — **-m** — **?** — *QmgrName* ➔

Required parameters

-m *QmgrName*

The queue manager for which authentication details are stored.

Optional parameters

-x *ResourceMgrName*

Specifies the resource manager name as defined in the `qm.ini` file.

-u *user*

Specifies the user name to use to connect to the database.

-p password

Specifies the password for the user.

-d

Deletes the credentials for the named resource manager.

-l

Lists the credentials in the queue manager store.

Examples

To add credentials for the queue manager QM1 for the resource mqdb2:

```
# setmqxacred -m QM1 -x mydb2 -u user1 -p Password1
Successfully added credentials for XA Resource Manager mydb2
```

To delete the credentials for the queue manager QM1 for the resource mqdb2:

```
# setmqxacred -m QM1 -x mydb2 -d
Successfully removed credentials for XA Resource Manager mydb2
```

To list details about the credentials stored in the credentials store.

```
# setmqxacred -m QM1 -l
ResourceName(mydb2) UserName(user1)
ResourceName(myora) UserName(user2)
```

setmqxr (set MQTT server properties)

Use the **setmqxr properties** command to configure MQTT server properties.

The command allows you to individually configure the properties that are specified in the following configuration files:

- mqxrtraceOff.properties
- mqxrtraceOn.properties
- java.properties
- mqxr_unix.properties
- mqxr_win.properties

Notes:

- From IBM MQ 10.0.0, the MQTT server only supports FIPS 140-3. FIPS 140-2 is no longer supported.
- To enable FIPS 140-3, you need to include two new JVM properties in the `java.properties` file. For more information, see [Table 142 on page 293](#).
- FIPS is not supported on Linux s390.

Syntax

Required parameters

-m QMgrName

The queue manager you are setting MQTT properties for.

-k name

The name of the MQTT property that you want to set. You must combine this parameter with one of the following parameters:

-d

Delete the specified MQTT property.

-v value

The value that the property is set to.

-r

Reset the specified property to its default value.

Optional parameters

-l

Enable verbose logging. Diagnostic information is written to a log file.

The following table lists some of the properties can be configured by the **setmqxr properties** command on all platforms. A full list of properties that can be configured using this command can be viewed by using the [dspmqxr](#) command.

Table 142. MQTT Server properties and values	
Property	Description
-Dcom.ibm.mq.MQXR.GenerateHeapDump	Specifies whether or not a Java heap dump is generated when the service encounters a low memory exception. It accepts a value of <code>true</code> and <code>false</code> . If you do not specify a value for this attribute, the default value of <code>false</code> is used.
-Dcom.ibm.mq.MQXR.GenerateJavaDump	Specifies whether or not a Java core dump is generated when an FDC is generated. It accepts a value of <code>true</code> and <code>false</code> . If you do not specify a value for this attribute, the default value of <code>false</code> is used.
-Xms<size>	The <code>-Xms</code> option sets the initial and minimum Java heap size. The size is specified in megabytes. For example, <code>-Xms512m</code> . To configure this property, the <code>-v</code> argument must be left empty.
-Xmx<size>	This option sets the maximum Java heap size. The size is specified in megabytes. For example, <code>-Xmx1024m</code> . To configure this property, the <code>-v</code> argument must be left empty.
handlers	Specifies the log file handler to use. It accepts the values <code>com.ibm.mq.util.logging.MQErrorLogFileHandler</code> , <code>com.ibm.mq.util.logging.MQJSONErrorLogFileHandler</code> , <code>java.util.logging.MemoryHandler</code> , and <code>com.ibm.mq.util.logging.MQCommonServicesHandler</code> . A combination of these can also be used by specifying a comma-separated list.

Table 142. MQTT Server properties and values (continued)	
Property	Description
com.ibm.mq.MQXR.Workers	The number of server workers the service should use. If not set, the value defaults to the number of processors.
com.ibm.mq.MQXR.MQIBindType	The binding type for the service, one of: FASTPATH, SHARED, or ISOLATED. The default is FASTPATH.
 Dsemeru.fips	Specifies that FIPS is enabled when the value is set to TRUE. The default value is FALSE.
 Dsemeru.customprofile	Defines the cryptographic provider to use with FIPS 140-3. If the IBM MQ Telemetry server is running with FIPS 140-3, set this property to OpenJCEPlusFIPS.

Return codes

Table 143. Return code identifiers and descriptions

Return code	Description
0	Command successful
>0	Command not successful

Examples

- The following command enables JSON formatted logs for MQTT for the queue manager QM1:

```
setmqxr properties -m QM1 -k handlers -v com.ibm.mq.util.logging.MQJSONErrorLogFileHandler
```

- The following command resets the logging format back to its default setting of plain text logs:

```
setmqxr properties -m QM1 -k handlers -r
```

-  If **SSLFIPS** is enabled in the queue manager without setting both the **Dsemeru** Java properties, the MQTT service does not start and the following error message is logged:

```
AMQXR2125E: SSLFIPS property is set to YES in the Queue Manager configuration but the FIPS
140-3 JVM system
properties -Dsemeru.fips=true and -Dsemeru.customprofile=OpenJCEPlusFIPS are not set in the
java.properties file.
```

Related reference

[“dspmqxr \(display MQTT server properties\)” on page 135](#)

Use the dspmqxr command to display the configured MQTT server properties.

strmqcsv (start command server)

Use the **strmqcsv** command to start the command server for the specified queue manager. This enables IBM MQ to process commands sent to the command queue.

You must use the **strmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the dspmq -o installation command.

If the queue manager attribute, **SCMDSERV**, is specified as QMGR then changing the state of the command server using **strmqcsv** does not effect how the queue manager acts upon the **SCMDSERV** attribute at the next restart.

Syntax

Required parameters

None

Optional parameters

-a

Blocks the following PCF commands from modifying or displaying authority information:

- Inquire authority records (MQCMD_INQUIRE_AUTH_RECS)
- Inquire entity authority (MQCMD_INQUIRE_ENTITY_AUTH)
- Set authority record (MQCMD_SET_AUTH_REC).
- Delete authority record (MQCMD_DELETE_AUTH_REC).

QMgrName

The name of the queue manager on which to start the command server. If omitted, the default queue manager is used.

Return codes

Table 144. Return code identifiers and descriptions

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

Examples

The following command starts a command server for queue manager earth:

```
strmqcsv earth
```

Related commands

Table 145. Related command names and descriptions

Command	Description
endmqcsv	End a command server
dspmqcsv	Display the status of a command server

Related reference

[“dspmqcsv \(display command server\)” on page 99](#)

Use the **dspmqcsv** command to display the status of the command server for the specified queue manager.

[“endmqcsv \(end command server\)” on page 136](#)

Use the **endmqscv** command to stop the command server on the specified queue manager.

[“Command server commands” on page 7](#)

A table of command server commands, showing equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

strmqsvc (start IBM MQ service)

Use the **strmqsvc** command to start the IBM MQ service on Windows systems. Run the command to start the service if it has not been started automatically, or if the service has ended. Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke **strmqsvc** with elevated privileges.

Syntax

strmqsvc

Parameters

The **strmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **strmqsvc** binary file.

Return codes

Table 146. Return code identifiers and descriptions

Return code	Description
0	Successful operation
36	Invalid arguments provided
119	User not authorized to start the service
649	Service could not be started

Related reference

[“endmqsvc \(end IBM MQ service\)” on page 145](#)

End the IBM MQ service on Windows.

strmqm (start queue manager)

Use the **strmqm** command to start a queue manager or ready it for standby operation. If the queue manager startup takes more than a few seconds, IBM MQ shows intermittent messages detailing the startup progress.

You must use the **strmqm** command from the installation that is associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmq -o installation** command. If a queue manager has no associated installation and there is no installation of IBM MQ on the system, the **strmqm** command associates the queue manager with the installation that issued the **strmqm** command.

Usage notes

IBM MQ supports the use of back-up queue managers. That is, a queue manager where log extents are asynchronously copied to a backup machine, and where replay of the log records is periodically driven by use of the command **strmqm -r**. When the backup queue manager needs to be activated, use the command **strmqm -a** and then start the queue manager normally.

Attention: You cannot use **LogManagement=Automatic**, along with a backup queue manager, as extents might be reused before they are backed up. Furthermore, if you run the command **strmqm -r** together with **LogManagement=Automatic**, the command fails.

UNIX From IBM MQ 9.1, the security of `data path/log/qm` on UNIX systems is changed from 2775 to 2770.

The **strmqm** command checks the syntax of the CHANNELS and SSL stanzas in the `qm.ini` file early on, before starting the queue manager fully. If the `qm.ini` file contains any errors, this check makes it much easier to see what is wrong, and correct it quickly. If an error is found, **strmqm** outputs an AMQ9224 error message, describing the full details of the position of the error in the `qm.ini` file. It also ends immediately without starting the queue manager.

You can use the environment variable **MQLICENSE** to accept or view the license.

Syntax

Optional parameters

-a

Activate the specified backup queue manager. The backup queue manager is not started.

When activated, a backup queue manager can be started by using the control command **strmqm QMgrName**. The requirement to activate a backup queue manager prevents accidental startup.

When activated, a backup queue manager can no longer be updated.

For more information about using backup queue managers, see [Backing up and restoring IBM MQ queue manager data](#).

-c

Starts the queue manager, redefines the default and system objects, then stops the queue manager. Any existing system and default objects that belong to the queue manager are replaced if you specify this flag, and any non-default system object values are reset (for example, the value of MCAUSER is set to blank).

Use the **crtmqm** command to create the default and system objects for a queue manager.

Note: If you run **strmqm -c** on a queue manager that is being used as a Managed File Transfer coordination queue manager you must re-run the MQSC script that defines the coordination queue manager objects. This script is in a file called `queue_manager_name.mqsc`, which is in the Managed File Transfer configuration directory.

The -c option is not available for Native HA queue managers.

-d Information

Specifies whether information messages are displayed. Possible values for *Information* are as follows:

Value	Description
all	All information messages are displayed. This value is the default value.
minimal	The minimal number of information messages are displayed.
none	No information messages are displayed. This parameter is equivalent to -z .

The -z parameter takes precedence over this parameter.

-e CMDLEVEL = Level

Enables a command level for this queue manager, and then stops the queue manager.

The queue manager is now able to use all functions that are provided by the specified command level. You can start the queue manager only with an installation that supports the new command level.

This option is only valid if the current command level that is used by the queue manager is lower than the maximum command level supported by the installation. Specify a command level that is greater than the current command level of the queue manager and less than or equal to the maximum command level supported by the installation.

Use exactly the command level as a value for *Level* that is associated with the function you want to enable.

This flag cannot be specified with -a, -c, -r or -x.

-f

Use this option if you know that a queue manager is not starting because its data directories are missing or corrupted.

The **strmqm -f qmname** command attempts to re-create the queue manager data directory and reset file permissions. If it is successful, the queue manager starts, unless the queue manager configuration information is missing. If the queue manager fails to start because the configuration information is missing, re-create the configuration information, and restart the queue manager.

The default behavior of **strmqm**, with no -f option, is not to recover missing or corrupted data directories automatically, but to report an error, such as AMQ6235 or AMQ7001, and not start the queue manager.

You can think of the -f option as performing the recover actions that used to be performed automatically by **strmqm**.

You must not use **strmqm -f** to re-create the queue manager data directories if you can restore the directories by correcting the configuration.

Possible solutions to problems with **strmqm** are to make the networked file storage location accessible to the queue manager, or to ensure the gid and uid of the mqm group and user ID on the server hosting the queue manager match the gid and uid of the mqm group and user ID on the server that is hosting the queue manager data directory.

If you are performing media recovery for a queue manager, then you must use the -f option to re-create the queue manager data directory.

-ns

Prevents any of the following processes from starting automatically when the queue manager starts:

- The channel initiator
- The command server
- Listeners
- Services

This parameter also runs the queue manager as if the CONNAUTH attribute is blank, regardless of its current value. Client applications cannot connect because there are no listeners. Authorization of applications and control commands will occur based on the local OS user under which you run them. If the queue manager had previously used LDAP users/groups for its authorization records, then:

1. These records will be ignored while the queue manager is running in **-ns** mode.
2. You should not make changes to authorization records or create new objects while in this mode, because the authorization records that are created or amended in this mode will then contain user names derived from the operating system, not the LDAP repository.

Administrative changes must be made by using **runmqsc** because the command server is not running.

To re-enable the normal authorization service processing, that is, return the effective CONNAUTH value to its normal setting, you must end and start the queue manager without the **-ns** parameter.

-r

Updates the backup queue manager. The backup queue manager is not started.

IBM MQ updates the objects of the backup queue manager by reading the queue manager log and replaying updates to the object files.

For more information about using backup queue managers, see [Backing up and restoring IBM MQ queue manager data](#).

Note:  The **-r** option is not available for Native HA queue managers.

-si

Interactive (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs under the logged on (interactive) user. Queue managers that are configured with interactive startup end when the user who started them logs off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

If you do not specify a startup type of either **-si** or **-ss**, the queue manager startup type that is specified on the **crtmqm** command is used.

-ss

Service (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs as a service. Queue managers that are configured with service startup continue to run even after the interactive user is logged off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

-x

Start an instance of a multi-instance queue manager on the local server, permitting it to be highly available. If an instance of the queue manager is not already running elsewhere, the queue manager starts and the instance becomes active. The active instance is ready to accept local and remote connections to the queue manager on the local server.

If a multi-instance queue manager instance is already active on a different server the new instance becomes a standby, permitting it to takeover from the active queue manager instance. While it is in standby, it cannot accept local or remote connections.

You must not start a second instance of a queue manager on the same server.

The default behavior, omitting the **-x** optional parameter, is to start the instance as a single instance queue manager, forbidding standby instances from being started.

-z

Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted information messages. Because using this flag can result in loss of information, do not use it when you are entering commands on a command line.

This parameter takes precedence over the -d parameter.

QMgrName

The name of a local queue manager. If omitted, the default queue manager is used.

Return codes

Table 147. Return code identifiers and descriptions

Return code	Description
0	Queue manager started
1	The location chosen for the queue manager data directory is invalid
3	Queue manager being created
5	Queue manager running
16	Queue manager does not exist
23	Log not available
24	A process that was using the previous instance of the queue manager has not yet disconnected
30	A standby instance of the queue manager started. The active instance is running elsewhere
31	The queue manager already has an active instance. The queue manager permits standby instances
39	Invalid parameter specified
43	The queue manager already has an active instance. The queue manager does not permit standby instances
47	The queue manager already has the maximum number of standby instances
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started
91	The command level is outside the range of acceptable values
92	The queue manager's command level is greater or equal to the specified value
94	A replica instance of the queue manager has been started
100	Log location invalid
114	Invalid qm.ini file stanza
119	User not authorized to start the queue manager

Examples

The following command starts the queue manager account:

```
strmqm account
```

Use the **dlmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

[dspmqver \(display IBM MQ version information\)](#)

By default, the **dspmqver** command displays version and build information for the installation from which it was started. A note is displayed if other installations exist; use the **-i** parameter to display their details.

[endmqm \(end queue manager\)](#)

Stop a queue manager. or switch to a standby queue manager or replica queue manager.

[“amqmdain \(services control\)” on page 28](#)

amqmdain is used to configure or control some Windows specific administrative tasks.

[“strmqsvc \(start IBM MQ service\)” on page 296](#)

Use the **strmqsvc** command to start the IBM MQ service on Windows systems. Run the command to start the service if it has not been started automatically, or if the service has ended. Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

[“endmqsvc \(end IBM MQ service\)” on page 145](#)

End the IBM MQ service on Windows.

strmqtrc (start trace)

Use the **strmqtrc** command to enable tracing at a specified level of detail, or report the current level of tracing.

You must use the **strmqtrc** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with by using the **dspmq** command as follows:

```
dspmq -o installation
```

Syntax

The syntax of this command is as follows:

Description

The **strmqtrc** command enables tracing. The command has optional parameters that specify the level of tracing you want:

- One or more queue managers
- Levels of trace detail
- One or more IBM MQ processes. The processes can be either part of the IBM MQ product or customer applications that use the IBM MQ API
- Specific threads within customer applications, either by IBM MQ thread number or by operating system thread number
- Events. These can be either the entry or exit from internal IBM MQ functions or the occurrence of a first failure data capture (FDC).

Each combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them. You can start the strmqtrc command multiple times, regardless of whether tracing is already enabled. If tracing is already enabled, the trace options that are in effect are modified to those specified on the most recent invocation of the command. Multiple invocations of the command, without an intervening enmqtrc command, are interpreted by IBM MQ as having a logical OR between them. The maximum number of concurrent strmqtrc commands that can be in effect at one time is 16.

Optional parameters

-m *QMgrName*

The name of the queue manager to trace.

The following wildcards are allowed: asterisk (*), replacing zero or more characters, and question mark (?), replacing any single character. In command environments such as the UNIX shell, where the asterisk (*) and question mark (?) characters have special meaning, you must either escape the wildcard character or enclose it in quotation marks to prevent the command environment from operating on the wildcard character.

-e

Requests early tracing of all processes, making it possible to trace the creation or startup of a queue manager. If you include this parameter, any process belonging to any component of any queue manager traces its early processing. The default is not to perform early tracing.

Use the following command to trace a client:

```
strmqtrc -e
```

You cannot use the **-e** parameter with the **-m** parameter, **-i** parameter, the **-p** parameter, the **-c** parameter, or the **-b** parameter. If you try to use the **-e** parameter with the **-m** parameter, the **-i** parameter, the **-p** parameter, the **-c** parameter, or the **-b** parameter, then an error message is issued.

-t TraceType

The points to trace and the amount of trace detail to record. By default **all** trace points are enabled and a default-detail trace is generated.

Alternatively, you can supply one or more of the options in the following list. For each *Tracetype* value you specify, including **-t all**, specify either **-t parms** or **-t detail** to obtain the appropriate level of trace detail. If you do not specify either **-t parms** or **-t detail** for any particular trace type, only a default-detail trace is generated for that trace type.

Attention: When using the **-t api** option, you will see trace of the MQI calls, with all the input and output data blocks dumped in hexadecimal form.

You should be aware that IBM MQ internal programs also make MQI calls, and you will see trace files for those programs. Normally, the program names begin **amq** or **runmq**.

You should be aware that **amqrmppa** programs host many threads, some of which receive MQI calls over the network from client applications. In these threads you will see MQI calls in the **-t api** traces, but you must remember that the input arguments to those MQI calls traced in the **amqrmppa** program might not match every detail of the MQI calls made originally by the client.

Therefore, if you need to know, reliably, the input arguments to MQI calls made by the client application, you must use **-t api** tracing on the client machine directly.

If you supply multiple trace types, each must have its own **-t** parameter. You can include any number of **-t** parameters, if each has a valid trace type associated with it.

It is not an error to specify the same trace type on multiple **-t** parameters.

Table 148. TraceType parameter values.	
Value	Description
all	Output data for every trace point in the system (the default). The all parameter activates tracing at default detail level.
amqp	Output data for the AMQP service
api	Output data for trace points associated with the MQI and major queue manager components.
commentary	Output data for trace points associated with comments in the IBM MQ components.
comms	Output data for trace points associated with data flowing over communications networks.
csdata	Output data for trace points associated with internal data buffers in common services.
csflows	Output data for trace points associated with processing flow in common services.
detail	Activate tracing at high-detail level for flow processing trace points.
explorer	Output data for trace points associated with the IBM MQ Explorer.

Table 148. <i>TraceType</i> parameter values. (continued)	
Value	Description
java	Output data for trace points associated with applications using the IBM MQ classes for Java API.
lqmdata	Output data for trace points associated with internal data buffers in the local queue manager.
lqmflows	Output data for trace points associated with processing flow in the local queue manager.
mqxr	Output data for the Telemetry (MQXR) service.
otherdata	Output data for trace points associated with internal data buffers in other components.
otherflows	Output data for trace points associated with processing flow in other components.
parms	Activate tracing at default-detail level for flow processing trace points.
remotedata	Output data for trace points associated with internal data buffers in the communications component.
remoteflows	Output data for trace points associated with processing flow in the communications component.
servicedata	Output data for trace points associated with internal data buffers in the service component.
serviceflows	Output data for trace points associated with processing flow in the service component.
spldata	Output data for trace points associated with buffers and control blocks that use a security policy (AMS) operation.
splflows	Output data for trace points associated with entry and exit data for functions that use a security policy (AMS) operation.
ssl	Output data associated with using IBM Global Security Kit (GSKit) to enable TLS channel security.
versiondata	Output data for trace points associated with the version of IBM MQ running.

-x *TraceType*

The points **not** to trace. By default **all** trace points are enabled and a default-detail trace is generated. The trace points you can specify are those listed for the **-t** parameter.

You can use the **-x** parameter with *Tracetype* values to exclude those entry points you do not want to record. This is useful in reducing the amount of trace produced.

If you supply multiple trace types, each must have its own **-x** parameter. You can include any number of **-x** parameters, if each has a valid *Tracetype* associated with it.

-l *MaxSize*

The maximum size of a trace file (*AMQppppp.qq.TRC*) in megabytes (MB), where *ppppp* refers to the operating system process ID of the particular IBM MQ process being traced and *qq* is a sequence number if there is already a file with that name. For example, if you specify a *MaxSize* of 1, the size of the trace is limited to 1 MB.

When a trace file reaches the specified maximum, it is renamed to `AMQppppp.qq.TRS` and a new `AMQppppp.qq.TRC` file is started. If a previous copy of an `AMQppppp.qq.TRS` file exists, it is deleted.

The highest value that *MaxSize* can be set to is 2048 MB.

-d

Trace options. The value can be:

0

Trace no user data.

-1 or all

Trace all user data.

NumOfBytes

- For a communication trace; trace the specified number of bytes of data including the transmission segment header (TSH).
- For an MQPUT or MQGET call; trace the specified number of bytes of message data held in the message buffer.
- Values in the range 1 through 15 are not allowed.

-i PidTids

Process identifier (PID) and thread identifier (TID) to which the trace generation is restricted. You cannot use the **-i** parameter with the **-e** parameter. If you try to use the **-i** parameter with the **-e** parameter, then an error message is issued.

The precise format of this parameter is `PID[.TID]`. For example:

Coding **-i 12345** traces all threads in PID 12345, whereas

Coding **-i 12345.67** traces only thread 67 in PID 12345

This parameter is not supported for .NET clients if `NMQ_MQ_LIB` is set to managed, so that the client uses managed IBM MQ problem diagnostics.

-p Apps

The named processes to which the trace generation is restricted. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (*) or question mark (?) wildcards are allowed. You cannot use the **-p** parameter with the **-e** parameter. If you try to use the **-p** parameter with the **-e** parameter, then an error message is issued.

This parameter is not supported for .NET clients if `NMQ_MQ_LIB` is set to managed, so that the client uses managed IBM MQ problem diagnostics.

-s

Reports the tracing options that are currently in effect. You must use this parameter on its own with no other parameters.

A limited number of slots are available for storing trace commands. When all slots are in use, then no more trace commands can be accepted unless they replace an existing slot. Slot numbers are not fixed, so if the command in slot number 0 is removed, for example by an `endmqtrc` command, then all the other slots move up, with slot 1 becoming slot 0, for example. An asterisk (*) in a field means that no value is defined, and is equivalent to the asterisk wildcard.

An example of the output from this command is as follows:

Listing Trace Control Array

Used slots = 2 of 15

EarlyTrace	[OFF]
TimedTrace	[OFF]
TraceUserData	[0]
MaxSize	[0]
Trace Type	[1]

Slot position 1

```

Untriggered
Queue Manager [avocet]
Application    [*]
PID.TID       [*]
TraceOptions   [1f4ffff]
TraceInterval  [0]
Trace Start Time [0]
Trace Stop Time [0]
Start Trigger  [KN346050K]
Start Trigger  [KN346080]

```

Slot position 2

```

Untriggered
Queue Manager [*]
Application    [*]
PID.TID       [*]
TraceOptions   [1fcffff]
TraceInterval  [0]
Trace Start Time [0]
Trace Stop Time [0]
Start Trigger  [KN346050K]
Start Trigger  [KN346080]

```

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

-b Start_Trigger

FDC probe IDs for which tracing must be turned on. *Start_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (*) and question mark (?) wildcards in the specification of probe IDs. You cannot use the **-b** parameter with the **-e** parameter. If you try to use the **-b** parameter with the **-e** parameter, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

Table 149. Start trigger and effect	
Start_Trigger	Effect
FDC=comma-separated list of FDC probe IDs.	Turns on tracing when any FDCs with the specified FDC probe IDs are generated.

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

-c Stop_Trigger

FDC probe IDs for which tracing must be turned off, or interval in seconds after which tracing must be turned off. *Stop_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (*) and question mark (?) wildcards in the specification of probe IDs. This parameter should be used only under the guidance of IBM Service personnel.

Table 150. Stop triggers and their effects	
Stop_Trigger	Effect
FDC=comma-separated list of FDC probe IDs.	Turns tracing off when any FDCs with the specified FDC probe IDs are generated.
interval=n where n is an unsigned integer between 1 and 32,000,000.	Turns tracing off n seconds after it starts or, if it tracing is already enabled, turns tracing off n seconds after this instance of the command is issued.

This parameter is not supported for .NET clients if NMQ_MQ_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

-o

mqm

Enables IBM MQ trace as in previous releases.

This is the default value if no -o option is supplied.

aix

Enables IBM MQ to write AIX system trace, provided AIX system trace is enabled.

As previously, you must use the AIX operating system trace command for any output to actually be produced.

This is a legacy option, and you should use this option only when directed to do so by IBM service personnel.

Return codes

Table 151. Return code identifiers and descriptions

Return code	Description
0	Command successful
36	Non-valid arguments supplied to the command
58	Inconsistent use of installations detected
71	Nine concurrent traces (the maximum) already running
119	You are not authorized to perform the requested operation

Examples of enabling tracing at different levels of detail

  This command enables tracing of processing flow from common services and the local queue manager for a queue manager called QM1 on IBM MQ for AIX or Linux systems. Trace data is generated at the default level of detail.

```
strmqtrc -m QM1 -t csflows -t lqmflows -t parms
```

This command disables tracing of TLS activity on a queue manager called QM1. Other trace data is generated at the parms level of detail.

```
strmqtrc -m QM1 -x ssl -t parms
```

This command enables high-detail tracing of the processing flow for all components:

```
strmqtrc -t all -t detail
```

Examples of enabling tracing for an FDC

This command enables tracing when FDC KN346050 or FDC KN346080 occur on any process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050,KN346080
```

This command enables tracing when FDC KN34650 occurs, and stops tracing when FDC KN346080 occurs. In both cases the FDC must occur on a process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050 -c FDC=KN346080
```

Examples of using the -p and -m parameters for individual and multiple invocations of strmqtrc

The following examples use the -p and -m parameters to show:

- How a combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them.

- How multiple invocations of the command, without an intervening `enmqtrc` command, are interpreted by IBM MQ as having a logical OR between them:

1. This command enables tracing for all threads that result from any executing process called `amqxxx.exe`:

```
strmqtrc -p amqxxx.exe
```

2. After running the **strmqtrc** command as shown in step 1, you can then enter either of the following commands without an intervening **endmqtrc** command.

- If you start the following command after the command in step 1, without an intervening **endmqtrc** command, then tracing is limited to all threads that result from any executing process called `amqxxx.exe` *and* that are using queue manager QM2:

```
strmqtrc -p amqxxx.exe -m QM2
```

- If you start the following command after the command in step 1, without an intervening **endmqtrc** command, then tracing is limited to all processes and threads that result from executing `amqxxx.exe` *or* that are using queue manager QM2:

```
strmqtrc -m QM2
```

Example of enabling dynamic tracing of LDAP client library code shipped with IBM MQ

You can switch LDAP client trace on and off without also stopping or starting the queue manager.

You can use the following command to switch on the trace:

```
strmqtrc -m QMNAME -t servicedata
```

To enable this behavior, it is also necessary to set an environment variable `AMQ_LDAP_TRACE` to a non-null value. For more information, see [Enabling dynamic tracing of LDAP client library code](#).

Related commands

Table 152. Related command names and descriptions

Command	Description
dspmqtrc	Display formatted trace output
endmqtrc	End trace

Related tasks

Related reference

[“dspmqtrc \(display formatted trace\)” on page 117](#)

Use the **dspmqtrc** command to format and display IBM MQ trace.

[“endmqtrc \(end trace\)” on page 146](#)

Use the **endmqtrc** command to end tracing for the specified entity or all entities. The **endmqtrc** command ends only the trace that is described by its parameters. Using **endmqtrc** with no parameters ends early tracing of all processes.

[Command sets comparison: Other commands](#)

A table of other commands, showing the command description, and the equivalent PCF commands, MQSC commands, and control commands. The REST API resource and HTTP method equivalents, and IBM MQ Explorer equivalents, are included if available.

Multi **strmqweb (start mqweb server)**

Use the **strmqweb** command to start the mqweb server that is used to support the IBM MQ Console and REST API.

Usage notes

Linux Before you issue the **strmqweb** command in a stand-alone IBM MQ Web Server installation, you must set the **MQ_OVERRIDE_DATA_PATH** environment variable to the IBM MQ Web Server data directory.

- If the mqweb server is part of an IBM MQ installation, you must start the mqweb server as a [privileged user](#).
- **Linux** If the mqweb server is part of a stand-alone IBM MQ Web Server installation, you must start the mqweb server as a user that has read and write access to the IBM MQ Web Server data directory.

Linux Before you start the mqweb server, you must accept the IBM MQ license. On Linux, you can accept the license after installation. For more information, see [“mqlicense \(accept license after installation\)”](#) on page 154.

Syntax

```
➔ strmqweb [ --clean ] ➔
```

Optional parameters

--clean

Cleans all persistent cached information that is related to the specified server instance, which includes OSGi resolver metadata and persistent OSGi bundle data. If you use this option, the server will be required to recompute any cached data at the next startup, which might take more time than a restart that can reuse cached data.

Note: This option is not necessary for normal operation. IBM service might request that you use this option when providing an interim fix, or if there is a suspected problem with the cached data.

Return codes

Table 153. Return code identifiers and descriptions

Return code	Description
0	Command successful.
>0	Command not successful.

For a full list of server command exit codes, see [Liberty:server command options](#) in the WebSphere Application Server documentation.

Related commands

Table 156. MQSC object synonyms (continued)	
Object	Synonym
TCLUSTER	
TOPIC	TPC
TPSTATUS	TPS

Table 157. IBM MQ MQSC commands and their purpose	
Command name	Purpose
“ALTER AUTHINFO (alter authentication information object)” on page 319	Use the MQSC command ALTER AUTHINFO to alter an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.
“ALTER BUFFPOOL (alter buffer pool settings) on z/OS” on page 332	Use the MQSC command ALTER BUFFPOOL to dynamically change the settings of a predefined buffer pool on z/OS.
“ALTER CFSTRUCT (alter CF application structure) on z/OS” on page 334	On z/OS, use the MQSC command ALTER CFSTRUCT to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.
“ALTER CHANNEL (alter channel settings)” on page 341	Use the MQSC command ALTER CHANNEL to alter the parameters of a channel.
“ALTER CHANNEL (alter channel settings) MQTT” on page 395	Use the MQSC command ALTER CHANNEL to alter the parameters of a telemetry channel.
“ALTER COMMINFO (alter communication information object) on Multiplatforms” on page 399	Use the MQSC command ALTER COMMINFO to alter the parameters of a communication information object.
“ALTER LISTENER (alter an existing listener) on Multiplatforms” on page 403	Use MQSC command ALTER LISTENER to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.
“ALTER NAMELIST (alter a list of names)” on page 406	Use the MQSC command ALTER NAMELIST to alter a list of names. This list is most commonly a list of cluster names or queue names.
“ALTER PROCESS (alter an existing process definition)” on page 409	Use the MQSC command ALTER PROCESS to alter the parameters of an existing IBM MQ process definition.
“ALTER PSID (change page set expansion method) on z/OS” on page 414	Use the MQSC command ALTER PSID to change the expansion method for a page set.
“ALTER QMGR (alter queue manager settings)” on page 415	Use the MQSC command ALTER QMGR to alter the queue manager parameters for the local queue manager.
“ALTER queues (alter queue settings)” on page 453	Use the MQSC ALTER command to alter the parameters of a queue. A queue might be a local queue (ALTER QLOCAL), alias queue (ALTER QALIAS), model queue (ALTER QMODEL), a remote queue, a queue manager alias, or a reply-to queue alias (ALTER QREMOTE).
“ALTER SECURITY (alter security options) on z/OS” on page 487	Use the MQSC command ALTER SECURITY to define system-wide security options.
“ALTER SERVICE (alter a service definition) on Multiplatforms” on page 489	Use the MQSC command ALTER SERVICE to alter the parameters of an existing IBM MQ service definition.
“ALTER SMDS (alter shared message data sets) on z/OS” on page 492	Use the MQSC command ALTER SMDS to alter the parameters of existing IBM MQ definitions relating to one or more shared message data sets associated with a specific application structure. It is only supported when the CFSTRUCT definition is using the option OFFLOAD(SMDS) .
“ALTER STGCLASS (alter storage class settings) on z/OS” on page 494	Use the MQSC command ALTER STGCLASS to alter the characteristics of a storage class.

Table 157. IBM MQ MQSC commands and their purpose (continued)	
Command name	Purpose
“ALTER SUB (alter subscription settings)” on page 497	Use the MQSC command ALTER SUB to alter the characteristics of an existing subscription.
“ALTER TOPIC (alter topic settings)” on page 501	Use the MQSC command ALTER TOPIC to alter the parameters of an existing IBM MQ topic object.
“ALTER TRACE (alter trace event settings) on z/OS” on page 511	Use the MQSC command ALTER TRACE to change the trace events being traced for a particular active queue manager trace. ALTER TRACE stops the specified trace, and restarts it with the altered parameters.
“ARCHIVE LOG (back up the active log) on z/OS” on page 513	Use the MQSC command ARCHIVE LOG as part of your backup procedure. It takes a copy of the current active log (or both logs if you are using dual logging).
“BACKUP CFSTRUCT (back up a CF application structure) on z/OS” on page 516	Use the MQSC command BACKUP CFSTRUCT to initiate a CF application structure backup.
“CLEAR QLOCAL (clear messages from local queue)” on page 517	Use the MQSC command CLEAR QLOCAL to clear the messages from a local queue.
“CLEAR TOPICSTR (clear topic string)” on page 519	Use the MQSC command CLEAR TOPICSTR to clear the retained message which is stored for the specified topic string.
“DEFINE AUTHINFO (define an authentication information object)” on page 521	Use the MQSC command DEFINE AUTHINFO to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.
“DEFINE BUFFPOOL (define a buffer pool) on z/OS” on page 535	Use the MQSC command DEFINE BUFFPOOL to define a buffer pool that is used for holding messages in main storage.
“DEFINE CFSTRUCT (define coupling facility application structure) on z/OS” on page 537	Use the MQSC command DEFINE CFSTRUCT to define queue manager CF level capability, message offload environment, and backup and recovery parameters for a coupling facility application structure.
“DEFINE CHANNEL (define a new channel)” on page 544	Use the MQSC command DEFINE CHANNEL to define a new channel and set its parameters.
“DEFINE CHANNEL (define a new channel) for MQTT” on page 599	Use the MQSC command DEFINE CHANNEL to define a new IBM MQ Telemetry channel, and set its parameters.
“DEFINE COMMINFO (define a new communication information object) on Multiplatforms” on page 603	Use the MQSC command DEFINE COMMINFO to define a new communication information object. These objects contain the definitions required for Multicast messaging.
“DEFINE LISTENER (define a new listener) on Multiplatforms” on page 608	Use the MQSC command DEFINE LISTENER to define a new IBM MQ listener definition, and set its parameters.
“DEFINE LOG (define a new active log) on z/OS” on page 611	Use the MQSC command DEFINE LOG to add a new active log data set in the ring of active logs.
“DEFINE MAXSMGS (define maximum messages setting) on z/OS” on page 613	Use the MQSC command DEFINE MAXSMGS to define the maximum number of messages that a task can get or put within a single unit of recovery.
“DEFINE NAMELIST (define a list of names)” on page 614	Use the MQSC command DEFINE NAMELIST to define a list of names. This is most commonly a list of cluster names or queue names.
“DEFINE PROCESS (create a new process definition)” on page 618	Use the MQSC command DEFINE PROCESS to define a new IBM MQ process definition, and set its parameters.
“DEFINE PSID (define page set and buffer pool) on z/OS” on page 623	Use the MQSC command DEFINE PSID to define a page set and associated buffer pool.
“DEFINE queues” on page 625	Use the MQSC DEFINE command to define a local, model, or remote queue, or a queue alias, reply-to queue alias, or a queue manager alias.

Table 157. IBM MQ MQSC commands and their purpose (continued)	
Command name	Purpose
“DEFINE SERVICE (create a new service definition) on Multiplatforms” on page 662	Use the MQSC command DEFINE SERVICE to define a new IBM MQ service definition, and set its parameters.
“DEFINE STGCLASS (define storage class to page set mapping) on z/OS” on page 665	Use the MQSC command DEFINE STGCLASS to define a storage class to page set mapping.
“DEFINE SUB (create a durable subscription)” on page 669	Use the MQSC command DEFINE SUB to allow an existing application to participate in a publish/subscribe application by allowing the administrative creation of a durable subscription.
“DEFINE TOPIC (define a new administrative topic)” on page 675	Use the MQSC command DEFINE TOPIC to define a new IBM MQ administrative topic in a topic tree, and set its parameters.
“DELETE AUTHINFO (delete authentication information)” on page 687	Use the MQSC command DELETE AUTHINFO to delete an authentication information object.
“DELETE AUTHREC (delete authority records) on Multiplatforms” on page 690	Use the MQSC command DELETE AUTHREC to delete authority records associated with a profile name.
“DELETE BUFFPOOL (delete a buffer pool) on z/OS” on page 692	Use the MQSC command DELETE BUFFPOOL to delete a buffer pool that is used for holding messages in main storage.
“DELETE CFSTRUCT (delete CF application structure) on z/OS” on page 693	Use the MQSC command DELETE CFSTRUCT to delete a CF application structure definition.
“DELETE CHANNEL (delete a channel)” on page 694	Use the MQSC command DELETE CHANNEL to delete a channel definition.
“DELETE CHANNEL (delete a channel) MQTT” on page 697	Use the MQSC command DELETE CHANNEL to delete an IBM MQ Telemetry channel definition.
“DELETE COMMINFO (delete communications information) on Multiplatforms” on page 698	Use the MQSC command DELETE COMMINFO to delete a communication information object.
“DELETE LISTENER (delete a listener) on Multiplatforms” on page 699	Use the MQSC command DELETE LISTENER to delete a listener definition.
“DELETE NAMELIST (delete a name list)” on page 700	Use the MQSC command DELETE NAMELIST to delete a namelist definition.
“DELETE POLICY (delete a security policy) on Multiplatforms” on page 702	Use the MQSC command DELETE POLICY to delete a security policy.
“DELETE PROCESS (delete a process definition)” on page 703	Use the MQSC command DELETE PROCESS to delete a process definition.
“DELETE PSID (delete a page set) on z/OS” on page 705	Use the MQSC command DELETE PSID to delete a page set. This command closes the page set and de-allocates it from the queue manager.
“DELETE queues” on page 706	Use the MQSC DELETE command to delete a queue definition for a local, model, or remote queue, or a queue alias.
“DELETE SERVICE (delete a service definition) on Multiplatforms” on page 712	Use the MQSC command DELETE SERVICE to delete a service definition.
“DELETE STGCLASS (delete a storage class) on z/OS” on page 713	Use the MQSC command DELETE STGCLASS to delete a storage class definition.
“DELETE SUB (delete a durable subscription)” on page 715	Use the MQSC command DELETE SUB to remove a durable subscription from the system. For a managed destination, any unprocessed messages left on the destination are removed.
“DELETE TOPIC (delete an administrative topic node)” on page 717	Use the MQSC command DELETE TOPIC to delete an IBM MQ administrative topic node.
“DISPLAY APSTATUS (display application status) on Multiplatforms” on page 720	Use the MQSC command DISPLAY APSTATUS to display the status of one or more applications and application instances connected to a queue manager or a uniform cluster.
“DISPLAY ARCHIVE (display archive system information) on z/OS” on page 726	Use the MQSC command DISPLAY ARCHIVE to display archive system parameters and information.

Table 157. IBM MQ MQSC commands and their purpose (continued)

Command name	Purpose
“DISPLAY AUTHINFO (display authentication information)” on page 728	Use the MQSC command DISPLAY AUTHINFO to display the attributes of an authentication information object.
“DISPLAY AUTHREC (display authority records) on Multiplatforms” on page 735	Use the MQSC command DISPLAY AUTHREC to display the authority records associated with a profile name.
“DISPLAY AUTHSERV (display authorization services information) on AIX, Linux, and Windows” on page 738	Use the MQSC command DISPLAY AUTHSERV to display information about the level of function supported by the installed authorization services.
“DISPLAY CFSTATUS (display CF application structure status) on z/OS” on page 739	Use the MQSC command DISPLAY CFSTATUS to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
“DISPLAY CFSTRUCT (display CF application structure settings) on z/OS” on page 747	Use the MQSC command DISPLAY CFSTRUCT to display the attributes of one or more CF application structures. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.
“DISPLAY CHANNEL (display channel definition)” on page 751	Use the MQSC command DISPLAY CHANNEL to display a channel definition.
“DISPLAY CHANNEL (display channel definition) MQTT” on page 767	Use the MQSC command DISPLAY CHANNEL (MQTT) to display an IBM MQ Telemetry channel definition.
“DISPLAY CHINIT (display channel initiator information) on z/OS” on page 770	Use the MQSC command DISPLAY CHINIT to display information about the channel initiator. The command server must be running.
“DISPLAY CHLAUTH (display channel authentication record)” on page 772	Use the MQSC command DISPLAY CHLAUTH to display the attributes of a channel authentication record.
“DISPLAY CHSTATUS (display channel status)” on page 777	Use the MQSC command DISPLAY CHSTATUS to display the status of one or more channels.
“DISPLAY CHSTATUS (display channel status) AMQP” on page 798	Use the MQSC command DISPLAY CHSTATUS (AMQP) to display the status of one or more AMQP channels.
“DISPLAY CHSTATUS (display channel status) MQTT” on page 802	Use the MQSC command DISPLAY CHSTATUS (MQTT) to display the status of one or more IBM MQ Telemetry channels.
“DISPLAY CLUSQMGR (display channel information for cluster queue managers)” on page 806	Use the MQSC command DISPLAY CLUSQMGR to display information about cluster channels for queue managers in a cluster.
“DISPLAY CMDSERV (display command server status) on z/OS” on page 815	Use the MQSC command DISPLAY CMDSERV to display the status of the command server.
“DISPLAY COMMINFO (display communication information) on Multiplatforms” on page 816	Use the MQSC command DISPLAY COMMINFO to display the attributes of a communication information object.
“DISPLAY CONN (display application connection information)” on page 819	Use the MQSC command DISPLAY CONN to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.
“DISPLAY ENTAUTH (display entity authorizations) on Multiplatforms” on page 833	Use the MQSC command DISPLAY ENTAUTH to display the authorizations an entity has to a specified object.
“DISPLAY GROUP (display QSG information) on z/OS” on page 835	Use the MQSC command DISPLAY GROUP to display information about the queue sharing group to which the queue manager is connected. This command is valid only when the queue manager is a member of a queue sharing group.
“DISPLAY LISTENER (display listener information) on Multiplatforms” on page 836	Use the MQSC command DISPLAY LISTENER to display information about a listener.
“DISPLAY LOG (display log information) on z/OS” on page 840	Use the MQSC command DISPLAY LOG to display log system parameters and information.
“DISPLAY LSSTATUS (display listener status) on Multiplatforms” on page 841	Use the MQSC command DISPLAY LSSTATUS to display status information for one or more listeners.

Table 157. IBM MQ MQSC commands and their purpose (continued)

Command name	Purpose
“DISPLAY MAXSMSGS (display maximum messages setting) on z/OS” on page 845	Use the MQSC command DISPLAY MAXSMSGS to see the maximum number of messages that a task can get or put within a single unit of recovery.
“DISPLAY NAMELIST (display a list of names)” on page 846	Use the MQSC command DISPLAY NAMELIST to display the names in a namelist.
“DISPLAY POLICY (display a security policy) on Multiplatforms” on page 850	Use the MQSC command DISPLAY POLICY to display a security policy.
“DISPLAY PROCESS (display process information)” on page 851	Use the MQSC command DISPLAY PROCESS to display the attributes of one or more IBM MQ processes.
“DISPLAY PUBSUB (display publish/subscribe status information)” on page 855	Use the MQSC command DISPLAY PUBSUB to display publish/subscribe status information for a queue manager.
“DISPLAY QMGR (display queue manager settings)” on page 860	Use the MQSC command DISPLAY QMGR to display the queue manager parameters for this queue manager.
“DISPLAY QMSTATUS (display queue manager status) on Multiplatforms” on page 876	Use the MQSC command DISPLAY QMSTATUS to display status information associated with this queue manager.
“DISPLAY QSTATUS (display queue status)” on page 890	Use the MQSC command DISPLAY QSTATUS to display the status of one or more queues.
“DISPLAY QUEUE (display queue attributes)” on page 903	Use the MQSC command DISPLAY QUEUE to display the attributes of one or more queues of any type.
“DISPLAY SBSTATUS (display subscription status)” on page 919	Use the MQSC command DISPLAY SBSTATUS to display the status of a subscription.
“DISPLAY SECURITY (display security settings) on z/OS” on page 923	Use the MQSC command DISPLAY SECURITY to display the current settings for the security parameters.
“DISPLAY SERVICE (display service information) on Multiplatforms” on page 925	Use the MQSC command DISPLAY SERVICE to display information about a service.
“DISPLAY SMDS (display shared message data sets information) on z/OS” on page 928	Use the MQSC command DISPLAY SMDS to display the parameters of existing IBM MQ shared message data sets associated with a specified application structure.
“DISPLAY SMDSCONN (display shared message data sets connection information) on z/OS” on page 930	Use the MQSC command DISPLAY SMDSCONN to display status and availability information about the connection between the queue manager and the shared message data sets for the specified CFSTRUCT .
“DISPLAY STGCLASS (display storage class information) on z/OS” on page 934	Use the MQSC command DISPLAY STGCLASS to display information about storage classes.
“DISPLAY SUB (display subscription information)” on page 938	Use the MQSC command DISPLAY SUB to display the attributes associated with a subscription.
“DISPLAY SVSTATUS (display services status) on Multiplatforms” on page 946	Use the MQSC command DISPLAY SVSTATUS to display status information for one or more services. Only services with a SERVTYPE of SERVER are displayed.
“DISPLAY SYSTEM (display system information) on z/OS” on page 949	Use the MQSC command DISPLAY SYSTEM to display general system parameters and information.
“DISPLAY TCLUSTER (display cluster topic attributes)” on page 951	Use the MQSC command DISPLAY TCLUSTER to display the attributes of the IBM MQ cluster topic object.
“DISPLAY THREAD (display thread information) on z/OS” on page 957	Use the MQSC command DISPLAY THREAD to display information about active and in-doubt threads.
“DISPLAY TOPIC (display topic information)” on page 959	Use the MQSC command DISPLAY TOPIC to display the attributes of one or more IBM MQ topic objects of any type.
“DISPLAY TPSTATUS (display topic status)” on page 969	Use the MQSC command DISPLAY TPSTATUS to display the status of one or more topics in a topic tree.
“DISPLAY TRACE (display active traces list) on z/OS” on page 978	Use the MQSC command DISPLAY TRACE to display a list of active traces.

Table 157. IBM MQ MQSC commands and their purpose (continued)	
Command name	Purpose
“DISPLAY USAGE (display usage information) on z/OS” on page 981	Use the MQSC command DISPLAY USAGE to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.
“MOVE QLOCAL (move messages between local queues) on z/OS” on page 983	Use the MQSC command MOVE QLOCAL to move all the messages from one local queue to another.
“PING CHANNEL (test channel response)” on page 985	Use the MQSC command PING CHANNEL to test a channel by sending data as a special message to the remote queue manager, and checking that the data is returned. The data is generated by the local queue manager.
“PING QMGR (test queue manager response) on Multiplatforms” on page 989	Use the MQSC command PING QMGR to test whether the queue manager is responsive to commands.
“PURGE CHANNEL (stop and purge a channel) on AIX, Linux, and Windows” on page 990	Use the MQSC command PURGE CHANNEL to stop and purge an IBM MQ Telemetry or AMQP channel. Purging an IBM MQ Telemetry or AMQP channel disconnects all the MQTT or AMQP clients connected to it, cleans up the state of the MQTT or AMQP clients, and stops the IBM MQ Telemetry or AMQP channel. Cleaning the state of a client deletes all the pending publications, including any last will and testament message required by the client, and removes all the subscriptions from the client.
“RECOVER BSDS (recover bootstrap data set) on z/OS” on page 991	Use the MQSC command RECOVER BSDS to reestablish a dual bootstrap data set (BSDS), after a data set error one has caused one to stop working.
“RECOVER CFSTRUCT (recover CF application structure) on z/OS” on page 992	Use the MQSC command RECOVER CFSTRUCT to initiate recovery of CF application structures and associated shared message data sets. This command is valid only when the queue manager is a member of a queue sharing group.
“REFRESH CLUSTER (rebuild a cluster)” on page 994	Use the MQSC command REFRESH CLUSTER to discard all locally held cluster information and force it to be rebuilt. The command also processes any auto-defined channels that are in doubt. After the command completes processing, you can perform a "cold-start" on the cluster.
“REFRESH QMGR (refresh a queue manager)” on page 997	Use the MQSC command REFRESH QMGR to perform special operations on queue managers.
“REFRESH SECURITY (refresh security settings)” on page 1001	Use the MQSC command REFRESH SECURITY to perform a security refresh.
“RESET CFSTRUCT (reset a CF application structure) on z/OS” on page 1006	Use the MQSC command RESET CFSTRUCT to modify the status of a specific application structure.
“RESET CHANNEL (reset message sequence number for a channel)” on page 1007	Use the MQSC command RESET CHANNEL to reset the message sequence number for an IBM MQ channel with, optionally, a specified sequence number to be used the next time that the channel is started. This command is normally used when message AMQ9526E is received, where a channel is unable to start because of a sequence number error.
“RESET CLUSTER (remove a cluster member)” on page 1010	Use the MQSC command RESET CLUSTER on a full repository queue manager to remove a partial repository queue manager from a cluster. Only use this command in an emergency, where normal methods cannot be used.
“RESET QMGR (reset a queue manager)” on page 1012	Use the MQSC command RESET QMGR as part of your backup and recovery procedures.
“RESET QSTATS (report and reset queue performance data) on z/OS” on page 1016	Use the MQSC command RESET QSTATS to report performance data for a queue and then to reset that data.
“RESET SMDS (reset shared message data sets) on z/OS” on page 1018	Use the MQSC command RESET SMDS to modify availability or status information relating to one or more shared message data sets associated with a specific application structure.

Table 157. IBM MQ MQSC commands and their purpose (continued)	
Command name	Purpose
“RESET TPIPE (reset sequence numbers for an IMS Tpipe) on z/OS” on page 1020	Use the MQSC command RESET TPIPE to reset the recoverable sequence numbers for an IMS Tpipe used by the IBM MQ - IMS bridge.
“RESOLVE CHANNEL (ask a channel to resolve in-doubt messages)” on page 1022	Use the MQSC command RESOLVE CHANNEL to request a channel to commit or back out in-doubt messages.
“RESOLVE INDOUBT (resolve threads left in doubt) on z/OS” on page 1024	Use the MQSC command RESOLVE INDOUBT to resolve threads left in doubt because IBM MQ or a transaction manager could not resolve them automatically.
“RESUME QMGR (resume a cluster queue manager)” on page 1026	Use the MQSC command RESUME QMGR to inform other queue managers in a cluster that the local queue manager is available again for processing and can be sent messages. It reverses the action of the SUSPEND QMGR command.
“RVERIFY SECURITY (set a user reverification flag) on z/OS” on page 1028	Use the MQSC command RVERIFY SECURITY to set a reverification flag for all specified users. The user is reverified the next time that security is checked for that user.
“SET ARCHIVE (change archive system settings) on z/OS” on page 1030	Use the MQSC command SET ARCHIVE to dynamically change certain archive system parameter values initially set by your system parameter module at queue manager startup.
“SET AUTHREC (set authority records) on Multiplatforms” on page 1035	Use the MQSC command SET AUTHREC to set authority records associated with a profile name.
“SET CHLAUTH (create or modify a channel authentication record)” on page 1041	Use the MQSC command SET CHLAUTH to create or modify a channel authentication record.
“SET LOG (notify completion of log archiving) on Multiplatforms” on page 1050	On Multiplatforms, use the MQSC command SET LOG to notify the queue manager that archiving of a log extent is complete. If the log management type is not ARCHIVE, the command fails.
“SET LOG (change log system settings) on z/OS” on page 1051	On z/OS, use the MQSC command SET LOG to dynamically change certain log system parameter values that were initially set by your system parameter module at queue manager startup.
“SET POLICY (set security policy) on Multiplatforms” on page 1054	Use the MQSC command SET POLICY to set a security policy.
“SET SYSTEM (change system settings) on z/OS” on page 1057	Use the MQSC command SET SYSTEM to dynamically change certain general system parameter values that were initially set from your system parameter module at queue manager startup. To permanently change these, either change the CSQ6SYSP parameters and regenerate the parameter module, or put the SET SYSTEM commands into a data set in the CSQINP2 concatenation.
“START CHANNEL (start a channel)” on page 1061	Use the MQSC command START CHANNEL to start a channel.
“START CHANNEL (start a channel) MQTT” on page 1065	Use the MQSC command START CHANNEL to start an IBM MQ Telemetry channel.
“START CHINIT (start a channel initiator) on z/OS” on page 1066	Use the MQSC command START CHINIT to start a channel initiator.
“START CMDSERV (start the command server) on z/OS” on page 1067	Use the MQSC command START CMDSERV to initialize the command server.
“START LISTENER (start a channel listener)” on page 1068	Use the MQSC command START LISTENER to start a channel listener.
“START QMGR (start queue manager) on z/OS” on page 1071	Use the MQSC command START QMGR to initialize the queue manager. You can also use this command to prepare its data for backwards migration using the BACKMIG parameter.
“START SERVICE (start a service) on Multiplatforms” on page 1074	Use the MQSC command START SERVICE to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.
“START SMDSCONN (restart a shared message data set connection) on z/OS” on page 1075	Use the MQSC command START SMDSCONN to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

Table 157. IBM MQ MQSC commands and their purpose (continued)	
Command name	Purpose
“START TRACE (start trace) on z/OS” on page 1076	Use the MQSC command START TRACE to start traces.
“STOP CHANNEL (stop a channel)” on page 1082	Use the MQSC command STOP CHANNEL to stop a channel.
“STOP CHANNEL (stop a channel) MQTT” on page 1088	Use the MQSC command STOP CHANNEL to stop an IBM MQ Telemetry channel.
“STOP CHINIT (stop channel initiator) on z/OS” on page 1089	Use the MQSC command STOP CHINIT to stop a channel initiator. The command server must be running.
“STOP CMDSERV (stop the command server) on z/OS” on page 1090	Use the MQSC command STOP CMDSERV to stop the command server.
“STOP CONN (stop a connection) on Multiplatforms” on page 1091	Use the MQSC command STOP CONN to break a connection between an application and the queue manager.
“STOP LISTENER (stop a channel listener)” on page 1092	Use the MQSC command STOP LISTENER to stop a channel listener.
“STOP QMGR (stop queue manager) on z/OS” on page 1095	Use the MQSC command STOP QMGR to stop the queue manager.
“STOP SERVICE (stop a service) on Multiplatforms” on page 1097	Use the MQSC command STOP SERVICE to stop a service.
“STOP SMDSCONN (stop shared message data sets connection) on z/OS” on page 1098	Use the MQSC command STOP SMDSCONN to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.
“STOP TRACE (stop trace) on z/OS” on page 1099	Use the MQSC command STOP TRACE to stop tracing.
“SUSPEND QMGR (suspend a cluster queue manager)” on page 1102	Use the MQSC command SUSPEND QMGR to advise other queue managers in a cluster to avoid sending messages to the local queue manager if possible.

Related concepts

[“IBM MQ control commands reference” on page 21](#)

Reference information about the IBM MQ control commands.

[Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#)

Related tasks

[Administering IBM MQ using MQSC commands](#)

Related reference

[“CL commands for IBM i reference” on page 1695](#)

CL commands are the preferred way to issue administration commands to IBM MQ on IBM i. These commands perform similar functions to PCF commands, but have a different format.

[“Programmable command formats \(PCFs\) reference” on page 1105](#)

PCFs define command and reply messages that can be exchanged across a network between a program and any queue manager that supports PCFs. This simplifies queue manager administration and other network administration.

Related information

[Clustering: Using REFRESH CLUSTER best practices](#)

ALTER AUTHINFO (alter authentication information object)

Use the MQSC command **ALTER AUTHINFO** to alter an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER AUTHINFO** command result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

There are separate syntax diagrams for each **AUTHTYPE** parameter option:

- [Syntax diagram for TYPE\(CRLLDAP\)](#)
- [Syntax diagram for TYPE\(OCSP\)](#)
- [Syntax diagram for TYPE\(IDPWOS\)](#)
- [Syntax diagram for TYPE\(IDPWLDAP\)](#)
- [“Parameter descriptions for ALTER AUTHINFO” on page 323](#)

Syntax diagram for AUTHTYPE (CRLLDAP)

Synonym: ALT AUTHINFO

Syntax diagram for AUTHTYPE (OCSP)

Synonym: ALT AUTHINFO

ALTER AUTHINFO

➤ ALTER AUTHINFO — (— *name* —) — AUTHTYPE(OCSP) ➤

Notes:

¹ Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

² Valid only on z/OS.

Syntax diagram for AUTHTYPE (IDPWOS)

Synonym: ALT AUTHINFO

ALTER AUTHINFO

➤ ALTER AUTHINFO — (— *name* —) — AUTHTYPE(IDPWOS) ➤

Notes:

- ¹ Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
- ² Valid only on z/OS.
- ³ Not valid on z/OS and PAM value can be set only on AIX and Linux.
- ⁴ Not valid on z/OS.

Syntax diagram for AUTHTYPE (IDPWLDAP)

Synonym: ALT AUTHINFO

ALTER AUTHINFO

► ALTER AUTHINFO — (— *name* —) — AUTHTYPE(IDPWLDAP) ¹ —►

Notes:

¹ Not valid on z/OS.

Parameter descriptions for ALTER AUTHINFO

name

Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See [Rules for naming IBM MQ objects](#).

ADOPTCTX

Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

YES

The user ID in the authentication credentials presented in the MQCSP structure, which have been successfully validated, is adopted as the context to use for this application. Therefore, this user ID has the credentials checked for authorization to use IBM MQ resources.

If the application presents a user ID and password, the user ID in the MQCSP structure is adopted if the password is successfully validated.

  If the application presents an authentication token, and the token is successfully validated, the user ID in the token user claim is adopted as the context for the application. The name of the token user claim is specified by the **UserClaim** attribute in the **AuthToken** stanza of the `qm.ini` file. For more information about the **UserClaim** attribute, see [UserClaim](#).

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the [SHORTUSR](#) associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

ADOPTCTX(YES) has an effect only if **CHCKCLNT** or **CHCKLOCL** is set to a value that causes the credentials to be validated.

NO

Authentication is performed on the credentials presented in the MQCSP structure, but then the credentials are not adopted for further use. Authorization is performed using the user ID that the application is running under.

The **ADOPTCTX** attribute is only valid for an **AUTHTYPE** of **IDPWOS** and **IDPWLDP**.

AUTHENMD

Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

OS

  Use the traditional UNIX password verification method.

PAM

Use the PAM to authenticate the user password.

  You can set the PAM value only on AIX and Linux.

Changes to this attribute are effective only after you run the [REFRESH SECURITY TYPE\(CONNAUTH\)](#) command.

The **AUTHENMD** attribute is valid only for an **AUTHTYPE** of **IDPWOS**.

AUTHORMD

Authorization method.

OS

Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

SEARCHGRP

A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all the users belonging to that group. Membership is indicated by the attribute defined in [FINDGRP](#). This value is typically *member* or *uniqueMember*.

SEARCHUSR

A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs. The attribute to query is defined by the [FINDGRP](#) value, typically *memberOf*.

SRCHGRPSN

A group entry in the LDAP repository contains an attribute listing the short user name of all the users belonging to that group. The attribute in the user record that contains the short user name is specified by [SHORTUSR](#).

Membership is indicated by the attribute defined in [FINDGRP](#). This value is typically *memberUid*.

Note: This authorization method should only be used if all user short names are distinct.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to SEARCHGRP.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

AUTHTYPE

The type of authentication information.

CRLLDAP

Certificate Revocation List checking is done using LDAP servers.

IDPWLDAP

Connection authentication user ID and password checking is done using an LDAP server.

IDPWOS

Connection authentication user ID and password checking is done using the operating system.

  Authentication tokens supplied by IBM MQ MQI clients are validated if the queue manager is configured to accept authentication tokens using the **AuthToken** stanza of the `qm.ini` file. For more information about the **AuthToken** stanza, see [AuthToken stanza of the qm.ini file](#).

OCSP

Certificate revocation checking is done using OCSP.

  An authentication information object with **AUTHTYPE(OCSP)** does not apply for use on IBM i or z/OS queue managers. However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

The **AUTHTYPE** parameter is required.

You cannot define an authentication information object as LIKE another authentication object with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

BASEDNG

Base DN for groups.

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

BASEDNU(base DN)

In order to be able to find the short user name attribute, [SHORTUSR](#), this parameter must be set with the base DN to search for users within the LDAP server.

The **BASEDNU** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

CHCKCLNT

This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP. The possible values are:

NONE

Authentication credentials supplied by client applications are not checked. If a user ID and password, or an authentication token, is supplied by a client application, the credentials are ignored. **ADOPTCTX** will have no effect and any user IDs contained within the MQCSP will not be used for authorization checks later.

OPTIONAL

Client applications are not required to provide authentication credentials.

Any applications that do provide a user ID and password in the [MQCSP](#) structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

This option might be useful during migration, for example.

REQUIRED

All client applications must provide authentication credentials in the [MQCSP](#) structure.

If an application provides a user ID and password, these credentials are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

If an application does not provide any authentication credentials, the connection is rejected.

REQDADM

All client applications using a privileged user ID must provide authentication credentials in the [MQCSP](#) structure. Any client applications using a non-privileged user ID are not required to provide authentication credentials and are treated as with the **OPTIONAL** setting.

A privileged user is one that has full administrative authorities for IBM MQ. See [Privileged users](#) for more information.

Any provided user ID and password are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

Note: The **REQDADM** value for the **CHCKCLNT** attribute is irrelevant if the authentication type is LDAP. This is because there is no concept of privileged user ID when using LDAP user accounts. LDAP user accounts and groups must be assigned permission explicitly.

► **z/OS** This setting is not allowed on z/OS systems.

Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the **CHLAUTH** rule that matches the client connection. The [CONNAUTH AUTHINFO CHCKCLNT](#) attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a **CHLAUTH** rule, or where the **CHLAUTH** rule matched has **CHCKCLNT** **ASQMGR**.
2. ► **Multi** On Multiplatforms, if you select **NONE** and the client connection matches a **CHLAUTH** record with **CHCKCLNT** **REQDADM**, the connection fails. You receive message AMQ9793.
3. ► **z/OS** On z/OS, if you select **NONE** and the client connection matches a **CHLAUTH** record with **CHCKCLNT** **REQUIRED**, the connection fails. You receive message CSQX793E.

4. This parameter is valid only with **TYPE (USERMAP)**, **TYPE (ADDRESSMAP)** and **TYPE (SSLPEERMAP)**, and only when **USERSRC** is not set to NOACCESS.
5. This parameter applies only to inbound connections that are server-connection channels.

CHKLOCL

This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP.

 For information about use of this attribute on IBM MQ Appliance, see [Control commands on the IBM MQ Appliance in the IBM MQ Appliance documentation](#).

The possible values are:

NONE

Authentication credentials supplied by client applications are not checked. If a user ID and password is supplied by a locally bound application, the credentials are ignored.

OPTIONAL

Locally bound applications are not required to provide authentication credentials.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

  Authentication tokens cannot be supplied by locally bound applications.

This option might be useful during migration, for example.

REQUIRED

All locally bound applications must provide authentication credentials in the MQCSP structure.

If an application provides a user ID and password, these credentials are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

  Authentication tokens cannot be supplied by locally bound applications.

If an application does not provide any authentication credentials, the connection is rejected.

 If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHKLOCL (REQUIRED)** as if it is **CHKLOCL (OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one.

See [Using CHKLOCL on locally bound applications](#).

REQADM

All locally bound applications using a privileged user ID must provide authentication credentials in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide authentication credentials and are treated as with the OPTIONAL setting.

A privileged user is one that has full administrative authorities for IBM MQ. See [Privileged users](#) for more information.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

  Authentication tokens cannot be supplied by locally bound applications.

 (This setting is not allowed on z/OS systems.)

CLASSGRP

The LDAP object class used for group records in the LDAP repository.

If the value is blank, groupOfNames is used.

Other commonly used values include `groupOfUniqueNames` or `group`.

CLASSUSR(LDAP class user)

The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to `inetOrgPerson`, which is generally the value needed.

For Microsoft Active Directory, the value you require is often `user`.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

•

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of `*` is the same as entering the command on every queue manager in the queue sharing group.

CONNAME(connection name)

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the **AUTHINFO** object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

 On z/OS, if a **CONNAME** is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for **CONNAME** is the same as for channels. For example,

```
conname('hostname (nnn)')
```

where *nnn* is the port number.

The maximum length for the field is:

-  264 characters on [Multiplatforms](#).
-  48 characters on z/OS.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP, when the attribute is mandatory.

When used with an **AUTHTYPE** of IDPWLDAP, this can be a comma separated list of connection names.

DESCR(string)

Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the **DISPLAY AUTHINFO** command (see [“DISPLAY AUTHINFO \(display authentication information\)”](#) on page 728).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

FAILDLAY(delay time)

When authentication credentials are provided for connection authentication, and the authentication fails due to the credentials being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

The **FAILDLAY** attribute is valid only for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

FINDGRP

Name of the attribute used within an LDAP entry to determine group membership.

When **AUTHORMD** = *SEARCHGRP*, the **FINDGRP** attribute is typically set to *member* or *uniqueMember*.

When **AUTHORMD** = *SEARCHUSR*, the **FINDGRP** attribute is typically set to *memberOf*.

When **AUTHORMD** = *SRCHGRPSN*, the **FINDGRP** attribute is typically set to *memberUid*.

When left blank, if:

- **AUTHORMD** = *SEARCHGRP*, the **FINDGRP** attribute defaults to *memberOf*
- **AUTHORMD** = *SEARCHUSR*, the **FINDGRP** attribute defaults to *member*
- **AUTHORMD** = *SRCHGRPSN*, the **FINDGRP** attribute defaults to *memberUid*

GRPFIELD

LDAP attribute that represents a simple name for the group.

If the value is blank, commands like **setmqaut** must use a qualified name for the group. The value can either be a full DN, or a single attribute.

LDAPPWD(LDAP password)

The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

 On z/OS, the **LDAPPWD** used for accessing the LDAP server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPPWD** in the first AUTHINFO object is used for accessing all LDAP Servers.

The **GRPFIELD** attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

LDAPUSER(LDAP user)

The Distinguished Name of the user who is accessing the LDAP server. (See the **SSLPEER** parameter for more information about distinguished names.)

The maximum size for the user name is:

-  1024 characters on Multiplatforms.
-  256 characters on z/OS.

 On z/OS, the **LDAPUSER** used for accessing the LDAP server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPUSER** in the first AUTHINFO object is used for accessing all LDAP Servers.

If more than one OCSP type AUTHINFO objects is referenced in the NAMELIST, only the first entry is used.

 On Multiplatforms, the maximum accepted line length is defined to be BUFSIZ, which can be found in stdio.h.

The **LDAPUSER** attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

NESTGRP

Group nesting.

NO

Only the initially discovered groups are considered for authorization.

YES

The group list is searched recursively to enumerate all the groups to which a user belongs.

The group's Distinguished Name is used when searching the group list recursively, regardless of the authorization method selected in [AUTHORMD](#).

OCSPURL(Responder URL)

The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation. To preserve case, use single quotation marks to specify the OCSPURL parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for **AUTHTYPE(OCSP)**, when it is mandatory.

z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 158. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR) , is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE AUTHINFO(name) REPLACE QSGDISP(COPY)</pre> The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY) . Any object residing in the shared repository is unaffected.

Table 158. Behavior for each of the QSGDISP values (continued)	
QSGDISP	ALTER
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR) . Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

SECCOMM

Whether connectivity to the LDAP server should be done securely using TLS

YES

Connectivity to the LDAP server is made securely using TLS.

The certificate used is the default certificate for the queue manager, named in CERTLABL on the queue manager object, or if that is blank, the one described in [Digital certificate labels, understanding the requirements](#).

The certificate is located in the key repository specified in SSLKEYR on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use **SSLFIPS(YES)** or SUITEB cipher specs, then this is taken account of in the connection to the LDAP server as well.

ANON

Connectivity to the LDAP server is made securely using TLS just as for **SECCOMM(YES)** with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in SSLKEYR, on the queue manager object, does not contain a certificate marked as the default.

NO

Connectivity to the LDAP server does not use TLS.

The **SECCOMM** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

SHORTUSR(user name)

A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.
- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

The **SHORTUSR** attribute is valid only for an **AUTHTYPE** of IDPWLDAP and is mandatory.

USRFIELD(user field)

If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an '=' sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the [SHORTUSR](#) parameter to interpret the provided user ID.

The contents of this field are concatenated with an '=' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application

provides a user of fred and this field has the value cn, then the LDAP repository will be searched for cn=fred.

The **USRFIELD** attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

[“DEFINE AUTHINFO \(define an authentication information object\)” on page 521](#)

Use the MQSC command **DEFINE AUTHINFO** to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.

[“DELETE AUTHINFO \(delete authentication information\)” on page 687](#)

Use the MQSC command **DELETE AUTHINFO** to delete an authentication information object.

[“DISPLAY AUTHINFO \(display authentication information\)” on page 728](#)

Use the MQSC command **DISPLAY AUTHINFO** to display the attributes of an authentication information object.

ALTER BUFFPOOL (alter buffer pool settings) on z/OS

Use the MQSC command **ALTER BUFFPOOL** to dynamically change the settings of a predefined buffer pool on z/OS.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER BUFFPOOL** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER BUFFPOOL” on page 332](#)
- [“Usage notes for ALTER BUFFPOOL” on page 332](#)
- [“Parameter descriptions for ALTER BUFFPOOL” on page 333](#)

Syntax diagram for ALTER BUFFPOOL

Synonym: **ALT BP**

Usage notes for ALTER BUFFPOOL

1. Buffers are added or removed according to whether the value is more than or less than the current allocation (which can be shown by the **DISPLAY USAGE** command).
2. If there is insufficient storage, of the type specified by the **PAGECLAS** attribute to add the requested number, as many as possible are added.

3. The command runs asynchronously. Message CSQP023I is sent to the console when the command is complete.
4. **ALTER BUFFPOOL** cannot be issued from CSQINPT.
5. If you have made changes to buffer pools by using the **ALTER BUFFPOOL** command, particularly if you have reduced the buffer pools by large quantities, you should recycle the queue manager as soon as possible, to clear up any storage fragmentation caused by the change in buffer pool size.

Failure to recycle the queue manager, might result in you receiving the following error code, ABEND878-10 - Virtual private region depleted, caused by the fragmentation of region storage in the IBM MQ MSTR address space.
6. The **ALTER BUFFPOOL** command cannot be issued from the CSQINP1 DD concatenation. If you need to apply the changes at queue manager startup, use the **DEFINE BUFFPOOL** command in the CSQINP1 file instead of **ALTER BUFFPOOL**.

Parameter descriptions for ALTER BUFFPOOL

(buf-pool-id)

Buffer pool identifier.

This parameter is an integer in the range zero through 99.

BUFFERS(integer)

This parameter is optional and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the **LOCATION** parameter is **BELOW**, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the **LOCATION** parameter is **ABOVE**, then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool with **LOCATION ABOVE** is obtained in multiples of 4MB. Therefore specifying a **BUFFERS** value which is a multiple of 1024 will make the most efficient use of storage.

See [Buffers and buffer pools](#) for guidance on the number of buffers you can define in each buffer pool.

When altering a buffer pool care should be taken to ensure that there is sufficient storage available for it either above or below the bar. For more information, see [Address space storage](#).

Note: Altering a large buffer pool can take several minutes depending on size of the buffer pool and machine configuration. In some cases message CSQP061I might be output.

LOCATION or LOC(BELOW or ABOVE)

LOCATION and **LOC** are synonyms and either, but not both, can be used.

The **LOCATION** or **LOC** parameter specifies where the memory used by the specified buffer pool is located.

Attention: Deprecated From IBM MQ 9.1, **LOCATION (BELOW)** is deprecated and you should use **LOCATION (ABOVE)** only.

This memory location can be either **ABOVE** (64 bit) or **BELOW** (31 bit) the bar, with **BELOW** being the default.

When altering a buffer pool, you should take care to make sure that there is sufficient storage available if increasing the number of buffers, or changing the **LOCATION** value. Switching the location of the buffer pool can be a CPU and I/O intensive task. You should perform this task when the queue manager is not being heavily used.

For more information, see [Address space storage](#).

PAGECLAS(4KB or FIXED4KB)

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the **ALTER BUFFPOOL** command. The default value is 4KB, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its location attribute set to BELOW. If the buffer pool has its LOCATION attribute set to ABOVE, it is also possible to specify FIXED4KB. This means that fixed 4KB pages, which are permanently in real storage and will never be paged out to auxiliary storage, are used to back the buffers in the buffer pool.

The **PAGECLAS** attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar, to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

The current value of **PAGECLAS** can be checked by issuing the **DISPLAY USAGE PSID(*)** command. Doing this also results in a CSQP062I message being output, if the current value of **PAGECLAS** is different from the value in the log of the queue manager. For example:

- Buffer pool 7 currently has **LOCATION(ABOVE)** and **PAGECLAS(4KB)** specified. If **ALTER BUFFPOOL(7) PAGECLAS(FIXED4KB)** is specified, the buffer pool continues to be backed by pageable 4KB pages as the **LOCATION** has not been changed.
- Buffer pool 8 currently has **LOCATION(BELOW)** and **PAGECLAS(4KB)** specified. If **ALTER BUFFPOOL(8) LOCATION(ABOVE) PAGECLAS(FIXED4KB)** is specified, the buffer pool is moved above the bar and has its buffers backed by fixed 4KB pages, if any are available.

When you specify **PAGECLAS(FIXED4KB)** the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start, or other address spaces might be impacted; for more information, see [Address space storage](#).

See IBM MQ Support Pac MP16: [IBM MQ for z/OS - Capacity planning & tuning](#) for advice on when to use the FIXED4KB value of the **PAGECLAS** attribute.

Use the MQSC command **DELETE BUFFPOOL** to delete a buffer pool that is used for holding messages in main storage.

ALTER CFSTRUCT (alter CF application structure) on z/OS

On z/OS, use the MQSC command **ALTER CFSTRUCT** to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER CFSTRUCT** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER CFSTRUCT” on page 334](#)
- [“Usage notes for ALTER CFSTRUCT” on page 335](#)
- [“Parameter descriptions for ALTER CFSTRUCT” on page 335](#)

Syntax diagram for ALTER CFSTRUCT

Synonym: ALT CFSTRUCT

ALTER CFSTRUCT

Offload attributes

Usage notes for ALTER CFSTRUCT

- This command cannot specify the CF administration structure (CSQ_ADMIN).
- This command is valid only when the queue manager is a member of a queue sharing group.

Parameter descriptions for ALTER CFSTRUCT

(*structure-name*)

Name of the coupling facility application structure with queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative

structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

CFCONLOS

This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

ASQMGR

The action taken is based on the setting of the **CFCONLOS** queue manager attribute.

TERMINATE

The queue manager terminates when connectivity to the structure is lost. This is the default value when **CFLEVEL** is increased to 5.

TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

The **CFCONLOS** parameter is only valid from **CFLEVEL (5)**.

CFLEVEL(integer)

Specifies the functional capability level for this CF application structure. Value can be one of the following:

1

A CF structure that can be "auto-created" by a queue manager at command level 520.

2

A CF structure at command level 520 that can only be created or deleted by a queue manager at command level 530 or greater.

3

A CF structure at command level 530. This **CFLEVEL** is required if you want to use persistent messages for either one or both of the following reasons:

- On shared queues, if **RECOVER(YES)** is set.
- For message grouping when a local queue is defined with **INDXTYPE (GROUPID)**.

You can only increase the value of **CFLEVEL** to 3 if all the queue managers in the queue sharing group are at command level 530 or greater - this is to ensure that there are no latent command level 520 connections to queues referencing the structure.

You can only decrease the value of **CFLEVEL** from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

4

This **CFLEVEL** supports all the **CFLEVEL (3)** functions. **CFLEVEL (4)** allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

Only a queue manager with a command level of 600 or greater can connect to a CF structure at **CFLEVEL (4)**.

You can only increase the value of **CFLEVEL** to 4 if all the queue managers in the queue sharing group are at command level 600 or greater.

You can only decrease the value of **CFLEVEL** from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

5

This **CFLEVEL** supports all functions for **CFLEVEL (4)**. In addition, **CFLEVEL (5)** enables the following new functions. If altering an existing **CFSTRUCT** to **CFLEVEL (5)**, you must review other attributes as indicated:

- Queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2®, under control of the **OFFLOAD** attribute. The offload threshold and size parameters (such as **OFFLD1TH**, and **OFFLD1SZ**) determine whether any particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the **DSGROUP**, **DSBUFS**, **DSEXPAND** and **DSBLOCK** attributes are respected.

- Structures at **CFLEVEL (5)** allow the queue manager to tolerate a loss of connectivity to the CF structure. The **CFCONLOS** attribute determines queue manager behavior when a loss of connectivity is detected, and the **RECAUTO** attribute controls subsequent automatic structure recovery behavior.
- Messages containing IBM MQ message properties are stored in a different format on shared queues in a **CFLEVEL (5)** structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue **PROPCTL** attribute.

Only a queue manager with a command level of 710 or above can connect to a CF structure at **CFLEVEL (5)**.

Note: You can decrease the value of **CFLEVEL** from 5 if all the queues that reference the CF structure are both empty, that is the queues, and CF structure have no messages or uncommitted activity, and are closed.

DESCR(string)

Plain-text comment that provides descriptive information about the object when an operator issues the **DISPLAY CFSTRUCT** command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

OFFLOAD

Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

SMDS

Offload messages from coupling facility to shared message data set (SMDS).

DB2

Offload messages from coupling facility to Db2. This value is the default assumption when **CFLEVEL** is increased to 5.

Offloading messages using Db2 has significant performance impact. If you want to use offload rules as a means of increasing capacity, the SMDS option should be specified.

This parameter is only valid from **CFLEVEL (5)**. At **CFLEVEL (4)** any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

Note: If you change the offload technique (from DB2 to SMDS or the other way) then all new messages are written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified, then the **DSGROUP** parameter is also required. It can be specified either on the same command or on a previous **DEFINE** or **ALTER** command for the same structure.

OFFLD1TH(percentage) OFFLD1SZ(size)

OFFLD2TH(percentage) OFFLD2SZ(size)

OFFLD3TH(percentage) OFFLD3SZ(size)

Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure. The offloaded message still requires an entry in the coupling facility containing message control information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (less than approximately 140 bytes) it may fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case, no space can be saved, so any offload rules are ignored and the message data is not offloaded.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. Headers and descriptors typically require approximately 400 bytes.

percentage

The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full).

size

The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range 0K to 64K. As messages exceeding 63.75 KB are always offloaded, the value 64K is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure **ALTER** processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during **ALTER** processing but the total is only updated when the **ALTER** completes. At such times, a rule specifying 100 for the threshold may temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at **CFLEVEL (5)** or upgrading an existing structure to **CFLEVEL (5)** depend on the **OFFLOAD** method option. For **OFFLOAD (SMDS)**, the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For **OFFLOAD (Db2)**, the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for **CFLEVEL (4)**.

For **OFFLOAD (SMDS)** the defaults are:

- **OFFLD1TH(70) OFFLD1SZ(32K)**
- **OFFLD2TH(80) OFFLD2SZ(4K)**
- **OFFLD3TH(90) OFFLD3SZ(0K)**

For **OFFLOAD (Db2)** the defaults are:

- **OFFLD1TH(70) OFFLD1SZ(64K)**
- **OFFLD2TH(80) OFFLD2SZ(64K)**
- **OFFLD3TH(90) OFFLD3SZ(64K)**

If the **OFFLOAD** method option is changed from Db2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from **CFLEVEL (5)**. At **CFLEVEL (4)**, any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

DSGROUP

For **OFFLOAD (SMDS)**, specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

'data.set.name.*'

The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters. The queue manager name can form all or part of any qualifier in the data set name.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified, then the **DSGROUP** parameter must also be specified.

The **DSGROUP** parameter is only valid from **CFLEVEL (5)**.

DSBLOCK

For **OFFLOAD (SMDS)**, specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

8K

16K

32K

64K

128K

256K

512K

1M

Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

The **DSBLOCK** parameter is only valid from **CFLEVEL (5)**.

DSBUFS

For **OFFLOAD (SMDS)**, specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

number

This parameter can be overridden for individual queue managers using the **DSBUFS** parameter on **ALTER SMDS**.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSBUFS override value) dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the **DSBUFS** parameter associated with its own individual SMDS definition (as for the **ALTER SMDS** command) to match the actual new number of buffers.

These buffers use virtual storage. You should work with the z/OS systems programmer to ensure there is sufficient auxiliary storage available before increasing the number of buffers.

The **DSBUFS** parameter is only valid from **CFLEVEL (5)**.

DSEXPA

For **OFFLOAD (SMDS)**, this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES

Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

NO

No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the **DSEXPAND** parameter on **ALTER SMDS**.

If an expansion attempt fails, the **DSEXPAND** override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any queue managers that are already connected to the structure (and that do not have an individual **DSEXPAND** override value) immediately start using the new parameter value.

The **DSEXPAND** parameter is only valid from **CFLEVEL (5)**.

RECOVER

Specifies whether CF recovery is supported for the application structure. Values are:

NO or N

CF application structure recovery is not supported.

YES or Y

CF application structure recovery is supported.

You can only set **RECOVER(YES)** if the structure has a **CFLEVEL** of 3 or higher. Set **RECOVER(YES)** if you intend to use persistent messages.

You can only change **RECOVER(NO)** to **RECOVER(YES)** if all the queue managers in the queue sharing group are at command level 530 or greater ; this is to ensure that there are no latent command level 520 connections to queues referencing the **CFSTRUCT**.

You can only change **RECOVER(YES)** to **RECOVER(NO)** if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

RECAUTO

Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values can be:

YES or Y

The structure and associated shared message data sets which also need recovery are automatically recovered.

NO or N

The structure is not automatically recovered. This is the default value when **CFLEVEL** is increased to 5.

This parameter has no effect for structures defined with **RECOVER(NO)**.

The **RECAUTO** parameter is only valid from **CFLEVEL (5)**.

Syntax diagrams for ALTER CHANNEL

Synonym: ALT CHL

There is a separate syntax diagram for each type of channel:

SDR

[Syntax diagram for sender channel](#)

SVR

[Syntax diagram for server channel](#)

RCVR

[Syntax diagram for receiver channel](#)

RQSTR

[Syntax diagram for requester channel](#)

CLNTCONN

[Syntax diagram for client-connection channel](#)

SVRCONN

[Syntax diagram for server-connection channel](#)

CLUSSDR

[Syntax diagram for cluster-sender channel](#)

CLUSRCVR

[Syntax diagram for cluster-receiver channel](#)

AMQP

[Syntax diagram for AMQP channel](#)

Usage notes for ALTER CHANNEL

- Changes take effect after the channel is next started.

- For cluster channels (the CLUSSDR and CLUSRCVR columns in the table), if an attribute can be set on both channels, set it on both and ensure that the settings are identical. If there is any discrepancy between the settings, those that you specify on the CLUSRCVR channel are likely to be used. This is explained in [Cluster channels](#).
- If you change the **XMITQ** name or the **CONNAME**, you must reset the sequence number at both ends of the channel. (See [“RESET CHANNEL \(reset message sequence number for a channel\)”](#) on page 1007 for information about the **SEQNUM** parameter.)
- Successful completion of the command does not mean that the action completed. To check for true completion, see the [ALTER CHANNEL](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for ALTER CHANNEL

The following table shows the parameters that are relevant for each type of channel.

- SDR: sender channel
- SVR: server channel
- RCVR: receiver channel
- RQSTR: requester channel
- CLNTCONN: client-connection channel
- SVRCONN: server-connection channel
- CLUSSDR: cluster-sender channel
- CLUSRCVR: cluster-receiver channel
-  AMQP: AMQP channel

There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

AFFINITY

The channel affinity attribute is used so client applications that connect multiple times using the same queue manager name can choose whether to use the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the weighting with any applicable **CLNTWGHT (0)** definitions first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non-**CLNTWGHT (0)** definitions are moved to the end of the list. **CLNTWGHT (0)** definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created. Each client process with the same host name creates the same list.

NONE

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable **CLNTWGHT (0)** definitions selected first in alphabetical order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created.

For example, suppose the CCDT includes the following definitions:

```
CHLNAME(A) QMNAME(QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME(QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME(QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list CHLNAME(B), CHLNAME(A), CHLNAME(C).

For **AFFINITY(PREFERRED)**, each connection in the process attempts to connect using **CHLNAME(B)**. If a connection is unsuccessful the definition is moved to the end of the list which now becomes CHLNAME(A), CHLNAME(C), CHLNAME(B). Each connection in the process then attempts to connect using **CHLNAME(A)**.

For **AFFINITY(NONE)**, each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

When sharing conversations is enabled with a non-zero channel weighting and **AFFINITY(NONE)**, multiple connections in a process using the same queue manager name can connect using different applicable definitions rather than sharing an existing channel instance.

AMQPKA(integer)

The keep alive time for an AMQP channel in milliseconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

BATCHHB(integer)

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages, so that if the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range zero through 999999. A value of zero indicates that batch heartbeating is not used.

The **BATCHHB** parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHINT(integer)

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages have been sent.
- **BATCHLIM** bytes have been sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty, or the **BATCHSZ** or **BATCHLIM** limit is reached.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

BATCHLIM(integer)

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached has flowed across

the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages have been sent.
- **BATCHLIM** bytes have been sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

The **BATCHLIM** parameter is supported on all platforms.

BATCHSZ(integer)

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The **BATCHSZ** of the sending channel.
- The **BATCHSZ** of the receiving channel.
-  **z/OS** On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  **Multi** On Multiplatforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  **z/OS** On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
-  **Multi** On Multiplatforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

The maximum number of uncommitted messages is specified by the **MAXUMSGS** parameter of the **ALTER QMGR** command.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 through 9999.

CERTLABL

Certificate labels for this channel to use.

 **Multi** On AIX, Linux, IBM i, and Windows, this can be a comma or space separated list of certificates.

 **z/OS** On z/OS, this must be a single certificate label.

The labels identify which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL**, or  **z/OS** on z/OS the **CERTQSG** (if the queue manager is part of a queue sharing group) parameter.

Note that inbound channels (including receiver, requester, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec. See [Interoperability of Elliptic Curve and RSA CipherSpecs](#) for further information.

An unqualified server channel is one that does not have the **CONNAME** field set.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent.

 You must run a **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on the queue manager or any inbound channels. However, you do not need to run the **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on an outbound channel.

 Generally, it is not recommended to include commas or spaces within certificate labels. If, however, your certificate labels do contain a comma or space they must be escaped with a backslash (\) to prevent them being mistaken for a separation character.  IBM i does not support space as a separator and thus you do not need to escape this character.

 When a list of certificates is provided, the first certificate in the list that is valid for the CipherSpec is chosen. When a TLS 1.2 CipherSpec is used the certificate type on the inbound channel definition must match the CipherSpec type. A list of certificates allows a channel to use different CipherSpec types and supply a different certificate as needed. For outbound channels or channels when TLS 1.3 is used, the first certificate in the list is selected.

Note: All certificates in the list of certificates must exist in the keystore and be valid certificates.

Note: It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF_WRONG_CHANNEL_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

(channel-name)

The name of the new channel definition.

This parameter is required on all types of channel.

 On CLUSSDR channels, it can take a different form from the other channel types. If your convention for naming cluster-sender channels includes the name of the queue manager, you can define a cluster-sender channel using the +QMNAME+ construction. After connection to the matching cluster-receiver channel, IBM MQ substitutes the correct repository queue manager name in place of +QMNAME+ in the cluster-sender channel definition. For more information see [Components of a cluster](#).

The name must not be the same as any existing channel defined on this queue manager (unless **REPLACE** or **ALTER** is specified).

 On z/OS, client-connection channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see [Rules for naming IBM MQ objects](#).

CHLTYPE

Channel type. This parameter is required. It must follow immediately after the *(channel-name)* parameter on all platforms except z/OS.

- SDR: sender channel
- SVR: server channel
- RCVR: receiver channel
- RQSTR: requester channel
- CLNTCONN: client-connection channel
- SVRCONN: server-connection channel
- CLUSSDR: cluster-sender channel
- CLUSRCVR: cluster-receiver channel
-  AMQP: AMQP channel

Note: If you are using the **REPLACE** option, you cannot change the channel type.

CLNTWGHT

The client channel weighting attribute is used so client channel definitions can be selected at random based on their weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. To enable random load balancing the value can be in the range 1 through 99 where 1 is the lowest weighting and 99 is the highest.

When a client issues an MQCONN with queue manager name *"*name"* and more than one suitable definition is available in the CCDT the choice of definition to use is randomly selected based on the weighting with any applicable **CLNTWGHT(0)** definitions selected first in alphabetical order. The distribution is not guaranteed.

For example, suppose the CCDT includes the following two definitions:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name *"*GRP1"* would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 would be generated. If the integer was in the range 1 through 2 address1 would be used otherwise address2 would be used). If this connection was unsuccessful the client would then use the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weightings are chosen first and in alphabetical order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose the CCDT includes the following four definitions:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name *"*GRP1"* would first choose definition "TO.QM3". If this connection was unsuccessful the client would then choose definition "TO.QM4". If this connection was also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT support is added for all supported transport protocols.

CLUSNL(*nlname*)

The name of the namelist that specifies a list of clusters to which the channel belongs.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

CLUSTER(*clustername*)

The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

CLWLPRTY(*integer*)

Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see [CLWLPRTY queue attribute](#).

CLWLRANK(*integer*)

Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see [CLWLRANK channel attribute](#).

CLWLWGHT(*integer*)

Specifies the weighting to be applied to the channel for the purposes of cluster workload distribution so that the proportion of messages sent down the channel can be controlled. The value must be in the range 1 through 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see [CLWLWGHT channel attribute](#).

z/OS

CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

.

The command is executed on the queue manager on which it was entered.

qmgr-name

The command is executed on the queue manager you specify, providing the queue manager is active within the queue sharing group. You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

The command is executed on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of ***** is the same as entering the command on every queue manager in the queue sharing group.

COMPHDR

The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

NONE

No header data compression is performed.

SYSTEM

Header data compression is performed.

COMPMSG

The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

NONE

No message data compression is performed.

RLE

Message data compression is performed using run-length encoding.

ZLIBFAST

Message data compression is performed using ZLIB encoding with speed prioritized.

► **z/OS** On z/OS systems with [zEDC Express facility](#) enabled, compression can be offloaded to zEDC Express.

ZLIBHIGH

Message data compression is performed using ZLIB encoding with compression prioritized.

► **Multi** LZ4FAST

Message data compression is performed using LZ4 encoding with speed prioritized.

► **Multi** LZ4HIGH

Message data compression is performed using LZ4 encoding with compression prioritized.

ANY

Any compression technique supported by the queue manager can be used. This value is only valid for receiver, requester, and server-connection channels.

CONNAME(string)

Connection name.

For cluster-receiver channels (when specified) **CONNAME** relates to the local queue manager, and for other channels it relates to the target queue manager.

► **Multi** On [Multiplatforms](#), the maximum length of the string is 264 characters.

► **z/OS** On z/OS, the maximum length of **CONNAME** varies:

- For channels of **TRPTYPE (LU62)**, the maximum length is always 48 characters.
- ≥ V 10.0.0 For channels of **TRPTYPE (TCP)**, from IBM MQ 10.0.0, the maximum length is 264 characters. Lengths greater than 48 characters cannot be used for **QSGDISP (GROUP | COPY)** channel definitions until all queue managers in the queue sharing group are at IBM MQ 10.0.0 or later.
- For client-connection channels, the maximum length is always 48 characters.

A workaround to the 48 character limit might be one of the following suggestions:

- ≥ V 10.0.0 Migrate to IBM MQ 10.0.0 or later.
- Set up your DNS servers so that you use, for example, host name of "myserver" instead of "myserver.location.company.com", ensuring that you can use the short host name.
- Use IP addresses.

Specify **CONNAME** as a comma-separated list of names of machines for the stated **TRPTYPE**. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the **CLNTWGHT** attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

This parameter is required for channels with a channel type (**CHLTYPE**) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of **TRPTYPE (TCP)**, and is not valid for RCVR or SVRCONN channels.

► **Multi** On [Multiplatforms](#), the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default

port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

```
(1415)
```

The generated **CONNNAME** is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

Note: If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type (**TRPTYPE**) to be used:

LU 6.2

- ▶ **Multi** On Multiplatforms, **CONNNAME** is the name of the CPI-C communications side object. Or, if the **TPNAME** is not blank, **CONNNAME** is the fully qualified name of the partner logical unit.
- ▶ **z/OS** On z/OS, there are two forms in which to specify the value:

Logical unit name

The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Table 160. Logical unit name forms and examples	
Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the **TPNAME** and **MODENAME** parameters; otherwise these parameters must be blank.

Note: For client-connection channels, only the first form is allowed.

Symbolic name

The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The **TPNAME** and **MODENAME** parameters must be blank.

Note: For cluster-receiver channels, the side information is on the other queue managers in the cluster. Alternatively, in this case it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

For more information, see [Configuration parameters for an LU 6.2 connection](#).

NetBIOS

A unique NetBIOS name (limited to 16 characters).

SPX

The 4 byte network address, the 6 byte node address, and the 2 byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

```
CONNNAME('0a0b0c0d.804abcde23a1(5e86)')
```

TCP

Either the host name, or the network address of the remote machine (or the local machine for cluster-receiver channels). This address can be followed by an optional port number, enclosed in parentheses.

If the **CONNAME** is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on both the value specified for **CONNAME** and the value specified for **LOCLADDR**. See [LOCLADDR](#) for information about how this value is resolved.

 On z/OS, the connection name can include the IP_name of an z/OS dynamic DNS group or a Network Dispatcher input port.

Important: Do not include the IP_name or input port for channels with a channel type (**CHLTYPE**) of CLUSSDR.

On all platforms, when you define a channel with a channel type (**CHLTYPE**) of CLUSRCVR that is using TCP/IP, you do not need to specify the network address of your queue manager. IBM MQ generates a **CONNAME** for you, assuming the default port and using the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

Note: If you are using clustering between IPv6-only and IPv4-only queue managers, do not specify an IPv6 network address as the **CONNAME** for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a cluster sender channel definition that specifies the CONNAME in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

CONVERT

Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

NO

No conversion by sender

YES

Conversion by sender

 On z/OS, N and Y are accepted as synonyms of NO and YES.

The **CONVERT** parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

DEFCDISP

Specifies the default channel disposition of the channel.

PRIVATE

The intended disposition of the channel is as a PRIVATE channel.

FIXSHARED

The intended disposition of the channel is as a FIXSHARED channel.

SHARED

The intended disposition of the channel is as a SHARED channel.

This parameter does not apply to channels with a channel type (**CHLTYPE**) of CLNTCONN, CLUSSDR, or CLUSRCVR.

DEFRECON

Specifies whether a client connection automatically reconnects a client application if its connection breaks.

NO (default)

Unless overridden by **MQCONN**, the client is not reconnected automatically.

YES

Unless overridden by **MQCONN**, the client reconnects automatically.

QMGR

Unless overridden by **MQCONN**, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO_RECONNECT_Q_MGR.

DISABLED

Reconnection is disabled, even if requested by the client program using the **MQCONN** MQI call.

Table 161. Automatic reconnection depends on the values set in the application and in the channel definition				
DEFRECON	Reconnection options set in the application			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO (default)	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

DESCR(string)

Plain-text comment. It provides descriptive information about the channel when an operator issues the **DISPLAY CHANNEL** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DISCINT(integer)

The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue, after a batch ends, before terminating the channel. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range zero through 999 999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN , SDR, SVR, CLUSSDR, CLUSRCVR.

For SVRCONN channels using the TCP protocol, this parameter is the minimum time in seconds for which the SVRCONN instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The SVRCONN inactivity interval only applies between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

HBINT(integer)

This attribute specifies the approximate time between heartbeat flows that are to be passed from a sending MCA when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that have been allocated for large messages and close any queues that have been left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 through 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For server-connection and client-connection channels, heartbeats can flow from both the server side as well as the client side independently. If no data has been transferred across the channel for the heartbeat interval, the client-connection MQI agent sends a heartbeat flow and the server-connection MQI agent responds to it with another heartbeat flow. This happens irrespective of the state of the channel, for example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The server-connection MQI agent is also capable of initiating a heartbeat

to the client, again irrespective of the state of the channel. To prevent both server-connection and client-connection MQI agents heart beating to each other at the same time, the server heartbeat is flowed after no data has been transferred across the channel for the heartbeat interval plus 5 seconds.

For more information, see [Heartbeat interval \(HBINT\)](#).

KAINT(integer)

The value passed to the communications stack for KeepAlive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

z/OS On z/OS, you enable TCP/IP keepalive in the queue manager by issuing the **ALTER QMGR TCPKEEP(YES)** command; if the **TCPKEEP** queue manager parameter is NO, the value is ignored, and the KeepAlive facility is not used.

Multi On Multiplatforms, TCP/IP keepalive is enabled when the **KEEPALIVE=YES** parameter is specified in the TCP stanza in the distributed queuing configuration file, `qm.ini`, or through the IBM MQ Explorer.

Keepalive must also be enabled within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive:

- **AIX** On AIX, use the **no** command.
- **Windows** On Windows, edit the registry.
- **z/OS** On z/OS, update your TCP/IP PROFILE data set and add or change the **INTERVAL** parameter in the TCPCONFIG section.

z/OS Although this parameter is available on all platforms, its setting is implemented only on z/OS.

Multi On Multiplatforms, you can access and modify the parameter, but it is only stored and forwarded; there is no functional implementation of the parameter. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on AIX, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster.

Multi On Multiplatforms, if you need the functionality provided by the **KAINT** parameter, use the Heartbeat Interval (**HBINT**) parameter, as described in [HBINT](#).

(integer)

The KeepAlive interval to be used, in seconds, in the range 1 through 99 999.

0

The value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

AUTO

The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated **HBINT** is greater than zero, KeepAlive interval is set to that value plus 60 seconds.
- If the negotiated **HBINT** is zero, the value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

This parameter is valid for all channel types. It is ignored for channels with a **TRPTYPE** other than TCP or SPX.

LIKE(channel-name)

The name of a channel. The parameters of this channel are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from one of the following default channels, depending upon the channel type:

SYSTEM.DEF.SENDER

Sender channel

SYSTEM.DEF.SERVER

Server channel

SYSTEM.DEF.RECEIVER

Receiver channel

SYSTEM.DEF.REQUESTER

Requester channel

SYSTEM.DEF.SVRCONN

Server-connection channel

SYSTEM.DEF.CLNTCONN

Client-connection channel

SYSTEM.DEF.CLUSSDR

Cluster-sender channel

SYSTEM.DEF.CLUSRCVR

Cluster-receiver channel

This parameter is equivalent to defining the following object for a sender channel, and similarly for other channel types:

```
LIKE(SYSTEM.DEF.SENDER)
```

These default channel definitions can be altered by the installation to the default values required.

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object and channel type you are defining.

Note:

1. **QSGDISP (GROUP)** objects are not searched.
2. # **LIKE** is ignored if **QSGDISP (COPY)** is specified. However, the group object defined is used as a **LIKE** object.

LOCLADDR(string)

LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. **LOCLADDR** might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 stack on a dual-stack system. You can also use **LOCLADDR** to force a channel to use a dual-mode stack on a single-stack system.

Note: AMQP channels do not support the same format of **LOCLADDR** as other IBM MQ channels. For the format supported by AMQ, see the next parameter **AMQP: LOCLADDR**.

For channels other than AMQP channels, the **LOCLADDR** parameter is valid only for channels with a transport type (**TRPTYPE**) of TCP. If **TRPTYPE** is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr] [(low-port[,high-port])] [, [ip-addr] [(low-port[,high-port])]])
```

The maximum length of **LOCLADDR**, including multiple addresses, is MQ_LOCAL_ADDRESS_LENGTH. If you omit **LOCLADDR**, a local address is automatically allocated.

Note, that you can set **LOCLADDR** for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the `ip-addr` part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having to identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify `[, [ip-addr] [(low-port[,high-port])]]` multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use `[, [ip-addr] [(low-port[,high-port])]]` to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

ip-addr

`ip-addr` is specified in one of three forms:

IPv4 dotted decimal

For example, 192.0.2.1

IPv6 hexadecimal notation

For example, 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example WWW.EXAMPLE.COM

low-port and high-port

`low-port` and `high-port` are port numbers enclosed in parentheses.

The following table shows how the **LOCLADDR** parameter can be used:

<i>Table 162. Examples of how the LOCLADDR parameter can be used</i>	
LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the **LOCLADDR** parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the **LOCLADDR** parameter is used.

 This port range does not apply to z/OS systems.

Note: Do not put an IP address in the **LOCLADDR** field of a CLUSRCVR channel, unless all queue managers are on the same server. The **LOCLADDR** IP address is propagated to the auto-defined CLUSSDR channels of all queue managers that connect using the CLUSRCVR channel.

Even though this parameter is similar in form to **CONNAME**, it must not be confused with it. The **LOCLADDR** parameter specifies the characteristics of the local communications, whereas the **CONNAME** parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for **CONNAME** and **LOCLADDR** determine the IP stack to be used for communication; see the following table and [Local Address \(LOCLADDR\)](#).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

 For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the connect() request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 163. How the IP stack to be used for communication is determined			
Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address ¹		Channel binds to IPv4 stack
	IPv6 address ²		Channel fails to resolve CONNAME
	IPv4 and 6 host name ³		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address ⁴	IPv6 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack

Table 163. How the IP stack to be used for communication is determined (continued)			
Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by IPADDRV
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by IPADDRV
IPv6 only	IPv4 address		Channel maps CONNAME to IPv6 ⁵
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

Table 163. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
Notes: 1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example 1.2.3.4. This note applies to all occurrences of 'IPv4 address' in this table. 2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example 4321:54bc. This note applies to all occurrences of 'IPv6 address' in this table. 3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of 'IPv4 and 6 host name' in this table. 4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table. 5. Maps IPv4 CONNAME to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the CONNAME. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.			

AMQP: LOCLADDR(ip-addr)

Note: For the format of **LOCLADDR** that other IBM MQ channels use, see the previous parameter **LOCLADDR**.

For AMQP channels, **LOCLADDR** is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr

ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal

For example, 192.0.2.1

IPv6 hexadecimal notation

For example, 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example, WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

LONGRTY(integer)

When a sender, server, or cluster-sender channel is attempting to connect to the remote queue manager, and the count specified by **SHORTRTY** has been exhausted, this parameter specifies the maximum number of further attempts that are made to connect to the remote queue manager, at intervals specified by **LONGTMR**.

If this count is also exhausted without success, an error is logged to the operator, and the channel is stopped. The channel must then be restarted with a command (it is not started automatically by the channel initiator).

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

LONGTMR(*integer*)

For long retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

Note: For implementation reasons, the maximum retry interval that can be used is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

MAXINST(*integer*)

The maximum number of simultaneous instances of an individual server-connection channel or AMQP channel that can be started.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that are currently running, then those running instances are not affected. However, new instances cannot start until sufficient existing instances have ceased to run so that the number of currently running instances is less than the value of this parameter.

If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached **MAXINST**, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached **MAXINST**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN or AMQP.

MAXINSTC(*integer*)

The maximum number of simultaneous individual server-connection channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that is currently running from individual clients, then those running instances are not affected. However, new instances from those clients cannot start until sufficient instances have ceased to run that the number of running instances is less than the value of this parameter.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN.

MAXMSGL(*integer*)

Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type (**CHLTYPE**) is SVRCONN.

The value zero means the maximum message length for the queue manager.

 **Multi** On Multiplatforms, specify a value in the range zero through to the maximum message length for the queue manager.

► **z/OS** On z/OS, specify a value in the range zero through 104857600 bytes (100 MB).

See the **MAXMSGL** parameter of the **ALTER QMGR** command for more information.

MCANAME(string)

Message channel agent name.

This parameter is reserved, and if specified must only be set to blanks (maximum length 20 characters).

MCATYPE

Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

PROCESS

The message channel agent runs as a separate process.

THREAD

The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners through the port number specified on the listener.

► **Multi** On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR.

► **z/OS** On z/OS, this parameter is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, **MCATYPE** is used by a remote machine to determine the corresponding CLUSSDR definition.

MCAUSER(string)

Message channel agent user identifier.

Note: An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both **MCAUSER** on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The **MCAUSER** on the channel definition is only used if the channel authentication record uses **USERSRC (CHANNEL)**. For more details, see [Channel authentication records](#).

This parameter interacts with **PUTAUT**, see the definition of that parameter for more information.

If it is nonblank, it is the user identifier that is to be used by the message channel agent for authorization to access IBM MQ resources, including (if **PUTAUT** is DEF) authorization to put the message to the destination queue for receiver or requester channels.

If it is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

- ► **z/OS** On z/OS, the user ID assigned to the channel-initiator started task by the z/OS started-procedures table.
- ► **Multi** For TCP/IP, on [Multiplatforms](#), the user ID from the `inetd.conf` entry, or the user that started the listener.
- ► **Multi** For SNA, on [Multiplatforms](#), the user ID from the SNA server entry or, in the absence of this user ID the incoming attach request, or the user that started the listener.
- For NetBIOS or SPX, the user ID that started the listener.

The maximum length of the string is:

- ► **Windows** 64 characters on Windows.

- 12 characters on platforms other than Windows.

Windows On Windows, you can optionally qualify a user identifier with the domain name in the format `user@domain`.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLNTCONN, CLUSSDR.

MODENAME(string)

LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU 6.2. If **TRPTYPE** is not LU 6.2, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the **CONNAME** contains a side-object name, in which case it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set.

z/OS See [Configuration parameters for an LU 6.2 connection](#) for more information about configuration parameters for an LU 6.2 connection for your platform.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR or SVRCONN.

MONCHL

Controls the collection of online monitoring data for channels:

QMGR

Collect monitoring data according to the setting of the queue manager parameter MONCHL.

OFF

Monitoring data collection is turned off for this channel.

LOW

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a low rate of data collection, for this channel.

MEDIUM

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a moderate rate of data collection, for this channel.

HIGH

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data collection is turned on, with a high rate of data collection, for this channel.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of cluster-sender channels.

For auto-defined cluster-sender channels, the value of this parameter is taken from the queue manager attribute **MONACLS**. If you want to modify the value, use the command `ALTER QMGR MONACLS(HIGH)`, then restart the auto-defined sender channel.

Changes to this parameter take effect only on channels started after the change occurs.

MRDATA(string)

Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MREXIT(string)

Channel message-retry exit name.

The format and maximum length of the name is the same as for MSGEXIT, however you can only specify one message-retry exit.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRRTY(integer)

The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRRTY** is passed to the exit to use, but the number of retries performed (if any) is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999999999. A value of zero means that no retries are performed.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRTMR(integer)

The minimum interval of time that must pass before the channel can try the MQPUT operation again. This time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRTMR** is passed to the exit to use, but the retry interval is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999 999 999. A value of zero means that the retry is performed as soon as possible (if the value of **MRRTY** is greater than zero).

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MSGDATA(string)

User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

 On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

 On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

 On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

Note: This parameter is accepted but ignored for server-connection and client-connection channels.

MSGEXIT(string)

Channel message exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after a message has been retrieved from the transmission queue (sender or server), or immediately before a message is put to a destination queue (receiver or requester).

The exit is given the entire application message and transmission queue header for modification.

- At initialization and termination of the channel.

 On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

 On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

► **z/OS** On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one message exit name for each channel.

For channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN, this parameter is accepted but ignored, because message exits are not invoked for such channels.

The format and maximum length of the name depends on the environment:

- **Linux** ► **AIX** On AIX and Linux, it is of the form:

```
libraryname(functionname)
```

The maximum length of the string is 128 characters.

- **Windows** On Windows, it is of the form:

```
dllname(functionname)
```

where *dllname* is specified without the suffix .DLL. The maximum length of the string is 128 characters.

- **IBM i** On IBM i, it is of the form:

```
progrname libname
```

where *progrname* occupies the first 10 characters and *libname* the second 10 characters (both padded to the right with blanks if necessary). The maximum length of the string is 20 characters.

- **z/OS** On z/OS, it is a load module name, maximum length 8 characters (128 characters are allowed for exit names for client-connection channels, subject to a maximum total length including commas of 999).

NETPRTY(integer)

The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range zero through 9; zero is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

NPMSPEED

The class of service for nonpersistent messages on this channel:

FAST

Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO_SYNCPOINT_IF_PERSISTENT and so are not included in the batch unit of work.

NORMAL

Normal delivery for nonpersistent messages.

If the sending side and the receiving side do not agree about this parameter, or one does not support it, NORMAL is used.

Notes:

1. If the active recovery logs for IBM MQ for z/OS are switching and archiving more frequently than expected, given that the messages being sent across a channel are non-persistent, setting NPMSPEED(FAST) on both the sending and receiving ends of the channel can minimize the SYSTEM.CHANNEL.SYNCQ updates.
2. If you are seeing high CPU usage relating to updates to the SYSTEM.CHANNEL.SYNCQ, setting NPMSPEED(FAST) can significantly reduce the CPU usage.

This parameter is valid only for channels with a **CHLTYPE** of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

PASSWORD(string)

Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

 On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

 On z/OS, it is supported only for channels with a channel type (**CHLTYPE**) of CLNTCONN.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

PORT(integer)

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

PROPCTL

Property control attribute.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

COMPAT

COMPAT allows applications which expect JMS-related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

<i>Table 164. Range of results, depending on which message properties are set, when PROPCTL value is COMPAT</i>	
Message properties	Result
The message contains a property with a prefix of mcd., jms., usr. or mqext.	All optional message properties (where the Support value is MQPD_SUPPORT_OPTIONAL), except properties in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of mcd., jms., usr. or mqext.	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the Support field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the Support field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the <i>content='properties'</i> attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

NONE

All properties of the message, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

ALL

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT

Specifies which user identifiers are used to establish authority to put messages to the destination queue (for messages channels) or to execute an MQI call (for MQI channels).

DEF

The default user ID is used.

► **z/OS** On z/OS, DEF might involve using both the user ID received from the network and that derived from **MCAUSER**.

CTX

The user ID from the *UserIdentifier* field of the message descriptor is used.

► **z/OS** On z/OS, CTX might involve also using the user ID received from the network or that derived from **MCAUSER**, or both.

► **z/OS** ONLYMCA

The user ID derived from **MCAUSER** is used. Any user ID received from the network is not used. This value is supported only on z/OS.

► **z/OS** ALTMCA

The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

► **z/OS** On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF® class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one or two user IDs are checked. To see how many user IDs are checked, see [RESLEVEL and channel initiator connections](#). For more information about which user IDs are checked, see [User IDs used by the channel initiator](#).

► **z/OS** On z/OS, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

► **Multi** On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

QMNAME(string)

Queue manager name.

For channels with a channel type (**CHLTYPE**) of CLNTCONN, this parameter is the name of a queue manager to which an application that is running in a client environment and using the client channel definition table can request connection. This parameter need not be the name of the queue manager on which the channel is defined, to allow a client to connect to different queue managers.

For channels of other types, this parameter is not valid.

► **z/OS** QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 165. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP (COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP (QMGR) , is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP (GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE CHANNEL(channel-name) CHLTYPE(type) REPLACE QSGDISP(COPY)</pre> The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP (COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP (QMGR) or QSGDISP (COPY) . Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP (QMGR) . Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

RCVDATA(string)

Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

RCVEXIT(string)

Channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.
The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SCYDATA(string)

Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

SCYEXIT(string)

Channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.

Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.

- Upon receipt of a response to a security message flow.

Any security message flows received from the remote processor on the remote queue manager are given to the exit.

- At initialization and termination of the channel.

The format and maximum length of the name is the same as for **MSGEXIT** but only one name is allowed.

SENDATA(string)

Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

SENDEXIT(string)

Channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SEQWRAP(integer)

When this value is reached, sequence numbers wrap to start again at 1.

This value is nonnegotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

SHARECNV(integer)

Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A **SHARECNV** value of:

1

Specifies no sharing of conversations over a TCP/IP channel instance. Client heartbeating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.

0

Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN. If the client-connection **SHARECNV** value does not match the server-connection **SHARECNV** value, the lower of the two values is used. This parameter is ignored for channels with a transport type (**TRPTYPE**) other than TCP.

All the conversations on a socket are received by the same thread.

High **SHARECNV** limits have the advantage of reducing queue manager thread usage. However, if many conversations sharing a socket are all busy, there is a possibility of delays as the conversations contend with one another to use the receiving thread. In this situation, a lower **SHARECNV** value is better.

The number of shared conversations does not contribute to the **MAXINST** or **MAXINSTC** totals.

Note: You should restart the client for this change to take effect.

SHORTRTY(integer)

The maximum number of attempts that are made by a sender, server, or cluster-sender channel to connect to the remote queue manager, at intervals specified by **SHORTTMR**, before the (normally longer) **LONGRTY** and **LONGTMR** are used.

Retry attempts are made if the channel fails to connect initially (whether it is started automatically by the channel initiator or by an explicit command), and also if the connection fails after the channel has successfully connected. However, if the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

SHORTTMR(integer)

For short retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

Note: For implementation reasons, the maximum retry interval that can be used is 999999; values exceeding this maximum are treated as 999999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

SPLPROT

SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

This parameter applies to z/OS only, from IBM MQ 9.1.3 onwards.

The permitted values are:

PASSTHRU

Pass through, unchanged, any messages sent or received by the message channel agent for this channel.

This value is valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, or RQSTR, and is the default value.

REMOVE

Remove any AMS protection from messages retrieved from the transmission queue by the message channel agent, and send the messages to the partner.

When the message channel agent gets a message from the transmission queue, if an AMS policy is defined for the transmission queue, it is applied to remove any AMS protection from the message prior to sending the message across the channel. If an AMS policy is not defined for the transmission queue, the message is sent as is.

This value is valid only for channels with a channel type of SDR or SVR.

ASPOLICY

Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

When the message channel agent receives an inbound message, if an AMS policy is defined for the target queue, AMS protection is applied to the message prior to the message being put to the target queue. If an AMS policy is not defined for the target queue, the message is put to the target queue as is.

This value is valid only for channels with a channel type of RCVR or RQSTR.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, SVRCONN, CLUSRCVR, SVR, or RQSTR.

The parameter is used only for channels with **SSLCIPH** specified. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

REQUIRED

IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL

The peer TLS client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

SSLCIPH(string)

Specifies the CipherSpec that is used on the channel. The maximum length is 32 characters.

Attention:   On IBM MQ for z/OS, you can also specify the four digit hexadecimal code of a CipherSpec, whether or not it appears in [Table 1 of Enabling CipherSpecs](#). On IBM i, you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in [Table 1 of Enabling CipherSpecs](#). Also, on IBM i, installation of AC3 is a prerequisite for the use of TLS. You should not specify hexadecimal cipher values in **SSLCIPH**, because it is unclear from the value which cipher will be used, and the choice of which protocol to be used is indeterminate. Using hexadecimal cipher values can lead to CipherSpec mismatch errors.

The **SSLCIPH** values must specify compatible CipherSpecs for both ends of the channel.

This parameter is valid on all channel types that use transport type **TRPTYPE(TCP)**. If the parameter is blank, no attempt is made to use TLS on the channel.

 If [SecureCommsOnly](#) is enabled, plain text communication is not supported and the channel fails to start.

The value for this parameter is also used to set the value of **SECPROT**, which is an output field on the [DISPLAY CHSTATUS](#) command.

Note: When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. See the **SSLCIPH** description for **DEFINE CHANNEL (MQTT)**.

  You can specify a specific CipherSpec or an alias CipherSpec. An alias CipherSpec allows a range of CipherSpecs to be used based on protocol. For more information see [Relationship between alias CipherSpec settings](#).

Attention: If your enterprise needs to guarantee that a certain CipherSpec is negotiated and used, you must not use an alias CipherSpec value.

For information on changing your existing security configurations to use an alias CipherSpec, for example, `ANY_TLS12_OR_HIGHER`, `ANY_TLS13_OR_HIGHER`, and so on, see [Migrating existing security configurations to use an alias CipherSpec](#).

For more information about CipherSpecs, see [Enabling CipherSpecs](#).

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

-   On z/OS, AIX, Linux, and Windows, when a CipherSpec name includes `_EXPORT`, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
-  For z/OS, System SSL states that if a TLS V1.3 connection is being negotiated:
 - The minimum key size for an RSA peer certificate is the larger of the following two values: 2048, or the value specified in the **GSK_PEER_RSA_MIN_KEY_SIZE** attribute.
 - The minimum key size for an ECC peer certificate is the larger of the following two values: 256, or the value specified in the **GSK_PEER_ECC_MIN_KEY_SIZE** attribute.
-  On AIX, Linux, and Windows, when a CipherSpec name includes `_EXPORT1024`, the handshake key size is 1024 bits.

- Otherwise the handshake key size is the size stored in the certificate.

SSLPEER(string)

Specifies the filter to use to compare with the Distinguished Name of the certificate from the peer queue manager or client at the other end of the channel. (A Distinguished Name is the identifier of the TLS certificate.) If the Distinguished Name in the certificate received from the peer does not match the **SSLPEER** filter, the channel does not start.

Note: An alternative way of restricting connections into channels by matching against the TLS Subject Distinguished Name, is to use channel authentication records. With channel authentication records, different TLS Subject Distinguished Name patterns can be applied to the same channel. If both **SSLPEER** on the channel and a channel authentication record are used to apply to the same channel, the inbound certificate must match both patterns in order to connect. For more information, see [Channel authentication records](#).

This parameter is optional; if it is not specified, the Distinguished Name of the peer is not checked at channel startup. (The Distinguished Name from the certificate is still written into the **SSLPEER** definition held in memory, and passed to the security exit). If **SSLCIPH** is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The **SSLPEER** value is specified in the standard form used to specify a Distinguished Name. For example:

```
SSLPEER( ' SERIALNUMBER=4C:D0:49:D5:02:5F:38, CN="H1_C_FR1", O=IBM, C=GB' )
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

<i>Table 166. Attribute types supported by SSLPEER</i>	
Summary attribute	Description
SERIALNUMBER	Certificate serial number
MAIL	Email address
 DEPRECATED E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zip code
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address

Table 166. Attribute types supported by SSLPEER (continued)	
Summary attribute	Description
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the **SSLPEER** string, an error is output either when the attribute is defined or at run time (depending on which platform you are running on), and the string is deemed not to have matched the Distinguished Name of the flowed certificate.

If the Distinguished Name of the flowed certificate contains multiple OU (organizational unit) attributes, and **SSLPEER** specifies these attributes to be compared, they must be defined in descending hierarchical order. For example, if the Distinguished Name of the flowed certificate contains the OUs OU=Large Unit, OU=Medium Unit, OU=Small Unit, specifying the following **SSLPEER** values works:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following **SSLPEER** values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, ('OU=Large Unit,OU=Medium Unit') is equivalent to ('OU=Large Unit,OU=Medium Unit,OU=*)

If two DN's are equal in all respects except for their DC values, the same matching rules apply as for OUs except that in DC values the left-most DC is the lowest-level (most specific) and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk (*) on its own, or a stem with initiating or trailing asterisks. Asterisks allow the **SSLPEER** to match any Distinguished Name value, or any value starting with the stem for that attribute.

If an asterisk is specified at the beginning or end of any attribute value in the Distinguished Name on the certificate, you can specify '*' to check for an exact match in **SSLPEER**. For example, if you have an attribute of CN='Test*' in the Distinguished Name of the certificate, you can use the following command:

```
SSLPEER('CN=Test\*')
```

ALW The maximum length of the parameter is 1024 bytes on AIX, Linux, and Windows.

IBM i The maximum length of the parameter is 1024 bytes on IBM i.

z/OS The maximum length of the parameter is 256 bytes on z/OS.

Channel authentication records provide greater flexibility when using **SSLPEER** and support 1024 bytes on all platforms.

SSLQS

Requests which quantum safe keys share the channel should attempt to be secured with.

NONE

Do not use a quantum safe algorithms for this link.

MLKEM

Attempt to use the ML-KEM quantum safe algorithm to secure this link.

HYBMLKEM

Attempt to use the Hybrid ML-KEM quantum safe algorithm to secure this link.

Note: To select a quantum safe algorithm, it must be enabled by using the **AllowedQuantumSafeAlgorithms** configuration option.

When a value other than NONE is specified, the channel will attempt to negotiate a quantum safe key exchange during the TLS handshake. If the channel is unable to negotiate, it will fall back to using traditional TLS key exchanges. To prevent fallback, use the **SSLQSR** setting. For a quantum safe key exchange to be successful, both sides of the channel must support the selected quantum safe algorithm and TLS 1.3 must be enabled and selected by using the **SSLCIPH** setting of the channel.

For more information, see [Quantum Safe TLS](#).

SSLQSR

Whether a quantum safe communication is optional or required for a link:

OPTIONAL

Quantum safe communication may be attempted but if unsuccessful, traditional TLS is allowed as a fallback.

REQUIRED

This channel must use quantum safe communications.

Note: To select a **SSLQSR** value of REQUIRED, a quantum safe algorithm must have been selected by using the **SSLQS** setting or a quantum safe algorithm must have been enabled by using the **AllowedQuantumSafeAlgorithms** configuration option.

For more information, see [Quantum Safe TLS](#).

STATCHL

Controls the collection of statistics data for channels:

QMGR

The value of the **STATCHL** parameter of the queue manager is inherited by the channel.

OFF

Statistics data collection is turned off for this channel.

LOW

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a low rate of data collection, for this channel.

MEDIUM

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a moderate rate of data collection, for this channel.

HIGH

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on, with a high rate of data collection, for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

 On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

For cluster channels, the value of this parameter is not replicated in the repository and used in the auto-definition of cluster-sender channels. For auto-defined cluster-sender channels, the value of this parameter is taken from the attribute **STATACLS** of the queue manager. This value might then be overridden in the channel auto-definition exit.

TMPMODEL(string)

The name of the model queue to be used while creating a temporary queue (maximum length 48 characters).

The default queue is `SYSTEM.DEFAULT.MODEL.QUEUE`.

Multi **TMPQPRFX(string)**

The temporary queue name prefix to add to the beginning of the model queue when deriving a temporary queue name (maximum length 48 characters).

The default is AMQP.*.

TPNAME(string)

LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU 6.2.

Set this parameter to the SNA transaction program name, unless the **CONNAME** contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set.

z/OS See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

Windows **z/OS** On Windows SNA Server, and in the side object on z/OS, the **TPNAME** is wrapped to uppercase.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR.

TPROOT

The topic root for an AMQP channel. The default value for **TPROOT** is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other IBM MQ publish/subscribe applications. To have AMQP clients publish and subscribe under a topic prefix, first create an IBM MQ topic object with a topic string set to the prefix you want, then set **TPROOT** to the name of the IBM MQ topic object you created.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

TRPTYPE

Transport type to be used.

On all platforms, this parameter is optional because, if you do not enter a value, the value specified in the SYSTEM.DEF.channel-type definition is used. However, no check is made that the correct transport type has been specified if the channel is initiated from the other end.

z/OS On z/OS, if the SYSTEM.DEF.channel-type definition does not exist, the default is LU62.

This parameter is required on all other platforms.

LU62

SNA LU 6.2

NETBIOS

Windows NetBIOS (supported only on Windows, and DOS).

z/OS This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

SPX

Windows Sequenced packet exchange (supported only on Windows, and DOS).

z/OS This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting SPX.

TCP

Transmission Control Protocol - part of the TCP/IP protocol suite

Multi **USECLTID**

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the **MCAUSER** attribute value.

NO

The MCA user ID should be used for authorization checks.

YES

The client ID should be used for authorization checks.

USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

NO

Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the **NPMSPEED** setting.

YES

When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

USERID(string)

Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

On z/OS, it is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

On the receiving end, if passwords are kept in encrypted format and the LU 6.2 software is using a different encryption method, an attempt to start the channel fails with invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

XMITQ(string)

Transmission queue name.

The name of the queue from which messages are retrieved. See Rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR or SVR. For these channel types, this parameter is required.

ALW

ALTER CHANNEL (alter channel settings) MQTT

Use the MQSC command **ALTER CHANNEL** to alter the parameters of a telemetry channel.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for ALTER CHANNEL \(MQTT\)” on page 396](#)
- [“Usage notes for ALTER CHANNEL \(MQTT\)” on page 396](#)
- [“Parameter descriptions for ALTER CHANNEL \(MQTT\)” on page 396](#)

Syntax diagram for ALTER CHANNEL (MQTT)

Synonym: ALT CHL

Usage notes for ALTER CHANNEL (MQTT)

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see [Configuring a queue manager for telemetry on Linux or Configuring a queue manager for telemetry on Windows](#).

Parameter descriptions for ALTER CHANNEL (MQTT)

(*channel-name*)

The name of the channel definition.

BACKLOG(*integer*)

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

CHLTYPE

Channel type. MQTT (telemetry) channel.

JAASCFG(string)

The name of a stanza in the JAAS configuration file.

See [Authenticating an MQTT client Java app with JAAS](#)

LOCLADDR(ip-addr)

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr

ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal

For example 192.0.2.1

IPv6 hexadecimal notation

For example 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

MCAUSER(string)

Message channel agent user identifier.

The maximum length of the string is 12 characters. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is not blank, and **USECLNTID** is set to N0, then this user identifier is used by the IBM MQ Telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to N0, then the user name flowed in the MQTT CONNECT Packet is used. See [MQTT client identity and authorization](#).

PORT(integer)

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

PROTOCOL

The following communication protocols are supported by the channel:

MQTTV311

The channel accepts connections from clients using the protocol defined by the [MQTT 3.1.1](#) Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

MQTTV3

The channel accepts connections from clients using the [MQTT V3.1 Protocol Specification](#) from mqtt.org.

HTTP

The channel accepts HTTP requests for pages, or WebSockets connections to IBM MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify MQTTV3, HTTP the channel accepts connections

from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

If your configuration includes an MQTT channel that was last modified in an earlier version of the product, you must explicitly change the protocol setting to prompt the channel to use the MQTTV311 option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the product have no awareness of the MQTTV311 option. To prompt a channel in this state to use the MQTTV311 option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the MQTTV311 option is still included in the stored list of supported protocols.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

NEVER

IBM MQ never requests a certificate from the TLS client.

REQUIRED

IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL

IBM MQ lets the TLS client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

SSLCIPH(string)

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. The TLS cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the parameter is blank, no attempt is made to use TLS on the channel.

V 10.0.0 For a list of supported **SSLCIPH** values from IBM MQ 10.0.0, see [CipherSuites supported by the MQ Telemetry service from IBM MQ 10.0.0](#).

If you plan to use SHA-2 cipher suites, see [System requirements for using SHA-2 cipher suites with MQTT channels](#).

SSLKEYP(string)

The passphrase for the TLS key repository.

If the MQXR service is configured for encryption of passphrases by specifying the **-sf** option in **STARTARG** for the service, then the pass phrase will be encrypted. For more information on encryption of passphrases, see [Encryption of passphrases for MQTT TLS channels](#).

SSLKEYR(string)

The full path name of the TLS key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, TLS is not used.

The maximum length of the string is 256 characters;

- ▶ **Linux** ▶ **AIX** On AIX and Linux, the name is of the form *pathname/keyfile*.
- ▶ **Windows** On Windows, the name is of the form *pathname\keyfile*.

where *keyfile* is specified without the suffix *.jks*, and identifies a Java keystore file.

TRPTYPE (string)

The transmission protocol to be used:

TCP

TCP/IP

USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLNTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See [MQTT client identity and authorization](#).

ALTER COMMINFO (alter communication information object) on Multiplatforms

Use the MQSC command **ALTER COMMINFO** to alter the parameters of a communication information object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER COMMINFO** command result in the existing values for those parameters being left unchanged.

- [“Syntax diagram for ALTER COMMINFO” on page 399](#)
- [“Parameter descriptions for ALTER COMMINFO” on page 400](#)

Syntax diagram for ALTER COMMINFO

Synonym: ALT COMMINFO

ALTER COMMINFO

Notes:

Parameter descriptions for ALTER COMMINFO

(*comminfo name*)

Name of the communications information object. This parameter is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See [Rules for naming IBM MQ objects](#).

BRIDGE

Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST (ONLY)**. As these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast.

ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast.

CCSID(*integer*)

The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The CCSID must specify a value that is defined for use on your platform, and use a character set that is appropriate to the queue manager's platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID therefore you must stop and restart all running applications before you continue. Running applications include the command server and channel programs. Stop and restart all running applications, stop and restart the queue manager after changing this parameter.

The CCSID can also be set to ASPUB, which means that the coded character set is taken from that supplied in the published message.

COMMEV

Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events are only generated if they are enabled using the **MONINT** parameter.

DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast.

ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast.

EXCEPTION

Event messages are written if the message reliability is below the reliability threshold. The reliability threshold is set to 90 by default.

DESCR(*string*)

Plain-text comment. It provides descriptive information about the communication information object when an operator issues the **DISPLAY COMMINFO** command (see [“DISPLAY COMMINFO \(display communication information\) on Multiplatforms”](#) on page 816).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

ENCODING

The encoding that the messages are transmitted in.

AS PUB

The encoding of the message is taken from that supplied in the published message.

NORMAL**REVERSED****S390****TNS****encoding****GRPADDR**

The group IP address or DNS name.

It is the responsibility of the administrator to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client has to examine and process every multicast packet in the network. It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this allocation requires careful management, especially if other non-MQ multicast applications are in use on the network.

MCHBINT

The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available.

MCPROP

The multicast properties control how many of the MQMD properties and user properties flow with the message.

All

All user properties and all the fields of the MQMD are transported.

Reply

Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

User

Only the user properties are transmitted.

NONE

No user properties or MQMD fields are transmitted.

COMPAT

This value causes the transmission of the message to be done in a compatible mode to RMM allowing some inter-operation with the current XMS applications and Broker RMM applications.

 XMS .NET Multicast messaging (using RMM) was deprecated from IBM MQ 9.2 and removed at IBM MQ 9.3.

MONINT(*integer*)

How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this COMMINFO object.

A value of 0 means that there is no monitoring.

MSGHIST

The maximum message history is the amount of message history that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

A value of 0 gives the least level of reliability.

NSUBHIST

The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

NONE

A value of NONE causes the transmitter to transmit only publication made from the time of the subscription.

ALL

A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances, this retransmission can give a similar behavior to retained publications.

Note: Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is retransmitted.

PORT(*integer*)

The port number to transmit on.

ALTER LISTENER (alter an existing listener) on Multiplatforms

Use MQSC command **ALTER LISTENER** to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER LISTENER** command result in the existing values for those parameters being left unchanged.

- [“Syntax diagram for ALTER LISTENER” on page 403](#)
- [“Parameter descriptions for ALTER LISTENER” on page 404](#)

Syntax diagram for ALTER LISTENER

Synonym: ALT LSTR

ALTER LISTENER

Notes:

- ¹ Valid only on Windows.
- ² Valid only on Windows when TRPTYPE is NETBIOS.
- ³ Valid when TRPTYPE is TCP.
- ⁴ Valid on Windows when TRPTYPE is SPX.
- ⁵ Valid only on Windows when TRPTYPE is LU62.

Parameter descriptions for ALTER LISTENER

(*listener-name*)

Name of the IBM MQ listener definition (see [Rules for naming IBM MQ objects](#)). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

Windows ADAPTER(*integer*)

The adapter number on which NetBIOS listens. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

BACKLOG(*integer*)

The number of concurrent connection requests that the listener supports.

► **Windows** **COMMANDS(integer)**

The number of commands that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

CONTROL(string)

Specifies how the listener is to be started and stopped.:

MANUAL

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(string)

Plain-text comment. It provides descriptive information about the listener when an operator issues the **DISPLAY LISTENER** command (see [“DISPLAY LISTENER \(display listener information\) on Multiplatforms”](#) on page 836).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

IPADDR(string)

IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

LIKE(listener-name)

The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the **DEFINE LISTENER** command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.LISTENER)
```

A default listener is provided but it can be altered by the installation of the default values required. See [Rules for naming IBM MQ objects](#).

► **Windows** **LOCLNAME(string)**

The NetBIOS local name that the listener uses. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

► **Windows** **NTBNAMES(integer)**

The number of names that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

PORT(integer)

The port number for TCP/IP. This is valid only when **TRPTYPE** is TCP. It must not exceed 65535.

► **Windows** **SESSIONS(integer)**

The number of sessions that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

SOCKET(integer)

The SPX socket on which to listen. This is valid only if **TRPTYPE** is SPX.

Windows **TPNAME(string)**

The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when **TRPTYPE** is LU62.

TRPTYPE(string)

The transmission protocol to be used:

Windows **LU62**

SNA LU 6.2. This is valid only on Windows.

Windows **NETBIOS**

NetBIOS. This is valid only on Windows.

Windows **SPX**

Sequenced packet exchange. This is valid only on Windows.

TCP

TCP/IP.

ALTER NAMELIST (alter a list of names)

Use the MQSC command **ALTER NAMELIST** to alter a list of names. This list is most commonly a list of cluster names or queue names.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER NAMELIST** command result in the existing values for those parameters being left unchanged.

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER NAMELIST” on page 406](#)
- [“Usage notes for ALTER NAMELIST” on page 407](#)
- [“Parameter descriptions for ALTER NAMELIST” on page 407](#)

Syntax diagram for ALTER NAMELIST

Synonym: ALT NL

ALTER NAMELIST

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.

Usage notes for ALTER NAMELIST

Successful completion of the command does not mean that the action completed. To check for true completion, see the [ALTER NAMELIST](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for ALTER NAMELIST

(name)

Name of the list.

The name must not be the same as any other namelist name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See [Rules for naming IBM MQ objects](#).

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of specifying * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(string)

Plain-text comment. It provides descriptive information about the namelist when an operator issues the **DISPLAY NAMELIST** command (see “[DISPLAY NAMELIST \(display a list of names\)](#)” on page 846).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

NAMES(name, ...)

List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify **NAMES()**. The maximum number of names in the list is 256.

NLTYPE

Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

NONE

The names are of no particular type.

QUEUE or Q

A namelist that holds a list of queue names.

CLUSTER

A namelist that is associated with clustering, containing a list of the cluster names.

AUTHINFO

This namelist is associated with TLS and contains a list of authentication information object names.

Namelists used for clustering must have **NLTYPE (CLUSTER)** or **NLTYPE (NONE)**.

Namelists used for TLS must have **NLTYPE (AUTHINFO)**.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 167. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP (COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP (QMGR) , is not affected by this command.

Table 167. Behavior for each of the QSGDISP values (continued)	
QSGDISP	ALTER
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE NAMELIST(name) REPLACE QSGDISP(COPY)</pre> The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

ALTER PROCESS (alter an existing process definition)

Use the MQSC command **ALTER PROCESS** to alter the parameters of an existing IBM MQ process definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- “[Syntax diagram for ALTER PROCESS](#)” on page 409
- “[Parameter descriptions for ALTER PROCESS](#)” on page 410

Syntax diagram for ALTER PROCESS

Synonym: ALT PRO

ALTER PROCESS

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.

Parameter descriptions for ALTER PROCESS

process-name

Name of the IBM MQ process definition (see [Rules for naming IBM MQ objects](#)). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless **REPLACE** is specified).

APPLCID(string)

The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS® application the name is a CICS transaction ID, and for an IMS application it is an IMS transaction ID.

 On z/OS, for distributed queuing, it must be "CSQX start".

APPLTYPE(string)

The type of application to be started. Valid application types are:

integer

A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

CICS

Represents a CICS transaction.

 **IMS**

Represents an IMS transaction.

 **MVS**

Represents a z/OS application (batch or TSO).

NOTESAGENT

Represents a Lotus Notes agent.

 **OS400**

Represents an IBM i application.

 **UNIX**

Represents a Linux or AIX application.

 **WINDOWS**

Represents a Windows application.

 **WLM**

Represents a z/OS workload manager application.

DEF

Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command runs:

-  On z/OS: CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported
-  On IBM i: OS400, CICS, and DEF are supported
-   On AIX and Linux: UNIX, WINDOWS, CICS, and DEF are supported
-  On Windows, UNIX, WINDOWS, CICS, and DEF are supported

 **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

DESCR(string)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY PROCESS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

ENVRDATA(string)

A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of **ENVRDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends **ENVRDATA** to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

Note:

1.  On z/OS, **ENVRDATA** is not used by the trigger-monitor applications provided by IBM MQ.
2.  On z/OS, if **APPLTYPE** is WLM, the default values for the **ServiceName** and **ServiceStep** fields in the work information header (MQWIH) can be supplied in **ENVRDATA**. The format must be:

```
SERVICENAME=servname,SERVICESTEP=stepname
```

where:

SERVICENAME=

is the first 12 characters of **ENVRDATA**.

servname

is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

SERVICESTEP=

is the next 13 characters of **ENVRDATA**.

stepname

is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

If the format is incorrect, the fields in the MQWIH are set to blanks.

3.   On AIX and Linux, **ENVRDATA** can be set to the ampersand character to make the started application run in the background.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 168. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR) , is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). On the page set of the queue manager that executes the command, only a local copy of the object is altered by this command. If the command is successful, the following command is generated. <pre>DEFINE PROCESS(process-name) REPLACE QSGDISP(COPY)</pre> The command is sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero. The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY) . Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR) . Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

USERDATA(string)

A character string that contains user information pertaining to the application defined in the **APPLICID** that is to be started. The maximum length is 128 characters.

The meaning of **USERDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes **USERDATA** to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing **USERDATA**), followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See [Managing objects for triggering](#) for information about what **APPLICID** to provide to message channel agents.

Windows For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

Use the MQSC command **DELETE PROCESS** to delete a process definition.

[“DISPLAY PROCESS \(display process information\)” on page 851](#)

Use the MQSC command **DISPLAY PROCESS** to display the attributes of one or more IBM MQ processes.

ALTER PSID (change page set expansion method) on z/OS

Use the MQSC command **ALTER PSID** to change the expansion method for a page set.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER PSID** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER PSID” on page 414](#)
- [“Usage notes for ALTER PSID” on page 414](#)
- [“Parameter descriptions for ALTER PSID” on page 414](#)

Syntax diagram for ALTER PSID

Synonym: ALT PSID

Usage notes for ALTER PSID

You can use **ALTER PSID** to reset an internal IBM MQ indicator that prevents the page set from being expanded; for example, after the data set has been **ALTERed** to **ADDVOLUMES**.

In this instance, although the **EXPAND** keyword must be specified with a value, you do not have to change the value from that already configured. For example, if **DISPLAY USAGE** shows page set 3 configured with **EXPAND(SYSTEM)**, you issue the following command to allow IBM MQ to retry page set expansion:

```
ALTER PSID(3) EXPAND(SYSTEM)
```

Note: Changes made with the **ALTER PSID** command are recorded in checkpoint records. During a queue manager restart, recovered PSID attributes from checkpoints take effect after any **DEFINE PSID** command in CSQINP1 are processed. This means a previously altered **EXPAND** parameters will persist across restarts, even if CSQINP1 specifies a different **EXPAND** value in the **DEFINE PSID** command.

Parameter descriptions for ALTER PSID

(psid-number)

Identifier of the page set. This is required.

EXPAND

Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in it.

USER

The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or if it was specified as zero, then no dynamic page set expansion can take place.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It might be rounded up depending on the characteristics of the DASD.

The secondary extent size that was specified when the page set was defined is ignored; dynamic expansion can occur if it was zero or not specified.

NONE

No further page set expansion is to take place.

Syntax diagram for ALTER QMGR

Synonym: ALT QMGR

1	Valid only on z/OS when the queue manager is a member of a queue sharing group.
2	Valid only on z/OS.

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.

³ Not valid on z/OS.

⁴ Valid only on AIX, Linux, and Windows.

⁵ Not valid on IBM i.

Parameter descriptions for ALTER QMGR

The parameters you specify override the current values. Attributes that you do not specify are unchanged.

Note:

1. If you do not specify any parameters, the command completes successfully, but no queue manager options are changed.
2. Changes made using this command persist when the queue manager is stopped and restarted.

FORCE

Specify this parameter to force completion of the command in the following situations:

- If both of the following statements are true:
 - The **DEFXMITQ** parameter is specified
 - An application has a remote queue open, the resolution for which would be affected by this change

If you do not specify the **FORCE** parameter in this situation, the command is unsuccessful.

- [V 3000](#) If you are modifying the queue manager coded character set identifier (CCSID) in a manner which might be unsafe. For more information, see “[UNIX, Linux, Windows, IBM i]CCSID(integer)” on [page 421](#).

Queue manager parameters

These parameters are the queue manager parameters for the **ALTER QMGR** command:

ACCTCONO

Specifies whether applications can override the settings of the **ACCTQ** and **ACCTMQI** queue manager parameters:

DISABLED

Applications cannot override the settings of the **ACCTQ** and **ACCTMQI** parameters.

This is the queue manager's initial default value.

ENABLED

Applications can override the settings of the **ACCTQ** and **ACCTMQI** parameters by using the options field of the MQCNO structure of the MQCONN API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on [Multiplatforms](#).

ACCTINT(integer)

The time interval, in seconds, at which intermediate accounting records are written.

Specify a value in the range 1 through 604800.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on [Multiplatforms](#).

ACCTMQI

Specifies whether accounting information for MQI data is to be collected:

OFF

MQI accounting data collection is disabled.

This is the queue manager's initial default value.

ON

MQI accounting data collection is enabled.

If queue manager attribute **ACCTCONO** is set to ENABLED, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on [Multiplatforms](#).

ACCTQ

Specifies whether accounting data is to be collected for all queues.

 On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting).

OFF

Accounting data collection is disabled for all queues which specify QMGR as the value for their **ACCTQ** parameter.

ON

Accounting data collection is enabled for all queues which specify QMGR as the value of their **ACCTQ** parameter.

 On z/OS systems, you must switch on class 3 accounting by the **START TRACE** command.

NONE

Accounting data collection for all queues is disabled regardless of the value of the **ACCTQ** parameter of the queue.

Changes to this parameter are effective only for connections to the queue manager occurring after the change to the parameter.

 ACTCHL(integer)

The maximum number of channels that can be *active* at any time, unless the value is reduced below the number of currently active channels.

Specify a value from 1 through 9999 that is not greater than the value of **MAXCHL**. **MAXCHL** defines the maximum number of channels available.

If you change this value, you must also review the **MAXCHL**, **LU62CHL**, and **TCPCHL** values to ensure that there is no conflict of values

For an explanation of which channel states are considered active; see [Channel states](#).

If the value of **ACTCHL** is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of **ACTCHL**, more channels can be started. Increasing the value of **ACTCHL** to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of **ACTCHL** takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

This parameter is valid only on z/OS.

ACTIVREC

Specifies whether activity reports are generated if requested in the message:

DISABLED

Activity reports are not generated.

MSG

Activity reports are generated and sent to the reply queue specified by the originator in the message causing the report.

This is the queue manager's initial default value.

QUEUE

Activity reports are generated and sent to `SYSTEM.ADMIN.ACTIVITY.QUEUE`

See [Activity recording](#).

Multi ACTVCONO

Specifies whether applications can override the settings of the **ACTVTRC** queue manager parameter:

DISABLED

Applications cannot override the settings of the **ACTVTRC** queue manager parameter.

This is the queue manager's initial default value.

ENABLED

Applications can override the settings of the **ACTVTRC** queue manager parameter by using the options field of the MQCNO structure of the MQCONN API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on [Multiplatforms](#).

Multi ACTVTRC

Specifies whether MQI application activity tracing information is to be collected. See [Setting ACTVTRC to control collection of activity trace information](#).

OFF

IBM MQ MQI application activity tracing information collection is not enabled.

This is the queue manager's initial default value.

ON

IBM MQ MQI application activity tracing information collection is enabled.

If the queue manager attribute **ACTVCONO** is set to **ENABLED**, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on [Multiplatforms](#).

z/OS ADOPTCHK

Specifies which elements are checked to determine whether an MCA is adopted. The check is made when a new inbound channel is detected with the same name as an already active MCA.

ALL

Check the queue manager name and the network address. Perform this check to prevent your channels from being inadvertently or maliciously shut down.

This is the queue manager's initial default value.

NETADDR

Check the network address.

NONE

Do no checking.

QMNAME

Check the queue manager name.

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

This parameter is valid only on z/OS.

► **z/OS** **ADOPTMCA**

Specifies whether an orphaned instance of an MCA restarts immediately when a new inbound channel request matching the **ADOPTCHK** parameter is detected:

ALL

Adopt all channel types.

This is the queue manager's initial default value.

NO

Adoption of orphaned channels is not required.

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

This parameter is valid only on z/OS.

AUTHOREV

Specifies whether authorization events are generated.

DISABLED

Authorization events are not generated.

This is the queue manager's initial default value.

ENABLED

Authorization events are generated.

► **z/OS** This value is not supported on z/OS.

► V 10.0.0

From IBM MQ 10.0.0, **AUTHOREV** applies to successful and unsuccessful authorization events.

► **Multi** **AUTHEVSC**

Specifies the scope of authorization events generated when authorization events are enabled:

FAILURES

Only Not Authorized authorization events are generated. This is the queue manager's initial default value.

ALLCONNS

All Not Authorized and Authorized Connection events are generated.

ALLCHECKS

ALLCHECKS includes ALLCONNS, so all Not Authorized and Authorized events, including connection events, are generated, which means that a larger number of entries are generated.

► **z/OS** This parameter is not supported on z/OS.

► **z/OS** **BRIDGEEV**

Specifies whether IMS bridge events are generated.

DISABLED

IMS bridge events are not generated.

This is the queue manager's initial default value.

ENABLED

All IMS bridge events are generated.

This parameter is valid only on z/OS.

► **Multi** **CCSID(integer)**

The coded character set identifier (CCSID) for the queue manager. The CCSID specifies the code page that is used for character or string data within the queue manager. If you set the CCSID in the

message descriptor (MQMD) to MQCCSI_Q_MGR, the queue manager CCSID also applies to application data in the body of a message, when the message is put to a queue.

Usually, you do not have to change the queue manager CCSID. Ensure that you understand the implications and risks before you make the change. For example:

- Existing character data that is persisted within the queue manager is not converted to the new code page. If characters outside the *invariant character set* for the platform (the set of characters whose code point assignments do not change from code page to code page) were used before the change, they might not display or be processed correctly after the change. So, ensure that only invariant ASCII or EBCDIC characters were used throughout the lifetime of the queue manager.
- Changing the CCSID from a smaller to a larger character set, for example ISO-8859-1, CCSID 819 to UTF-8, CCSID 1208, is relatively low risk because in most cases, conversion is not required anyway. You might make such a change if you are migrating queue managers from older releases or older operating system environments and you want to take advantage of a wider range of natural language and other characters.

Important: Modification from a larger to a smaller character set, for example by converting a queue manager that is running in CCSID 1208 to run in CCSID 819, is higher risk. The reduction in available characters increases the chance that data in the queue manager contains characters that cannot be converted. Ensure that no such characters were used before you make the change. For example, ensure that all object names, user names, descriptions and other items throughout the queue manager configuration are supported in the target CCSID. V 10.0.0 To make such a change, you must also specify the **FORCE** parameter.

Specify a permitted value, in the range 1 through 65535, that is native for your platform. For compatibility with operating system libraries, compilers, and application environments, the code page that is used for the queue manager must be compatible with the C locale, which is therefore effectively the common invariant character set for the platform. So, on IBM MQ for IBM i the queue manager CCSID must provide the standard invariant EBCDIC characters, and on all other IBM MQ for Multiplatforms products the queue manager CCSID must provide the standard invariant ASCII characters. The following CCSIDs are therefore permitted:

-  On IBM i, single byte or double byte EBCDIC-based CCSIDs
- On all other platforms, single or multi-byte character sets that are descended from ASCII (including UTF-8)

If the CCSID of the locale is a mixed code page (containing both single-byte and double-byte characters), IBM MQ uses the single-byte character set (SBCS) part of the mixed code page for the queue manager CCSID.

See National languages for the native CCSIDs for each supported language by platform. In addition, on all platforms except IBM MQ for IBM i, you can select UTF-8 and the related GB18030 CCSIDs.

After you change the CCSID, stop the queue manager and any other IBM MQ processes (including the command server and channel programs), then restart them. Otherwise, applications that were running when you changed the CCSID continue to use the original CCSID, and different processes could use either the old or the new CCSIDs.

This parameter is valid only on Multiplatforms.

 To carry out the equivalent tasks on z/OS, use CSQ6SYSP to set your system parameters.

CERTLABL

Certificate labels for this queue manager to use. The label identifies which personal certificate in the key repository has been selected.

 On AIX, Linux, IBM i, and Windows, this can be a comma or space separated list of certificates.

 On z/OS, this must be a single certificate label.

The default and migrated queue manager values are:

- ▶ **ALW** On AIX, Linux, and Windows: *ibmwebspheremqxxxx* where *xxxx* is the queue manager name folded to lowercase.
- ▶ **IBM i** On IBM i:
 - If you specified **SSLKEYR(*SYSTEM)**, the value is blank.
Note that it is forbidden to use a non-blank queue manager **CERTLABL** with **SSLKEYR(*SYSTEM)**. Attempting to do so results in an MQRCCF_Q_MGR_ATTR_CONFLICT error.
 - Otherwise, *ibmwebspheremqxxxx* where *xxxx* is the queue manager name folded to lowercase.
- ▶ **z/OS** On z/OS: *ibmWebSphereMQXXXX* where *XXXX* is the queue manager name.

See [z/OS systems](#) for more information.

▶ **Multi** Multiple certificate labels can be configured in the **CERTLABL** attribute, separated by a ▶ **ALW** space or ▶ **Multi** comma. When multiple labels are specified, the queue manager will try each label to decide if the certificate selected will result in a valid CipherSuite selection during the TLS handshake. This intended to be used where clients offer either TLS 1.2 RSA or ECC CipherSuites.

▶ **Multi** When specifying multiple labels, use **one** comma or space between them. Extraneous delimiters will raise errors.

▶ Generally, it is not recommended to include commas or spaces within certificate labels. If an existing certificate label contains commas or spaces, escape them with a backspace. For example if the certificate label in the keystore is *val , val2* (comma-space) then the **CERTLABL** value would be *val1\, \ val2*. Escaping tells the queue manager that the comma or space is part of the label.

▶ **IBM i** On IBM i systems, the space character is not a supported separator and should not be escaped.

Important: You must run a **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on the queue manager. However, you do not need to run the **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on a channel.

▶ **z/OS** **CERTQSG**

Queue sharing group (QSG) certificate label.

This parameter takes precedence over **CERTLABL** in the event that the queue manager is a member of a QSG.

The default value for this parameter is *ibmWebSphereMQXXXX* where *XXXX* is the queue sharing group name.

This parameter is valid only on z/OS.

See [z/OS systems](#) for more information.

▶ **Multi** **CERTVPOL**

Specifies which TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards.

ANY

Apply each of the certificate validation policies supported by the secure sockets library and accept the certificate chain if any of the policies considers the certificate chain valid. This setting can be used for maximum backwards compatibility with older digital certificates which do not comply with the modern certificate standards.

RFC5280

Apply only the RFC 5280 compliant certificate validation policy. This setting provides stricter validation than the ANY setting, but rejects some older digital certificates.

For more information about certificate validation policies, see [Certificate validation policies in IBM MQ](#).

Changes to the parameter take effect only after a **REFRESH SECURITY TYPE(SSL)** command is issued.

This parameter is valid only on [Multiplatforms](#).

z/OS CFCNLOS

Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with **CFCNLOS** set to ASQMGR.

TERMINATE

The queue manager terminates when connectivity to CF structures is lost.

TOLERATE

The queue manager tolerates loss of connectivity to CF structures without terminating.

This parameter is valid only on z/OS.

Multi CHAD

Specifies whether receiver and server-connection channels can be defined automatically:

DISABLED

Auto-definition is not used.

This is the queue manager's initial default value.

ENABLED

Auto-definition is used.

Cluster-sender channels can always be defined automatically, regardless of the setting of this parameter.

This parameter is valid only on [Multiplatforms](#).

Multi CHADEV

Specifies whether channel auto-definition events are generated.

DISABLED

Auto-definition events are not generated.

This is the queue manager's initial default value.

ENABLED

Auto-definition events are generated.

This parameter is valid only on [Multiplatforms](#).

CHADEXIT(string)

Auto-definition exit name.

If this name is non-blank, the exit is called when an inbound request for an undefined receiver, server-connection, or cluster-sender channel is received. It is also called when starting a cluster-receiver channel.

The format and maximum length of the name depends on the environment:

- **Linux** **AIX** On AIX and Linux, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.
- **Windows** On Windows, it is of the form *dllname(functionname)* where *dllname* is specified without the suffix .DLL. The maximum length is 128 characters.

- ▶ **IBM i** On IBM i, it is of the form:

```
progname libname
```

where *program_name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length of the string is 20 characters.

- ▶ **z/OS** On z/OS, it is a load module name, the maximum length is eight characters.

▶ **z/OS** On z/OS, the **CHADEXIT** parameter applies only to cluster-sender and cluster-receiver channels.

▶ **z/OS** **CHIADAPS(integer)**

The number of channel initiator adapter subtasks to use for processing IBM MQ calls.

Specify a value in the range 0 - 9999. Suggested settings are:

- Test system: 8
- Production system: 30

Changes to this parameter take effect when the channel initiator is restarted.

For more information about the relationship between **CHIADAPS**, **CHIDISPS** and **MAXCHL**, see [Tailor the channel initiator parameters](#).

This parameter is valid only on z/OS.

▶ **z/OS** **CHIDISPS (integer)**

The number of dispatchers to use in the channel initiator.

Specify a value in the range 1 through 9999. Suggested settings are:

- Test system: 5
- Production system: 20

Changes to this parameter take effect when the channel initiator is restarted.

For more information about the relationship between **CHIADAPS**, **CHIDISPS** and **MAXCHL**, see [Tailor the channel initiator parameters](#).

This parameter is valid only on z/OS.

▶ **z/OS** **CHISERV**

This parameter is reserved for IBM use only; it is not for general use.

This parameter is valid only on z/OS.

CHLAUTH

Specifies whether the rules defined by channel authentication records are used. **CHLAUTH** rules can still be set and displayed regardless of the value of this attribute.

Changes to this parameter take effect the next time that an inbound channel attempts to start. Channels that are currently started are unaffected by changes to this parameter.

DISABLED

Channel authentication records are not checked.

ENABLED

Channel authentication records are checked.

CHLEV

Specifies whether channel events are generated.

DISABLED

Channel events are not generated. This is the queue manager's initial default value.

ENABLED

All channel events are generated.

EXCEPTION

All exception channel events are generated.

CLWLDATA(string)

Cluster workload exit data. The maximum length of the string is 32 characters.

This string is passed to the cluster workload exit when it is called.

CLWLEXIT(string)

Cluster workload exit name.

If this name is non-blank, the exit is called when a message is put to a cluster queue. The format and maximum length of the name depends on the environment:

-   On AIX and Linux, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.
-  On Windows, it is of the form *dllname(functionname)*, where *dllname* is specified without the suffix .DLL. The maximum length is 128 characters.
-  On z/OS, it is a load module name. The maximum length is eight characters.
-  On IBM i, it is of the form:

```
programe libname
```

where *program_name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length is 20 characters.

CLWLEN(integer)

The maximum number of bytes of message data that is passed to the cluster workload exit.

Specify a value in the range:

-  0 - 999,999,999 on AIX, Linux, and Windows.
-  0 - 999,999,999 on IBM i.
-  0 - 100 MB on z/OS systems.

CLWLMRUC(integer)

The maximum number of most recently used outbound cluster channels.

Specify a value in the range 1 through 999,999,999.

See **CLWLMRUC** [queue manager attribute](#).

CLWLUSEQ

The attribute applies to queues with the queue attribute **CLWLUSEQ** set to QMGR. It specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. It does not apply if the MQPUT originates from a cluster channel.

Specify either:

LOCAL

The local queue is the only target for MQPUT operations.

This is the queue manager's initial default value.

ANY

The queue manager treats the local queue as another instance of the cluster queue for the purposes of workload distribution.

See **CLWLUSEQ** [queue manager attribute](#).

CMDEV

Specifies whether command events are generated:

DISABLED

Command events are not generated.

This is the queue manager's initial default value.

ENABLED

Command events are generated for all successful commands.

NODISPLAY

Command events are generated for all successful commands, other than **DISPLAY** commands.

► z/OS CMDSCOPE

Specifies how the command is run when the queue manager is a member of a queue sharing group.

•

The command is run on the queue manager on which it was entered.

qmgr-name

The command is run on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a different queue manager. You can do so if you are using a queue sharing group environment, and if the command server is enabled. You can then specify a different queue manager to the one on which the command is entered.

★

The command is run on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of entering this value is the same as entering the command on every queue manager in the queue sharing group.

This parameter is valid only on z/OS.

CONFIGEV

Specifies whether configuration events are generated:

ENABLED

Configuration events are generated. After setting this value, issue **REFRESH QMGR TYPE(CONFIGEV)** commands for all objects to bring the queue manager configuration up to date.

DISABLED

Configuration events are not generated.

This is the queue manager's initial default value.

CONNAUTH

The name of an authentication information object that is used to provide the location of user ID and password authentication. If **CONNAUTH** is blank, no user ID and password checking is done by the queue manager. The maximum length of the string is **MQ_AUTH_INFO_NAME_LENGTH**.

Only authentication information objects with type **IDPWOS** or **IDPWLDAP** can be specified; other types result in an error message when:

- ► Multi The OAM reads the configuration on [Multiplatforms](#).
- ► z/OS The security component reads the configuration on z/OS.

Changes to this configuration, or the object to which it refers, take effect when a **REFRESH SECURITY TYPE(CONNAUTH)** command is issued.

If you leave **CONNAUTH** blank, and attempt to connect to a channel (matching a **CHLAUTH** record) set in the **CHKCLNT** field, the connection fails:

- ► Multi REQDADM

-  REQUIRED

CUSTOM(string)

The custom attribute for new features.

This attribute is reserved for the configuration of new features before named attributes are introduced. It can contain the values of zero or more attributes as pairs of attribute name and value, separated by at least one space. The attribute name-value pairs have the form NAME (VALUE) . Escape a single quotation mark with another single quotation mark.

No values are defined for **Custom**.

DEADQ(string)

The local name of a dead-letter queue (or undelivered-message queue) on which messages that cannot be routed to their correct destination are put.

The queue named must be a local queue; see [Rules for naming IBM MQ objects](#).

DEFCLXQ

The **DEFCLXQ** attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

SCTQ

All cluster-sender channels send messages from SYSTEM . CLUSTER . TRANSMIT . QUEUE. The correlID of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined. **DEFCLXQ** was not present.

CHANNEL

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue SYSTEM . CLUSTER . TRANSMIT . MODEL . QUEUE.

If the queue manager attribute, **DEFCLXQ**, is set to CHANNEL, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue SYSTEM . CLUSTER . TRANSMIT . MODEL . QUEUE. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

DEFXMITQ(string)

Local name of the default transmission queue on which messages destined for a remote queue manager are put. The default transmission queue is used if there is no other suitable transmission queue defined.

The cluster transmission queue must not be used as the default transmission queue of the queue manager.

The queue named must be a local transmission queue; see [Rules for naming IBM MQ objects](#).

DESCR(string)

Plain-text comment. It provides descriptive information about the queue manager.

It contains only displayable characters. The maximum length of the string is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

If the characters in the descriptive information are in the coded character set identifier (CCSID) for this queue manager they are translated correctly. They are translated when the descriptive information is sent to another queue manager. If they are not in the CCSID for this queue manager, they might be translated incorrectly.

➤ **z/OS** **DNSGROUP(string)**

This parameter is no longer used. See [z/OS: WLM/DNS no longer supported](#).

➤ **z/OS** **DNSWLM**

This parameter is no longer used. See [z/OS: WLM/DNS no longer supported](#).

NO

This value is the only value accepted.

➤ **z/OS** **EXPRYINT**

Specifies how often queues are scanned to discard expired messages:

OFF

Queues are not scanned. No internal expiry processing is performed.

integer

The approximate interval in seconds at which queues are scanned. Each time that the expiry interval is reached, the queue manager looks for candidate queues that are worth scanning to discard expired messages.

The queue manager maintains information about the expired messages on each queue, and therefore whether a scan for expired messages is worthwhile. So, only a selection of queues is scanned at any time.

The value must be in the range 1 through 99999999. The minimum scan interval used is 5 seconds, even if you specify a lower value.

You must set the same **EXPRYINT** value for all queue managers within a queue sharing group that support this attribute. Shared queues are scanned by only one queue manager in a queue sharing group. This queue manager is either the first queue manager to restart, or the first queue manager for which **EXPRYINT** is set.

Changes to **EXPRYINT** take effect when the current interval expires. Changes also take effect if the new interval is less than the unexpired portion of the current interval. In this case, a scan is scheduled and the new interval value takes immediate effect.

This parameter is valid only on z/OS.

➤ **z/OS** **GROUPUR**

This parameter controls whether CICS and XA client applications can establish transactions with a GROUP unit of recovery disposition.

The property can be enabled only when the queue manager is a member of a queue sharing group.

ENABLED

CICS and XA client applications can establish transactions with a group unit of recovery disposition by specifying a queue sharing group name when they connect.

DISABLED

CICS and XA client applications must connect using a queue manager name.

This parameter is valid only on z/OS.

➤ **z/OS** **IGQ**

Specifies whether intra-group queuing is used.

The **IGQ** parameter is valid only on z/OS when the queue manager is a member of a queue sharing group.

ENABLED

Message transfer between queue managers within a queue sharing group uses the shared transmission queue, `SYSTEM. QSG. TRANSMIT. QUEUE`.

DISABLED

Message transfer between queue managers within a queue sharing group uses non-shared transmission queues and channels. Queue managers that are not part of a queue sharing group also use this mechanism.

If intra-group queuing is enabled, but the intra-group queuing agent is stopped, use the following command to restart it:

```
ALTER QMGR IGQ(ENABLED)
```

This parameter is valid only on z/OS.

▶ z/OS **IGQAUT**

Specifies the type of authority checking and, therefore, the user IDs, to be used by the IGQ agent (IGQA). This parameter establishes the authority to put messages to a destination queue.

The **IGQAUT** parameter is valid only on z/OS when the queue manager is a member of a queue sharing group.

DEF

Indicates that the default user ID is used to establish authority to put messages to a destination queue.

For a one user ID check, the default user ID is the user ID of a queue manager within the queue sharing group. The default user ID is the user ID of the queue manager that put the messages to the `SYSTEM.QSG.TRANSMIT.QUEUE`. This user ID is referred to as the `QSGSEND` user ID.

For two user ID checks, the default second user ID is the IGQ user ID.

CTX

Indicates that the user ID from a *UserIdentifier* field is used to establish authority to put messages to a destination queue. The user ID is the *UserIdentifier* field in the message descriptor of a message on the `SYSTEM.QSG.TRANSMIT.QUEUE`.

For one user ID check, the `QSGSEND` user ID is used.

For two user ID checks, the `QSGSEND` user ID, the IGQ user ID and the alternate user ID are used. The alternate user ID is taken from the *UserIdentifier* field in the message descriptor of a message on the `SYSTEM.QSG.TRANSMIT.QUEUE`. The alternate user ID is referred to as `ALT`.

ONLYIGQ

Indicates that only the IGQ user ID is used to establish authority to put messages to a destination queue.

For all ID checks, the IGQ user ID is used.

ALTIGQ

Indicates that the IGQ user ID and the ALT user ID are used to establish authority to put messages to a destination queue.

For one user ID check, the IGQ user ID is used.

For two user ID checks, the IGQ user ID and the ALT user ID are used.

This parameter is valid only on z/OS.

▶ z/OS **IGQUSER**

Nominates a user ID to be used by the IGQ agent (IGQA) to establish authority to put messages to a destination queue. The user ID is referred to as the IGQ user ID.

This parameter is valid only on z/OS when the queue manager is a member of a queue sharing group. Possible values are:

Blanks

Indicates that the user ID of the receiving queue manager within the queue sharing group is used.

Specific_user_ID

Indicates that the user ID specified in the **IGUSER** parameter of the receiving queue manager is used.

Note:

1. As the receiving queue manager has authority to all queues it can access, security checking might not be performed for this user ID type.
2. As the value of blanks has a special meaning, you cannot use **IGUSER** to specify a real user ID of blanks.

This parameter is valid only on z/OS.

Multi **IMGINTVL**

The target frequency with which the queue manager automatically writes media images, in minutes since the previous media image for the object.

Possible values are:

1 - 999 999 999

The time in minutes at which the queue manager automatically writes media images.

The default value is 60 minutes.

OFF

Automatic media images are not written on a time interval basis.

The interval specified by **IMGINTVL** is honored when enough new work has been carried out on the queue manager to make it worthwhile recording a new image. Otherwise the taking of new images is delayed.

This parameter is valid only on [Multiplatforms](#).

Multi **IMGLOGLN**

The target size of recovery log, written before the queue manager automatically writes media images, in number of megabytes since the previous media image for the object. This limits the amount of log to be read when recovering an object.

Possible values are:

1 - 999 999 999

The target size of the recovery log in megabytes.

OFF

Automatic media images are not written based on the size of log written.

OFF is the default value (except when creating a Native HA queue manager).

Native HA queue managers are created with **IMGLOGLN** set to the value of 25% of the available space on the volume where the recovery logs are to be written. This value is calculated at queue manager creation time, but can be altered subsequently, if required.

This parameter is valid only on [Multiplatforms](#).

Multi **IMGRCOVO**

Specifies whether authentication information, channel, client connection, listener, namelist, process, alias queue, remote queue, and service objects are recoverable from a media image, if linear logging is being used.

Possible values are:

NO

The “[rcdmqimg \(record media image\)](#)” on page 160 and “[rcrmqobj \(re-create object\)](#)” on page 163 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

YES

These objects are recoverable.

YES is the default value.

This parameter is valid only on [Multiplatforms](#).

Multi **IMGRCOVQ**

Specifies the default **IMGRCOVQ** attribute for local and permanent dynamic queue objects, when used with this parameter.

Possible values are:

NO

The **IMGRCOVQ** attribute for local and permanent dynamic queue objects is set to NO.

YES

The **IMGRCOVQ** attribute for local and permanent dynamic queue objects is set to YES.

YES is the default value.

This parameter is valid only on [Multiplatforms](#).

Multi **IMGSCHED**

Whether the queue manager automatically writes media images.

Possible values are:

AUTO

The queue manager attempts to automatically write a media image for an object, before **IMGINTVL** minutes have elapsed, or **IMGLOGLN** megabytes of recovery log have been written, since the previous media image for the object was taken.

The previous media image might have been taken manually or automatically, depending on the settings of **IMGINTVL** or **IMGLOGLN**.

The interval specified by **IMGINTVL** is honored when enough new work has been carried out on the queue manager to make it worthwhile recording a new image. Otherwise the taking of new images is delayed.

MANUAL

Automatic media images are not written.

MANUAL is the default value.

This parameter is valid only on [Multiplatforms](#).

INHIBTEV

Specifies whether inhibit events are generated. The events are generated for **Inhibit Get** and **Inhibit Put**.

ENABLED

Inhibit events are generated.

DISABLED

Inhibit events are not generated.

This is the queue manager's initial default value.

Multi **INITKEY**

The initial key for the password protection system.

IBM MQ encrypts the value of the **KEYRPWD** queue manager attribute with the IBM MQ password protection system. An encryption key, which is known as the initial key, is used by the encryption algorithm to encrypt and decrypt this attribute. Use this attribute to set a unique initial key for the queue manager, before setting the value of the **KEYRPWD** attribute.

The maximum length of the initial key is 256 bytes.

If this attribute is not set, the value of the **KEYRPWD** is encrypted with the default initial key.

CAUTION: The default initial key is the same for all IBM MQ installations. To protect passwords securely, supply an initial key that is unique to your installation when you encrypt passwords.

Warning:

If you change the value of this attribute, the value of the **KEYRPWD** attribute is not encrypted with the new initial key. Therefore, the queue manager cannot decrypt the TLS key repository password that is needed to access the TLS key repository until the value of the **KEYRPWD** attribute is reset.

To change the value of this attribute, complete the following steps in the order shown:

1. Change the value of the **INITKEY** attribute.
2. Set the value of the **KEYRPWD** attribute so that it is encrypted with the new initial key.

IPADDRV

Specifies which IP protocol is to be used for channel connections.

IPv4

The IPv4 IP address is to be used.

This is the queue manager's initial default value.

IPv6

The IPv6 IP address is to be used.

This parameter is used only in systems running IPv4 and IPv6. It applies to channels defined only with a **TRPTYPE** of TCP when either of the following two conditions is true:

- The **CONNAME** parameter of the channel contains a host name that resolves to both an IPv4 and an IPv6 address, and the **LOCLADDR** parameter is not specified.
- The value of the **CONNAME** and **LOCLADDR** parameters of the channel is a host name that resolves to both an IPv4 and IPv6 address.

These values have the same meanings as the values set in the **IPAddressVersion** attribute of the TCP stanza of the client configuration file and the **MQIPADDRV** environment variable.

ALW KEYRPWD

The password to access the TLS key repository that is specified with the **SSLKEYR** attribute.

If a value is specified for this attribute, it is used as the password to access the Secure Sockets Layer key repository. If this attribute is blank, the password in the stash file that is associated with the key repository is used. If the stash file is not present or cannot be read, the key repository cannot be accessed and channels that use TLS fail to start.

The value of this attribute is encrypted by using the IBM MQ password protection system. Use the **INITKEY** attribute to set the encryption key to a unique value before this attribute is set.

The default value of this attribute is blank.

LOCALEV

Specifies whether local error events are generated, caused by an application or the queue manager not being able to access a local queue or other local object, for example, because the object has not been defined:

ENABLED

Local error events are generated.

DISABLED

Local error events are not generated.

This is the queue manager's initial default value.

Multi LOGGEREV

Specifies whether recovery log events are generated:

DISABLED

Logger events are not generated.

This is the queue manager's initial default value.

ENABLED

Logger events are generated. This value is not valid on queue managers that are using circular logs.

This parameter is valid only on [Multiplatforms](#).

➤ **z/OS** **LSTRTMR(integer)**

The time interval, in seconds, between attempts by IBM MQ to restart a listener after an APPC or TCP/IP failure. When the listener is restarted on TCP/IP, it uses the same port and IP address as it used when it first started.

Specify a value in the range 5 through 9999.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

➤ **z/OS** **LUGROUP(string)**

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue sharing group. The maximum length of this parameter is eight characters.

If this name is blank, the listener cannot be used.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

➤ **z/OS** **LUNAME(string)**

The name of the LU to use for outbound LU 6.2 transmissions. Set this parameter to be the same as the name of the LU to be used by the listener for inbound transmissions. The maximum length of this parameter is eight characters.

If this name is blank, the APPC/MVS default LU name is used. This name is variable, so LUNAME must always be set if you are using LU 6.2

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

➤ **z/OS** **LU62ARM(string)**

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC=xx is issued.

If you do not provide a value for this parameter, no SET APPC=xx command is issued.

The maximum length of this parameter is two characters.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

➤ **z/OS** **LU62CHL(integer)**

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol.

Specify a value 0- 9999 that is not greater than the value of **MAXCHL**. **MAXCHL** defines the maximum number of channels available. If you specify zero, the LU 6.2 transmission protocol is not used.

If you change this value, also review the **MAXCHL**, **LU62CHL**, and **ACTCHL** values. Ensure that there is no conflict of values and if necessary, raise the value of **MAXCHL** and **ACTCHL**.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of **LU62CHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **LU62CHL** is zero when the channel initiator starts up, a later **ALTER** command does not take effect. In this case, you should carry out an **ALTER** command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid only on z/OS.

MARKINT(integer)

The time interval, expressed in milliseconds, for which messages marked as browsed by a call to MQGET, with the get message option MQGMO_MARK_BROWSE_CO_OP, are expected to remain marked-browsed.

If messages are marked for more than approximately **MARKINT** milliseconds, the queue manager might automatically unmark messages. It might unmark messages that are marked as browsed for the cooperating set of handles.

This parameter does not affect the state of any message marked as browse by a call to MQGET with the get message option MQGMO_MARK_BROWSE_HANDLE.

Specify a value up to the maximum of 999,999,999. The default value is 5000.

Attention: You should not reduce the value below the default of 5000.

The special value NOLIMIT indicates that the queue manager does not automatically unmark messages by this process.

MAXCHL(integer)

The maximum number of channels that can be current (including server-connection channels with connected clients).

Specify a value in the range 1- 9999. If you change this value, also review the **TCPCHL**, **LU62CHL**, and **ACTCHL** values to ensure that there is no conflict of values. If necessary, increase the number of active channels with the **ACTCHL** value. The values of **ACTCHL**, **LU62CHL**, and **TCPCHL** must not be greater than the maximum number of channels. Suggested settings are:

- Test system: 200
- Production system: 1000

For an explanation of which channel states are considered current; see [Channel states](#).

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of **MAXCHL** is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of **MAXCHL**, more channels can be started. Increasing the value of **MAXCHL** to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of **MAXCHL** takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

For more information about the relationship between **CHIADAPS**, **CHIDISPS**, and **MAXCHL**, see [Tailor the channel initiator parameters](#).

This parameter is valid only on z/OS.

MAXHANDS(integer)

The maximum number of open handles that any one connection can have at the same time.

This value is a value in the range 0 - 999,999,999.

MAXMSGL(integer)

The maximum length of messages allowed on queues for this queue manager.

This value is in the range 32 KB through 100 MB.

Ensure that you also consider the length of any message properties when deciding the value for the **MAXMSGL** parameter of a channel.

If you reduce the maximum message length for the queue manager, you must also reduce the maximum message length of the `SYSTEM.DEFAULT.LOCAL.QUEUE` definition. You must also reduce the maximum message length for all other queues defined on the queue manager. This change ensures that the limit of the queue manager is not less than the limit of any of the queues associated with it. If you do not change these lengths, and applications inquire only the **MAXMSGL** value of the queue, they might not work correctly.

Note that by adding the digital signature and key to the message, [Advanced Message Security](#) increases the length of the message.

MAXPROPL (integer)

The maximum length of property data in bytes that can be associated with a message.

This value is in the range 0 through 100 MB (104 857 600 bytes).

The special value `NOLIMIT` indicates that the size of the properties is not restricted, except by the upper limit.

MAXUMSGS(integer)

The maximum number of uncommitted messages within a sync point.

MAXUMSGS is a limit on the number of messages that can be retrieved, plus the number of messages that can be put, within any single sync point. The limit does not apply to messages that are put or retrieved outside sync point.

The number includes any trigger messages and report messages generated within the same unit of recovery.

If existing applications and queue manager processes are putting and getting a larger number of messages in sync point, reducing **MAXUMSGS** might cause problems.

 An example of queue manager processes that might be affected is clustering on z/OS.

Specify a value in the range 1 through 999,999,999. The default value is 10000.

MAXUMSGS has no effect on IBM MQ Telemetry. IBM MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

MONACLS

Controls the collection of online monitoring data for auto-defined cluster-sender channels:

QMGR

Collection of online monitoring data is inherited from the setting of the **MONCHL** parameter of the queue manager.

This is the queue manager's initial default value.

OFF

Monitoring for the channel is disabled.

LOW

Unless **MONCHL** is `NONE`, monitoring is enabled with a low rate of data collection with a minimal effect on system performance. The data collected is not likely to be the most current.

MEDIUM

Unless **MONCHL** is `NONE`, monitoring is enabled with a moderate rate of data collection with limited effect on system performance.

HIGH

Unless **MONCHL** is **NONE**, monitoring is enabled with a high rate of data collection with a likely effect on system performance. The data collected is the most current available.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

MONCHL

Controls the collection of online monitoring data for channels. The channels defined with **MONCHL (QMGR)** are affected by changing the QMGR **MONCHL** attribute.

OFF

Online monitoring data collection is turned off for channels specifying a value of QMGR in their **MONCHL** parameter.

This is the queue manager's initial default value.

NONE

Online monitoring data collection is turned off for channels regardless of the setting of their **MONCHL** parameter.

LOW

Online monitoring data collection is turned on, with a low ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

MEDIUM

Online monitoring data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

HIGH

Online monitoring data collection is turned on, with a high ratio of data collection, for channels specifying a value of QMGR in their **MONCHL** parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

MONQ

Controls the collection of online monitoring data for queues.

OFF

Online monitoring data collection is turned off for queues specifying a value of QMGR in their **MONQ** parameter.

This is the queue manager's initial default value.

NONE

Online monitoring data collection is turned off for queues regardless of the setting of their **MONQ** parameter.

LOW

Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

MEDIUM

Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

HIGH

Online monitoring data collection is turned on for queues specifying a value of QMGR in their **MONQ** parameter.

In contrast to **MONCHL**, there is no distinction between the values **LOW**, **MEDIUM**, and **HIGH**. These values all turn data collection on, but do not affect the rate of collection.

Changes to this parameter are effective only for queues opened after the parameter is changed.

z/OS **OPORTMAX(integer)**

The maximum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535. A value of zero means that all outgoing channels bind to any available port number.

Specify a corresponding value for **OPORTMIN** to define a range of port numbers. Ensure that the value you specify for **OPORTMAX** is greater than or equal to the value you specify for **OPORTMIN**.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

z/OS **OPORTMIN(integer)**

The minimum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535.

Specify a corresponding value for **OPORTMAX** to define a range of port numbers. Ensure that the value you specify for **OPORTMIN** is less than or equal to the value you specify for **OPORTMAX**.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

z/OS **OTELPCTL**

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**, or from the message to the environment on **MQGET**. V 10.0.0 For IMS bridge queues, also controls whether the IMS bridge automatically propagates trace context from the messages it gets to IMS.

Can be one of the following values. The **OTELPCTL** value on individual queues might override this value.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties. This is the queue manager's initial default value.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation. If the queue manager is in a queue sharing group, this value can only be set if all queue managers have been started at IBM MQ 9.4.3 or above. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

z/OS **OTELTRAC**

Whether the queue manager emits spans as messages are sent to or consumed from queues. V 10.0.0 For IMS bridge queues, also controls whether the IMS bridge emits spans when it sends the messages it gets to IMS.

Can be one of the following values. The **OTELTRAC** value on individual queues might override this value, unless NONE is specified.

OFF

Spans are not emitted even if messages have trace context. This is the queue manager's initial default value.

ON

Spans are emitted if messages have trace context.

NONE

Spans are not emitted even if **OTELTRAC(ON)** is specified on the queue the application is using.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PARENT(parentname)

The name of the parent queue manager to which the local queue manager is to connect as its child in a hierarchy.

A blank value indicates that the queue manager has no parent queue manager.

If there is an existing parent queue manager it is disconnected.

IBM MQ hierarchical connections require that the queue manager attribute **PSMODE** is set to **ENABLED**.

The value of **PARENT** can be set to a blank value if **PSMODE** is set to **DISABLED**.

Before a queue manager can connect to a queue manager as its child in a hierarchy, channels must exist in both directions. The channels must exist between the parent queue manager and the child queue manager.

If a parent is already defined, the **ALTER QMGR PARENT** command disconnects from the original parent and sends a connection flow to the new parent queue manager.

Successful completion of the command does not mean that the action completed. To check that this command has completed, see the [ALTER QMGR](#) step in [Checking that async commands for distributed networks have finished](#).

PERFMEV

Specifies whether performance-related events are generated:

ENABLED

Performance-related events are generated.

DISABLED

Performance-related events are not generated.

This is the queue manager's initial default value.

z/OS

On IBM MQ for z/OS, all the queue managers in a queue sharing group must have the same setting.

PSCLUS

Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from **ENABLED** to **DISABLED**.

For more information about **PSCLUS**, see [Inhibiting clustered publish/subscribe](#).

Note: To change a **PSCLUS** parameter status, the CHIN address space needs to be running.

ENABLED

This queue manager can define clustered topic objects, publish to subscribers on other queue managers, and register subscriptions that receive publications from other queue managers. All queue managers in the cluster running a version of IBM MQ that supports this option must specify **PSCLUS(ENABLED)** for the publish/subscribe activity to function as expected. **ENABLED** is the default value when a queue manager is created.

DISABLED

This queue manager cannot define clustered topic objects and ignores their definition on any other queue manager in the cluster.

Publications are not forwarded to subscribers elsewhere in the cluster, and subscriptions are not registered other than on the local queue manager.

To ensure that no publish/subscribe activity occurs in the cluster, all queue managers must specify **PSCLUS(DISABLED)**. As a minimum, full repositories must be consistent in enabling or disabling publish/subscribe participation.

PSMODE

Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running. It controls whether applications can publish or subscribe by using the application programming interface. It also controls whether the queues that are monitored by the queued publish/subscribe interface, are monitored.

Changing the **PSMODE** attribute can change the **PSMODE** status. Use one of the following commands to determine the current state of the publish/subscribe engine and the queued publish/subscribe interface:

- **DISPLAY PUBSUB**
-  **DSPMQM** (on IBM i only)

COMPAT

The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface.

The queued publish/subscribe interface is not running. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

Use this setting for compatibility with IBM Integration Bus (formerly known as WebSphere Message Broker) V6 or earlier versions that use this queue manager.

DISABLED

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe by using the application programming interface. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

If a queue manager is in a publish/subscribe cluster or hierarchy, it might receive publish/subscribe messages from other queue managers in the cluster or hierarchy. Examples of such messages are publication messages or proxy subscriptions. While **PSMODE** is set to **DISABLED** those messages are not processed. For this reason, disable any queue manager in a publish/subscribe cluster or hierarchy only for as long as there is little build-up of messages.

ENABLED

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface.

This is the queue manager's initial default value.

Note: If a queue manager is in a publish/subscribe cluster or hierarchy, and you change **PSMODE** to **ENABLED**, you might have to run the command **REFRESH QMGR TYPE(PROXY)**. The command ensures that non-durable subscriptions are known across the cluster or hierarchy when **PSMODE** is set back to **ENABLED**. The circumstance in which you must run the command is as follows. If **PSMODE** is changed from **ENABLED** to **DISABLED** and back to **ENABLED**, and one or more non-durable subscriptions exist across all three stages.

PSNPMMSG

If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue. Whether it attempts to do so depends on the report options of the input message. The attempt to write the input message to the dead-

letter queue might fail. In this case, the queued publish/subscribe interface might discard the input message. If MQRO_DISCARD_MSG is specified on the input message, the input message is discarded. If MQRO_DISCARD_MSG is not set, setting **PSNPMSG** to KEEP prevents the input message from being discarded. The default is to discard the input message.

Note: If you specify a value of IFPER for **PSSYNCPT**, you must not specify a value of KEEP for **PSNPMSG**.

DISCARD

Non-persistent input messages might be discarded if they cannot be processed.

KEEP

Non-persistent input messages are not discarded if they cannot be processed. In this situation, the queued publish/subscribe interface continues to try to process this message again at appropriate intervals and does not continue processing subsequent messages.

PSNPRES

The **PSNPRES** attribute controls whether the queued publish/subscribe interface writes an undeliverable reply message to the dead-letter queue, or discards the message. The choice is necessary if the queued publish/subscribe interface cannot deliver a reply message to the reply-to queue.

For new queue managers, the initial value is NORMAL. If you specify a value of IFPER for **PSSYNCPT**, you must not specify a value of KEEP or SAFE for **PSNPRES**.

 For migrated queue managers on Multiplatforms, the value depends on DLQNonPersistentResponse and DiscardNonPersistentResponse.

NORMAL

Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If they cannot be placed on the dead-letter queue then they are discarded.

SAFE

Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If the response cannot be sent and cannot be placed on the dead-letter queue, the queued publish/subscribe interface backs out of the current operation. It tries again at appropriate intervals, and does not continue processing subsequent messages.

DISCARD

Non-persistent responses which cannot be placed on the reply queue are discarded

KEEP

Non-persistent responses are not placed on the dead-letter queue or discarded. Instead the queued publish/subscribe interface backs out the current operation and then tries it again at appropriate intervals and does not continue processing subsequent messages.

PSRTYCNT

If the queued publish/subscribe interface fails to process a command message under sync point, the unit of work is backed out. The command tries to process the message a number of times again, before the publish/subscribe broker processes the command message according to its report options instead. This situation can arise for a number of reasons. For example, if a publish message cannot be delivered to a subscriber, and it is not possible to put the publication on the dead letter queue.

The initial value for this parameter on a new queue manager is 5.

Range is 0 - 999,999,999.

PSSYNCPT

Controls whether the queued publish/subscribe interface processes command messages (publishes or delete publication messages) under sync point.

YES

All messages are processed under sync point.

IFPER

Only persistent messages are part of the sync point

The initial value of the queue manager is IFPER.

RCVTIME (integer)

The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to the inactive state.

This parameter applies only to message channels and to MQI server-connection and client-connection channels where **SHARECNV** is greater than zero, when the channel receive timeout is set based on the negotiated heartbeat interval in the same way as for message channels. This number can be qualified as follows:

- To specify that this number is a multiplier to apply to the negotiated **HBINT** value to determine how long a channel is to wait, set **RCVTTYPE** to MULTIPLY. Specify a **RCVTIME** value of zero or in the range 2 through 99. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.
- To specify that **RCVTIME** is the number of seconds to add to the negotiated **HBINT** value to determine how long a channel is to wait, set **RCVTTYPE** to ADD. Specify an **RCVTIME** value in the range 1 through 999999.
- To specify that **RCVTIME** is a value, in seconds, that the channel is to wait, set **RCVTTYPE** to EQUAL. Specify an **RCVTIME** value in the range 0 - 999,999. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.

Note: For MQI channels that use sharing conversations, the heartbeat interval used by **ReceiveTimeout**, **ReceiveTimeMin**, or **ReceiveTimeoutType** is five seconds greater than the negotiated heartbeat interval.

For channels with **SHARECNV** equal to zero, **RCVTMIN** does not apply.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

This parameter is valid only on z/OS.

RCVTMIN(integer)

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

This parameter applies only to message channels and to MQI server-connection and client-connection channels where **SHARECNV** is greater than zero, when the channel receive timeout is set based on the negotiated heartbeat interval in the same way as for message channels.

Note: For MQI channels that use sharing conversations, the heartbeat interval used by **ReceiveTimeout**, **ReceiveTimeMin**, or **ReceiveTimeoutType** is five seconds greater than the negotiated heartbeat interval.

For channels with **SHARECNV** equal to zero, **RCVTMIN** does not apply.

The TCP/IP channel wait time can be configured relative to the negotiated value of **HBINT**. If **RCVTTYPE** is MULTIPLY or ADD, the resultant value might be less than the value set in **RCVTMIN**. In this case, the TCP/IP channel wait time is set to **RCVTMIN**. If **RCVTTYPE** is EQUAL then **RCVTMIN** does not apply.

Specify a value, in seconds, between zero and 999999.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

This parameter is valid only on z/OS.

RCVTTYPE

The qualifier to apply to the value in **RCVTIME**.

MULTIPLY

Specifies that **RCVTIME** is a multiplier to be applied to the negotiated **HBINT** value to determine how long a channel waits.

ADD

Specifies that **RCVTIME** is a value, in seconds, to be added to the negotiated **HBINT** value to determine how long a channel waits.

EQUAL

Specifies that **RCVTIME** is a value, in seconds, representing how long the channel waits.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

This parameter is valid only on z/OS.

REMOTEV

Specifies whether remote error events are generated, caused by an application or the queue manager not being able to access a remote queue on another queue manager, for example, the transmission queue not being correctly defined:

DISABLED

Remote error events are not generated.

This is the queue manager's initial default value.

ENABLED

Remote error events are generated.

 If you are using the reduced function form of IBM MQ for z/OS supplied with WebSphere Application Server, only **DISABLED** is valid.

REPOS(*clustname*)

The name of a cluster for which this queue manager provides a repository manager service. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

You can specify either the **REPOS** or the **REPOSNL** parameter, but not both. Both **REPOS** and **REPOSNL** might be blank, or **REPOS** might be blank and the namelist specified by **REPOSNL** might be empty. In these cases, this queue manager does not have a full repository. It might be a client of other repository services defined in the cluster.

Use a cluster-sender channel to connect this queue manager to at least one other full repository queue manager in the cluster (if specifying **REPOS**) or in each cluster named in the namelist (if specifying **REPOSNL**). See the information in [Components of a cluster](#) for details about using cluster-sender channels with full repository queue managers.

Successful completion of the command does not mean that the action completed. To check for true completion, see the **ALTER QMGR** step in [Checking that async commands for distributed networks have finished](#).

REPOSNL(*nlname*)

The name of a namelist of clusters for which this queue manager provides a repository manager service. The maximum length is 48 characters conforming to the rules for naming an IBM MQ namelist object.

See the description of **REPOS** for information on specifying either **REPOS** or **REPOSNL**.

REVDNS

Controls whether reverse lookup of the host name from a Domain Name Server (DNS) is done for the IP address from which a channel has connected. This attribute has an effect only on channels using a transport type (TRPTYPE) of TCP:

ENABLED

DNS host names are reverse looked-up for the IP addresses of inbound channels when this information is required. This setting is required for matching against CHLAUTH rules that contain

host names, and to include the host name in error messages. The IP address is still included in messages that provide a connection identifier.

This is the initial default value for the queue manager.

DISABLED

DNS host names are not reverse looked-up for the IP addresses of inbound channels. With this setting any CHLAUTH rules using host names are not matched.

ROUTEREC

Specifies whether trace-route information is recorded if requested in the message. If this parameter is not set to **DISABLED**, it controls whether any reply generated is sent to `SYSTEM.ADMIN.TRACE.ROUTE.QUEUE`, or to the destination specified by the message itself. If

ROUTEREC is not **DISABLED**, messages not yet at the final destination might have information added to them.

DISABLED

Trace-route information is not recorded.

MSG

Trace-route information is recorded and sent to the destination specified by the originator of the message causing the trace route record.

This is the queue manager's initial default value.

QUEUE

Trace-route information is recorded and sent to `SYSTEM.ADMIN.TRACE.ROUTE.QUEUE`.

SCHINIT

Specifies whether the channel initiator starts automatically when the queue manager starts.

QMGR

The channel initiator starts automatically when the queue manager starts.

MANUAL

The channel initiator does not start automatically.

This parameter is valid only on [Multiplatforms](#).

SCMDSERV

Specifies whether the command server starts automatically when the queue manager starts.

QMGR

The command server starts automatically when the queue manager starts.

MANUAL

The command server does not start automatically.

This parameter is valid only on [Multiplatforms](#).

SCYCASE

Specifies whether the security profiles are uppercase or mixed case.

UPPER

The security profiles are uppercase only. However, `MXTOPIC` and `GMXTOPIC` are used for topic security, and can contain mixed-case profiles.

MIXED

The security profiles are mixed case. `MQCMD` and `MQCONN` are used for command and connection security but they can contain only uppercase profiles.

Changes to **SCYCASE** become effective after you run the following command:

```
REFRESH SECURITY(*) TYPE(CLASSES)
```

This parameter is valid only on z/OS.

SQQMNAME

The **SQQMNAME** attribute specifies whether a queue manager in a queue sharing group opens a shared queue in the same group directly. The processing queue manager calls MQOPEN for a shared queue and sets the *ObjectQmgrName* parameter for the queue. If the shared queue is in the same queue sharing group as the processing queue manager, the queue can be opened directly by the processing queue manager. Set the **SQQMNAME** attribute to control if the queue is opened directly, or by the *ObjectQmgrName* queue manager. The attribute will also be honored when opening a QALIAS with copy disposition, if the target queue is a shared queue in the same queue sharing group as the processing queue manager. In this situation it is important that the QALIAS copy object on each queue manager in the queue sharing group has the same target queue.

USE

The *ObjectQmgrName* is used, and the appropriate transmission queue is opened.

IGNORE

The processing queue manager opens the shared queue directly. Setting the parameter to this value can reduce the traffic in your queue manager network.

This parameter is valid only on z/OS.

SSLCRLNL (nlname)

The name of a namelist of authentication information objects which are used to provide certificate revocation locations to allow enhanced TLS certificate checking.

Attention: The namelist can reference a maximum of one OCSP type AUTHINFO object only.

If more than one OCSP type AUTHINFO object is referenced in the NAMELIST, only the first entry is used.

If **SSLCRLNL** is blank, certificate revocation checking is not invoked unless one of the TLS certificates used contains an AuthorityInfoAccess or CrlDistributionPoint X.509 certificate extension.

Changes to **SSLCRLNL**, or to the names in a previously specified namelist, or to previously referenced authentication information objects become effective as follows:

- When a **REFRESH SECURITY TYPE(SSL)** command is issued.
 -  On AIX, Linux, and Windows:
 - When a new channel process is started
 - For channels that run as threads of the channel initiator, when the channel initiator is restarted
 - For channels that run as threads of the listener, when the listener is restarted
 -  On IBM i:
 - When a new channel process is started
 - For channels that run as threads of the channel initiator, when the channel initiator is restarted
 - For channels that run as threads of the listener, when the listener is restarted
- On IBM i queue managers, this parameter is ignored. However, it is used to determine which authentication information objects are written to the AMQCLCHL .TAB file.
-  On z/OS, when the channel initiator is restarted.

Only authentication information objects with types of CRLLDAP or OCSP are allowed in the namelist referred to by **SSLCRLNL**. Any other type results in an error message when the list is processed and is subsequently ignored.

SSLCRYP(string)

Sets the name of the parameter string required to configure the cryptographic hardware present on the system.

All supported cryptographic hardware supports the PKCS #11 interface. Specify a string of the following format:

```
GSK_PKCS11= the PKCS #11 driver path and file name>  
; the PKCS #11 token label> ;  
the PKCS #11 token password> ; symmetric cipher setting>  
;
```

The PKCS #11 driver path is an absolute path to the shared library providing support for the PKCS #11 card. The PKCS #11 driver file name is the name of the shared library. An example of the value required for the PKCS #11 driver path and file name is `/usr/lib/pkcs11/PKCS11_API.so`

To access symmetric cipher operations through IBM Global Security Kit (GSKit), specify the symmetric cipher setting parameter. The value of this parameter is either:

SYMMETRIC_CIPHER_OFF

Do not access symmetric cipher operations.

SYMMETRIC_CIPHER_ON

Access symmetric cipher operations.

If the symmetric cipher setting parameter is not specified, it has the same effect as specifying **SYMMETRIC_CIPHER_OFF**.

The maximum length of the string is 256 characters.

If you specify a string that is not in the format listed, you get an error.

When the **SSLCRYPT** value is changed, the cryptographic hardware parameters specified become the ones used for new TLS connection environments. The new information becomes effective:

- When a new channel process is started.
- For channels that run as threads of the channel initiator, when the channel initiator is restarted.
- For channels that run as threads of the listener, when the listener is restarted.
- When a **REFRESH SECURITY TYPE(SSL)** command is issued.

SSLEV

Specifies whether TLS events are generated.

DISABLED

TLS events are not generated.

This is the queue manager's initial default value.

ENABLED

All TLS events are generated.

SSLFIPS

SSLFIPS specifies whether only FIPS-certified algorithms are to be used if cryptography is carried out in IBM MQ, rather than in cryptographic hardware. If cryptographic hardware is configured, the cryptographic modules used are those modules provided by the hardware product. These might, or might not, be FIPS-certified to a particular level. Whether the modules are FIPS certified depends on the hardware product in use. For more information about FIPS, see the [Federal Information Processing Standards \(FIPS\) manual](#).

Attention: V1000 V1000 FIPS support is currently not available for Linux s390x. Enabling FIPS on a queue manager will prevent all TLS and AMS related operations. Customers on this platform who require FIPS support should remain at a previous version of IBM MQ. Support for FIPS 140-3 will be enabled in a future FixPack once the IBM Crypto for C (ICC) cryptographic module has received its certification on this platform.

Attention: Over time, the Federal Information Processing Standards are updated to reflect new attacks against encryption algorithms and protocols. For example, some CipherSpecs might cease to be FIPS certified. When such changes occur, IBM MQ is also updated to implement the latest standard. As a result, you might see changes in behavior after applying maintenance.

NO

If you set **SSLFIPS** to NO, you can use either FIPS certified or non-FIPS certified CipherSpecs.

If the queue manager runs without using cryptographic hardware, refer to the CipherSpecs listed in [Specifying CipherSpecs](#).

This is the queue manager's initial default value.

YES

Specifies that only FIPS certified algorithms are to be used in the CipherSpecs allowed on all TLS connections from and to this queue manager.

For a listing of appropriate FIPS 140-2 certified CipherSpecs; see [Specifying CipherSpecs](#).

Changes to **SSLFIPS** become effective as follows:

-  **ALW** On AIX, Linux, and Windows:
 - When a **REFRESH SECURITY TYPE(SSL)** command is issued
 - When a new channel process is started
 - For channels that run as threads of the channel initiator, when the channel initiator is restarted
 - For channels that run as threads of the listener, when the listener is restarted
 - For channels that run as threads of a process pooling process, when the process pooling process is started or restarted and first runs a TLS channel. If the process pooling process has already run a TLS channel, and you want the change to become effective immediately, run the MQSC command **REFRESH SECURITY TYPE(SSL)**. The process pooling process is **amqzmpa**
-  **z/OS** On z/OS, when the channel initiator is restarted.

This parameter is valid on z/OS, AIX, Linux, and Windows.

SSLKEYR(string)

The name of the Secure Sockets Layer key repository. The maximum length of the string is 256 characters.

The format of the name depends on the environment:

-  **z/OS** On z/OS, it is the name of a key ring.
-  **IBM i** On IBM i, it is the full path and the file name of the key repository in the form *pathname/keyfile.kdb*, where *keyfile* identifies a GSKit CMS key database file.
 - The default value is `/QIBM/UserData/ICSS/Cert/Server/Default`.
 - If you specify `*SYSTEM`, IBM MQ uses the system certificate store as the key repository for the queue manager. The queue manager is registered as a server application in the Digital Certificate Manager (DCM). You can assign any server/client certificate in the system store to the queue manager.
 - If you change the **SSLKEYR** parameter to a value other than `*SYSTEM`, IBM MQ unregisters the queue manager as an application with DCM.
-  **Linux**  **AIX** On AIX and Linux, it is the full path and the file name of the key repository in the form *pathname/keyfile* where *keyfile* identifies a GSKit CMS or PKCS #12 key database file.

The default value is `/var/mqm/qmgrs/QMGR/ssl/key`, where *QMGR* is the queue manager name.

-  **Windows** On Windows, it is the full path and the file name of the key repository in the form *pathname\keyfile* where *keyfile* identifies a GSKit CMS or PKCS #12 key database file.

The default value is `MQ_DATA_PATH\qmgrs\QMGR\ssl\key`, where *MQ_DATA_PATH* is the IBM MQ data path that is selected during the installation of IBM MQ, and *QMGR* is the queue manager name.

-  **Multi** On [Multiplatforms](#), the syntax of this parameter is validated to ensure that it contains a valid and absolute directory path.

-  A check is made for the existence of a file with extension .p12 and, if present, this file is used. If there is no file with an extension of .p12, a file with an extension of .kdb is assumed.
-  If the file suffix is not specified, it is assumed to be .kdb. To use a PKCS #12 key repository, the file suffix must be specified.

On Windows and Linux if TLS AMQP channels are used, you must use a PKCS #12 key repository with a file suffix of .p12 or .pkcs12.

If **SSLKEYR** is blank, or is set to a value that does not correspond to a key ring or key database file, channels that are configured to use TLS cannot start.

Changes to the **SSLKEYR** attribute, changes to the keystore contents or changes to the filesystem which would cause a different keystore to be selected per the rules above, become effective as follows:

- When a **REFRESH SECURITY TYPE(SSL)** command is issued.
-  On Multiplatforms:
 - When a new channel process is started.
 - For channels that run as threads of the channel initiator, when the channel initiator is restarted.
 - For channels that run as threads of the listener, when the listener is restarted.
 - For channels that run as threads of a process pooling process, **amqrmppa**, when the process pooling process is started or restarted and first runs a TLS channel. If the process pooling process has already run a TLS channel, and you want the change to become effective immediately, run the MQSC command **REFRESH SECURITY TYPE(SSL)**.
-  On z/OS, when the channel initiator is restarted.

SSLRKEYC(integer)

The number of bytes to be sent and received within an TLS conversation before the secret key is renegotiated. The number of bytes includes control information.

SSLRKEYC is used only by TLS channels which initiate communication from the queue manager. For example, the sender channel initiates communication in a sender and receiver channel pairing.

If a value greater than zero is specified, the secret key is also renegotiated before message data is sent or received following a channel heartbeat. The count of bytes until the next secret key renegotiation is reset after each successful renegotiation.

Specify a value in the range 0 - 999,999,999. A value of zero means that the secret key is never renegotiated. If you specify an TLS secret key reset count in the range 1 - 32767 bytes (32 KB), TLS channels use a secret key reset count of 32 KB. The larger reset count value avoids the cost of excessive key resets which would occur for small TLS secret key reset values.

Attention: If your enterprise has applied APAR *PH30305*, the following statement no longer applies:

- Non-zero values less than 4096 (4 KB) might cause channels to fail to start, or might cause inconsistencies in the values of **SSLKEYDA**, **SSLKEYTI**, and **SSLRKEYS**.

SSLTASKS(integer)

The number of server subtasks to use for processing TLS calls. To use TLS channels, you must have at least two of these tasks running.

This value is in the range 0 - 9999. To avoid problems with storage allocation, do not set the **SSLTASKS** parameter to a value greater than 50.

Changes to this parameter are effective when the channel initiator is restarted.

This parameter is valid only on z/OS.

STATACLS

Specifies whether statistics data is to be collected for auto-defined cluster-sender channels:

QMGR

Collection of statistics data is inherited from the setting of the **STATCHL** parameter of the queue manager.

This is the queue manager's initial default value.

OFF

Statistics data collection for the channel is disabled.

LOW

Unless **STATCHL** is **NONE**, statistics data collection is switched on with a low ratio of data collection with a minimal effect on system performance.

MEDIUM

Unless **STATCHL** is **NONE**, statistics data collection is switched on with a moderate ratio of data collection.

HIGH

Unless **STATCHL** is **NONE**, statistics data collection is switched on with a high ratio of data collection.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

 On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying **LOW**, **MEDIUM**, or **HIGH** makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

STATCHL

Specifies whether statistics data is to be collected for channels:

NONE

Statistics data collection is turned off for channels regardless of the setting of their **STATCHL** parameter.

OFF

Statistics data collection is turned off for channels specifying a value of **QMGR** in their **STATCHL** parameter.

This is the queue manager's initial default value.

LOW

Statistics data collection is turned on, with a low ratio of data collection, for channels specifying a value of **QMGR** in their **STATCHL** parameter.

MEDIUM

Statistics data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of **QMGR** in their **STATCHL** parameter.

HIGH

Statistics data collection is turned on, with a high ratio of data collection, for channels specifying a value of **QMGR** in their **STATCHL** parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

 On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying **LOW**, **MEDIUM**, or **HIGH** makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

 STATINT(integer)

The time interval, in seconds, at which statistics monitoring data is written to the monitoring queue.

Specify a value in the range 1 through 604800.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.
This parameter is valid only on [Multiplatforms](#).

► **Multi** **STATMQI**

Specifies whether statistics monitoring data is to be collected for the queue manager:

OFF

Data collection for MQI statistics is disabled.
This is the queue manager's initial default value.

ON

Data collection for MQI statistics is enabled.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.
This parameter is valid only on [Multiplatforms](#).

STATQ

Specifies whether statistics data is to be collected for queues:

► **Multi** **NONE**

Statistics data collection is turned off for queues regardless of the setting of their **STATQ** parameter.

OFF

Statistics data collection is turned off for queues specifying a value of QMGR or OFF in their **STATQ** parameter. OFF is the default value.

ON

Statistics data collection is turned on for queues specifying a value of QMGR or ON in their **STATQ** parameter.

► **z/OS** On z/OS, you must switch on class 5 statistics by the START TRACE command.

Statistics messages are generated only for queues which are opened after statistics collection is enabled. You do not need to restart the queue manager for the new value of STATQ to take effect.

STRSTPEV

Specifies whether start and stop events are generated:

ENABLED

Start and stop events are generated.
This is the queue manager's initial default value.

DISABLED

Start and stop events are not generated.

SUITEB

Specifies whether Suite B-compliant cryptography is used and what strength is required.

NONE

Suite B is not used. NONE is the default

128_BIT

Suite B 128-bit level security is used.

192_BIT

Suite B 192-bit level security is used

128_BIT, 192_BIT

Both Suite B 128-bit and 192-bit level security is used

► **z/OS** **TCPCHL(integer)**

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol.

The maximum number of sockets used is the sum of the values in **TCPCHL** and **CHIDISPS**. The z/OS UNIX System Services **MAXFILEPROC** parameter (specified in the BPXPRMxx member of SYS1.PARMLIB) controls how many sockets each task is allowed, and thus how many channels each dispatcher is allowed. In this case, the number of channels using TCP/IP is limited to the value of **MAXFILEPROC** multiplied by the value of **CHIDISPS**.

Specify a value 0-9999. The value must not be greater than the value of **MAXCHL**. **MAXCHL** defines the maximum number of channels available. TCP/IP might not support as many as 9999 channels. If so, the value you can specify is limited by the number of channels TCP/IP can support. If you specify zero, the TCP/IP transmission protocol is not used.

If you change this value, also review the **MAXCHL**, **LU62CHL**, and **ACTCHL** values to ensure that there is no conflict of values. If necessary, raise the value of **MAXCHL** and **ACTCHL**.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

Sharing conversations do not contribute to the total for this parameter.

If the value of **TCPCHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **TCPCHL** is zero when the channel initiator starts up, a later **ALTER** command does not take effect. In this case, you should carry out an **ALTER** command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid only on z/OS.

► z/OS **TCPKEEP**

Specifies whether the **KEEPALIVE** facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

NO

The TCP **KEEPALIVE** facility is not to be used.

This is the queue manager's initial default value.

YES

The TCP **KEEPALIVE** facility is to be used as specified in the TCP profile configuration data set. The interval is specified in the **KAINT** channel attribute.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

This parameter is valid only on z/OS.

Using the **TCPKEEP** parameter is no longer required for 'modern' queue managers. The replacement is a combination of:

- using 'modern' client channels (**SHARECNV** <> 0)
- using receive timeout for message channels **RCVTIME**.

For more information, see the technote *Setting the TCP/IP KeepAlive interval to be used by IBM MQ*, at: <https://www.ibm.com/support/pages/node/342737>

► z/OS **TCPNAME(string)**

The name of either the only, or preferred, TCP/IP stack to be used, depending on the value of **TCPSTACK**. This name is the name of the z/OS UNIX System Services stack for TCP/IP, as specified in the **SUBFILESYSTYPE** NAME parameter in the BPXPRMxx member of SYS1.PARMLIB. **TCPNAME** is only applicable in CINET multiple stack environments. The queue manager's initial default value is TCPIP.

In INET single stack environments the channel initiator uses the only available TCP/IP stack.

The maximum length of this parameter is eight characters.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

➤ **z/OS** **TCPSTACK**

Specifies whether the channel initiator can use only the TCP/IP stack specified in **TCPNAME**, or optionally bind to any selected TCP/IP stack defined. This parameter is only applicable in CINET multiple stack environments.

SINGLE

The channel initiator can use only the TCP/IP address space specified in **TCPNAME**.

MULTIPLE

The channel initiator can use any TCP/IP address space available to it.

Changes to this parameter take effect when the channel initiator is restarted.

This parameter is valid only on z/OS.

➤ **z/OS** **TRAXSTR**

Specifies whether the channel initiator trace starts automatically:

YES

Channel initiator trace is to start automatically.

NO

Channel initiator trace is not to start automatically.

Changes to this parameter take effect when the channel initiator is restarted. If you want to start or stop channel initiator trace without restarting the channel initiator, use the **START TRACE** or **STOP TRACE** commands after starting the channel initiator.

This parameter is valid only on z/OS.

➤ **z/OS** **TRAXTBL(integer)**

The size, in megabytes, of the trace data space of the channel initiator.

Specify a value in the range 2 through 2048.

Note:

1. Changes to this parameter take effect immediately; any existing trace table contents are lost.
2. The **CHINIT** trace is stored in a dataspace called qmidCHIN.CSQXTRDS. When you use large z/OS data spaces, ensure that sufficient auxiliary storage is available on your system to support any related z/OS paging activity. You might also need to increase the size of your SYS1.DUMP data sets.

This parameter is valid only on z/OS.

TREELIFE (integer)

The lifetime, in seconds of non-administrative topics.

Non-administrative topics are those topics created when an application publishes to, or subscribes on, a topic string that does not exist as an administrative node. When this non-administrative node no longer has any active subscriptions, this parameter determines how long the queue manager waits before removing that node. Only non-administrative topics that are in use by a durable subscription remain after the queue manager is recycled.

Specify a value in the range 0 through 604000. A value of 0 means that non-administrative topics are not removed by the queue manager.

TRIGINT(integer)

A time interval expressed in milliseconds.

The **TRIGINT** parameter is relevant only if the trigger type (**TRIGTYPE**) is set to FIRST (see [“DEFINE QLOCAL \(define a new local queue\)”](#) on page 654 for details). In this case trigger messages are normally generated only when a suitable message arrives on the queue, and the queue was previously empty. Under certain circumstances, however, an additional trigger message can be generated with

FIRST triggering even if the queue was not empty. These additional trigger messages are not generated more often than every **TRIGINT** milliseconds; see [Special case of trigger type FIRST](#).

Specify a value in the range 0 - 999,999,999.

<u>USAGE</u>	✓	✓		
<u>XMITQ</u>				✓

queue-name

Local name of the queue, except the remote queue where it is the local definition of the remote queue.

See [Rules for naming IBM MQ objects](#).

ACCTQ

Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). For the accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONN call.

QMGR

The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

ON

Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE.

► **z/OS** On z/OS systems, you must enable class 3 accounting by using the **START TRACE** command.

OFF

Accounting data collection is disabled for the queue.

BOQNAME(queue-name)

The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** attribute.

BOTHRESH(integer)

The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times to allow a message to be backed out. When the value is exceeded, the message is transferred to the queue named by the **BOQNAME** parameter.

Specify a value in the range 0 - 999,999,999.

CAEXPRY(integer)

The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

For more information on message expiry processing, and what happens if you migrate from an earlier version of the product, see [CAEXPRY: Limit message expiry time](#).

integer

The value must be in the range one through to 999 999 999.

NOLIMIT

There is no limit on the expiry time of messages put using this object. This is the default value.

If you set **CAEXPRY** to NOLIMIT, you can set the **CUSTOM** CAEXPRY attribute as well.

Note that existing messages in the queue, prior to a change in **CAEXPRY**, are not affected by the change (that is, their expiry time remains intact). Only new messages that are put into the queue after the change in **CAEXPRY** have the new expiry time.

► **z/OS** You cannot specify an integer value for the CAEXPRY attribute on a queue object with QSGDISP(SHARED|GROUP|COPY), which resides in a queue sharing group that contains queue managers running any version of IBM MQ for z/OS older than IBM MQ 9.4.0. Attempting to do so, results in messages CSQM532I and CSQM533I to identify which queue managers do not support CAEXPRY, and no modification to the object.

► **z/OS** CFSTRUCT(structure-name)

Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

For **ALTER QLOCAL**, **ALTER QMODEL**, **DEFINE QLOCAL** with **REPLACE**, and **DEFINE QMODEL** with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP**(SHARED), **CFSTRUCT** cannot change.
- If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For **DEFINE QLOCAL** with **NOREPLACE** and **DEFINE QMODEL** with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP**(SHARED) or a model queue with a **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

Note: Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

CLCHNAME(channel name)

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute **CLCHNAME** attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the **CLCHNAME** attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either **SYSTEM.CLUSTER.TRANSMIT.ChannelName** or **SYSTEM.CLUSTER.TRANSMIT.QUEUE**, depending on the value of the queue manager **DEFCLXQ** attribute.

By specifying asterisks, **"*"**, in **CLCHNAME**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **CLCHNAME** is limited to a length of 48 characters, **MQ_OBJECT_NAME_LENGTH**. A channel name is limited to 20 characters: **MQ_CHANNEL_NAME_LENGTH**. If you specify an asterisk you must also set the **SHARE** attribute so that multiple channels can concurrently access the transmission queue.

 If you specify a **"*"** in **CLCHNAME**, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks, you receive the message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. The default configuration can be modified by changing the queue manager attribute, **DEFCLXQ**. The default value of the attribute is `SCTQ`. You can change the value to `CHANNEL`. If you set the **DEFCLXQ** attribute to `CHANNEL`, each cluster-sender channel defaults to using a specific cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.ChannelName`.

► **z/OS** On z/OS, if this parameter is set, the queue:

- Must be shareable by specifying the queue attribute `SHARE`.
- Must be indexed on the correlation ID by specifying **INDXTYPE(CORRELID)**.
- Must not be a dynamic or a shared queue.

► **z/OS** ► **ALW** **CLUSNL(namelist name)**

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- `SYSTEM.CHANNEL.xx` queues
- `SYSTEM.CLUSTER.xx` queues
- `SYSTEM.COMMAND.xx` queues
- ► **z/OS** On z/OS only, `SYSTEM.QSG.xx` queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

► **z/OS** ► **ALW** **CLUSTER(cluster name)**

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- `SYSTEM.CHANNEL.xx` queues
- `SYSTEM.CLUSTER.xx` queues
- `SYSTEM.COMMAND.xx` queues
- ► **z/OS** On z/OS only, `SYSTEM.QSG.xx` queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

CLWLPRTY(*integer*)

Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see [CLWLPRTY queue attribute](#).

CLWLRANK (*integer*)

Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest. For more information about this attribute, see [CLWLRANK queue attribute](#).

CLWLUSEQ

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

QMGR

The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

ANY

The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

LOCAL

The local queue is the only target of the MQPUT operation.

 CMDSCOPE

This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

..

The command runs on the queue manager on which it was entered.

QmgrName

The command runs on the queue manager that you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

CUSTOM(*string*)

This attribute contains the values of attributes, as pairs of name and value, which are separated by at least one space.

The attribute name-value pairs have the form NAME (VALUE). Attribute names beginning **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPRT**, **SQGETTMR**, and **PAGEVAL**. As an administrator, you can set and use other names for your own purposes.

The maximum length is defined by the IBM MQ constant **MQ_CUSTOM_LENGTH** and is set to 128 on all platforms.

The **CUSTOM** value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. The property names and values are case-sensitive, and must be specified in uppercase. The values can contain spaces, parentheses, and single quotation marks (which must be escaped with another single-quote). Other characters, including nested parentheses (), can be included by enclosing them in two single quotation marks on either side. Examples of valid syntax are:

- CUSTOM('')
- CUSTOM('A(B)')
- CUSTOM('C(D) E(F)')
- CUSTOM('G(5000) H(''9.20.4.6(1415)''')')

The last syntax uses pairs of single quotation marks, not double quotation marks.

Note:  From IBM MQ 9.4.0, the **CAEXPRY** queue attribute replaces the use of the **CAEXPRY** option in the **CUSTOM** field. You cannot set the **CAEXPRY** queue attribute if the **CUSTOM** attribute has the **CAEXPRY** option defined in it already. You should alter existing queues to set the **CAEXPRY** queue attribute and unset the **CAEXPRY** option from the **CUSTOM** attribute. For example:

```
ALTER TOPIC(T1) CAEXPRY(1000) CAEXPRY('')
```

For more information about the permitted values, see [CAEXPRY](#).

DEFBIND

Specifies the binding to be used when the application specifies MQ00_BIND_AS_Q_DEF on the MQOPEN call, and the queue is a cluster queue.

OPEN

The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

NOTFIXED

The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

GROUP

Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQ00_BIND_ON_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQ00_BIND_NOT_FIXED. It can allow an application to request that a group of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid on all platforms.

DEFPRESP

Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO_RESPONSE_AS_Q_DEF.

SYNC

Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE is specified instead.

ASYN

Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_ASYNC_RESPONSE is specified instead; see [MQPMO options \(MQLONG\)](#).

DEFPRTY(integer)

The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

DEFPSIST

Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_Q_DEF option.

NO

Messages on this queue are lost across a restart of the queue manager.

YES

Messages on this queue survive a restart of the queue manager.

► **z/OS** On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFREADA

Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

NO

Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

YES

Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

DISABLED

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

DEFSOPT

The default share option for applications opening this queue for input:

EXCL

The open request is for exclusive input from the queue.

► **z/OS** On z/OS, EXCL is the default value.

SHARED

The open request is for shared input from the queue.

► **Multi** On Multiplatforms, SHARED is the default value.

DEFTYPE

Queue definition type.

This parameter is supported only on model queues.

PERMDYN

A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor (MQOD).

► **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

► **z/OS** **SHAREDYN**

This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

The dynamic queue has a disposition of SHARED.

TEMPDYN

A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

► **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

► **z/OS** Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

► **z/OS** If you specify this option, do not specify **INDXTYPE**(MSGTOKEN).

DESCR(string)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY QUEUE** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

 DISTL

Sets whether distribution lists are supported by the partner queue manager.

YES

Distribution lists are supported by the partner queue manager.

NO

Distribution lists are not supported by the partner queue manager.

Note: You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, Linux, and Windows.

FORCE

This parameter applies only to the **ALTER** command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following statements are true:

- The **TARGET** parameter specifies a queue
- An application has this alias queue open

For a local queue, if both of the following statements are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

FORCE is also needed if both of the following statements are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following statements are true:

- The **XMITQ** parameter is changed
- One or more applications has this queue open as a remote queue

FORCE is also needed if both of the following statements are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

Note: **FORCE** is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

When you use the **ALTER QLOCAL** command with the **FORCE** parameter, IBM MQ force allows the changes with open handles on the queue. However, these existing open handles become invalid for some attributes and the next operation on these open handles will return the error message:

MQRC_OBJECT_CHANGED (2041)

Any of the following operations will fail with the error MQRC 2041:

- MQPUT
- MQGET
- MQINQ
- MQSET
- MQCTL
- MQCB

You can fix the applications that receive the error MQRC_OBJECT_CHANGED by the following steps:

1. Close the handle ([MQCLOSE](#))
2. Reopen the object ([MQOPEN](#)) to select the new queue definition

GET

Specifies whether applications are to be permitted to get messages from this queue:

ENABLED

Messages can be retrieved from the queue, by suitably authorized applications.

DISABLED

Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

HARDENBO and NOHARDENBO

Specifies whether the count of the number of times that a message was backed out is hardened. When the count is hardened, the value of the **BackoutCount** field of the message descriptor is written to the log before the message is returned by an MQGET operation. Writing the value to the log ensures that the value is accurate across restarts of the queue manager.

This parameter is supported only on local and model queues.

When the backout count is hardened, the performance of MQGET operations for persistent messages on this queue is impacted.

HARDENBO

The message backout count for messages on this queue is hardened to ensure that the count is accurate.

NOHARDENBO

The message backout count for messages on this queue is not hardened and might not be accurate over queue manager restarts.

Note:  This parameter affects only z/OS. You can set this parameter on Multiplatforms but it is ineffective.

IMGRCOVQ

Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used. Possible values are:

YES

These queue objects are recoverable.

NO

The “[rcdmqimg \(record media image\)](#)” on page 160 and “[rcrmqobj \(re-create object\)](#)” on page 163 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR

If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies YES, these queue objects are recoverable.

If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies NO, the “[rcdmqimg \(record media image\)](#)” on page 160 and “[rcrmqobj \(re-create object\)](#)” on page 163

commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR is the default value.

This parameter is not valid on z/OS.

► z/OS **INDXTYPE**

The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on z/OS.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

<i>Table 170. Index type required for different retrieval selection criteria</i>		
Retrieval selection criterion	Index type required	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

NONE

No index is maintained. Use NONE when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the MQGET call.

MSGID

An index of message identifiers is maintained. Use MSGID when messages are typically retrieved using the message identifier as a selection criterion on the MQGET call with the correlation identifier set to NULL.

CORRELID

An index of correlation identifiers is maintained. Use CORRELID when messages are typically retrieved using the correlation identifier as a selection criterion on the MQGET call with the message identifier set to NULL.

GROUPID

An index of group identifiers is maintained. Use GROUPID when messages are retrieved using message grouping selection criteria.

Note:

1. You cannot set **INDXTYPE** to GROUPID if the queue is a transmission queue.
2. The queue must use a CF structure at CFLEVEL (3), to specify a shared queue with **INDXTYPE(GROUPID)**.

► z/OS **MSGTOKEN**

An index of message tokens is maintained. Use MSGTOKEN when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

Note: You cannot set **INDXTYPE** to MSGTOKEN if:

- The queue is a model queue with a definition type of SHAREDYN
- The queue is a temporary dynamic queue
- The queue is a transmission queue
- You specify **QSGDISP**(SHARED)

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Queue type		NON-SHARED			SHARED	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change INDXTYPE from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPLD	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-
MSGID	GROUPLD	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPLD	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPLD	No	No	Yes	-	-
GROUPLD	NONE	No	No	Yes	No	Yes
GROUPLD	MSGID	No	No	Yes	No	Yes
GROUPLD	CORRELID	No	No	Yes	No	Yes
GROUPLD	MSGTOKEN	No	No	Yes	-	-

On a private queue, maintaining an index when the queue contains a large number of messages can use significant 64 bit storage. See [Indexed queues](#) for more information.

INITQ(string)

The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written. See [Rules for naming IBM MQ objects](#).

This parameter is supported only on local and model queues.

LIKE(qtype-name)

The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Table 172. Queue types and their corresponding definitions	
Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE(SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

z/OS On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

z/OS ALW MAXDEPTH(integer)

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On the following platforms, specify a value in the range zero through 999999999:

- **ALW** AIX, Linux, and Windows
- **z/OS** z/OS

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

Multi MAXFSIZE

The maximum size, in megabytes, that a queue file can grow to. It is possible for a queue file to exceed this size if you have configured the value to be lower than the current queue file size.

If that happens the queue file no longer accepts new messages, but allows existing messages to be consumed. When the queue file size has dropped below the configured value, new messages can be put to the queue.

Note: This figure can differ from the value of the attribute configured on the queue, because internally the queue manager might need to use a larger block size to reach the chosen size. See [Modifying IBM MQ queue files](#) for more information on changing the size of queue files and block size and granularity.

When the granularity needs changing because this attribute has been increased, warning message AMQ7493W Granularity changed is written to the AMQERR logs. This gives you an indication that you need to plan for the queue to be emptied, in order for IBM MQ to adopt the new granularity.

Specify a value greater than or equal to 20, and less than or equal to 267,386,880.

The default value for this attribute is *DEFAULT*, which equates to a hard-coded value of 2,088,960 MB, the maximum for a queue in versions of IBM MQ prior to IBM MQ 9.1.5.

MAXMSGL(integer)

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

 **ALW** On AIX, Linux, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, [ALTER QMGR MAXMSGL](#).

 **z/OS** On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, [Advanced Message Security](#) increases the length of the message.

MONQ

Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

QMGR

Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

OFF

Online monitoring data collection is turned off for this queue.

LOW

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

MEDIUM

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

HIGH

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

There is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

MSGDLVSQ

Message delivery sequence.

This parameter is supported only on local and model queues.

PRIORITY

Messages are delivered (in response to MQGET API calls) in first-in-first-out (FIFO) order within priority.

FIFO

Messages are delivered (in response to MQGET API calls) in FIFO order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from PRIORITY to FIFO while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from FIFO to PRIORITY, the messages put on the queue while the queue was set to FIFO take the default priority.

Note:  If **INDXTYPE**(GROUPID) is specified with **MSGDLVSQ**(PRIORITY), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

NPMCLASS

The level of reliability to be assigned to non-persistent messages that are put to the queue:

NORMAL

Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

HIGH

The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

 You cannot set this parameter on z/OS.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**, or from the message to the environment on **MQGET**.  For IMS bridge queues, also controls whether the IMS bridge automatically propagates trace context from the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation.

If the queue manager is in a queue sharing group, and the queue has a **QSGDISP** of SHARED, COPY or GROUP, this value can only be set if all queue managers have been started at IBM MQ 9.4.3 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are sent to or consumed from this queue.  For IMS bridge queues, also controls whether the IMS bridge emits spans when it sends the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PROCESS(string)

The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see [Rules for naming IBM MQ objects](#).

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on the following platforms:

-  IBM i
-  AIX, Linux, and Windows
-  z/OS

If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

PROPTL

Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

Note: If your application is opening an alias queue you must set this value on both the alias and target queues.

PROPTL options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

COMPAT

Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of mcd., jms., usr., or mqext., all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

FORCE

Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the MsgHandle field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

NONE

If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

PUT

Specifies whether messages can be put on the queue.

ENABLED

Messages can be added to the queue (by suitably authorized applications).

DISABLED

Messages cannot be added to the queue.

This parameter can also be changed using the MQSET API call.

QDEPTHHI(integer)

The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.

 For more information about the effect that shared queues on z/OS have on this event; see [Shared queues and queue depth events on z/OS](#).

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

QDEPTHLO(integer)

The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.

 For more information about the effect that shared queues on z/OS have on this event; see [Shared queues and queue depth events on z/OS](#).

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

QDPHIEV

Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

ENABLED

Queue Depth High events are generated.

DISABLED

Queue Depth High events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Depth High](#).

QDPLOEV

Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

ENABLED

Queue Depth Low events are generated.

DISABLED

Queue Depth Low events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Depth Low](#).

QDPMAXEV

Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

ENABLED

Queue Full events are generated.

DISABLED

Queue Full events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Full](#).

 **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 173. Action of ALTER depending on different values of QSGDISP .	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP (COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP (QMGR), is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object), or any object defined using a command that had the parameters QSGDISP(SHARED), is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE QUEUE(QNAME) REPLACE QSGDISP(COPY)</pre> The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP (QMGR) or QSGDISP (COPY). Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP (QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.
SHARED	This value applies only to local queues. The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP (SHARED). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters QSGDISP (GROUP), is not affected by this command. If the queue is clustered, a command is generated and sent to all active queue managers in the queue sharing group to notify them of this clustered, shared queue.

QSVCI EV

Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the **QSVCI NT** parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the **QSVCI NT** parameter.

Note: The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in [Queue Service Interval High](#) and [Queue Service Interval OK](#).

HIGH

Service Interval High events are generated

OK

Service Interval OK events are generated

NONE

No service interval events are generated

QSVCIINT(integer)

The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the **QSVCIIEV** parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

RETINTVL(integer)

The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The **CRDATE** and **CRTIME** can be displayed using the **DISPLAY QUEUE** command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

Note: The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

RNAME(string)

Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.

- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see [Rules for naming IBM MQ objects](#).

RQMNAME(string)

The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see [Rules for naming IBM MQ objects](#).

ALW **SCOPE**

Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

QMGR

The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

CELL

The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

Restriction: The DCE name service is no longer supported.

This parameter is valid only on AIX, Linux, and Windows.

SHARE and NOSHARE

Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

SHARE

More than one application instance can get messages from the queue.

NOSHARE

Only a single application instance can get messages from the queue.

STATQ

Specifies whether statistics data collection is enabled:

QMGR

Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

ON

If the value of the **STATQ** parameter of the queue manager is not NONE, statistics data collection for the queue is enabled.

▶ **z/OS** On z/OS systems, you must enable class 5 statistics using the START TRACE command.

OFF

Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

▶ **z/OS** **STGCLASS(string)**

The name of the storage class.

This parameter is supported only on local and model queues.

Note: You can change this parameter only if the queue is empty and closed.

This parameter is an installation-defined name. The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

This parameter is valid only on z/OS; see [Storage classes](#).

STREAMQ

The name of a secondary queue where a copy of each message is put.

Attention: If the user setting the **STREAMQ** attribute does not have change authority on the chosen stream queue, the command fails with error message AMQ8135E, or the equivalent message CSQ9016E on z/OS.

In addition, if the stream queue does not exist, error message AMQ8135E (CSQ9016E on z/OS) is returned instead of AMQ8147E, or the equivalent message CSQM125I on z/OS.

For information on when you can set **STREAMQ**, see [Streaming queue restrictions](#).

STRMQOS

The quality of service to use when delivering messages to the streaming queue.

The value can be one of:

BESTEF

If the original message can be delivered, but the streamed message cannot, the original message is still delivered to its queue.

This is the default value.

MUSTDUP

The queue manager ensures that both the original message and the streamed message are successfully delivered to their queues.

If, for some reason, the streamed message cannot be delivered to its queue, then the original message is not delivered to its queue either. The putting application receives an error reason code and must try to put the message again.

TARGET(string)

The name of the queue or topic object being aliased; See [Rules for naming IBM MQ objects](#). The object can be a queue or a topic as defined by **TARGETTYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic. The default value for TARGET is a queue, therefore TARGET(my_queue_name) is the same as TARGQ(my_queue_name). The TARGQ attribute is retained for compatibility with your existing programs. If you specify **TARGET**, you cannot also specify **TARGQ**.

TARGETTYPE(string)

The type of object to which the alias resolves.

QUEUE (default)

The alias resolves to a queue.

TOPIC

The alias resolves to a topic.

TRIGDATA(string)

The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the MQSET API call.

TRIGDPH(integer)

The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is DEPTH. The value must be in the range 1 - 999,999,999. The default value is 1.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGGER and NOTRIGGER

Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

TRIGGER

Triggering is active, and trigger messages are written to the initiation queue.

NOTRIGGER

Triggering is not active, and trigger messages are not written to the initiation queue. This is the default value.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGMPRI(integer)

The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see [“DISPLAY QMGR \(display queue manager settings\)”](#) on page 860 for details. The default value is zero.

This parameter can also be changed using the MQSET API call.

TRIGTYPE

Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is named by the **INITQ** parameter.

This parameter is supported only on local and model queues.

FIRST

Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue. This is the default value.

EVERY

Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

DEPTH

When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPTH** parameter.

NONE

No trigger messages are written.

This parameter can also be changed using the MQSET API call.

USAGE

Queue usage.

This parameter is supported only on local and model queues.

NORMAL

The queue is not a transmission queue.

XMITQ

The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

 Additionally, on z/OS, do not specify **INDXTYPE**(MSGTOKEN) or **INDXTYPE**(GROUPID).

XMITQ(string)

The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **QMNAME** is used as the transmission queue.

It is also ignored if the definition is used as a reply-to queue alias definition.

Syntax diagram for ALTER QREMOTE

Synonym: ALT QR

ALTER QREMOTE

Common q attrs

Remote q attrs

The parameters are described in [“ALTER queues \(alter queue settings\)”](#) on page 453.

ALTER SECURITY (alter security options) on z/OS

Use the MQSC command **ALTER SECURITY** to define system-wide security options.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER SECURITY** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- “Syntax diagram for ALTER SECURITY” on page 488
- “Parameter descriptions for ALTER SECURITY” on page 488

Syntax diagram for ALTER SECURITY

Synonym: ALT SEC

Parameter descriptions for ALTER SECURITY

The parameters you specify override the current parameter values. Attributes that you do not specify are unchanged.

Note: If you do not specify any parameters, the command completes successfully, but no security options are changed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' '

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

INTERVAL(integer)

The interval between checks for user IDs and their associated resources to determine whether the **TIMEOUT** has expired. The value is in minutes, in the range zero through 10080 (one week). If **INTERVAL** is specified as zero, no user timeouts occur.

TIMEOUT(integer)

How long security information about an unused user ID and associated resources is retained by IBM MQ. The value specifies a number of minutes in the range zero through 10080 (one week). If

TIMEOUT is specified as zero, and **INTERVAL** is nonzero, all such information is discarded by the queue manager every **INTERVAL** number of minutes.

The length of time that an unused user ID and associated resources are retained by IBM MQ depends on the value of **INTERVAL**. The user ID times out at a time between **TIMEOUT** and **TIMEOUT** plus **INTERVAL**.

When the **TIMEOUT** and **INTERVAL** parameters are changed, the previous timer request is canceled and a new timer request is scheduled immediately, using the new **TIMEOUT** value. When the timer request is actioned, a new value for **INTERVAL** is set.

Related concepts

User ID timeouts

ALTER SERVICE (alter a service definition) on Multiplatforms

Use the MQSC command **ALTER SERVICE** to alter the parameters of an existing IBM MQ service definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER SERVICE** command result in the existing values for those parameters being left unchanged.

- [“ALTER SERVICE \(alter a service definition\) on Multiplatforms” on page 489](#)
- [“Parameter descriptions for ALTER SERVICE” on page 490](#)

Syntax diagram for **ALTER SERVICE**

Synonym:

ALTER SERVICE

Parameter descriptions for ALTER SERVICE

The parameter descriptions apply to the **ALTER SERVICE** and **DEFINE SERVICE** commands, with the following exceptions:

- The **LIKE** parameter applies only to the **DEFINE SERVICE** command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the **DEFINE SERVICE** command.

(service-name)

Name of the IBM MQ service definition (see [Rules for naming IBM MQ objects](#)).

The name must not be the same as any other service definition currently defined on this queue manager (unless **REPLACE** is specified).

CONTROL(string)

Specifies how the service is to be started and stopped:

MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR

The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(string)

Plain-text comment. It provides descriptive information about the service when an operator issues the **DISPLAY SERVICE** command (see [“DISPLAY SERVICE \(display service information\) on Multiplatforms”](#) on page 925).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(service-name)

The name of a service the parameters of which are used to model this definition.

This parameter applies only to the **DEFINE SERVICE** command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.SERVICE)
```

A default service is provided but it can be altered by the installation of the default values required. See [Rules for naming IBM MQ objects](#).

REPLACE and NOREPLACE

Whether the existing definition is to be replaced with this one.

This parameter applies only to the **DEFINE SERVICE** command.

REPLACE

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition should not replace any existing definition of the same name.

SERVTYPE

Specifies the mode in which the service is to run:

COMMAND

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the **DISPLAY SVSTATUS** command.

STARTARG(string)

Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD(string)

Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

STDERR(string)

Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

STDOUT(string)

Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

STOPARG(string)

Specifies the arguments to be passed to the stop program when instructed to stop the service.

STOPCMD(string)

Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the **STARTCMD**, **STARTARG**, **STOPCMD**, **STOPARG**, **STDOUT** or **STDERR** strings, for more information, see [Replaceable inserts on service definitions](#).

Use the MQSC command **STOP SERVICE** to stop a service.

ALTER SMDS (alter shared message data sets) on z/OS

Use the MQSC command **ALTER SMDS** to alter the parameters of existing IBM MQ definitions relating to one or more shared message data sets associated with a specific application structure. It is only supported when the **CFSTRUCT** definition is using the option OFFLOAD (SMDS).

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER SMDS** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER SMDS” on page 492](#)
- [“Parameter descriptions for ALTER SMDS” on page 493](#)

Syntax diagram for ALTER SMDS

Synonym:

Parameter descriptions for ALTER SMDS

SMDS(*qmgr-name*[*])

Specify the queue manager for which the shared message data set properties are to be modified, or an asterisk to modify the properties for all data sets associated with the specified **CFSTRUCT**.

CFSTRUCT(*structure-name*)

Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be modified.

DSBUFS(*number*|DEFAULT)

Specify an override value for the number of buffers to be allocated in the specified queue manager or queue managers for accessing shared message data sets for this structure, as a number in the range 1 to 9999, or specify DEFAULT to cancel a previous override and resume using the **DSBUFS** value from the **CFSTRUCT** definition. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

When this parameter is altered, any affected queue managers which are already connected to the structure dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager replaces the specified **DSBUFS** parameter with the actual new number of buffers. If the queue manager is not active, the change will come into effect when the queue manager is restarted.

DSEXPAND(YES|NO|DEFAULT)

Specify an override value to be used by the specified queue manager or queue managers to control expansion of shared message data sets for this structure.

This parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES

Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used.

NO

No automatic data set expansion is to take place.

DEFAULT

Cancels a previous override.

If you used DEFAULT to cancel a previous override it resumes using the **DSEXPAND** value from the **CFSTRUCT** definition.

If an expansion attempt fails, the **DSEXPAND** override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any affected queue managers which are already connected to the structure immediately start using the new parameter value.

“[START SMDSCONN \(restart a shared message data set connection\) on z/OS](#)” on page 1075

Use the MQSC command **START SMDSCONN** to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

“[STOP SMDSCONN \(stop shared message data sets connection\) on z/OS](#)” on page 1098

Use the MQSC command **STOP SMDSCONN** to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.

ALTER STGCLASS (alter storage class settings) on z/OS

Use the MQSC command **ALTER STGCLASS** to alter the characteristics of a storage class.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER STGCLASS** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER STGCLASS” on page 494](#)
- [“Parameter descriptions for ALTER STGCLASS” on page 495](#)

Syntax diagram for ALTER STGCLASS

Synonym: ALT STC

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for ALTER STGCLASS

(storage-class)

Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

Note: Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of ★ is the same as entering the command on every queue manager in the queue sharing group.

DESCR(description)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY STGCLASS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager

PASSTKTA(application name)

The application name that is passed to RACF when authenticating the PassTicket specified in the MQIIH header.

PSID(integer)

The page set identifier that this storage class is to be associated with.

Note: No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC_PAGESET_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See [“DEFINE PSID \(define page set and buffer pool\) on z/OS” on page 623](#).

QSGDISP

Specifies the disposition of the object in the group.

Table 174. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR) , is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE STGCLASS(storage-class) REPLACE QSGDISP(COPY)</pre> The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY) . Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR) . Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

XCFGNAME(group name)

If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

XCFMNAME(member name)

If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in **XCFGNAME**. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

ALTER SUB (alter subscription settings)

Use the MQSC command **ALTER SUB** to alter the characteristics of an existing subscription.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER SUB** command result in the existing values for those parameters being left unchanged.

 You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER SUB” on page 497](#)
- [“Usage notes for ALTER SUB” on page 498](#)
- [“Parameter descriptions for ALTER SUB” on page 499](#)

Syntax diagram for ALTER SUB

Synonym: ALT SUB

ALTER SUB

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

Usage notes for ALTER SUB

- The following forms are valid for the command:

```

ALT SUB(xyz)
ALT SUB SUBID(123)
ALT SUB(xyz) SUBID(123)

```

- Although permitted on the **DEFINE** command, you cannot alter the following fields using **ALTER SUB**:

- **TOPICOBJ**
- **TOPICSTR**
- **WSHEMA**
- **SELECTOR**

- **SUBSCOPE**
 - **DESTCLAS**
 - **SUBLEVEL**
3. At the time the **ALT SUB** command processes, no check is performed that the named **DEST** or **DESTQMGR** exists. These names are used at publishing time as the *ObjectName* and *ObjectQMgrName* for an MQOPEN call. These names are resolved according to the IBM MQ name resolution rules.
 4. Subscriptions with a **SUBTYPE** of PROXY cannot be modified. Attempts to modify a proxy subscription by using the PCF interface return MQRCCF_SUBSCRIPTION_IN_USE. MQSC reports the following message:
AMQ8469: IBM MQ subscription SYSTEM.PROXY in use.

Parameter descriptions for ALTER SUB

(string)

A mandatory parameter. Specifies the unique name for this subscription, see **SUBNAME** property.

➤ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

DEST(string)

The destination for messages published to this subscription; this parameter is the name of a queue.

DESTCRL(string)

The **CorrelId** used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' 0000000000000000000000000000000000000000000000000000000000000000 ' (48 zeros) the **CorrelId** set by the publishing application is maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

Note: You cannot set the **DESTCRL** property programmatically with JMS.

DESTQMGR(string)

The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the **XMITQ**, and a sender channel. If you do not, messages do not arrive at the destination.

EXPIRY

The time to expiry of the subscription object from the creation date and time.

(integer)

The time to expiry, in tenths of a second, from the creation date and time.

UNLIMITED

There is no expiry time. This is the default option supplied with the product.

PSPROP

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE

Do not add publish subscribe properties to the message.

COMPAT

Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP

Publish/subscribe properties are added as message properties.

RFH2

Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(string)

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the AccountingToken field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(string)

Identity data passed by the subscriber, for propagation into messages published to this subscription in the ApplIdentityData field of the MQMD.

PUBPRTY

The priority of the message sent to this subscription.

AS PUB

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

ASQDEF

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)

An integer providing an explicit priority for messages published to this subscription.

REQONLY

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO

All publications on the topic are delivered to this subscription. This is the default value.

YES

Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SUBUSER(string)

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

USERDATA(string)

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription

as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see [Retrieval of user subscription data](#).

VARUSER

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY

Any user can connect to and takeover ownership of the subscription.

FIXED

Takeover by another USERID is not permitted.

Related tasks

Use the MQSC command **DISPLAY SUB** to display the attributes associated with a subscription.

ALTER TOPIC (alter topic settings)

Use the MQSC command **ALTER TOPIC** to alter the parameters of an existing IBM MQ topic object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

Parameters not specified in the **ALTER TOPIC** command result in the existing values for those parameters being left unchanged.

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER TOPIC” on page 501](#)
- [“Usage notes for ALTER TOPIC” on page 503](#)
- [“Parameter descriptions for ALTER TOPIC” on page 503](#)

Syntax diagram for ALTER TOPIC

Synonym: ALT TOPIC

ALTER TOPIC

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ Not valid on z/OS.

Usage notes for ALTER TOPIC

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [ALTER TOPIC](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for ALTER TOPIC

(topic-name)

Name of the IBM MQ topic definition (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless REPLACE is specified).

CAEXPRY(integer)

The maximum time, expressed in tenths of a second, that a message published to a topic, which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see [CAEXPRY: Limit message expiry time](#).

integer

The value must be in the range one through to 999 999 999.

 You cannot specify an integer value for the **CAEXPRY** attribute on a queue object with QSGDISP (GROUP | COPY), which resides in a queue sharing group that contains queue managers running any version of IBM MQ for z/OS below IBM MQ for z/OS 9.4.0. Attempting to do so, results in messages CSQM532I and CSQM533I to identify which queue managers do not support **CAEXPRY**, and no modification to the object.

NOLIMIT

There is no limit on the expiry time of messages put to this topic.

ASPARENT

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

CLROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

DIRECT

When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

TOPICHOST

When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to ' ') before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this

should be considered when performing this change. See [The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager](#). If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an **MQRCCF_CLROUTE_NOT_ALTERABLE** exception.

See also [Routing for publish/subscribe clusters: Notes on behavior](#) and [Designing publish/subscribe clusters](#).

CLUSTER

The name of the cluster to which this topic belongs. Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see [Distributed publish/subscribe networks](#).

• •

If no topic object above this topic in the topic tree has set this parameter to a cluster name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

string

The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics **SYSTEM.BASE.TOPIC** and **SYSTEM.DEFAULT.TOPIC**, except in special circumstances, for example to support migration.

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to **GROUP**.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

•

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of ***** is the same as entering the command on every queue manager in the queue sharing group.

COMMINFO(comminfo-name)

The name of the communication information object associated with this topic object.

CUSTOM(string)

The **CUSTOM** attribute contains the values of attributes, as pairs of name and value, which are separated by at least one space. The attribute name-value pairs have the form **NAME (VALUE)**.

Attribute names beginning with **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPRT**, **SQGETTMR**, and **PAGEVAL**. As an administrator, you can set and use other names for your own purposes.

The maximum length is defined by the IBM MQ constant **MQ_CUSTOM_LENGTH** and is set to 128 on all platforms.

The **CUSTOM** value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. The property names and values are case-sensitive, and must be specified in uppercase. The values can contain spaces, parentheses, and single quotation marks (which must be enclosed by another single-quote). Other characters, including nested parentheses (), can be included by enclosing them in two single quotation marks on either side. Examples of valid syntax are:

- CUSTOM('')
- CUSTOM('A(B)')
- CUSTOM('C(D) E(F)')
- CUSTOM('G(5000) H(''9.20.4.6(1415)''')')

The last syntax uses pairs of single quotation marks, not double quotation marks.

Note:  From IBM MQ 9.4.0, the **CAEXPRY** queue attribute replaces the use of the **CAEXPRY** option in the **CUSTOM** field. You cannot set the **CAEXPRY** queue attribute if the **CUSTOM** attribute has the **CAEXPRY** option defined in it already. You should alter existing topics to set the **CAEXPRY** queue attribute and unset the **CAEXPRY** option from the **CUSTOM** attribute. For example:

```
ALTER TOPIC(T1) CAEXPRY(1000) CAEXPRY('')
```

For more information about the permitted values, see [CAEXPRY](#).

DEFPRTY(integer)

The default priority of messages published to the topic.

(integer)

The value must be in the range zero (the lowest priority), through to the **MAXPRTY** queue manager parameter (**MAXPRTY** is 9).

ASPARENT

The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

DEFPSIST

Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_TOPIC_DEF option.

ASPARENT

The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

NO

Messages on this queue are lost during a restart of the queue manager.

YES

Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFPRESP

Specifies the put response to be used when applications specify the MQPMO_RESPONSE_AS_DEF option.

ASPARENT

The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

SYNC

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

ASYNCR

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are always issued as if MQPMO_ASYNC_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application. However, an improvement in performance might be seen for messages put in a transaction and any non-persistent messages

DESCR(string)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY TOPIC** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DURSUB

Specifies whether applications are permitted to make durable subscriptions on this topic.

ASPARENT

Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

NO

Durable subscriptions cannot be made on this topic.

YES

Durable subscriptions can be made on this topic.

MCAST

Specifies whether multicast is allowable in the topic tree. The values are:

ASPARENT

The multicast attribute of the topic is inherited from the parent.

DISABLED

No multicast traffic is allowed at this node.

ENABLED

Multicast traffic is allowed at this node.

ONLY

Only subscriptions from a multicast capable client are allowed.

MDURMDL(string)

The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

If **MDURMDL** is blank, it operates in the same way as **ASPARENT** values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MDURMDL**.

If you use **MDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of **SYSTEM.MANAGED.DURABLE**

MNDURMDL(string)

The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

If **MNDURMDL** is blank, it operates in the same way as **ASPARENT** values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MNDURMDL**.

If you use **MNDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of **SYSTEM.MANAGED.NDURABLE**.

NPMMSGDLV

The delivery mechanism for non-persistent messages published to this topic:

ASPARENT

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL

Non-persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL

Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR

Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**.

Can be one of the following values:

ASPARENT

The default for everything other than **SYSTEM.BASE.TOPIC**, delegate to the parent topic's configuration.

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default for **SYSTEM.BASE.TOPIC**.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation. If the queue manager is in a queue sharing group, this value can only be set if all queue managers have been started at IBM MQ 9.4.5 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are published to this topic.

Can be one of the following values:

ASPARENT

The default for everything other than **SYSTEM.BASE.TOPIC**, delegate to the parent topic's configuration.

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default for **SYSTEM.BASE.TOPIC**.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PMSGDLV

The delivery mechanism for persistent messages published to this topic:

ASPARENT

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL

Persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

ALLAVAIL

Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR

Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

PROXYSUB

Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see [Subscription performance in publish/subscribe networks](#).

FIRSTUSE

For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers when a local subscription is created or a proxy subscription is received that is propagated to further directly connected queue managers in a hierarchy.

FORCE

A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

Note: The proxy subscription is sent when this value is set on **DEFINE** or **ALTER**. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

PUB

Controls whether messages can be published to this topic.

ASPARENT

Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED

Messages can be published to the topic (by suitably authorized applications).

DISABLED

Messages cannot be published to the topic.

See also [Special handling for the **PUB** parameter](#).

PUBSCOPE

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a publication-by-publication basis, using MQPMO_SCOPE_QMGR on the Put Message options.

ASPARENT

Whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

QMGR

Publications for this topic are not propagated to connected queue managers.

ALL

Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 175. Behavior for each of the QSGDISP values	
QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY) . Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR) , is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to attempt to refresh local copies on page set zero: DEFINE TOPIC(name) REPLACE QSGDISP(COPY) The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY) . Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR) . Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

SUB

Controls whether applications are to be permitted to subscribe to this topic.

ASPARENT

Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED

Subscriptions can be made to the topic (by suitably authorized applications).

DISABLED

Applications cannot subscribe to the topic.

SUBSCOPE

Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO_SCOPE_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**. Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO_SCOPE_QMGR** subscription option when creating a subscription.

ASPARENT

Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

QMGR

Only publications that are published on this queue manager reach the subscriber.

ALL

A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

TOPICSTR(*string*)

The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

TYPE (topic-type)

If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms  except z/OS.

LOCAL

A local topic object.

USEDLQ

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

ASPARENT

Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree.

NO

Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The **MQPUT** of an application to a topic fails in accordance with the settings of **NPMGDLV** and **PMSGDLV**.

YES

When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

WILDCARD

The behavior of wildcard subscriptions with respect to this topic.

PASSTHRU

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

BLOCK

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the WILDCARD attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

ALTER TRACE (alter trace event settings) on z/OS

Use the MQSC command **ALTER TRACE** to change the trace events being traced for a particular active queue manager trace. **ALTER TRACE** stops the specified trace, and restarts it with the altered parameters.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Parameters not specified in the **ALTER TRACE** command result in the existing values for those parameters being left unchanged.

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ALTER TRACE” on page 511](#)
- [“Usage notes” on page 512](#)
- [“Parameter descriptions for ALTER TRACE” on page 512](#)
- [“Trace parameters” on page 513](#)

Syntax diagram for ALTER TRACE

Synonym: ALT TRACE

```

▶ ALTER TRACE — ( — GLOBAL — ) — TNO — ( — integer — ) →
                  |      |
                  |      |
                STAT    ACCTG

```

Diagram illustrating the grammar rules for CLASS and COMMENT:

- CLASS** is defined as `( * )`. The loop contains:
 - `integer`
 - `integer:integer`
- COMMENT** is defined as `( string )`.

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

Channel initiator traces cannot be altered.

Specify one of the following trace types:

Service data from the entire queue manager (the synonym is **G**)

Statistical data (the synonym is **S**)

Accounting data (the synonym is **A**)

TNO(*integer*)

The number of the trace to be altered (1 through 32). You can specify only one trace number.

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set **CSQINP1**.

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

Trace parameters**CLASS(*integer*)**

The new trace class. See [“START TRACE \(start trace\) on z/OS” on page 1076](#) for a list of allowed classes. A range of classes can be specified as *m:n* (for example, CLASS(01:03)).

For **GLOBAL** and **CHINIT** traces, CLASS(*) activates all classes.

For **ACCTG** and **STAT** traces, CLASS(*) activates classes 1 to 3. Channel initiator statistics and channel accounting data are not started with CLASS(*), and must be started with CLASS(4).

COMMENT(*string*)

A comment that is reproduced in the trace output record (except in the resident trace tables).

string is any character string. If it includes blanks, commas, or special characters, it must be enclosed between single quotation marks (').

IFCID(*ifcid*)

Reserved for IBM Service.

Use the MQSC command **START TRACE** to start traces.

[“STOP TRACE \(stop trace\) on z/OS” on page 1099](#)

Use the MQSC command **STOP TRACE** to stop tracing.

ARCHIVE LOG (back up the active log) on z/OS

Use the MQSC command **ARCHIVE LOG** as part of your backup procedure. It takes a copy of the current active log (or both logs if you are using dual logging).

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for ARCHIVE LOG” on page 513](#)
- [“Usage notes for ARCHIVE LOG” on page 514](#)
- [“Parameter descriptions for ARCHIVE LOG” on page 514](#)

Syntax diagram for ARCHIVE LOG

Synonym: ARC LOG

➡➡ ARCHIVE LOG ➡➡

CANCEL OFFLOAD

Cancels any offloading currently in progress and restarts the offload process. The process starts with the oldest active log data set and proceeds through all the active data sets that need offloading.

Use this command only if the offload task does not appear to be working, or if you want to restart a previous offload attempt that failed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

MODE (QUIESCE)

Stops any new update activity on the queue manager, and brings all existing users to a point of consistency after a commit. When this state is reached, or the number of active users is zero, the current active log is archived.

The time that the queue manager waits to reach such a state is limited to the value specified by **QUIESCE** in the CSQ6ARVP system parameter macro. The value of **QUIESCE** can be overridden by the **TIME** parameter of this command. If activity has not quiesced in that time, the command fails; no offload is done, and logging continues with the current active log data set.

TIME (nnn)

Overrides the quiesce time period specified by the **QUIESCE** value of the CSQ6ARVP system parameter macro.

nnn is the time, in seconds, in the range 001 through 999.

To specify the **TIME** parameter, you must also specify **MODE (QUIESCE)**.

If you specify the **TIME** parameter, you must specify an appropriate value for the quiesce period. If you make the period too short or too long, one of the following problems might occur:

- The quiesce might not be complete.
- IBM MQ lock contention might develop.
- A timeout might interrupt the quiesce.

WAIT

Specifies whether IBM MQ is to wait until the quiesce process has finished before returning to the issuer of the **ARCHIVE LOG** command.

To specify the **WAIT** parameter, you must also specify **MODE (QUIESCE)**.

NO

Specifies that control is returned to the issuer when the quiesce process starts. (The synonym is N.) This makes the quiesce process asynchronous to the issuer; you can issue further MQSC commands when the **ARCHIVE LOG** command returns control to you. This is the default.

YES

Specifies that control is returned to the issuer when the quiesce process finishes. (The synonym is Y.) This makes the quiesce process synchronous to the issuer; further MQSC commands are not processed until the **ARCHIVE LOG** command finishes.

Related tasks

[Archiving logs with the ARCHIVE LOG command](#)

BACKUP CFSTRUCT (back up a CF application structure) on z/OS

Use the MQSC command **BACKUP CFSTRUCT** to initiate a CF application structure backup.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for BACKUP CFSTRUCT” on page 516](#)
- [“Usage notes for BACKUP CFSTRUCT” on page 516](#)
- [“Keyword and parameter descriptions for BACKUP CFSTRUCT” on page 516](#)

Syntax diagram for BACKUP CFSTRUCT

Synonym: None

Usage notes for BACKUP CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.
2. Only persistent shared queue messages are backed up. Non-persistent messages are not backed up and cannot be recovered
3. You can concurrently run separate backups for different application structures on different queue managers within the queue sharing group. You can also concurrently run separate backups for different application structures on the same queue manager.
4. This command fails if the specified CF structure is defined with either a CFLEVEL less than 3, or with RECOVER set to NO.
5. The command fails if a specified application structure is currently in the process of being backed up by another queue manager within the queue sharing group.

Keyword and parameter descriptions for BACKUP CFSTRUCT

structure-name

The name of the coupling facility (CF) application structure to be backed up. An asterisk (*) on its own specifies all recoverable CF structures. A trailing asterisk (*) matches all recoverable structure names with the specified stem followed by zero or more characters. The value (CSQ*) matches all recoverable CF structures with the specified stem (CSQ) followed by zero or more characters.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and the command server is enabled.

EXCLINT(integer)

Specifies a value that defines a number of seconds that are used as an exclusion time. The backup excludes backing-up activity during this exclusion time. The exclusion time starts immediately before the back up starts. For example, if EXCLINT(30) is specified, the backup does not include the last 30 seconds of activity for this application structure before back up started.

The value must be in the range 30 through 600. The default value is 30.

Related reference

[“ALTER CFSTRUCT \(alter CF application structure\) on z/OS” on page 334](#)

On z/OS, use the MQSC command **ALTER CFSTRUCT** to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.

[“DEFINE CFSTRUCT \(define coupling facility application structure\) on z/OS” on page 537](#)

Use the MQSC command **DEFINE CFSTRUCT** to define queue manager CF level capability, message offload environment, and backup and recovery parameters for a coupling facility application structure.

[“DELETE CFSTRUCT \(delete CF application structure\) on z/OS” on page 693](#)

Use the MQSC command **DELETE CFSTRUCT** to delete a CF application structure definition.

[“DISPLAY CFSTRUCT \(display CF application structure settings\) on z/OS” on page 747](#)

Use the MQSC command **DISPLAY CFSTRUCT** to display the attributes of one or more CF application structures. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.

[“DISPLAY CFSTATUS \(display CF application structure status\) on z/OS” on page 739](#)

Use the MQSC command **DISPLAY CFSTATUS** to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

[“RECOVER CFSTRUCT \(recover CF application structure\) on z/OS” on page 992](#)

Use the MQSC command **RECOVER CFSTRUCT** to initiate recovery of CF application structures and associated shared message data sets. This command is valid only when the queue manager is a member of a queue sharing group.

[“RESET CFSTRUCT \(reset a CF application structure\) on z/OS” on page 1006](#)

Use the MQSC command **RESET CFSTRUCT** to modify the status of a specific application structure.

CLEAR QLOCAL (clear messages from local queue)

Use the MQSC command **CLEAR QLOCAL** to clear the messages from a local queue.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for CLEAR QLOCAL” on page 518](#)
- [“Parameter descriptions for CLEAR QLOCAL” on page 518](#)

Syntax diagram for CLEAR QLOCAL

Synonym: CLEAR QL

Parameter descriptions for CLEAR QLOCAL

You must specify which local queue you want to clear.

The command fails if any one of the following occurs. The queue:

- Has uncommitted messages that have been put on the queue under syncpoint.
- Is currently open by an application (with any open options).
- Is currently open by a channel.

For performance reasons, receiver channels cache opened queue handles for queues to which they deliver messages on behalf of remote queue managers. If a channel has cached a handle to this queue, it cannot be cleared.

To resolve this, stop the channel. Alternatively, empty the queue by getting all the messages from it, instead of using the CLEAR QLOCAL command.

If an application has this queue open, or has a queue open that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

(*q-name*)

The name of the local queue to be cleared. The name must be defined to the local queue manager.

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to SHARED.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

QSGDISP

Specifies whether the queue definition is shared. This parameter applies to z/OS only.

PRIVATE

Clear only the private queue named *q-name*. The queue is private if it was defined using a command that had the parameters QSGDISP (COPY) or QSGDISP (QMGR). This is the default value.

SHARED

Clear only the shared queue named *q-name*. The queue is shared if it was defined using a command that had the parameters QSGDISP (SHARED).

Related tasks

[Clearing a local queue](#)

Use the MQSC **ALTER** command to alter the parameters of a queue. A queue might be a local queue (**ALTER QLOCAL**), alias queue (**ALTER QALIAS**), model queue (**ALTER QMODEL**), a remote queue, a queue manager alias, or a reply-to queue alias (**ALTER QREMOTE**).

[“DEFINE queues” on page 625](#)

Use the MQSC **DEFINE** command to define a local, model, or remote queue, or a queue alias, reply-to queue alias, or a queue manager alias.

[“DISPLAY QSTATUS \(display queue status\)” on page 890](#)

Use the MQSC command **DISPLAY QSTATUS** to display the status of one or more queues.

[“DISPLAY QUEUE \(display queue attributes\)” on page 903](#)

Use the MQSC command **DISPLAY QUEUE** to display the attributes of one or more queues of any type.

CLEAR TOPICSTR (clear topic string)

Use the MQSC command **CLEAR TOPICSTR** to clear the retained message which is stored for the specified topic string.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for CLEAR TOPICSTR” on page 519](#)
- [Usage notes for CLEAR TOPICSTR](#)
- [Parameter descriptions for CLEAR TOPICSTR](#)

Syntax diagram for CLEAR TOPICSTR

Synonym: None.

CLEAR TOPICSTR

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.

Usage notes for CLEAR TOPICSTR

1. If the topic string specified has no retained message the command will complete successfully. You can find out whether a topic string has a retained message by using the DISPLAY TPSTATUS command. The RETAINED field shows whether there is a retained message.
2. The topic-string input parameter on this command must match the topic you want to act on. You are advised to keep the character strings in your topic strings as characters that can be used from location issuing the command. If you issue commands using MQSC, you will have fewer characters available to you than if you are using an application submitting PCF messages, such as the IBM MQ Explorer.
3. You might need to use CLEAR TOPICSTR to remove a retained publication from a publish/subscribe cluster. For example:
 - If you accidentally configure a retained publication, and then need to remove it from all cluster queue managers, you issue this command on all members of the cluster.
 - In a direct routed publish/subscribe cluster, if you move a publishing application to a new queue manager and the previous queue manager holds no subscriptions for the affected topic string, you need to ensure that the previous queue manager does not resend the old retained publication to other members of the cluster. To do this, wait until the application has published on the new queue manager, then issue this command on the previous queue manager to remove the retained publication held there.

See also [Design considerations for retained publications in publish/subscribe clusters](#)

Parameter descriptions for CLEAR TOPICSTR

You must specify the topic string from which you want to remove the retained publication.

(*topic-string*)

The topic string to be cleared. This string can represent several topics to be cleared by using wildcards as shown in the following table:

Table 176. Special characters for use in topic strings	
Special Character	Behavior
#	Wildcard, multiple topic level
+	Wildcard, single topic level

Note: the '+' and '#' are not treated as wildcards if they are mixed in with other characters (including themselves) within a topic level. In the following string, the '#' and '+' characters are treated as ordinary characters.

```
level0/level1/#+/level3/level#
```

To illustrate the effect of wildcards, the following example is used.

Clearing the following topic:

```
/a/b/#/z
```

clears the following topics:

```
/a/b/z  
/a/b/c/z  
/a/b/c/y/z
```

CLRTYPE

This is a mandatory parameter.

The value must be:

RETAINED

Remove the retained publication from the specified topic string.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the name of the local queue manager, if the shared queue object definition has its queue sharing group disposition attribute **QSGDISP** set to SHARED.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

SCOPE

The scope of the deletion of retained messages.

The value can be:

LOCAL

The retained message is removed from the specified topic string at the local queue manager only. This is the default value.

DEFINE AUTHINFO (define an authentication information object)

Use the MQSC command **DEFINE AUTHINFO** to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or

Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [Syntax diagram for TYPE\(CRLLDAP\)](#)
- [Syntax diagram for TYPE\(OCSP\)](#)
- [Syntax diagram for TYPE\(IDPWOS\)](#)
- [Syntax diagram for TYPE\(IDPWLDAP\)](#)
- [“Usage notes for DEFINE AUTHINFO” on page 526](#)
- [“Parameter descriptions for DEFINE AUTHINFO” on page 526](#)

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Syntax diagram for TYPE(CRLLDAP)

Synonym: DEF AUTHINFO

DEFINE AUTHINFO

➤ DEFINE AUTHINFO — (— *name* —) — AUTHTYPE(CRLLDAP) ➤

Notes:

¹ Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

² Valid only on z/OS.

Syntax diagram for TYPE(OCSP)

Synonym: DEF AUTHINFO

DEFINE AUTHINFO

➤ DEFINE AUTHINFO — (— *name* —) — AUTHTYPE(OCSP) ➔

Notes:

¹ Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.

² Valid only on z/OS.

Syntax diagram for TYPE(IDPWOS)

Synonym: DEF AUTHINFO

DEFINE AUTHINFO

➤ DEFINE AUTHINFO — (— *name* —) — AUTHTYPE(IDPWOS) ➤

Notes:

- ¹ Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
- ² Valid only on z/OS.
- ³ Not valid on z/OS and PAM value can be set only on AIX and Linux.
- ⁴ Not valid on IBM MQ for z/OS.
- ⁵ Default for platforms other than z/OS.
- ⁶ Default for z/OS.

Syntax diagram for TYPE(IDPWLDAP)

Synonym: DEF AUTHINFO

DEFINE AUTHINFO

► DEFINE AUTHINFO — (— *name* —) — AUTHTYPE(IDPWLDAP) — ¹ —►

Notes:

¹ Not valid on IBM MQ for z/OS.

Usage notes for DEFINE AUTHINFO

 On IBM i, authentication information objects of **AUTHTYPE(CRLLDAP)** and **AUTHTYPE(OCSP)** are only used for channels of type CLNTCONN through use of the **AMQCLCHL.TAB**. Certificates are defined by Digital Certificate Manager for each certificate authority, and are verified against the LDAP servers.

Attention: After running the **DEFINE AUTHINFO** command, you must restart the queue manager. If you do not restart the queue manager, the [setmqaut](#) command does not return the correct result.

Parameter descriptions for DEFINE AUTHINFO

name

Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless **REPLACE** or **ALTER** is specified). See [Rules for naming IBM MQ objects](#).

ADOPTCTX

Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

YES

The user ID in the authentication credentials presented in the MQCSP structure, which have been successfully validated, is adopted as the context to use for this application. Therefore, this user ID has the credentials checked for authorization to use IBM MQ resources.

If the application presents a user ID and password, the user ID in the MQCSP structure is adopted if the password is successfully validated.

  If the application presents an authentication token, and the token is successfully validated, the user ID in the token user claim is adopted as the context for the application. The name of the token user claim is specified by the **UserClaim** attribute in the **AuthToken** stanza of the `qm.ini` file. For more information about the **UserClaim** attribute, see [UserClaim](#).

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the [SHORTUSR](#) associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

ADOPTCTX(YES) has an effect only if **CHCKCLNT** or **CHCKLOCL** is set to a value that causes the credentials to be validated.

NO

Authentication is performed on the credentials presented in the MQCSP structure, but then the credentials are not adopted for further use. Authorization is performed using the user ID that the application is running under.

The **ADOPTCTX** attribute is only valid for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

AUTHENMD

Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

  **OS**

Use the traditional UNIX password verification method.

Use the PAM to authenticate the user password.

You can set the PAM value only on AIX and Linux.

Changes to this attribute are effective only after you run the [REFRESH SECURITY TYPE\(CONNAUTH\)](#) command.

This attribute is valid only for an **AUTHTYPE** of IDPWOS.

AUTHORMD

Authorization Method.

OS

Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

SEARCHGRP

A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all the users belonging to that group. Membership is indicated by the attribute defined in [FINDGRP](#). This value is typically *member* or *uniqueMember*.

SEARCHUSR

A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs. The attribute to query is defined by the [FINDGRP](#) value, typically *memberOf*.

SRCHGRPSN

A group entry in the LDAP repository contains an attribute listing the short user name of all the users belonging to that group. The attribute in the user record that contains the short user name is specified by [SHORTUSR](#).

Membership is indicated by the attribute defined in [FINDGRP](#). This value is typically *memberUid*.

Note: This authorization method should only be used if all user short names are distinct.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to SEARCHGRP.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

AUTHTYPE

The type of authentication information.

CRLLDAP

Certificate Revocation List checking is done using LDAP servers.

IDPWLDAP

Connection authentication user ID and password checking is done using an LDAP server.

Attention:  This option is not available on IBM MQ for z/OS

IDPWOS

Connection authentication user ID and password checking is done using the operating system.

Authentication tokens supplied by IBM MQ MQI clients are validated if the queue manager is configured to accept authentication tokens using the AuthToken stanza of the `qm.ini` file. For more information about the AuthToken stanza, see [AuthToken stanza of the qm.ini file](#).

OCSP

Certificate revocation checking is done using OCSP.

An authentication information object with **AUTHTYPE (OCSP)** does not apply for use on queue managers on the following platforms:

-  IBM i
-  z/OS

However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

This parameter is required.

You cannot define an authentication information object as LIKE one with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

BASEDNG

Base DN for groups.

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

BASEDNU(base DN)

In order to be able to find the short user name attribute (see [SHORTUSR](#)) this parameter must be set with the base DN to search for users within the LDAP server.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

CHKCLNT

This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP. The possible values are:

NONE

Authentication credentials supplied by client applications are not checked. If a user ID and password, or an authentication token, is supplied by a client application, the credentials are ignored. **ADOPTCTX** will have no effect and any user IDs contained within the MQCSP will not be used for authorization checks later.

OPTIONAL

Client applications are not required to provide authentication credentials.

Any applications that do provide a user ID and password in the [MQCSP](#) structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

  If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

This option might be useful during migration, for example.

REQUIRED

All client applications must provide authentication credentials in the [MQCSP](#) structure.

If an application provides a user ID and password, these credentials are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

  If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

If an application does not provide any authentication credentials, the connection is rejected.

REQDADM

All client applications using a privileged user ID must provide authentication credentials in the [MQCSP](#) structure. Any client applications using a non-privileged user ID are not required to provide authentication credentials and are treated as with the **OPTIONAL** setting.

A privileged user is one that has full administrative authorities for IBM MQ. See [Privileged users](#) for more information.

Any provided user ID and password are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** If an application provides an authentication token, and the queue manager is configured to accept authentication tokens, the token is validated. The connection is only allowed to continue if the token is issued by a trusted issuer.

Note: The REQDADM value for the **CHCKCLNT** attribute is irrelevant if the authentication type is LDAP. This is because there is no concept of privileged user ID when using LDAP user accounts. LDAP user accounts and groups must be assigned permission explicitly.

► **z/OS** This setting is not allowed on z/OS systems.

Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the CHLAUTH rule that matches the client connection. The CONNAUTH *AUTHINFO* **CHCKCLNT** attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a CHLAUTH rule, or where the CHLAUTH rule matched has **CHCKCLNT** ASQMGR.
2. ► **Multi** On Multiplatforms, if you select NONE and the client connection matches a CHLAUTH record with **CHCKCLNT** REQDADM, the connection fails. You receive message AMQ9793.
3. ► **z/OS** On z/OS, if you select NONE and the client connection matches a CHLAUTH record with **CHCKCLNT** REQUIRED, the connection fails. You receive message CSQX793E.
4. This parameter is valid only with **TYPE (USERMAP)**, **TYPE (ADDRESSMAP)** and **TYPE (SSLPEERMAP)**, and only when **USERSRC** is not set to NOACCESS.
5. This parameter applies only to inbound connections that are server-connection channels.

CHCKLOCL

This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP.

► **MQ Appliance** For information about use of this attribute on IBM MQ Appliance, see [Control commands on the IBM MQ Appliance](#) in the IBM MQ Appliance documentation.

The possible values are:

NONE

Authentication credentials supplied by client applications are not checked. If a user ID and password is supplied by a locally bound application, the credentials are ignored.

OPTIONAL

Locally bound applications are not required to provide authentication credentials.

Any applications that do provide a user ID and password in the **MQCSP** structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection is only allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** Authentication tokens cannot be supplied by locally bound applications.

This option might be useful during migration, for example.

REQUIRED

All locally bound applications must provide authentication credentials in the **MQCSP** structure.

If an application provides a user ID and password, these credentials are authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** Authentication tokens cannot be supplied by locally bound applications.

If an application does not provide any authentication credentials, the connection is rejected.

► **z/OS** If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHCKLOCL (REQUIRED)** as if it is **CHCKLOCL (OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one.

See [Using CHCKLOCL on locally bound applications](#).

REQDADM

All locally bound applications using a privileged user ID must provide authentication credentials in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide authentication credentials and are treated as with the OPTIONAL setting.

A privileged user is one that has full administrative authorities for IBM MQ. See [Privileged users](#) for more information.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

► **Linux** ► **AIX** Authentication tokens cannot be supplied by locally bound applications.

► **z/OS** (This setting is not allowed on z/OS systems.)

CLASSGRP

The LDAP object class used for group records in the LDAP repository.

If the value is blank, `groupOfNames` is used.

Other commonly used values include `groupOfUniqueNames` or `group`.

CLASSUSR(LDAP class name)

The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to `inetOrgPerson`, which is generally the value needed.

For Microsoft Active Directory, the value you require is often `user`.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

► **z/OS** CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of ★ is the same as entering the command on every queue manager in the queue sharing group.

CONNAME(connection name)

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the **AUTHINFO** object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

▶ **z/OS** On z/OS, if a **CONNAME** is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for **CONNAME** is the same as for channels. For example,

```
conname(' hostname (nnn)')
```

where *nnn* is the port number.

The maximum length for the field depends on your platform:

- ▶ **ALW** On AIX, Linux, and Windows, the maximum length is 264 characters.
- ▶ **IBM i** On IBM i, the maximum length is 264 characters.
- ▶ **z/OS** On z/OS, the maximum length is 48 characters.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP, when the attribute is mandatory.

When used with an **AUTHTYPE** of IDPWLDAP, this can be a comma separated list of connection names.

DESCR(string)

Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the **DISPLAY AUTHINFO** command (see [“DISPLAY AUTHINFO \(display authentication information\)”](#) on page 728).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

FAILDLAY(delay time)

When authentication credentials are provided for connection authentication, and the authentication fails due to the credentials being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

This attribute is only valid for an **AUTHTYPE** of IDPWOS and IDPWLDAP.

FINDGRP

Name of the attribute used within an LDAP entry to determine group membership.

When **AUTHORMD** = SEARCHGRP, the **FINDGRP** attribute is typically set to member or uniqueMember.

When **AUTHORMD** = SEARCHUSR, the **FINDGRP** attribute is typically set to memberOf.

When **AUTHORMD** = SRCHGRPSN, the **FINDGRP** attribute is typically set to memberUid.

When the **FINDGRP** attribute is left blank:

- If **AUTHORMD** = SEARCHGRP, the **FINDGRP** attribute defaults to memberOf.
- If **AUTHORMD** = SEARCHUSR, the **FINDGRP** attribute defaults to member.
- If **AUTHORMD** = SRCHGRPSN, the **FINDGRP** attribute defaults to memberUid.

GRPFIELD

LDAP attribute that represents a simple name for the group.

If the value is blank, commands like **setmqaut** must use a qualified name for the group. The value can either be a full DN, or a single attribute.

LDAPPWD(LDAP password)

The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

z/OS On z/OS, the **LDAPPWD** used for accessing the LDAP server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPPWD** in the first **AUTHINFO** object is used for accessing all LDAP servers.

LDAPUSER(LDAP user)

The Distinguished Name of the user who is accessing the LDAP server. (See the [SSLPEER](#) parameter for more information about distinguished names.)

This attribute is valid only for an **AUTHTYPE** of CRLLDAP and IDPWLDAP.

The maximum size for the user name is as follows:

- **Multi** 1024 characters on [Multiplatforms](#)
- **z/OS** 256 characters on z/OS

z/OS On z/OS, the **LDAPUSER** used for accessing the LDAP Server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the QMGR parameter **SSLCRLNL**, the **LDAPUSER** in the first **AUTHINFO** object is used for accessing all LDAP servers.

Multi On [Multiplatforms](#), the maximum accepted line length is defined to be BUFSIZ, which can be found in `stdio.h`.

LIKE(authinfo-name)

The name of an authentication information object, with parameters that are used to model this definition.

z/OS On z/OS, the queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

Note:

1. **QSGDISP (GROUP)** objects are not searched.
2. LIKE is ignored if **QSGDISP (COPY)** is specified. However, the group object defined is used as a LIKE object.

NESTGRP

Group nesting.

NO

Only the initially discovered groups are considered for authorization.

YES

The group list is searched recursively to enumerate all the groups to which a user belongs.

The group's Distinguished Name is used when searching the group list recursively, regardless of the authorization method selected in [AUTHORMD](#).

OCSPURL(Responder URL)

The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OSCP server implementation. To preserve case, use single quotation marks to specify the **OCSPURL** parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for **AUTHTYPE(OCSP)**, when it is mandatory.

➤ **z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 177. Behavior for each of the QSGDISP values	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE AUTHINFO(auth_name) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for an AUTHINFO definition called <i>auth_name</i>. If a matching AUTHINFO definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE AUTHINFO(auth_name) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. This parameter is optional. Any object with a different disposition is not changed.

REPLACE

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition must not replace any existing definition of the same name.

SECCOMM

Whether connectivity to the LDAP server should be done securely using TLS

YES

Connectivity to the LDAP server is made securely using TLS.

The certificate used is the default certificate for the queue manager, named in **CERTLABL** on the queue manager object, or if that is blank, the one described in [Digital certificate labels, understanding the requirements](#).

The certificate is located in the key repository specified in **SSLKEYR** on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use **SSLFIPS (YES)** or **SUITEB** cipher specs, then this is taken account of in the connection to the LDAP server as well.

ANON

Connectivity to the LDAP server is made securely using TLS just as for **SECCOMM (YES)** with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in **SSLKEYR**, on the queue manager object, does not contain a certificate marked as the default.

NO

Connectivity to the LDAP server does not use TLS.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

SHORTUSR(*user name*)

A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.
- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

The **SHORTUSR** attribute is valid only for an **AUTHTYPE** of IDPWLDAP and is mandatory.

USRFIELD(*LDAP field name*)

If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an equals (=) sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the **SHORTUSR** parameter to interpret the provided user ID.

The contents of this field will be concatenated with an '=' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application provides a user of fred and this field has the value cn, then the LDAP repository will be searched for cn=fred.

This attribute is valid only for an **AUTHTYPE** of IDPWLDAP.

Use the MQSC command **DISPLAY AUTHINFO** to display the attributes of an authentication information object.

➤ **z/OS** **DEFINE BUFFPOOL (define a buffer pool) on z/OS**

Use the MQSC command **DEFINE BUFFPOOL** to define a buffer pool that is used for holding messages in main storage.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 1. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE BUFFPOOL” on page 535](#)
- [“Usage notes” on page 535](#)
- [“Parameter descriptions for DEFINE BUFFPOOL” on page 535](#)

Syntax diagram for **DEFINE BUFFPOOL**

Synonym: DEF BP

Usage notes

1. Specify **DEFINE BUFFPOOL** commands in a data set identified by the CSQINP1 DD concatenation in the queue manager started task procedure.
2. Use the **DISPLAY USAGE TYPE(PAGESET)** command to display buffer pool information (see [“DISPLAY USAGE \(display usage information\) on z/OS” on page 981](#)).
3. Use the **ALTER BUFFPOOL** command to dynamically change the settings of a predefined buffer pool (see [“ALTER BUFFPOOL \(alter buffer pool settings\) on z/OS” on page 332](#)).

Parameter descriptions for **DEFINE BUFFPOOL**

If more than one **DEFINE BUFFPOOL** command is issued for the same buffer pool, only the last one is processed.

(buf-pool-id)

Buffer pool identifier.

This parameter is an integer in the range zero through 99.

BUFFERS(*integer*)

This parameter is required and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the **LOCATION** parameter is **BELOW**, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the **LOCATION** parameter is **ABOVE**, then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool with **LOCATION ABOVE** is obtained in multiples of 4MB. Therefore specifying a **BUFFERS** value which is a multiple of 1024 will make the most efficient use of storage.

When defining a buffer pool care should be taken to ensure that there is sufficient storage available for it either above or below the bar. For more information, see [Address space storage](#).

LOCATION(LOC)(*BELOW or ABOVE*)

LOCATION and **LOC** are synonyms and either, but not both, can be used.

The **LOCATION** or **LOC** parameter specifies where the memory used by the specified buffer pool is located.

Attention:  From IBM MQ 9.1, **LOCATION**(**BELOW**) is deprecated and you should use **LOCATION**(**ABOVE**) only.

This memory location can be either **ABOVE** (64 bit) or **BELOW** (31 bit) the bar. Valid values for this parameter are **BELOW** or **ABOVE**, with **BELOW** being the default.

For more information, see [Address space storage](#).

PAGECLAS(*4KB or FIXED4KB*)

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the **ALTER BUFFPOOL** command. The default value is **4KB**, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its **LOCATION** attribute set to **BELOW**. If the buffer pool has its **LOCATION** attribute set to **ABOVE**, it is also possible to specify **FIXED4KB**. This means that fixed 4KB pages, which are permanently in real storage and are never paged out to auxiliary storage, are used to back the buffers in the buffer pool.

The **PAGECLAS** attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar, to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

When you specify **PAGECLAS**(**FIXED4KB**) the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start, or other address spaces might be impacted. For more information, see [Address space storage](#).

See IBM MQ Support Pac MP16: [IBM MQ for z/OS - Capacity planning & tuning](#) for advice on when to use the **FIXED4KB** value of the **PAGECLAS** attribute.

REPLACE/NOREPLACE

Optional attribute describing whether this definition of a buffer pool overrides any definition that might already be contained in the log of the queue manager.

The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set.

Therefore, if you have used **ALTER BUFFPOOL** since the buffer pool was last defined, any **DEFINE BUFFPOOL** command in CSQINP1 is ignored at restart, unless the **REPLACE** attribute is specified.

Attention: If you specify the **REPLACE** attribute on the **DEFINE BUFFPOOL** command in CSQINP1, then some time later you specify the **ALTER BUFFPOOL** command to increase the buffer pool size (for example because of an increase in workload, and therefore an increase in demand on buffer pool usage) this could lead to an issue when the queue manager is next restarted.

Following restart, your buffer pools would revert to the original size defined in CSQINP1 and hence not be able to handle the increased workload. Therefore, you should consider removing the **REPLACE** attribute from the **DEFINE BUFFPOOL** commands in CSQINP1 as soon as the buffer pools are successfully defined.

This will ensure that any changes made to the buffer pools, as a result of specifying **ALTER BUFFPOOL** commands, are preserved across restarts of the queue manager.

REPLACE

This definition of the buffer pool overrides the definition stored in the log of the queue manager, if there is one. If the definition in the log of the queue manager is different from this definition, the differences are discarded and message [CSQP064I](#) is issued.

NOREPLACE

This is the default value, and provides the same behavior as with previous releases of IBM MQ. If there is a definition of the buffer pool in the log of the queue manager, that definition is used and this definition is ignored.

Attention: The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set. Therefore, if you have used **ALTER BUFFPOOL** since the buffer pool was last defined, any **DEFINE BUFFPOOL** command in CSQINP1 has been ignored at restart, unless the **REPLACE** attribute has been specified.

Syntax diagram for DEFINE CFSTRUCT

Synonym: DEF CFSTRUCT

DEFINE CFSTRUCT

Offload attributes

Usage notes for DEFINE CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.
2. This command cannot specify the CF administration structure (CSQ_ADMIN).
3. Before any newly defined CF structure can be used by any queues, the structure must be defined in the Coupling Facility Resource Management (CFRM) policy data set.
4. Only CF structures with RECOVER (YES) defined can be backed up and recovered.

Parameter descriptions for DEFINE CFSTRUCT

(*structure-name*)

Name of the coupling facility application structure that has queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

CFCONLOS

This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

ASQMGR

The action taken is based on the setting of the **CFCONLOS** queue manager attribute.

TERMINATE

The queue manager ends when connectivity to the structure is lost.

TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

This parameter is only valid from CFLEVEL (5).

CFLEVEL(*integer*)

Specifies the functional capability level for this CF application structure. Value can be one of the following:

1

Provided for backwards compatibility.

2

Provided for backwards compatibility.

3

This **CFLEVEL** is required if you want to use persistent messages on shared queues (if **RECOVER(YES)** is set), or for message grouping (when a local queue is defined with **INDXTYPE(GROUPID)**), or both.

A **CFSTRUCT** with CFLEVEL (3) is automatically created when an attempt to open a shared queue with no **CFSTRUCT** definition is found.

You can only decrease the value of **CFLEVEL** from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

4

This **CFLEVEL** supports all the CFLEVEL (3) functions. CFLEVEL (4) allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

You can only decrease the value of **CFLEVEL** from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

5

This **CFLEVEL** supports all functions for CFLEVEL (4). In addition, CFLEVEL (5) enables the following new functions. If altering an existing **CFSTRUCT** to CFLEVEL (5), you must review other attributes as indicated:

- Queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2, under control of the **OFFLOAD** attribute. The offload threshold and size parameters (such as **OFFLD1TH**, and **OFFLD1SZ**) determine whether any

particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the **DSGROUP**, **DSBUFS**, **DSEXPAND** and **DSBLOCK** attributes are respected.

- Structures at CFLEVEL (5) allow the queue manager to tolerate a loss of connectivity to the CF structure. The **CFCONLOS** attribute determines queue manager behavior when a loss of connectivity is detected, and the **RECAUTO** attribute controls subsequent automatic structure recovery behavior.
- Messages containing IBM MQ message properties are stored in a different format on shared queues in a CFLEVEL (5) structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue **PROPCTL** attribute.
- You can only decrease the value of **CFLEVEL** from 5 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

DESCR(*string*)

Plain-text comment that provides descriptive information about the object when an operator issues the **DISPLAY CFSTRUCT** command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(*cfstruct-name*)

The name of a CFSTRUCT object, with attributes used to model this definition.

The initial values of all attributes are copied from the object, except any **DSGROUP** attribute is ignored because each structure requires its own unique value.

OFFLOAD

Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

SMDS

Offload messages from coupling facility to shared message data set (SMDS). This value is the default assumption when a new structure is defined with CFLEVEL (5).

DB2

Offload messages from coupling facility to Db2. This value is the default assumption when an existing structure is increased to CFLEVEL (5) using **DEFINE** with the **REPLACE** option.

Offloading messages using Db2 has significant performance impact. If you want to use the offload rules as a means of increasing capacity, the SMDS option should be specified or assumed.

This parameter is only valid from CFLEVEL (5). At CFLEVEL (4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

Note:

If you change the offload technique (from DB2 to SMDS or the other way) then all new messages are written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified or assumed, then the **DSGROUP** parameter is also required. It can be specified either on the same command or on a previous **DEFINE** or **ALTER** command for the same structure.

OFFLD1TH(*percentage*) OFFLD1SZ(*size*)

OFFLD2TH(*percentage*) OFFLD2SZ(*size*)

OFFLD3TH(*percentage*) OFFLD3SZ(*size*)

Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure.

The offloaded message still requires an entry in the coupling facility containing message control information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (of the order of 100 bytes) it might fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case, no space can be saved, so any offload rules are ignored and the message data is not offloaded. The actual number varies, depending whether more than the default headers are used, or if message properties are being stored.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. The minimal set for the two elements of headers and descriptors require 512 bytes, however this could be greater if other headers or properties are added. This figure would also be greater if an MQMD version greater than 1 is used.

percentage

The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full). For example, OFFLD1TH(75) OFFLD1SZ(32K) means that when the structure is over 75% full, messages greater than 32 kilobytes in size are offloaded.

size

The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range 0K to 64K. This format (no space between the number and "K") is required. As messages exceeding 63.75 KB are always offloaded, the value 64K is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure **ALTER** processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during **ALTER** processing but the total is only updated when the **ALTER** completes. At such times, a rule specifying 100 for the threshold might temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at CFLEVEL(5) or upgrading an existing structure to CFLEVEL(5) depend on the **OFFLOAD** method option. For OFFLOAD(SMDS), the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For OFFLOAD(DB2), the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for CFLEVEL(4).

For OFFLOAD(SMDS) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(32K)
- OFFLD2TH(80) OFFLD2SZ(4K)
- OFFLD3TH(90) OFFLD3SZ(0K)

For OFFLOAD(DB2) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(64K)

- OFFLD2TH(80) OFFLD2SZ(64K)
- OFFLD3TH(90) OFFLD3SZ(64K)

If the **OFFLOAD** method option is changed from DB2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

DSGROUP

For OFFLOAD(SMDS), specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

dsname.prefix.*.dsname.suffix

The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified or assumed, then the **DSGROUP** parameter must also be specified.

This parameter is only valid from CFLEVEL(5).

DSBLOCK

For OFFLOAD(SMDS), specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

8K

16K

32K

64K

128K

256K

512K

1M

Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

This parameter is only valid from CFLEVEL(5).

DSBUFS

For OFFLOAD(SMDS), specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

number

This parameter can be overridden for individual queue managers using the **DSBUFS** parameter on **ALTER SMDS**.

When this parameter is altered, any queue managers that are already connected to the structure, and which do not have an individual **DSBUFS** override value, dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the **DSBUFS** parameter associated with its own individual SMDS definition (as for the **ALTER SMDS** command) to match the actual new number of buffers.

This parameter is only valid from CFLEVEL (5).

DSEXPEND

For OFFLOAD (SMDS), this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

YES

Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

NO

No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the **DSEXPEND** parameter on **ALTER SMDS**.

If an expansion attempt fails, the **DSEXPEND** override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual **DSEXPEND** override value) immediately start using the new parameter value.

This parameter is only valid from CFLEVEL (5).

RECOVER

Specifies whether CF recovery is supported for the application structure. Values are:

NO or N

CF application structure recovery is not supported.

YES or Y

CF application structure recovery is supported.

You can only set RECOVER (YES) if the structure has a **CFLEVEL** of 3 or higher. Set RECOVER (YES) if you intend to use persistent messages.

You can only change RECOVER (NO) to RECOVER (YES) if all the queue managers in the queue sharing group are at command level 530 or greater; this is to ensure that there are no latent command level 520 connections to queues referencing the CFSTRUCT.

You can only change RECOVER (YES) to RECOVER (NO) if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

RECAUTO

Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the sysplex have connectivity to the coupling facility that the structure is allocated in. Values can be:

YES or Y

The structure and associated shared message data sets that also need recovery are automatically recovered.)

NO or N

The structure is not automatically recovered.

This parameter has no effect for structures defined with RECOVER (NO).

This parameter is only valid from CFLEVEL (5).

REPLACE and NOREPLACE

Defines whether the existing definition is to be replaced with this one. This parameter is optional.

REPLACE

The definition should replace any existing definition of the same name. If a definition does not exist, one is created. If you use the **REPLACE** parameter, all queues that use this CF structure must be empty and closed.

NOREPLACE

The definition should not replace any existing definition of the same name.

AFFINITY

Use the channel affinity attribute when client applications connect multiple times using the same queue manager name. With the attribute, you can choose whether the client uses the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions. The list is based on the weightings, with any applicable **CLNTWGHT (0)** definitions first and in alphabetic order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non- **CLNTWGHT (0)** definitions are moved to the end of the list. **CLNTWGHT (0)** definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created. Each client process with the same host name creates the same list.

NONE

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable **CLNTWGHT (0)** definitions selected first in alphabetic order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created.

For example, suppose that we had the following definitions in the CCDT:

```
CHLNAME(A) QMNAME(QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME(QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME(QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list CHLNAME(B), CHLNAME(A), CHLNAME(C).

For **AFFINITY(PREFERRED)**, each connection in the process attempts to connect using CHLNAME(B). If a connection is unsuccessful the definition is moved to the end of the list which now becomes CHLNAME(A), CHLNAME(C), CHLNAME(B). Each connection in the process then attempts to connect using CHLNAME(A).

For **AFFINITY(NONE)**, each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

If sharing conversations is enabled with a non-zero channel weighting and **AFFINITY(NONE)**, multiple connections do not have to share an existing channel instance. They can connect to the same queue manager name using different applicable definitions rather than sharing an existing channel instance.

AMQPKA(integer)

The keep alive time for an AMQP channel in milliseconds. If the **AMQPKA** property is Auto, it uses a value based on the negotiated heartbeat interval value.

If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with an `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

BATCHHB(integer)

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages. If the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel received a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range 0 - 999999. A value of zero indicates that batch heart beats are not used.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHINT(integer)

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages are sent.
- **BATCHLIM** kilobytes are sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty, or the **BATCHSZ** limit is reached.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

BATCHLIM(integer)

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached flows across the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- **BATCHSZ** messages are sent.
- **BATCHLIM** kilobytes are sent.
- The transmission queue is empty and **BATCHINT** is exceeded.

This parameter is valid for channels with a channel type (**CHLTYPE**) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

This parameter is supported on all platforms.

BATCHSZ(integer)

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The **BATCHSZ** of the sending channel.
- The **BATCHSZ** of the receiving channel.
-  **z/OS** On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  **Multi** On Multiplatforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  **z/OS** On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
-  **Multi** On Multiplatforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

While non-persistent messages sent over an NPMSPEED (FAST) channel are delivered to a queue immediately (without waiting for a complete batch), the messages still contribute to the batch size for a channel and, therefore, cause confirm flows to occur when **BATCHSZ** messages have flowed.

If the batch flows are causing a performance impact when moving only non-persistent messages, and **NPMSPEED** is set to FAST, you should consider setting the **BATCHSZ** to the maximum permissible value of 9999, and **BATCHLIM** to zero.

Additionally, setting **BATCHINT** to a high value, for example, 999999999 keeps each batch "open" for longer, even if there are no new messages waiting on the transmission queue.

The above settings minimize the frequency of confirm flows, but be aware that if any persistent messages are moved over a channel with these settings, there will be significant delays in the delivery of those persistent messages only.

The maximum number of uncommitted messages is specified by the **MAXUMSGS** parameter of the **ALTER QMGR** command.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 - 9999.

CERTLABL

Certificate labels for this channel to use.

 On AIX, Linux, IBM i, and Windows, this can be a comma or space separated list of certificates.

 On z/OS, this must be a single certificate label.

The labels identify which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL**, or  on z/OS the **CERTQSG** (if the queue manager is part of a queue sharing group) parameter.

Note that inbound channels (including receiver, requester, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec. See [Interoperability of Elliptic Curve and RSA CipherSpecs](#) for further information.

An unqualified server channel is one that does not have the **CONNAME** field set.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent.

 You must run a **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on the queue manager or any inbound channels. However, you do not need to run the **REFRESH SECURITY TYPE(SSL)** command if you make any changes to **CERTLABL** on an outbound channel.

 Generally, it is not recommended to include commas or spaces within certificate labels. If, however, your certificate labels do contain a comma or space they must be escaped with a backslash (\) to prevent them being mistaken for a separation character.  IBM i does not support space as a separator and thus you do not need to escape this character.

 When a list of certificates is provided, the first certificate in the list that is valid for the CipherSpec is chosen. When a TLS 1.2 CipherSpec is used the certificate type on the inbound channel definition must match the CipherSpec type. A list of certificates allows a channel to use different CipherSpec types and supply a different certificate as needed. For outbound channels or channels when TLS 1.3 is used, the first certificate in the list is selected.

Note: All certificates in the list of certificates must exist in the keystore and be valid certificates.

Note: It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF_WRONG_CHANNEL_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

(channel-name)

The name of the new channel definition.

This parameter is required on all types of channel.

Multi On CLUSSDR channels, this parameter can take a different form to the other channel types. If your convention for naming CLUSSDR channels includes the name of the queue manager, you can define a CLUSSDR channel using the +QMNAME+ construction. After connection to the matching CLUSRCVR channel, IBM MQ substitutes the correct repository queue manager name in place of +QMNAME+ in the CLUSSDR channel definition. See [Components of a cluster](#).

The name must not be the same as any existing channel defined on this queue manager, unless REPLACE or ALTER is specified.

z/OS On z/OS, CLNTCONN channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see [Rules for naming IBM MQ objects](#).

Multi On CLUSRCVR channels when using automatic cluster setup, this parameter can use some additional inserts:

- +AUTOCL+ resolves to the automatic cluster name
- +QMNAME+ resolves to the local queue manager name.

When using these inserts, both the unexpanded string and the string with the replaced values must fit inside the maximum size of the field. If there are configured automatic cluster full repositories in the AutoCluster configuration, the channel name must also fit in the maximum channel name length when +QMNAME+ is replaced with each of the configured full repository names.

CHLTYPE

Channel type. This parameter is required.

Multi On [Multiplatforms](#), it must follow immediately after the (*channel-name*) parameter.

- SDR: sender channel
- SVR: server channel
- RCVR: receiver channel
- RQSTR: requester channel
- CLNTCONN: client-connection channel
- SVRCONN: server-connection channel
- CLUSSDR: cluster-sender channel
- CLUSRCVR: cluster-receiver channel
- **ALW** AMQP: AMQP channel

Note: If you are using the REPLACE option, you cannot change the channel type.

CLNTWGHT

Set the client channel weighting attribute to select a client channel definition at random based on its weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetic order. To enable random load balancing the value can be in the range 1 - 99, where 1 is the lowest weighting and 99 is the highest.

If a client application issues MQCONN with a queue manager name of **name* a client channel definition can be selected at random. The chosen definition is randomly selected based on the weighting. Any applicable **CLNTWGHT (0)** definitions selected are selected first in alphabetic order. Randomness in the selection of client connection definitions is not guaranteed.

For example, suppose that we had the following two definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name *GRP1 would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 is generated. If the integer is in the range 1 through 2, address1 is used otherwise address2 is used). If this connection is unsuccessful the client then uses the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weighting are chosen first and in alphabetical order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose that we had the following four definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name *GRP1 would first choose definition TO.QM3. If this connection was unsuccessful the client would then choose definition TO.QM4. If this connection was also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT is supported for all transport protocols.

CLUSNL(nlname)

The name of the namelist that specifies a list of clusters to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of **CLUSTER** or **CLUSNL** can be non-blank, the other must be blank.

CLUSTER(clustername)

The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of **CLUSTER** or **CLUSNL** can be non-blank, the other must be blank.

 On **CLUSRCVR** channels, when using automatic cluster setup, this parameter can use the value +AUTOCL+, which is automatically expanded to the name of the automatic cluster.

CLWLPRTY(integer)

Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see [CLWLPRTY channel attribute](#).

CLWLRANK(integer)

Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see [CLWLRANK channel attribute](#).

CLWLWGHT(integer)

Specifies the weighting to be applied to a channel so that the proportion of messages sent down the channel can be controlled by workload management. The value must be in the range 1 - 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLUSSDR and CLUSRCVR channels.

For more information about this attribute, see [CLWLWGHT channel attribute](#).

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

If **QSGDISP** is set to GROUP, **CMDSCOPE** must be set to the local queue manager name. Otherwise, **CMDSCOPE** must be left blank.

The command runs on the queue manager on which it was entered.

QmgrName

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered. To do so, you must be using a shared queue environment, and the command server must be enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

COMPHDR

The list of header data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

NONE

No header data compression is performed.

SYSTEM

Header data compression is performed.

COMPMSG

The list of message data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

NONE

No message data compression is performed.

RLE

Message data compression is performed using run-length encoding.

ZLIBFAST

Message data compression is performed using ZLIB encoding with speed prioritized.

 On z/OS systems with [zEDC Express facility](#) enabled, compression can be offloaded to zEDC Express.

ZLIBHIGH

Message data compression is performed using ZLIB encoding with compression prioritized.

Multi LZ4FAST

Message data compression is performed using LZ4 encoding with speed prioritized.

Multi LZ4HIGH

Message data compression is performed using LZ4 encoding with compression prioritized.

ANY

Any compression technique supported by the queue manager can be used. This value is only valid for RCVR, RQSTR, and SVRCONN channels.

CONNAME(string)

Connection name.

For CLUSRCVR channels, **CONNAME** relates to the local queue manager, and for other channels it relates to the target queue manager.

ALW On CLUSRCVR channels, when using automatic cluster setup, this parameter can use any variable configured at queue manager create time surrounded by +; for example +CONNAME+.

ALW See the [crtmqm -iv](#) option for more information.

Note: When using these inserts, both the unexpanded inserts and the expanded values must fit inside the field maximum size.

z/OS On z/OS, **CONNAME** is mandatory for CLUSRCVR channels. In addition, whether you specify **CONNAME**, or the name is generated for you, the **CONNAME** produced must be a valid connection name for the local queue manager, otherwise the full repository is not able to make a connection back to the local queue manager.

Multi On [Multiplatforms](#), the maximum length of the string is 264 characters.

z/OS On z/OS, the maximum length of **CONNAME** varies:

- For channels of **TRPTYPE (LU62)**, the maximum length is always 48 characters.
- **v 10.0.0** For channels of **TRPTYPE (TCP)**, from IBM MQ 10.0.0, the maximum length is 264 characters. Lengths greater than 48 characters cannot be used for **QSGDISP (GROUP | COPY)** channel definitions until all queue managers in the queue sharing group are at IBM MQ 10.0.0 or later.
- For client-connection channels, the maximum length is always 48 characters.

For channels of **TRPTYPE (TCP)**, a workaround to the 48 character limit might be one of the following suggestions:

- **v 10.0.0** Migrate to IBM MQ 10.0.0 or later.
- Set up your DNS servers so that you use, for example, host name of myserver instead of myserver.location.company.com, ensuring that you can use the short host name.
- Use IP addresses.

Specify **CONNAME** as a comma-separated list of names of machines for the stated **TRPTYPE**. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the **CLNTWGHT** attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

CONNAME is required for channels with a channel type (**CHLTYPE**) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of **TRPTYPE(TCP)**, and is not valid for RCVR or SVRCONN channels.

Multi On Multiplatforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

(1415)

The generated **CONNAME** is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

Tip: If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type (**TRPTYPE**) to be used:

LU62

- z/OS** On z/OS, there are two forms in which to specify the value:

Logical unit name

The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Table 179. Forms of logical unit name	
Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the **TPNAME** and **MODENAME** parameters; otherwise these parameters must be blank.

Note: For CLNTCONN channels, only the first form is allowed.

Symbolic name

The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The **TPNAME** and **MODENAME** parameters must be blank.

Note: For CLUSRCVR channels, the side information is on the other queue managers in the cluster. Alternatively, it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

- Multi** On Multiplatforms, **CONNAME** is the name of the CPI-C communications side object. Alternatively, if the **TPNAME** is not blank, **CONNAME** is the fully qualified name of the partner logical unit. See [Configuration parameters for an LU 6.2 connection](#).

NetBIOS

A unique NetBIOS name (limited to 16 characters).

SPX

The 4-byte network address, the 6-byte node address, and the 2-byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

```
CONNAME('0a0b0c0d.804abcde23a1(5e86)')
```

TCP

Either the host name, or the network address of the remote machine (or the local machine for CLUSRCVR channels). This address can be followed by an optional port number, enclosed in parentheses.

If the **CONNAME** is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on the value specified for **CONNAME** and the value specified for **LOCLADDR**. See **LOCLADDR** for information about how this value is resolved.

 On z/OS, the connection name can include the *IP_name* of an z/OS dynamic DNS group or a Network Dispatcher input port. Do not include the *IP_name* or input port for channels with a channel type (**CHLTYPE**) of CLUSSDR.

On all platforms, you do not always need to specify the network address of your queue manager. If you define a channel with a channel type (**CHLTYPE**) of CLUSRCVR that is using TCP/IP, IBM MQ generates a **CONNAME** for you. It assumes the default port and uses the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

Note: If you are using clustering between IPv6-only and IPv4-only queue managers, do not specify an IPv6 network address as the **CONNAME** for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a CLUSSDR channel definition that specifies the **CONNAME** in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

CONVERT

Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

NO

No conversion by sender

YES

Conversion by sender

 On z/OS, N and Y are accepted as synonyms of NO and YES.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

DEFCDISP

Specifies the default channel disposition of the channel.

PRIVATE

The intended disposition of the channel is as a private channel.

FIXSHARED

The intended disposition of the channel is as a shared channel associated with a specific queue manager.

SHARED

The intended disposition of the channel is as a shared channel.

This parameter does not apply to channels with a channel type (**CHLTYPE**) of CLNTCONN, CLUSSDR, or CLUSRCVR.

DEFRECON

Specifies whether a client connection automatically reconnects a client application if its connection breaks.

NO (default)

Unless overridden by **MQCONN**, the client is not reconnected automatically.

YES

Unless overridden by **MQCONN**, the client reconnects automatically.

QMGR

Unless overridden by **MQCONN**, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO_RECONNECT_Q_MGR.

DISABLED

Reconnection is disabled, even if requested by the client program using the **MQCONN** MQI call.

Table 180. Automatic reconnection depends on the values set in the application and in the channel definition				
DEFRECON	Reconnection options set in the application			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO (default)	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

DESCR(string)

Plain-text comment. It provides descriptive information about the channel when an operator issues the **DISPLAY CHANNEL** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If the information is sent to another queue manager they might be translated incorrectly. The characters must be in the coded character set identifier (CCSID) of the local queue manager.

DISCINT(integer)

The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue. The waiting period starts after a batch ends. After the end of the waiting period, if there are no more messages, the channel is ended. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range 0 - 999 999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN, SDR, SVR, CLUSSDR, CLUSRCVR.

For SVRCONN channels using the TCP protocol, **DISCINT** has a different interpretation. It is the minimum time in seconds for which the SVRCONN instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The SVRCONN inactivity interval applies only between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

HBINT(integer)

HBINT specifies the approximate time between heartbeat flows sent by a message channel agent (MCA). The flows are sent when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked, it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that are allocated for large messages. They also close any queues that are left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 - 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For SVRCONN and CLNTCONN channels, heartbeats can flow from both the server side as well as the client side independently. If no data is transferred across the channel during the heartbeat interval, the CLNTCONN MQI agent sends a heartbeat flow. The SVRCONN MQI agent responds to it with another heartbeat flow. The flows happen irrespective of the state of the channel. For example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The SVRCONN MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. The SVRCONN and CLNTCONN MQI agents are prevented from heart beating to each other at the same time. The server heartbeat is flowed if no data is transferred across the channel for the heartbeat interval plus 5 seconds.

For more information, see [Heartbeat interval \(HBINT\)](#).

KAINT(integer)

The value passed to the communications stack for keepalive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

z/OS On z/OS, enable TCP/IP keepalive in the queue manager by issuing the **ALTER QMGR TCPKEEP(YES)** command. If the **TCPKEEP** queue manager parameter is NO, the value is ignored, and the keepalive facility is not used.

Multi On [Multiplatforms](#), TCP/IP keepalive is enabled when the KEEPALIVE=YES parameter is specified in the TCP stanza. Modify the TCP stanza in the distributed queuing configuration file, qm.ini, or through the IBM MQ Explorer.

Keepalive must also be enabled within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive:

- **AIX** On AIX, use the **no** command.
- **Windows** On Windows, edit the registry.
- **z/OS** On z/OS, update your TCP/IP PROFILE data set and add or change the **INTERVAL** parameter in the TCPCONFIG section.

z/OS Although the **KAINT** parameter is available on all platforms, its setting is implemented only on z/OS.

Multi On [Multiplatforms](#) you can access and modify the parameter, but there is no functional implementation of the parameter, it is only stored and forwarded. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on AIX, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster. On [Multiplatforms](#), if you need the functionality provided by the **KAINT** parameter, use the Heartbeat Interval (**HBINT**) parameter, as described in [HBINT](#).

(integer)

The KeepAlive interval to be used, in seconds, in the range 1 through 999999.

0

The value used is that specified by the **INTERVAL** statement in the TCP profile configuration data set.

AUTO

The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated **HBINT** is greater than zero, keepalive interval is set to that value plus 60 seconds.

- If the negotiated **HBINT** is zero, the keepalive value used is that specified by the **INTERVAL** statement in the TCP/IP PROFILE configuration data set.

If AUTO is specified for **KAINT**, and it is a server-connection channel, the **TCP INTERVAL** value is used instead for the keepalive interval.

In this case, **KAINT** is zero in **DISPLAY CHSTATUS**; it would be non-zero if an integer had been coded instead of AUTO.

This parameter is valid for all channel types. It is ignored for channels with a **TRPTYPE** other than TCP or SPX.

LIKE(channel-name)

The name of a channel. The parameters of this channel are used to model this definition.

If you do not set **LIKE**, and do not set a parameter field related to the command, its value is taken from one of the default channels. The default values depend upon the channel type:

SYSTEM.DEF.SENDER

Sender channel

SYSTEM.DEF.SERVER

Server channel

SYSTEM.DEF.RECEIVER

Receiver channel

SYSTEM.DEF.REQUESTER

Requester channel

SYSTEM.DEF.SVRCONN

Server-connection channel

SYSTEM.DEF.CLNTCONN

Client-connection channel

SYSTEM.DEF.CLUSSDR

CLUSSDR channel

SYSTEM.DEF.CLUSRCVR

Cluster-receiver channel

SYSTEM.DEF.AMQP

AMQP channel

This parameter is equivalent to defining the following object for a SDR channel, and similarly for other channel types:

```
LIKE(SYSTEM.DEF.SENDER)
```

These default channel definitions can be altered by the installation to the default values required.

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object and channel type you are defining.

Note:

1. **QSGDISP(GROUP)** objects are not searched.
2. **LIKE** is ignored if **QSGDISP(COPY)** is specified. However, the group object defined is used as a **LIKE** object.

LOCLADDR(string)

LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. **LOCLADDR** might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. **LOCLADDR** is also useful to force a channel to use an IPv4 or

IPv6 stack on a dual-stack system. You can also use **LOCLADDR** to force a channel to use a dual-mode stack on a single-stack system.

Note: AMQP channels do not support the same format of **LOCLADDR** as other IBM MQ channels. For the format supported by AMQ, see the next parameter **AMQP: LOCLADDR**.

For channels other than AMQP channels, the **LOCLADDR** parameter is valid only for channels with a transport type (**TRPTYPE**) of TCP. If **TRPTYPE** is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr] [(low-port[,high-port])] [, [ip-addr] [(low-port[,high-port])]])
```

The maximum length of **LOCLADDR**, including multiple addresses, is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

Note, that you can set **LOCLADDR** for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the `ip-addr` part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having to identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify `[, [ip-addr] [(low-port[,high-port])]]` multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use `[, [ip-addr] [(low-port[,high-port])]]` to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

ip-addr

`ip-addr` is specified in one of three forms:

IPv4 dotted decimal

For example, 192.0.2.1

IPv6 hexadecimal notation

For example, 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example WWW.EXAMPLE.COM

low-port and high-port

`low-port` and `high-port` are port numbers enclosed in parentheses.

The following table shows how the **LOCLADDR** parameter can be used:

<i>Table 181. Examples of how the LOCLADDR parameter can be used</i>	
LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the **LOCLADDR** parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the **LOCLADDR** parameter is used.

► **z/OS** This port range does not apply to z/OS systems.

Note: Do not put an IP address in the **LOCLADDR** field of a CLUSRCVR channel, unless all queue managers are on the same server. The **LOCLADDR** IP address is propagated to the auto-defined CLUSSDR channels of all queue managers that connect using the CLUSRCVR channel.

Even though this parameter is similar in form to **CONNAME**, it must not be confused with it. The **LOCLADDR** parameter specifies the characteristics of the local communications, whereas the **CONNAME** parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for **CONNAME** and **LOCLADDR** determine the IP stack to be used for communication; see the following table and [Local Address \(LOCLADDR\)](#).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

► **z/OS** For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the connect() request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 182. How the IP stack to be used for communication is determined			
Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address ¹		Channel binds to IPv4 stack
	IPv6 address ²		Channel fails to resolve CONNAME
	IPv4 and 6 host name ³		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address ⁴	IPv6 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack

Table 182. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by IPADDRV
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by IPADDRV
IPv6 only	IPv4 address		Channel maps CONNAME to IPv6 ⁵
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps CONNAME to IPv6 ⁵
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

Table 182. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
Notes: 1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example 1.2.3.4. This note applies to all occurrences of 'IPv4 address' in this table. 2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example 4321:54bc. This note applies to all occurrences of 'IPv6 address' in this table. 3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of 'IPv4 and 6 host name' in this table. 4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table. 5. Maps IPv4 CONNAME to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the CONNAME. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.			

AMQP: LOCLADDR(ip-addr)

Note: For the format of **LOCLADDR** that other IBM MQ channels use, see the previous parameter **LOCLADDR**.

For AMQP channels, **LOCLADDR** is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr

ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal

For example, 192.0.2.1

IPv6 hexadecimal notation

For example, 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example, WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

LONGRTY(integer)

The **LONGRTY** parameter specifies the maximum number of further attempts that are made by a SDR, SVR, or CLUSSDR channel to connect to a remote queue manager. The interval between attempts is specified by **LONGTMR**. The **LONGRTY** parameter takes effect if the count specified by **SHORTRTY** is exhausted.

If this count is exhausted without success, an error is logged to the operator, and the channel stops. In this circumstance, the channel must be restarted with a command. It is not started automatically by the channel initiator.

The **LONGRTY** value must be in the range 0 - 9999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

LONGTMR(integer)

For **LONGRTY**, **LONGTMR** is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The **LONGTMR** value must be in the range 0 - 9999999.

Note: For implementation reasons, the maximum **LONGTMR** value is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum interval between attempting to reconnect is 2 seconds. Values less than this minimum are treated as 2 seconds.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

MAXINST(integer)

The maximum number of simultaneous instances of an individual SVRCONN channel or AMQP channel that can be started.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

New instances of SVRCONN channels cannot start if the number of running instances equals or exceeds the value of this parameter. If **MAXINST** is changed to less than the number of instances of the SVRCONN channel that are currently running, the number of running instances is not affected.

If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached **MAXINST**, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached **MAXINST**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN or AMQP.

MAXINSTC(integer)

The maximum number of simultaneous individual SVRCONN channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

If you reduce the value of **MAXINSTC** to less than the number of instances of the SVRCONN channel that is currently running from an individual client, the running instances are not affected. New SVRCONN instances from that client cannot start until the client is running fewer instances than the value of **MAXINSTC**.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SVRCONN.

MAXMSGL(integer)

Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type (**CHLTYPE**) is SVRCONN.

The value zero means the maximum message length for the queue manager; see [ALTER QMGR MAXMSGL](#).

Multi On [Multiplatforms](#), specify a value in the range zero to the maximum message length for the queue manager.

z/OS On z/OS, specify a value in the range 0 - 104857600 bytes (100 MB).

Note that by adding the digital signature and key to the message, [Advanced Message Security](#) increases the length of the message.

MCANAME(string)

Message channel agent name.

This parameter is reserved, and if specified must be set to blanks (maximum length 20 characters).

MCATYPE

Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

PROCESS

The message channel agent runs as a separate process.

THREAD

The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners though the port number specified on the listener.

Multi On [Multiplatforms](#), this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR.

z/OS On z/OS, this parameter is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, **MCATYPE** is used by a remote machine to determine the corresponding CLUSSDR definition.

MCAUSER(string)

Message channel agent user identifier.

Note: An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both **MCAUSER** on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The **MCAUSER** on the channel definition is only used if the channel authentication record uses **USERSRC (CHANNEL)**. For more details, see [Channel authentication records](#)

This parameter interacts with **PUTAUT**; see [PUTAUT](#).

If **MCAUSER** is non-blank, a user identifier is used by the message channel agent for authorization to access IBM MQ resources. If **PUTAUT** is set to DEF, authorization includes authorization to put the message to the destination queue for RCVR or RQSTR channels.

If **MCAUSER** is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

z/OS **z/OS**

The user ID assigned to the channel-initiator started task by the z/OS started-procedures table.

TCP/IP, Multiplatforms

The user ID from the `inetd.conf` entry, or the user that started the listener.

SNA, Multiplatforms

The user ID from the SNA server entry. In the absence of the user ID from the SNA server entry, the user from the incoming attach request, or the user that started the listener.

NetBIOS or SPX

The user ID that started the listener.

The maximum length of the string is:

- **Windows** 64 characters on Windows.
- 12 characters on platforms other than Windows.

Windows On Windows, you can optionally qualify a user identifier with the domain name in the format `user@domain`.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLNTCONN, CLUSSDR.

MODENAME(string)

LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU62. If **TRPTYPE** is not LU62, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the **CONNAME** contains a side-object name. If **CONNAME** is a side-object name it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set, see [Configuration parameters for an LU 6.2 connection](#).

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR or SVRCONN.

MONCHL

Controls the collection of online monitoring data for channels:

QMGR

Collect monitoring data according to the setting of the queue manager parameter **MONCHL**.

OFF

Monitoring data collection is turned off for this channel.

LOW

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data is collected at a low rate for this channel.

MEDIUM

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data is collected at a medium rate for this channel.

HIGH

If the value of the queue manager **MONCHL** parameter is not NONE, online monitoring data is turned on. Data is collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the queue manager attribute **MONACLS**. This value might then be overridden in the channel auto-definition exit.

MRDATA(string)

Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MREXIT(string)

Channel message-retry exit name.

The format and maximum length of the name is the same as for **MSGEXIT**, however you can specify only one message-retry exit.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRRTY(integer)

The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRRTY** is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that no attempts to redeliver the message are tried.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MRTMR(integer)

The minimum interval of time that must pass before the channel can try the **MQPUT** operation again. The time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of **MRTMR** is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that if the value of **MRRTY** is greater than zero, the channel reattempts delivery as soon as possible.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

MSGDATA(string)

User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

 **ALW** On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

 **IBM i** On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

 **z/OS** On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

Note: This parameter is accepted but ignored for SVRCONN and CLNTCONN channels.

MSGEXIT(string)

Channel message exit name.

If **MSGEXIT** is non-blank the exit is called at the following times:

- Immediately after a SDR or SVR channel retrieves a message from the transmission queue.
- Immediately before a RQSTR channel puts a message on destination queue.
- When the channel is initialized or ended.

The exit is passed the entire application message and transmission queue header for modification.

MSGEXIT is accepted and ignored by CLNTCONN and SVRCONN channels. CLNTCONN or SVRCONN channels do not call message exits.

The format and maximum length of the exit name depends on the platform; see [Table 183 on page 569](#).

If the **MSGEXIT**, **MREXIT**, **SCYEXIT**, **SENDEXIT**, and **RCVEXIT** parameters are all left blank, the channel user exit is not invoked. If any of these parameters is non-blank, the channel exit program is called. You can enter text string for these parameters. The maximum length of the string is 128 characters.

Table 183. Message exit format and length			
Platform	Exit name format	Maximum length	Comment
AIX and Linux	<i>libraryname (functionname)</i>	128	You can specify the name of more than one exit program. Specify multiple strings separated by commas. The total number of characters specified must not exceed 999.
Windows	<i>dllname (functionname)</i>	128	1. You can specify the name of more than one exit program. Specify multiple strings separated by commas. The total number of characters specified must not exceed 999. 2. <i>dllname</i> is specified without the suffix (.DLL).
IBM i	<i>progrname libname</i>	20	1. You can specify the names of up to 10 exit programs by specifying multiple strings separated by commas. 2. <i>program name</i> occupies the first 10 characters and <i>libname</i> the second 10 characters. If necessary, both fields are padded to the right with blanks.
z/OS	<i>loadModuleName</i>	8	1. You can specify the names of up to eight exit programs by specifying multiple strings separated by commas. 2. 128 characters are allowed for exit names for CLNTCONN channels, subject to a maximum total length including commas of 999.

NETPRTY(integer)

The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range 0 - 9; 0 is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

NPMSPEED

The class of service for nonpersistent messages on this channel:

FAST

Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO_SYNCPOINT_IF_PERSISTENT and so are not included in the batch unit of work.

NORMAL

Normal delivery for nonpersistent messages.

If the value of **NPMSPEED** differs between the sender and receiver, or either one does not support it, **NORMAL** is used.

Notes:

1. If the active recovery logs for IBM MQ for z/OS are switching and archiving more frequently than expected, given that the messages being sent across a channel are non-persistent, setting **NPMSPEED (FAST)** on both the sending and receiving ends of the channel can minimize the **SYSTEM.CHANNEL.SYNCQ** updates.
2. If you are seeing high CPU usage relating to updates to the **SYSTEM.CHANNEL.SYNCQ**, setting **NPMSPEED (FAST)** can significantly reduce the CPU usage.

This parameter is valid only for channels with a **CHLTYPE** of **SDR**, **SVR**, **RCVR**, **RQSTR**, **CLUSSDR**, or **CLUSRCVR**.

PASSWORD(string)

Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of **SDR**, **SVR**, **RQSTR**, **CLNTCONN**, or **CLUSSDR**.

 On z/OS, it is supported only for channels with a channel type (**CHLTYPE**) of **CLNTCONN**.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

PORT(integer)

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

PROPCTL

Property control attribute; see [PROPCTL channel options](#).

PROPCTL specifies what happens to message properties when a message is sent to another queue manager.

This parameter is applicable to **SDR**, **SVR**, **CLUSSDR**, and **CLUSRCVR** channels.

This parameter is optional.

Permitted values are:

COMPAT

COMPAT allows applications which expect JMS-related properties to be in an **MQRFH2** header in the message data to continue to work unmodified.

Table 184. Range of results, depending on which message properties are set, when PROPCTL value is COMPAT	
Message properties	Result
The message contains a property with a prefix of mcd. , jms. , usr. or mqext.	If the Support value is MQPD_SUPPORT_OPTIONAL , all optional message properties are placed in one or more MQRFH2 headers. This rule does not apply to properties in the message descriptor or extension, which remain in the same place. Optional message properties are moved into the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of mcd. , jms. , usr. or mqext.	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the Support field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

Table 184. Range of results, depending on which message properties are set, when **PROPCTL** value is **COMPAT** (continued)

Message properties	Result
The message contains one or more properties where the Support field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL. Other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.

NONE

All properties of the message, except properties in the message descriptor or extension, are removed from the message. The properties are removed before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY. The error is reported in accordance with the report options set in the message header.

ALL

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT

PUTAUT specifies which user identifiers are used to establish authority for a channel. It specifies the user identifier to put messages to the destination queue using a message channel, or to run an MQI call using an MQI channel.

DEF

The default user ID is used.

► **z/OS** On z/OS, DEF might involve using both the user ID received from the network and that derived from **MCAUSER**.

CTX

The user ID from the *UserIdentifier* field of the message descriptor is used.

► **z/OS** On z/OS, CTX might involve also using the user ID received from the network or that derived from **MCAUSER**, or both.

► **z/OS** ONLYMCA

The user ID derived from **MCAUSER** is used. Any user ID received from the network is not used. This value is supported only on z/OS.

► **z/OS** ALTMCA

The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

► **z/OS** On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the **MQADMIN** RACF class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one, or two user IDs are checked. To see how many user IDs are checked, see [RESLEVEL](#) and the [channel initiator connection](#). For more information about which user IDs are checked, see [User IDs used by the channel initiator](#).

► **z/OS** On z/OS, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

► **Multi** On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, RQSTR, or CLUSRCVR.

QMNAME(string)

Queue manager name.

For CLNTCONN channels, **QMNAME** is the name of a queue manager to which an IBM MQ MQI client application can request connection. **QMNAME** is not necessarily the same as the name of the queue manager on which the channel is defined; see [Queue manager groups in the CCDT](#).

For channels of other types, the **QMNAME** parameter is not valid.

 QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 185. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE CHANNEL(<channel_name>) CHLTYPE(<channel_type>) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for a CHANNEL definition for <i>channel_name</i> and <i>channel_type</i>. If a matching CHANNEL definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the <code>DEFINE CHANNEL(<i>channel_name</i>) CHLTYPE(<i>channel_type</i>) REPLACE QSGDISP(COPY)</code> command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

RCVDATA(string)

Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

 On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

RCVEXIT(string)

Channel receive exit name.

If this name is non-blank, the exit is called at the following times:

- Immediately before the received network data is processed.

The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

REPLACE and NOREPLACE

Replace the existing definition with this one, or not. This parameter is optional.

z/OS On z/OS it must have the same disposition. Any object with a different disposition is not changed.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created. **REPLACE** does not alter the channel status.

NOREPLACE

The definition does not replace any existing definition of the same name.

SCYDATA(string)

Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

SCYEXIT(string)

Channel security exit name.

If this name is non-blank, the exit is called at the following times:

- Immediately after establishing a channel.

Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.

- Upon receipt of a response to a security message flow.

Any security message flows received from the remote processor on the remote queue manager are given to the exit.

- At initialization and termination of the channel.

The format and maximum length of the name is the same as for **MSGEXIT** but only one name is allowed.

SENDDATA(string)

Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

ALW On AIX, Linux, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

IBM i On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

z/OS On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

SENDEXIT(string)

Channel send exit name.

If this name is non-blank, the exit is called at the following times:

- Immediately before data is sent out on the network.

The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

ALW On AIX, Linux, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

IBM i On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

z/OS On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for **MSGEXIT**.

SEQWRAP(integer)

When this value is reached, sequence numbers wrap to start again at 1.

This value is non-negotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 - 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

SHARECNV(integer)

Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A **SHARECNV** value of:

1

Specifies no sharing of conversations over a TCP/IP channel instance. Client heart beating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.

0

Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of CLNTCONN or SVRCONN. If the CLNTCONN **SHARECNV** value does not match the SVRCONN **SHARECNV** value, the lower of the two values is used. This parameter is ignored for channels with a transport type (**TRPTYPE**) other than TCP.

All the conversations on a socket are received by the same thread.

High **SHARECNV** limits have the advantage of reducing queue manager thread usage. If many conversations sharing a socket are all busy, there is a possibility of delays. The conversations contend with one another to use the receiving thread. In this situation, a lower **SHARECNV** value is better.

The number of shared conversations does not contribute to the **MAXINST** or **MAXINSTC** totals.

Note: You should restart the client for this change to take effect.

SHORTRTY(integer)

SHORTRTY specifies the maximum number of attempts that are made by a SDR, SVR, or CLUSSDR channel to connect to the remote queue manager, at intervals specified by **SHORTTMR**. After the number of attempts is exhausted, the channel tries to reconnect using the schedule defined by **LONGRTY**.

The value must be in the range 0 - 999999999.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

SHORTTMR(integer)

For **SHORTRTY**, **SHORTTMR** is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate. Zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The value must be in the range 0 - 999999999.

Note: For implementation reasons, the maximum **SHORTTMR** value is 999,999; values exceeding this maximum are treated as 999,999. If **SHORTTMR** is set to 1 then the minimum interval between attempting to connect is 2 seconds.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, CLUSSDR, or CLUSRCVR.

SPLPROT

SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

This parameter applies to z/OS only, from IBM MQ 9.1.3 onwards.

The permitted values are:

PASSTHRU

Pass through, unchanged, any messages sent or received by the message channel agent for this channel.

This value is valid for channels with a channel type (**CHLTYPE**) of SDR, SVR, RCVR, or RQSTR, and is the default value.

REMOVE

Remove any AMS protection from messages retrieved from the transmission queue by the message channel agent, and send the messages to the partner.

When the message channel agent gets a message from the transmission queue, if an AMS policy is defined for the transmission queue, it is applied to remove any AMS protection from the message prior to sending the message across the channel. If an AMS policy is not defined for the transmission queue, the message is sent as is.

This value is valid only for channels with a channel type of SDR or SVR.

ASPOLICY

Based on the policy defined for the target queue, apply AMS protection to inbound messages prior to putting them on to the target queue.

When the message channel agent receives an inbound message, if an AMS policy is defined for the target queue, AMS protection is applied to the message prior to the message being put to the target queue. If an AMS policy is not defined for the target queue, the message is put to the target queue as is.

This value is valid only for channels with a channel type of RCVR or RQSTR.

SSLCAUTH

SSLCAUTH defines whether IBM MQ requires a certificate from the TLS client. The TLS client is the initiating end of the channel. **SSLCAUTH** is applied to the TLS server, to determine the behavior required of the client. The TLS server is the end of the channel that receives the initiation flow.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of RCVR, SVRCONN, CLUSRCVR, SVR, OR RQSTR.

The parameter is used only for channels with **SSLCIPH** specified. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

REQUIRED

IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL

The peer TLS client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

SSLCIPH(string)

Specifies the CipherSpec that is used on the channel. The maximum length is 32 characters.

Attention:   On IBM MQ for z/OS, you can also specify the four digit hexadecimal code of a CipherSpec, whether or not it appears in [Table 1 of Enabling CipherSpecs](#). On IBM i, you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in [Table 1 of Enabling CipherSpecs](#). Also, on IBM i, installation of AC3 is a prerequisite for the use of TLS. You should not specify hexadecimal cipher values in **SSLCIPH**, because it is unclear from the value which cipher will be used, and the choice of which protocol to be used is indeterminate. Using hexadecimal cipher values can lead to CipherSpec mismatch errors.

The **SSLCIPH** values must specify compatible CipherSpecs for both ends of the channel.

This parameter is valid on all channel types that use transport type **TRPTYPE(TCP)**. If the parameter is blank, no attempt is made to use TLS on the channel.

If [SecureCommsOnly](#) is enabled, plain text communication is not supported and the channel fails to start.

The value for this parameter is also used to set the value of **SECPROT**, which is an output field on the [DISPLAY CHSTATUS](#) command.

Note: When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. See the [SSLCIPH](#) description for **DEFINE CHANNEL (MQTT)**.

You can specify a specific CipherSpec or an alias CipherSpec. An alias CipherSpec allows a range of CipherSpecs to be used based on protocol. For more information see [Relationship between alias CipherSpec settings](#).

Attention: If your enterprise needs to guarantee that a certain CipherSpec is negotiated and used, you must not use an alias CipherSpec value.

For information on changing your existing security configurations to use an alias CipherSpec, for example, ANY_TLS12_OR_HIGHER, ANY_TLS13_OR_HIGHER, and so on, see [Migrating existing security configurations to use an alias CipherSpec](#).

For more information about CipherSpecs, see [Enabling CipherSpecs](#).

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

-  On z/OS, AIX, Linux, and Windows, when a CipherSpec name includes _EXPORT, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
-  For z/OS, System SSL states that if a TLS V1.3 connection is being negotiated:
 - The minimum key size for an RSA peer certificate is the larger of the following two values: 2048, or the value specified in the **GSK_PEER_RSA_MIN_KEY_SIZE** attribute.
 - The minimum key size for an ECC peer certificate is the larger of the following two values: 256, or the value specified in the **GSK_PEER_ECC_MIN_KEY_SIZE** attribute.
-  On AIX, Linux, and Windows, when a CipherSpec name includes _EXPORT1024, the handshake key size is 1024 bits.
- Otherwise the handshake key size is the size stored in the certificate.

SSLPEER (*string*)

Specifies the certificate filter used by the peer queue manager or client at the other end of the channel. The filter is used to compare with the distinguished name of the certificate. A *distinguished name* is the identifier of the TLS certificate. If the distinguished name in the certificate received from the peer does not match the **SSLPEER** filter, the channel does not start.

Note: An alternative way of restricting connections into channels by matching against the TLS Subject distinguished name, is to use channel authentication records. With channel authentication records, different TLS subject distinguished name patterns can be applied to the same channel. Both **SSLPEER** and a channel authentication record can be applied to the same channel. If so, the inbound certificate must match both patterns in order to connect. For more information, see [Channel authentication records](#).

SSLPEER is optional. If it is not specified, the distinguished name of the peer is not checked at channel startup. The distinguished name from the certificate is still written into the **SSLPEER** definition held in memory, and passed to the security exit. If **SSLCIPH** is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The **SSLPEER** value is specified in the standard form used to specify a distinguished name. For example:

```
SSLPEER(' SERIALNUMBER=4C:D0:49:D5:02:5F:38,CN="H1_C_FR1",O=IBM,C=GB')
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

Table 186. Attribute types supported by **SSLPEER**

Attribute	Description
SERIALNUMBER	Certificate serial number
MAIL	Email address
 E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zipcode
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the **SSLPEER** string, an error is output either when the attribute is defined, or at run time. When the error is output depends on which platform you are running on. An error implies that the **SSLPEER** string does not match the distinguished name of the flowed certificate.

If the distinguished name of the flowed certificate contains multiple organizational unit (OU) attributes, and **SSLPEER** specifies that these attributes are to be compared, they must be defined in descending hierarchical order. For example, if the distinguished name of the flowed certificate contains the OUs OU=Large Unit, OU=Medium Unit, OU=Small Unit, specifying the following **SSLPEER** values succeeds:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following **SSLPEER** values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, ('OU=Large Unit,OU=Medium Unit') is equivalent to ('OU=Large Unit,OU=Medium Unit,OU=*').

If two DN's are equal in all respects except for their domain component (DC) values, almost the same matching rules apply as for OUs. The exception is that with DC values, the left-most DC is the lowest-level and most specific, and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk * on its own, or a stem with initiating or trailing asterisks. Asterisks allow the **SSLPEER** to match any distinguished name value, or any value starting with the stem for that attribute. You can specify an asterisk at the beginning or end of any attribute value in the DN on the certificate. If you do so, you can still check for an exact match with **SSLPEER**. Specify * to check for an exact match. For example, if you have an attribute of CN= 'Test*' in the DN of the certificate, you use the following command to check for an exact match:

```
SSLPEER('CN=Test\*')
```

Multi The maximum length of the parameter is 1024 bytes on [Multiplatforms](#).

z/OS The maximum length of the parameter is 256 bytes on z/OS.

[Channel authentication records](#) provide greater flexibility when using **SSLPEER** and support 1024 bytes on all platforms.

SSLQS

Requests which quantum safe keys share the channel should attempt to be secured with.

NONE

Do not use a quantum safe algorithms for this link.

MLKEM

Attempt to use the ML-KEM quantum safe algorithm to secure this link.

HYBMLKEM

Attempt to use the Hybrid ML-KEM quantum safe algorithm to secure this link.

Note: To select a quantum safe algorithm, it must be enabled by using the [AllowedQuantumSafeAlgorithms](#) configuration option.

When a value other than NONE is specified, the channel will attempt to negotiate a quantum safe key exchange during the TLS handshake. If the channel is unable to negotiate, it will fall back to using traditional TLS key exchanges. To prevent fallback, use the **SSLQSR** setting. For a quantum safe key exchange to be successful, both sides of the channel must support the selected quantum safe algorithm and TLS 1.3 must be enabled and selected by using the [SSLCIPH](#) setting of the channel.

For more information, see [Quantum Safe TLS](#).

SSLQSR

Whether a quantum safe communication is optional or required for a link:

OPTIONAL

Quantum safe communication may be attempted but if unsuccessful, traditional TLS is allowed as a fallback.

REQUIRED

This channel must use quantum safe communications.

Note: To select a **SSLQSR** value of REQUIRED, a quantum safe algorithm must have been selected by using the [SSLQS](#) setting or a quantum safe algorithm must have been enabled by using the [AllowedQuantumSafeAlgorithms](#) configuration option.

For more information see [Quantum Safe TLS](#).

STATCHL

Controls the collection of statistics data for channels:

QMGR

The value of the **STATCHL** parameter of the queue manager is inherited by the channel.

OFF

Statistics data collection is turned off for this channel.

LOW

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a low rate for this channel.

MEDIUM

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a medium rate for this channel.

HIGH

If the value of the **STATCHL** parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

z/OS On z/OS systems, enabling this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results. This parameter must be enabled in order to collect channel accounting records.

For cluster channels, the value of this parameter is not replicated in the repository and therefore is not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the attribute **STATACLS** of the queue manager. This value might then be overridden in the channel auto-definition exit.

Multi **TMPMODEL(string)**

The name of the model queue to be used while creating a temporary queue (maximum length 48 characters).

The default queue is SYSTEM.DEFAULT.MODEL.QUEUE.

Multi **TMPQPRFX(string?)**

The temporary queue name prefix to add to the beginning of the model queue when deriving a temporary queue name (maximum length 48 characters).

The default is AMQP.*.

TPNAME(string)

LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type (**TRPTYPE**) of LU62.

Set this parameter to the SNA transaction program name, unless the **CONNAME** contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set. See [Configuration parameters for an LU 6.2 connection](#).

Windows z/OS On Windows SNA Server, and in the side object on z/OS, the TPNAME is wrapped to uppercase.

This parameter is not valid for channels with a channel type (**CHLTYPE**) of RCVR.

TPROOT

The topic root for an AMQP channel. The default value for **TPROOT** is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other IBM MQ publish/subscribe applications. Alternatively, AMQP clients can publish and subscribe under a different topic prefix, specified in the **TPROOT** attribute.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP.

TRPTYPE

Transport type to be used:

LU62

SNA LU 6.2

NETBIOS

Windows Supported on Windows, and DOS.

► **z/OS** Also used on z/OS for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

SPX

Sequenced packet exchange

► **Windows** Supported on Windows, and DOS.

► **z/OS** Also used on z/OS for defining client-connection channels that connect to servers on the platforms supporting SPX.

TCP

Transmission Control Protocol - part of the TCP/IP protocol suite.

If you do not enter a value for this parameter, the value specified in the `SYSTEM.DEF.channel-type` definition is used. If the channel is initiated from the other end, no check is made that the correct transport type is specified.

► **Multi** On Multiplatforms, if the `SYSTEM.DEF.channel-type` definition does not exist, you must specify a value.

► **z/OS** On z/OS, if the `SYSTEM.DEF.channel-type` definition does not exist, the default is LU62.

► **Multi** **USECLTID**

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the **MCAUSER** attribute value.

NO

The MCA user ID should be used for authorization checks.

YES

The client ID should be used for authorization checks.

USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

NO

Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the **NPMSPEED** setting.

YES

When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

USERID(string)

Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

► **Multi** On Multiplatforms, this parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

► **z/OS** On z/OS, this parameter is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

At the receiving end, if passwords are encrypted and the LU 6.2 software is using a different encryption method, the channel does not start. The error is diagnosed as invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

XMITQ(string)

Transmission queue name.

The name of the queue from which messages are retrieved. See [Rules for naming IBM MQ objects](#).

This parameter is valid only for channels with a channel type (**CHLTYPE**) of SDR or SVR. For these channel types, this parameter is required.

- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (sender channel)

Synonym: DEF CHL

[illegible]

¹ This parameter must follow immediately after the channel name except on z/OS.

- ² Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Not valid on z/OS.
- ⁵ Valid only if TRPTYPE is LU62.
- ⁶ Not valid on IBM i.
- ⁷ Default for z/OS.
- ⁸ Default for Multiplatforms.
- ⁹ Valid only on Windows.

DEFINE CHANNEL (server channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new server channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

```

¹ Not valid on IBM i.

- ² This parameter must follow immediately after the channel name except on z/OS.
- ³ Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
- ⁴ Valid only on z/OS.
- ⁵ Not valid on z/OS.
- ⁶ Valid only if TRPTYPE is LU62.
- ⁷ Default for z/OS.
- ⁸ Default for Multiplatforms.
- ⁹ Valid only on Windows.

DEFINE CHANNEL (client-connection channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new client-connection channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

- [“Syntax diagram for DEFINE CHANNEL \(client-connection channel\)” on page 590](#)
- [“Usage notes for DEFINE CHANNEL” on page 545](#)
- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (client-connection channel)

Synonym: DEF CHL

DEFINE CHANNEL

Notes:

¹ This parameter must follow immediately after the channel name except on z/OS.

- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only if TRPTYPE is LU62.
- ⁵ Not valid on z/OS.
- ⁶ Not valid on IBM i.
- ⁷ Default for z/OS.
- ⁸ Default for Multiplatforms.
- ⁹ Valid only for clients to be run on DOS or Windows.

DEFINE CHANNEL (server-connection channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new server-connection channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

- [“Syntax diagram for DEFINE CHANNEL \(server-connection channel\)” on page 592](#)
- [“Usage notes for DEFINE CHANNEL” on page 545](#)
- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (server-connection channel)

Synonym: DEF CHL

DEFINE CHANNEL

Notes:

¹ This parameter must follow immediately after the channel name except on z/OS.

- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Not valid on z/OS.
- ⁵ Not valid on IBM i.
- ⁶ Default for z/OS.
- ⁷ Default for Multiplatforms.
- ⁸ Valid only for clients to be run on Windows.

DEFINE CHANNEL (cluster-sender channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new cluster-sender channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

- [“Syntax diagram for DEFINE CHANNEL \(cluster-sender channel\)” on page 594](#)
- [“Usage notes for DEFINE CHANNEL” on page 545](#)
- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (cluster-sender channel)

Synonym: DEF CHL

[illegible]

¹ Not valid on z/OS.

- ² This parameter must follow immediately after the channel name except on z/OS.
- ³ Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
- ⁴ Valid only on z/OS.
- ⁵ Valid only if TRPTYPE is LU62.
- ⁶ Not valid on IBM i.
- ⁷ Default for z/OS.
- ⁸ Default for Multiplatforms.
- ⁹ Valid only on Windows.

DEFINE CHANNEL (cluster-receiver channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new cluster-receiver channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

- [“Syntax diagram for DEFINE CHANNEL \(cluster-receiver channel\)” on page 596](#)
- [“Usage notes for DEFINE CHANNEL” on page 545](#)
- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (cluster-receiver channel)

Synonym: DEF CHL

[illegible]

¹ This parameter must follow immediately after the channel name except on z/OS.

- ² This parameter is optional if TRPTYPE is TCP.
- ³ Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.
- ⁴ Valid only on z/OS.
- ⁵ Valid only if TRPTYPE is LU62.
- ⁶ Not valid on z/OS.
- ⁷ Not valid on IBM i.
- ⁸ Default for z/OS.
- ⁹ Default for Multiplatforms.
- ¹⁰ Valid only on Windows.

DEFINE CHANNEL (AMQP channel)

Syntax diagram for the MQSC command **DEFINE CHANNEL** when defining a new AMQP channel and setting its parameters.

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

- [“Syntax diagram for DEFINE CHANNEL \(AMQP channel\)” on page 598](#)
- [“Usage notes for DEFINE CHANNEL” on page 545](#)
- [“Parameter descriptions for DEFINE CHANNEL” on page 545](#)

Syntax diagram for DEFINE CHANNEL (AMQP channel)

Synonym: DEF CHL

DEFINE CHANNEL

►► DEFINE CHANNEL — (— *channel-name* —) — CHLTYPE(AMQP) ►

ALW

DEFINE CHANNEL (define a new channel) for MQTT

Use the MQSC command **DEFINE CHANNEL** to define a new IBM MQ Telemetry channel, and set its parameters.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DEFINE CHANNEL \(MQTT\)” on page 600](#)
- [“Usage notes for DEFINE CHANNEL \(MQTT\)” on page 600](#)
- [“Parameter descriptions for DEFINE CHANNEL \(MQTT\)” on page 600](#)

Syntax diagram for DEFINE CHANNEL (MQTT)

Synonym: DEF CHL

Usage notes for DEFINE CHANNEL (MQTT)

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see [Configuring a queue manager for telemetry on Linux](#) or [Configuring a queue manager for telemetry on Windows](#).

Note: After an MQTT channel is defined, the MQTT service attempts to start it automatically.

Parameter descriptions for DEFINE CHANNEL (MQTT)

(*channel-name*)

The name of the new channel definition.

The name must not be the same as any existing channel defined on this queue manager (unless REPLACE or ALTER is specified).

The maximum length of the string is 20 characters, and the string must contain only valid characters; see [Rules for naming IBM MQ objects](#).

BACKLOG(*integer*)

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

CHLTYPE

Channel type. MQTT (telemetry) channel.

JAASCFG(*string*)

The name of a stanza in the JAAS configuration file.

See [Authenticating an MQTT client Java app with JAAS](#)

LOCLADDR(*ip-addr*)

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. **LOCLADDR** is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of **LOCLADDR** is MQ_LOCAL_ADDRESS_LENGTH.

If you omit **LOCLADDR**, a local address is automatically allocated.

ip-addr

ip-addr is a single network address, specified in one of three forms:

IPv4 dotted decimal

For example 192.0.2.1

IPv6 hexadecimal notation

For example 2001:DB8:0:0:0:0:0:0

Alphanumeric host name form

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

MCAUSER(*string*)

Message channel agent user identifier.

The maximum length of the string is 12 characters. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is not blank, and **USECLNTID** is set to N0, then this user identifier is used by the IBM MQ Telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to N0, then the user name flowed in the MQTT CONNECT Packet is used. See [MQTT client identity and authorization](#).

PORT(*integer*)

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

PROTOCOL

The following communication protocols are supported by the channel:

MQTTV311

The channel accepts connections from clients using the protocol defined by the [MQTT 3.1.1](#) Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

MQTTV3

The channel accepts connections from clients using the [MQTT V3.1 Protocol Specification](#) from [mqtt.org](#).

HTTP

The channel accepts HTTP requests for pages, or WebSockets connections to IBM MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify MQTTV3, HTTP the channel accepts connections from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

If your configuration includes an MQTT channel that was last modified in an earlier version of the product, you must explicitly change the protocol setting to prompt the channel to use the MQTTV311 option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the product have no awareness of the MQTTV311 option. To prompt a channel in this state to use the MQTTV311 option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the MQTTV311 option is still included in the stored list of supported protocols.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client. The initiating end of the channel acts as the TLS client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the TLS server.

NEVER

IBM MQ never requests a certificate from the TLS client.

REQUIRED

IBM MQ requires and validates a certificate from the TLS client.

OPTIONAL

IBM MQ lets the TLS client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

SSLCIPH(string)

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite. The TLS cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the parameter is blank, no attempt is made to use TLS on the channel.

V 10.0.0 For a list of supported **SSLCIPH** values from IBM MQ 10.0.0, see [CipherSuites supported by the MQ Telemetry service from IBM MQ 10.0.0](#).

If you plan to use SHA-2 cipher suites, see [System requirements for using SHA-2 cipher suites with MQTT channels](#).

SSLKEYP(string)

The passphrase for the TLS key repository.

If the MQXR service is configured for encryption of passphrases by specifying the **-sf** option in **STARTARG** for the service, then the pass phrase will be encrypted. For more information on encryption of passphrases, see [Encryption of passphrases for MQTT TLS channels](#).

SSLKEYR(string)

The full path name of the TLS key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, TLS is not used.

The maximum length of the string is 256 characters;

-   On AIX and Linux, the name is of the form *pathname/keyfile*.
-  On Windows, the name is of the form *pathname\keyfile*.

where *keyfile* is specified without the suffix .jks, and identifies a Java keystore file.

TRPTYPE (*string*)

The transmission protocol to be used:

TCP

TCP/IP

USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See [MQTT client identity and authorization](#).

DEFINE COMMINFO (define a new communication information object) on Multiplatforms

Use the MQSC command **DEFINE COMMINFO** to define a new communication information object. These objects contain the definitions required for Multicast messaging.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DEFINE COMMINFO” on page 603](#)
- [“Parameter descriptions for DEFINE COMMINFO” on page 605](#)

Syntax diagram for **DEFINE COMMINFO**

Synonym: DEF COMMINFO

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

DEFINE COMMINFO

Notes:

¹ Default for platforms other than IBM i.

² Default for IBM i.

Parameter descriptions for **DEFINE COMMINFO**

(*comminfo name*)

Name of the communications information object. This is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See [Rules for naming IBM MQ objects](#).

TYPE

The type of the communications information object. The only type supported is MULTICAST.

BRIDGE

Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST (ONLY)**. Because these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast.

 This is the default for IBM i.

ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast. This is the default for platforms other than IBM i.

CCSID(*integer*)

The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The **CCSID** must specify a value that is defined for use on your platform, and use a character set that is appropriate to the platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original **CCSID**. Because of this, you must stop and restart all running applications before you continue. This includes the command server and channel programs. To do this, stop and restart the queue manager after making the change.

The default value is ASPUB which means that the coded character set is taken from the one that is supplied in the published message.

COMMEV

Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events will only be generated if they are enabled using the **MONINT** parameter.

DISABLED

Event messages are not generated for Multicast handles that are created using the COMMINFO object. This is the default value.

ENABLED

Event messages are generated for Multicast handles that are created using the COMMINFO object.

EXCEPTION

Event messages are written if the message reliability is below the reliability threshold. The reliability threshold is set to 90 by default.

DESCR(*string*)

Plain-text comment. It provides descriptive information about the communication information object when an operator issues the **DISPLAY COMMINFO** command (see [“DISPLAY COMMINFO \(display communication information\) on Multiplatforms”](#) on page 816).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

ENCODING

The encoding that the messages are transmitted in.

AS PUB

The encoding of the message is taken from the one that is supplied in the published message. This is the default value.

REVERSED**NORMAL****S390****TNS****encoding****GRPADDR**

The group IP address or DNS name.

It is the administrator's responsibility to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client must examine and process every multicast packet in the network. It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this requires careful management, especially if other non-MQ multicast applications are in use on the network. The default value is 239.0.0.0.

MCHBINT

The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available. The value is in the range 0 to 999 999. The default value is 2000 milliseconds.

MCPROP

The multicast properties control how many of the MQMD properties and user properties flow with the message.

All

All user properties and all the fields of the MQMD are transported.

Reply

Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

User

Only the user properties are transmitted.

NONE

No user properties or MQMD fields are transmitted.

COMPAT

This value causes the transmission of the message to be done in a compatible mode to RMM. This allows some inter-operation with the current XMS applications and Broker RMM applications.

 **Removed** XMS .NET Multicast messaging (using RMM) was deprecated from IBM MQ 9.2 and removed at IBM MQ 9.3.

MONINT(integer)

How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this **COMMINFO** object.

A value of 0 means that there is no monitoring.

The default value is 60.

MSGHIST

This value is the amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

The value is in the range 0 to 999 999 999. A value of 0 gives the least level of reliability. The default value is 100.

NSUBHIST

The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

NONE

A value of NONE causes the transmitter to transmit only publication made from the time of the subscription. This is the default value.

ALL

A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances this can give a similar behavior to retained publications.

Note: Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is re-transmitted.

PORT(integer)

The port number to transmit on. The default port number is 1414.

LIKE(*authinfo-name*)

The name of a communication information object, with parameters that are used to model this definition.

If this field is not complete, and you do not complete the parameter fields related to the command, the values are taken from the default definition for an object of this type.

This default communication information object definition can be altered by the installation to the default values required.

REPLACE and NOREPLACE

Whether the existing definition is to be replaced with this one. This is optional. The default is **NOREPLACE**. Any object with a different disposition is not changed.

REPLACE

The definition replaces an existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition does not replace an existing definition of the same name.

Multi **DEFINE LISTENER (define a new listener) on Multiplatforms**

Use the MQSC command **DEFINE LISTENER** to define a new IBM MQ listener definition, and set its parameters.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- “Syntax diagram for **DEFINE LISTENER**” on page 608
- “Parameter descriptions for **DEFINE LISTENER**” on page 609

Syntax diagram for **DEFINE LISTENER**

Synonym: DEF LSTR

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

SPX attrrs

TCP attrrs

Define attrrs

Notes:

¹ Valid only on Windows.

² When the BACKLOG attribute is left unchanged or when it is explicitly set to zero, the attribute is stored as zero by default in the listener object created by the **DEFINE LISTENER** command. However, when the listener is started, the default backlog value takes effect. For information about the default value of the BACKLOG attribute, see [Using the TCP listener backlog option](#).

Parameter descriptions for DEFINE LISTENER

(*listener-name*)

Name of the IBM MQ listener definition (see [Rules for naming IBM MQ objects](#)). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

Windows ADAPTER(*integer*)

The adapter number on which NetBIOS listens. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

BACKLOG(*integer*)

The number of concurrent connection requests that the listener supports.

Windows COMMANDS(*integer*)

The number of commands that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

CONTROL(*string*)

Specifies how the listener is to be started and stopped.:

MANUAL

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(string)

Plain-text comment. It provides descriptive information about the listener when an operator issues the **DISPLAY LISTENER** command (see [“DISPLAY LISTENER \(display listener information\) on Multiplatforms”](#) on page 836).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

IPADDR(string)

IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

LIKE(listener-name)

The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the **DEFINE LISTENER** command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.LISTENER)
```

A default listener is provided but it can be altered by the installation of the default values required. See [Rules for naming IBM MQ objects](#).

Windows LOCLNAME(string)

The NetBIOS local name that the listener uses. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

Windows NTBNAMES(integer)

The number of names that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

PORT(integer)

The port number for TCP/IP. This is valid only when **TRPTYPE** is TCP. It must not exceed 65535.

Windows SESSIONS(integer)

The number of sessions that the listener can use. This parameter is valid only on Windows when **TRPTYPE** is NETBIOS.

SOCKET(integer)

The SPX socket on which to listen. This is valid only if **TRPTYPE** is SPX.

Windows TPNAME(string)

The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when **TRPTYPE** is LU62.

TRPTYPE(string)

The transmission protocol to be used:

Windows LU62

SNA LU 6.2. This is valid only on Windows.

Windows **NETBIOS**

NetBIOS. This is valid only on Windows.

Windows **SPX**

Sequenced packet exchange. This is valid only on Windows.

TCP

TCP/IP.

[“DISPLAY LSSTATUS \(display listener status\) on Multiplatforms” on page 841](#)

Use the MQSC command **DISPLAY LSSTATUS** to display status information for one or more listeners.

[“START LISTENER \(start a channel listener\)” on page 1068](#)

Use the MQSC command **START LISTENER** to start a channel listener.

[“STOP LISTENER \(stop a channel listener\)” on page 1092](#)

Use the MQSC command **STOP LISTENER** to stop a channel listener.

z/OS **DEFINE LOG (define a new active log) on z/OS**

Use the MQSC command **DEFINE LOG** to add a new active log data set in the ring of active logs.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

The named data set is dynamically allocated to the running queue manager, added to either the COPY1 or COPY2 active log and the BSDS updated with the information so it is retained over a queue manager restart. The data set is added to the active log ring in a position such that it will be switched to after the last-added active log fills.

- [“Syntax diagram for DEFINE LOG” on page 611](#)
- [“Usage note for DEFINE LOG” on page 612](#)
- [“Parameter descriptions for DEFINE LOG” on page 612](#)

Syntax diagram for **DEFINE LOG**

Synonym: DEF LOG

$\Rightarrow$ DEFINE LOG $\rightarrow$ ($\rightarrow$ *name* $\rightarrow$) $\rightarrow$ COPY $\rightarrow$ ($\underbrace{\quad\quad\quad}_2$ 1 $\underbrace{\quad\quad\quad}_2$) $\rightarrow$

¹ Valid only when the queue manager is a member of a queue sharing group.

If a log data set has to be added because there is no more log space and the queue manager is waiting, you must issue the command from the z/OS console, and not through the command server.

(name)

The maximum length of the string is 44 characters. The string must conform to z/OS data set naming conventions.

Specifies the number of an active log ring to which to add the new log data set. This is either 1 or 2 and is required.

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

The command runs on the queue manager on which it was entered. This is the default value.

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

“DISPLAY LOG (display log information) on z/OS” on page 840

“SET LOG (change log system settings) on z/OS” on page 1051

On z/OS, use the MQSC command **SET LOG** to dynamically change certain log system parameter values that were initially set by your system parameter module at queue manager startup.

z/OS **DEFINE MAXSMGS (define maximum messages setting) on z/OS**

Use the MQSC command **DEFINE MAXSMGS** to define the maximum number of messages that a task can get or put within a single unit of recovery.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE MAXSMGS” on page 613](#)
- [“Usage notes for DEFINE MAXSMGS” on page 613](#)
- [“Parameter descriptions for DEFINE MAXSMGS” on page 613](#)

Syntax diagram for DEFINE MAXSMGS

Synonym: DEF MAXSM

Usage notes for DEFINE MAXSMGS

1. This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization input data set. You should use the **MAXUMSGS** parameter of the **ALTER QMGR** command instead.
2. You can issue the **DEFINE MAXSMGS** command to change the number of messages allowed. After a value is set, it is preserved during a queue manager restart.

Parameter descriptions for DEFINE MAXSMGS

(*integer*)

The maximum number of messages that a task can get or put within a single unit of recovery. This value must be an integer in the range 1 through 999999999. The default value is 10000.

The number includes any trigger messages and report messages generated within the same unit of recovery.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Related reference

“DISPLAY MAXSMGS (display maximum messages setting) on z/OS” on page 845

Use the MQSC command **DISPLAY MAXSMGS** to see the maximum number of messages that a task can get or put within a single unit of recovery.

DEFINE NAMELIST (define a list of names)

Use the MQSC command **DEFINE NAMELIST** to define a list of names. This is most commonly a list of cluster names or queue names.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE NAMELIST” on page 614](#)
- [“Usage notes for DEFINE NAMELIST” on page 615](#)
- [“Parameter descriptions for DEFINE NAMELIST” on page 615](#)

Syntax diagram for DEFINE NAMELIST

Synonym: DEF NL

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Usage notes for DEFINE NAMESPACE

Successful completion of the command does not mean that the action completed. To check for true completion, see the [DEFINE NAMESPACE](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for DEFINE NAMESPACE

(*name*)

Name of the list.

The name must not be the same as any other namespace name currently defined on this queue manager (unless REPLACE or ALTER is specified). See [Rules for naming IBM MQ objects](#).

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of specifying * is the same as entering the command on every queue manager in the queue sharing group.

DESCR(string)

Plain-text comment. It provides descriptive information about the namelist when an operator issues the **DISPLAY NAMELIST** command (see [“DISPLAY NAMELIST \(display a list of names\)”](#) on page 846).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(namelist-name)

The name of a namelist, with parameters that are used to model this definition.

If this field is not completed and you do not complete the parameter fields related to the command, the values are taken from the default definition for name lists on this queue manager.

Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.NAMELIST)
```

A default namelist definition is provided, but it can be altered by the installation to the default values required. See [Rules for naming IBM MQ objects](#).

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP** (GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

NAMES(name, ...)

List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify **NAMES ()**. The maximum number of names in the list is 256.

NLTYPE

Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

NONE

The names are of no particular type.

QUEUE or Q

A namelist that holds a list of queue names.

CLUSTER

A namelist that is associated with clustering, containing a list of the cluster names.

AUTHINFO

This namelist is associated with TLS and contains a list of authentication information object names.

Namelists used for clustering must have **NLTYPE**(CLUSTER) or **NLTYPE**(NONE).

Namelists used for TLS must have **NLTYPE**(AUTHINFO).

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 187. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE NAMELIST(<i>namelist_name</i>) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for a NAMELIST definition called <i>namelist_name</i>. If a matching NAMELIST definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE NAMELIST(<i>namelist_name</i>) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition does not replace any existing definition of the same name.

DEFINE PROCESS (create a new process definition)

Use the MQSC command **DEFINE PROCESS** to define a new IBM MQ process definition, and set its parameters.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE PROCESS” on page 618](#)
- [“Parameter descriptions for DEFINE PROCESS” on page 619](#)

Syntax diagram for DEFINE PROCESS

Synonym: DEF PRO

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Parameter descriptions for **DEFINE PROCESS**

(process-name)

Name of the IBM MQ process definition (see [Rules for naming IBM MQ objects](#)). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless REPLACE is specified).

APPLICID(string)

The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS application the name is a CICS transaction ID.

z/OS For an IMS application, it is an IMS transaction ID.

z/OS On z/OS, for distributed queuing, it must be **CSQX START**.

APPLTYPE(string)

The type of application to start. The possible values are:

integer

A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

CICS

Represents a CICS transaction.

IMS

Represents an IMS transaction.

MVS

Represents a z/OS application (batch or TSO).

OS400

Represents an IBM i application.

UNIX

Represents a Linux or AIX application.

WINDOWS

Represents a Windows application.

WLM

Represents a z/OS workload manager application.

DEF

Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command is run:

-  On z/OS, CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported.
-  On IBM i, OS400, CICS, and DEF are supported.
-   On AIX and Linux, UNIX, WINDOWS, CICS, and DEF are supported.
-  On Windows, WINDOWS, UNIX, CICS, and DEF are supported.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

DESCR(string)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY PROCESS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

ENVRDATA(*string*)

A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of **ENVRDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends **ENVRDATA** to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

Notes:

1.  On z/OS, **ENVRDATA** is not used by the trigger-monitor applications provided by IBM MQ.
2.  On z/OS, if **APPLTYPE** is WLM, the default values for the ServiceName and ServiceStep fields in the work information header (MQWIH) can be supplied in **ENVRDATA**. The format must be:

```
SERVICENAME=servname,SERVICESTEP=stepname
```

where:

SERVICENAME=

is the first 12 characters of **ENVRDATA**.

servname

is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

SERVICESTEP=

is the next 13 characters of **ENVRDATA**.

stepname

is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

If the format is incorrect, the fields in the MQWIH are set to blanks.

3. On AIX and Linux, **ENVRDATA** can be set to the ampersand character to make the started application run in the background.

LIKE(*process-name*)

The name of an object of the same type, with parameters that are used to model this definition.

If this field is not provided, the values of fields you do not provide are taken from the default definition for this object.

Using **LIKE** is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.PROCESS)
```

A default definition for each object type is provided. You can alter the provided defaults to the default values required. See [Rules for naming IBM MQ objects](#).

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

Table 188. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE PROCESS(<i>process_name</i>) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for a PROCESS definition called <i>process_name</i>. If a matching PROCESS definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE PROCESS(<i>process_name</i>) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition  (and on z/OS, with the same disposition) is to be replaced with this one. **REPLACE** is optional. Any object with a different disposition is not changed.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition does not replace any existing definition of the same name.

USERDATA(*string*)

A character string that contains user information pertaining to the application defined in the **APPLICID** that is to be started. The maximum length is 128 characters.

The meaning of **USERDATA** is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes **USERDATA** to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing **USERDATA**), followed by one blank, followed by **ENVRDATA** with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See [Managing objects for triggering](#) for information about what **APPLICID** to provide to message channel agents.

Windows For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

- [“Parameter descriptions for DEFINE PSID” on page 624](#)

Syntax diagram for DEFINE PSID

Synonym: DEF PSID

Usage notes for DEFINE PSID

The command can be used in two ways:

1. **At restart, from the CSQINP1 initialization input data set, to specify your standard page sets:**
 - You cannot specify the DSN keyword if issuing the command from CSQINP1.
 - If more than one **DEFINE PSID** command is issued for the same page set, only the last one is processed.

2. While the queue manager is running, to dynamically add a page set:

- The command must specify the DSN keyword and can be issued from either of the following:
 - The z/OS console.
 - The command server and command queue by means of CSQUTIL, CSQINPX, or applications.
- The page set identifier (that is the PSID number) may have previously been used by a queue manager. It should therefore be freshly formatted by a FORMAT(RECOVER) statement in CSQUTIL, or formatted by with a FORMAT(REPLACE) in CSQUTIL.
- You cannot dynamically add page set zero.
- The **BUFFPOOL** parameter can specify a currently unused buffer pool. If the buffer pool was defined in CSQINP1 but not used by any PSID, then the number of buffers specified there is created if the required virtual storage is available. If this is not available, or if the buffer pool was not defined in CSQINP1, the queue manager attempts to allocate 1000 buffers. If this is not possible, 100 buffers are allocated.
- You should update your queue manager started task procedure JCL and your CSQINP1 initialization input data set to include the new page set.

One of the messages [CSQP042I](#) or [CSQP041E](#) is output when the command is complete.

You must use the ALTER PSID command to dynamically change the expansion method. For example, to change the **EXPAND** parameter from USER to SYSTEM, issue the following command:

```
ALTER PSID(page set id) EXPAND(SYSTEM)
```

You can use the **DISPLAY USAGE TYPE(PAGESET)** command to display information about page sets (see [“DISPLAY USAGE \(display usage information\) on z/OS”](#) on page 981).

Parameter descriptions for DEFINE PSID

(psid-number)

Identifier of the page set. This is required.

A one-to-one relationship exists between page sets and the VSAM data sets used to store the pages. The identifier consists of a number in the range 00 through 99. It is used to generate a *ddname*, which references the VSAM LDS data set, in the range CSQP0000 through CSQP0099.

The identifier must not be the same as any other page set identifier currently defined on this queue manager.

BUFFPOOL(integer)

The buffer pool number is in the range zero through 99. This is optional. The default is zero.

If the buffer pool has not already been created by a **DEFINE BUFFPOOL** command, the buffer pool is created with 1000 buffers, and a **LOCATION** value of BELOW.

If the *psid-number* is zero, the buffer pool number must be in the range 0 to 15, otherwise the command fails, and the queue manager does not start.

The changes made using the **ALTER PSID** command are recovered from checkpoint records after the **DEFINE PSID** command is processed in CSQINP1.

DSN(data set name)

The name of a cataloged VSAM LDS data set. This is optional. There is no default.

EXPAND

Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in a page set.

USER

The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or it was specified as zero, no dynamic page set expansion can take place if page set data set is non-striped.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It can be rounded up depending on the characteristics of the DASD.

NONE

No further page set expansion is to take place.

Related reference

[“ALTER PSID \(change page set expansion method\) on z/OS” on page 414](#)

Use the MQSC command **ALTER PSID** to change the expansion method for a page set.

[“DEFINE PSID \(define page set and buffer pool\) on z/OS” on page 623](#)

Use the MQSC command **DEFINE PSID** to define a page set and associated buffer pool.

[“DELETE PSID \(delete a page set\) on z/OS” on page 705](#)

Use the MQSC command **DELETE PSID** to delete a page set. This command closes the page set and de-allocates it from the queue manager.

[“DISPLAY USAGE \(display usage information\) on z/OS” on page 981](#)

Use the MQSC command **DISPLAY USAGE** to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.

DEFINE queues

Use the MQSC **DEFINE** command to define a local, model, or remote queue, or a queue alias, reply-to queue alias, or a queue manager alias.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagrams for DEFINE queues” on page 625](#)
- [“Usage notes for DEFINE queues” on page 625](#)
- [“Parameter descriptions for DEFINE queues” on page 626](#)

Syntax diagrams for DEFINE queues

There is a separate syntax diagram for each type of queue:

- [Syntax diagram for DEFINE QALIAS](#)
- [Syntax diagram for DEFINE QLOCAL](#)
- [Syntax diagram for DEFINE QMODEL](#)
- [Syntax diagram for DEFINE QREMOTE](#)

Usage notes for DEFINE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DEFINE queues](#) step in [Checking that async commands for distributed networks have finished](#).
- For local queues

1.  You can define a local queue with QSGDISP (SHARED) even though another queue manager in the queue sharing group already has a local version of the queue. However, when you try

to access the locally defined queue, it fails with reason code MQRC_OBJECT_NOT_UNIQUE (2343). A local version of the queue with the same name can be of type QLOCAL, QREMOTE, or QALIAS and has the disposition, QSGDISP(QMGR).

To resolve the conflict, you must delete one of the queues using the **DELETE** command. If the queue you want to delete contains messages, use the PURGE option or remove the messages first using the **MOVE** command.

For example, to delete the QSGDISP (LOCAL) version, which contains messages, and copy those messages to the QSGDISP (SHARED) version, then issue the following commands:

```
MOVE QLOCAL(Queue.1) QSGDISP(PRIVATE) TOQLOCAL(Queue.1) TYPE(ADD)
DELETE QLOCAL(Queue.1) QSGDISP(QMGR)
```

- For alias queues:
 1. DEFINE QALIAS(*aliasqueue*) TARGET(*otherqname*) CLUSTER(*c*) advertises the queue *otherqname* by the name *aliasqueue*.
 2. DEFINE QALIAS(*aliasqueue*) TARGET(*otherqname*) allows a queue advertised by the name *otherqname* to be used on this queue manager by the name *aliasqueue*.
 3. TARGTYPE and TARGET are not cluster attributes, that is, they are not shared in a cluster environment.
- For remote queues:
 1. DEFINE QREMOTE(*rqueue*) RNAME(*otherq*) RQMNAME(*otherqm*) CLUSTER(*cl*) advertises this queue manager as a store and forward gateway to which messages for queue *rqueue* can be sent. It has no effect as a reply-to queue alias, except on the local queue manager.
 DEFINE QREMOTE(*otherqm*) RNAME() RQMNAME(*anotherqm*) XMITQ(*xq*) CLUSTER advertises this queue manager as a store and forward gateway to which messages for *anotherqm* can be sent.
 2. RQMNAME can itself be the name of a cluster queue manager within the cluster. You can map the advertised queue manager name to another name locally. The pattern is the same as with QALIAS definitions.
 3. It is possible for the values of RQMNAME and QREMOTE to be the same if RQMNAME is itself a cluster queue manager. If this definition is also advertised using a CLUSTER attribute, do not choose the local queue manager in the cluster workload exit. If you do so, a cyclic definition results.
 4. Remote queues do not have to be defined locally. The advantage of doing so is that applications can refer to the queue by a simple, locally defined name. If you do then the queue name is qualified by the name of the queue manager on which the queue resides. Using a local definition means that applications do not need to be aware of the real location of the queue.
 5. A remote queue definition can also be used as a mechanism for holding a queue manager alias definition, or a reply-to queue alias definition. The name of the definition in these cases is:
 - The queue manager name being used as the alias for another queue manager name (queue manager alias), or
 - The queue name being used as the alias for the reply-to queue (reply-to queue alias).
 6. Define a reply-to queue or queue manager alias with the [“DEFINE QREMOTE \(define a new local remote queue definition\)”](#) on page 660 command.

Parameter descriptions for DEFINE queues

Table 189 on page 627 shows the parameters that are relevant for each type of queue. There is a description of each parameter after the table.

queue-name

Local name of the queue, except the remote queue where it is the local definition of the remote queue.

See [Rules for naming IBM MQ objects](#).

ACCTQ

Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). For the accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONN call.

QMGR

The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

ON

Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE.

► **z/OS** On z/OS systems, you must enable class 3 accounting by using the **START TRACE** command.

OFF

Accounting data collection is disabled for the queue.

BOQNAME (*queue-name*)

The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** parameter.

BOTHRESH(*integer*)

The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times to allow a message to be backed out. When the value is exceeded, the message is transferred to the queue named by the **BOQNAME** parameter.

Specify a value in the range 0 - 999,999,999.

CAEXPRY(*integer*)

The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

Important: ► **z/OS** You cannot specify an integer value for the **CAEXPRY** attribute on a queue object with **QSGDISP**(SHARED|GROUP|COPY), which resides in a queue sharing group that contains queue managers running any version of IBM MQ for z/OS below 9.4.0. Attempting to do so results in CSQM532I and CSQM533I messages to identify which queue managers do not support **CAEXPRY**, and no modification to the object.

For more information on message expiry processing, see [CAEXPRY: Limit message expiry time](#).

integer

The value must be in the range one through to 999 999 999.

NOLIMIT

There is no limit on the expiry time of messages put using this object. This is the default value.

If you set **CAEXPRY** to NOLIMIT, you can set the **CUSTOM** CAEXPRY attribute as well.

Note that existing messages in the queue, prior to a change in **CAEXPRY**, are not affected by the change (that is, their expiry time remains unchanged). Only new messages that are put into the queue after the change in **CAEXPRY** have the new expiry time.

► **z/OS** **CFSTRUCT**(*structure-name*)

Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue sharing group (in this case NY03CSQ_ADMIN) cannot be used for storing messages.

For **ALTER QLOCAL**, **ALTER QMODEL**, **DEFINE QLOCAL** with **REPLACE**, and **DEFINE QMODEL** with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP**(SHARED), **CFSTRUCT** cannot change.
- If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For **DEFINE QLOCAL** with **NOREPLACE** and **DEFINE QMODEL** with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP**(SHARED) or a model queue with a **DEFTYPE**(SHAREDYN), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

Note: Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

CLCHNAME(channel name)

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute **CLCHNAME** attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the **CLCHNAME** attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either `SYSTEM.CLUSTER.TRANSMIT.ChannelName` or `SYSTEM.CLUSTER.TRANSMIT.QUEUE`, depending on the value of the queue manager **DEFCLXQ** attribute.

By specifying asterisks, `"*"`, in **CLCHNAME**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **CLCHNAME** is limited to a length of 48 characters, `MQ_OBJECT_NAME_LENGTH`. A channel name is limited to 20 characters: `MQ_CHANNEL_NAME_LENGTH`. If you specify an asterisk you must also set the **SHARE** attribute so that multiple channels can concurrently access the transmission queue.

 If you specify a "*" in **CLCHNAME**, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks, you receive the message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. The default configuration can be modified by changing the queue manager attribute, **DEFCLXQ**. The default value of the attribute is `SCTQ`. You can change the value to `CHANNEL`. If you set the **DEFCLXQ** attribute to `CHANNEL`, each cluster-sender channel defaults to using a specific cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.ChannelName`.

▶ **z/OS** On z/OS, if this parameter is set, the queue:

- Must be shareable by specifying the queue attribute SHARE.
- Must be indexed on the correlation ID by specifying **INDXTYPE(CORRELID)**.
- Must not be a dynamic or a shared queue.

▶ **z/OS** ▶ **ALW** **CLUSNL(namelist name)**

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- ▶ **z/OS** On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

▶ **z/OS** ▶ **ALW** **CLUSTER(cluster name)**

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be non-blank; you cannot specify a value for both.

On local queues, this parameter cannot be set for the following queues:

- Transmission queues
- SYSTEM.CHANNEL.*xx* queues
- SYSTEM.CLUSTER.*xx* queues
- SYSTEM.COMMAND.*xx* queues
- ▶ **z/OS** On z/OS only, SYSTEM.QSG.*xx* queues

This parameter is valid only on the following platforms:

- AIX, Linux, and Windows
- z/OS

CLWLPRTY(integer)

Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see [CLWLPRTY queue attribute](#).

CLWLRRANK(integer)

Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where

zero is the lowest rank and 9 is the highest. For more information about this attribute, see [CLWLRANK queue attribute](#).

CLWLUSEQ

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

QMGR

The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

ANY

The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

LOCAL

The local queue is the only target of the MQPUT operation.

CMDSCOPE

This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

..

The command runs on the queue manager on which it was entered.

QmgrName

The command runs on the queue manager that you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of ★ is the same as entering the command on every queue manager in the queue sharing group.

CUSTOM(string)

This attribute contains the values of attributes, as pairs of name and value, which are separated by at least one space.

The attribute name-value pairs have the form NAME (VALUE). Attribute names beginning with **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPY**, **SQGETTMR**, and **PAGEVAL**. As an administrator, you can set and use other names for your own purposes.

The maximum length is defined by the IBM MQ constant **MQ_CUSTOM_LENGTH** and is set to 128 on all platforms.

The **CUSTOM** value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. The property names and values are case-sensitive, and must be specified in uppercase. The values can contain spaces, parentheses, and single quotation marks (which must be enclosed by another single-quote). Other characters, including nested parentheses (), can be included by enclosing them in two single quotation marks on either side. Examples of valid syntax are:

- CUSTOM(' ')
- CUSTOM('A(B)')
- CUSTOM('C(D) E(F)')
- CUSTOM('G(5000) H(''9.20.4.6(1415)''')')

The last syntax uses pairs of single quotation marks, not double quotation marks.

Note:  From IBM MQ 9.4.0, the **CAEXPRY** queue attribute replaces the use of the **CAEXPRY** option in the **CUSTOM** field. You cannot set the **CAEXPRY** queue attribute if the **CUSTOM** attribute has the **CAEXPRY** option defined in it already. You should alter existing queues to set the **CAEXPRY** queue attribute and unset the **CAEXPRY** option from the **CUSTOM** attribute. For example:

```
ALTER QL(Q1) CAEXPRY(1000) CAEXPRY('')
```

For more information about the permitted values, see [CAEXPRY](#).

DEFBIND

Specifies the binding to be used when the application specifies MQ00_BIND_AS_Q_DEF on the MQOPEN call, and the queue is a cluster queue.

OPEN

The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

NOTFIXED

The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

GROUP

Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQ00_BIND_ON_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQ00_BIND_NOT_FIXED. It can allow an application to request that a group of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid on all platforms.

DEFPRESP

Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO_RESPONSE_AS_Q_DEF.

SYNC

Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE is specified instead.

ASYN

Put operations to the queue specifying MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_ASYNC_RESPONSE is specified instead; see [MQPMO options \(MQLONG\)](#).

DEFPRTY(*integer*)

The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

DEFPSIST

Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_Q_DEF option.

NO

Messages on this queue are lost across a restart of the queue manager.

YES

Messages on this queue survive a restart of the queue manager.

 On z/OS, N and Y are accepted as synonyms of NO and YES.

DEFREADA

Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

NO

Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

YES

Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

DISABLED

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

DEFSOPT

The default share option for applications opening this queue for input:

EXCL

The open request is for exclusive input from the queue.

► **z/OS** On z/OS, EXCL is the default value.

SHARED

The open request is for shared input from the queue.

► **Multi** On Multiplatforms, SHARED is the default value.

DEFTYPE

Queue definition type.

This parameter is supported only on model queues.

PERMDYN

A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor (MQOD).

► **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

z/OS SHAREDYN

This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

The dynamic queue has a disposition of SHARED.

TEMPDYN

A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor (MQOD).

► **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

► **z/OS** Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

► **z/OS** If you specify this option, do not specify **INDXTYPE**(MSGTOKEN).

DESCR(string)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY QUEUE** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

ALW **DISTL**

Sets whether distribution lists are supported by the partner queue manager.

YES

Distribution lists are supported by the partner queue manager.

NO

Distribution lists are not supported by the partner queue manager.

Note: You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, Linux, and Windows.

FORCE

This parameter applies only to the **ALTER** command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following statements are true:

- The **TARGET** parameter specifies a queue
- An application has this alias queue open

For a local queue, if both of the following statements are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

FORCE is also needed if both of the following statements are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following statements are true:

- The **XMITQ** parameter is changed
- One or more applications has this queue open as a remote queue

FORCE is also needed if both of the following statements are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

Note: **FORCE** is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

When you use the **ALTER QLOCAL** command with the **FORCE** parameter, IBM MQ force allows the changes with open handles on the queue. However, these existing open handles become invalid for some attributes and the next operation on these open handles will return the error message:

MQRC_OBJECT_CHANGED (2041)

Any of the following operations will fail with the error MQRC 2041:

- MQPUT
- MQGET
- MQINQ

- MQSET
- MQCTL
- MQCB

You can fix the applications that receive the error MQRC_OBJECT_CHANGED by the following steps:

1. Close the handle ([MQCLOSE](#))
2. Reopen the object ([MQOPEN](#)) to select the new queue definition

GET

Specifies whether applications are to be permitted to get messages from this queue:

ENABLED

Messages can be retrieved from the queue, by suitably authorized applications.

DISABLED

Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

HARDENBO and NOHARDENBO

Specifies whether the count of the number of times that a message was backed out is hardened.

When the count is hardened, the value of the **BackoutCount** field of the message descriptor is written to the log before the message is returned by an MQGET operation. Writing the value to the log ensures that the value is accurate across restarts of the queue manger.

This parameter is supported only on local and model queues.

When the backout count is hardened, the performance of MQGET operations for persistent messages on this queue is impacted.

HARDENBO

The message backout count for messages on this queue is hardened to ensure that the count is accurate.

NOHARDENBO

The message backout count for messages on this queue is not hardened and might not be accurate over queue manager restarts.

Note:  This parameter affects only z/OS. You can set this parameter on Multiplatforms but it is ineffective.

IMGRCOVQ

Specifies whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used. Possible values are:

YES

These queue objects are recoverable.

NO

The “[rcdmqimg \(record media image\)](#)” on page 160 and “[rcrmqobj \(re-create object\)](#)” on page 163 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR

If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies YES, these queue objects are recoverable.

If you specify QMGR, and the **IMGRCOVQ** attribute for the queue manager specifies NO, the “[rcdmqimg \(record media image\)](#)” on page 160 and “[rcrmqobj \(re-create object\)](#)” on page 163 commands are not permitted for these objects, and automatic media images, if enabled, are not written for these objects.

QMGR is the default value.

This parameter is not valid on z/OS.

z/OS INDXTYPE

The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on z/OS.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

Table 190. Index type required for different retrieval selection criteria		
Retrieval selection criterion	Index type required	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

NONE

No index is maintained. Use NONE when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the MQGET call.

MSGID

An index of message identifiers is maintained. Use MSGID when messages are typically retrieved using the message identifier as a selection criterion on the MQGET call with the correlation identifier set to NULL.

CORRELID

An index of correlation identifiers is maintained. Use CORRELID when messages are typically retrieved using the correlation identifier as a selection criterion on the MQGET call with the message identifier set to NULL.

GROUPID

An index of group identifiers is maintained. Use GROUPID when messages are retrieved using message grouping selection criteria.

Note:

1. You cannot set **INDXTYPE** to GROUPID if the queue is a transmission queue.
2. The queue must use a CF structure at CFLEVEL (3), to specify a shared queue with **INDXTYPE(GROUPID)**.

z/OS MSGTOKEN

An index of message tokens is maintained. Use MSGTOKEN when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

Note: You cannot set **INDXTYPE** to MSGTOKEN if:

- The queue is a model queue with a definition type of SHAREDYN
- The queue is a temporary dynamic queue
- The queue is a transmission queue

- You specify **QSGDISP**(SHARED)

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Queue type		NON-SHARED			SHARED	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change INDXTYPE from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPLD	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-
MSGID	GROUPLD	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPLD	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPLD	No	No	Yes	-	-
GROUPLD	NONE	No	No	Yes	No	Yes
GROUPLD	MSGID	No	No	Yes	No	Yes
GROUPLD	CORRELID	No	No	Yes	No	Yes
GROUPLD	MSGTOKEN	No	No	Yes	-	-

On a private queue, maintaining an index when the queue contains a large number of messages can use significant 64 bit storage. See [Indexed queues](#) for more information.

INITQ(string)

The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written. See [Rules for naming IBM MQ objects](#).

This parameter is supported only on local and model queues.

LIKE(*qtype-name*)

The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Table 192. Queue types and their corresponding definitions	
Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE (SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

z/OS On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

z/OS ALW MAXDEPTH(*integer*)

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On the following platforms, specify a value in the range zero through 999999999:

- **ALW** AIX, Linux, and Windows
- **z/OS** z/OS

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

Multi MAXFSIZE

The maximum size, in megabytes, that a queue file can grow to. It is possible for a queue file to exceed this size if you have configured the value to be lower than the current queue file size.

If that happens the queue file no longer accepts new messages, but allows existing messages to be consumed. When the queue file size has dropped below the configured value, new messages can be put to the queue.

Note: This figure can differ from the value of the attribute configured on the queue, because internally the queue manager might need to use a larger block size to reach the chosen size. See [Modifying IBM MQ queue files](#) for more information on changing the size of queue files and block size and granularity.

When the granularity needs changing because this attribute has been increased, warning message AMQ7493W Granularity changed is written to the AMQERR logs. This gives you an indication that you need to plan for the queue to be emptied, in order for IBM MQ to adopt the new granularity.

Specify a value greater than or equal to 20, and less than or equal to 267,386,880.

The default value for this attribute is *DEFAULT*, which equates to a hard-coded value of 2,088,960 MB, the maximum for a queue in versions of IBM MQ prior to IBM MQ 9.1.5.

MAXMSGL(integer)

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

ALW On AIX, Linux, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, [ALTER QMGR MAXMSGL](#).

z/OS On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, [Advanced Message Security](#) increases the length of the message.

MONQ

Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

QMGR

Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

OFF

Online monitoring data collection is turned off for this queue.

LOW

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

MEDIUM

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

HIGH

If the value of the **MONQ** parameter of the queue manager is not NONE, online monitoring data collection is turned on for this queue.

There is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

MSGDLVSQ

Message delivery sequence.

This parameter is supported only on local and model queues.

PRIORITY

Messages are delivered (in response to MQGET API calls) in first-in-first-out (FIFO) order within priority.

FIFO

Messages are delivered (in response to MQGET API calls) in FIFO order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from PRIORITY to FIFO while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from FIFO to PRIORITY, the messages put on the queue while the queue was set to FIFO take the default priority.

Note:  If **INDXTYPE**(GROUPID) is specified with **MSGDLVSQ**(PRIORITY), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

NPMCLASS

The level of reliability to be assigned to non-persistent messages that are put to the queue:

NORMAL

Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

HIGH

The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

 You cannot set this parameter on z/OS.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**, or from the message to the environment on **MQGET**.  For IMS bridge queues, also controls whether the IMS bridge automatically propagates trace context from the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation.

If the queue manager is in a queue sharing group, and the queue has a **QSGDISP** of SHARED, COPY or GROUP, this value can only be set if all queue managers have been started at IBM MQ 9.4.3 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are sent to or consumed from this queue.  For IMS bridge queues, also controls whether the IMS bridge emits spans when it sends the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PROCESS(string)

The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see [Rules for naming IBM MQ objects](#).

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on the following platforms:

-  IBM i
-  ALW AIX, Linux, and Windows
-  z/OS

If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

PROPTL

Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

Note: If your application is opening an alias queue you must set this value on both the alias and target queues.

PROPTL options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

COMPAT

Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of `mc`, `jms`, `usr`, or `mqext`, all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

FORCE

Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the `MQGMO` structure on the `MQGET` call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

NONE

If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

PUT

Specifies whether messages can be put on the queue.

ENABLED

Messages can be added to the queue (by suitably authorized applications).

DISABLED

Messages cannot be added to the queue.

This parameter can also be changed using the `MQSET` API call.

QDEPTHHI(integer)

The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.

 For more information about the effect that shared queues on z/OS have on this event; see [Shared queues and queue depth events on z/OS](#).

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

QDEPTHLO(integer)

The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.

 For more information about the effect that shared queues on z/OS have on this event; see [Shared queues and queue depth events on z/OS](#).

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth (**MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

QDPHIEV

Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

ENABLED

Queue Depth High events are generated.

DISABLED

Queue Depth High events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Depth High](#).

QDPLOEV

Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

ENABLED

Queue Depth Low events are generated.

DISABLED

Queue Depth Low events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Depth Low](#).

QDPMAXEV

Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

ENABLED

Queue Full events are generated.

DISABLED

Queue Full events are not generated.

Note: The value of this parameter can change implicitly.

 On z/OS, shared queues affect the event.

For more information about this event, see [Queue Full](#).

 QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 193. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE QUEUE(q_name) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for a QUEUE definition called <i>q_name</i>. If a matching QUEUE definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE QUEUE(<i>q_name</i>) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.
SHARED	This option applies only to local queues. The object is defined in the shared repository. Messages are stored in the coupling facility and are available to any queue manager in the queue sharing group. You can specify SHARED only if: • CFSTRUCT is not blank • INDXTYPE is not MSGTOKEN • The queue is not: – SYSTEM.CHANNEL.INITQ – SYSTEM.COMMAND.INPUT If the queue is clustered, a command is generated. The command is sent to all active queue managers in the queue sharing group to notify them of this clustered, shared queue.

QSVCI EV

Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the **QSVCI NT** parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the **QSVCINT** parameter.

Note: The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in [Queue Service Interval High](#) and [Queue Service Interval OK](#).

HIGH

Service Interval High events are generated

OK

Service Interval OK events are generated

NONE

No service interval events are generated

QSVCINT(integer)

The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the **QSVCI EV** parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

REPLACE & NOREPLACE

This option controls whether any existing definition is to be replaced with this one.

Note:  On IBM MQ for z/OS, an existing definition is replaced only if it is of the same disposition. Any object with a different disposition is not changed.

REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** parameter and with all the other parameters specified. In particular, note that any messages that are on the existing queue are retained.

There is a difference between the **ALTER** command without the **FORCE** parameter, and the **DEFINE** command with the **REPLACE** parameter. The difference is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets all the parameters. If you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** parameter, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.

The command fails if both of the following statements are true:

- The command sets parameters that would require the use of the **FORCE** parameter if you were using the **ALTER** command
- The object is open

The **ALTER** command with the **FORCE** parameter succeeds in this situation.

 If **SCOPE(CELL)** is specified on AIX, Linux, and Windows, and there is already a queue with the same name in the cell directory, the command fails, even if **REPLACE** is specified.

NOREPLACE

The definition must not replace any existing definition of the object.

RETINTVL(integer)

The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The **CRDATE** and **CRTIME** can be displayed using the [DISPLAY QUEUE](#) command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

Note: The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

RNAME(string)

Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.

- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see [Rules for naming IBM MQ objects](#).

RQMNAME(string)

The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see [Rules for naming IBM MQ objects](#).

ALW SCOPE

Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

QMGR

The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

CELL

The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

Restriction: The DCE name service is no longer supported.

This parameter is valid only on AIX, Linux, and Windows.

SHARE and NOSHARE

Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

SHARE

More than one application instance can get messages from the queue.

NOSHARE

Only a single application instance can get messages from the queue.

STATQ

Specifies whether statistics data collection is enabled:

QMGR

Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

ON

If the value of the **STATQ** parameter of the queue manager is not NONE, statistics data collection for the queue is enabled.

 On z/OS systems, you must enable class 5 statistics using the START TRACE command.

OFF

Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

 **STGCLASS(string)**

The name of the storage class.

This parameter is supported only on local and model queues.

Note: You can change this parameter only if the queue is empty and closed.

This parameter is an installation-defined name. The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

This parameter is valid only on z/OS; see [Storage classes](#).

STREAMQ

The name of a secondary queue where a copy of each message is put.

Attention: If the user setting the **STREAMQ** attribute does not have the correct authority on the chosen stream queue, the command fails with error message AMQ8135E, or the equivalent message CSQ9016E on z/OS.

In addition, if the stream queue does not exist, error message AMQ8135E (CSQ9016E on z/OS) is returned instead of AMQ8147E, or the equivalent message CSQM125I on z/OS.

 For more information, see [Streaming queues](#), and for information on when you can set **STREAMQ**, see [Streaming queue restrictions](#).

STRMQOS

The quality of service to use when delivering messages to the streaming queue.

The value can be one of:

BESTEF

If the original message can be delivered, but the streamed message cannot, the original message is still delivered to its queue.

This is the default value.

MUSTDUP

The queue manager ensures that both the original message and the streamed message are successfully delivered to their queues.

If, for some reason, the streamed message cannot be delivered to its queue, then the original message is not delivered to its queue either. The putting application receives an error reason code and must try to put the message again.

TARGET(string)

The name of the queue or topic object being aliased; See [Rules for naming IBM MQ objects](#). The object can be a queue or a topic as defined by **TARGETTYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic. The default value for TARGET is a queue, therefore TARGET(my_queue_name) is the same as TARGQ(my_queue_name). The TARGQ attribute is retained for compatibility with your existing programs. If you specify **TARGET**, you cannot also specify **TARGQ**.

TARGETTYPE(string)

The type of object to which the alias resolves.

QUEUE (default)

The alias resolves to a queue.

TOPIC

The alias resolves to a topic.

TRIGDATA(string)

The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the MQSET API call.

TRIGDPTH(integer)

The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is DEPTH. The value must be in the range 1 - 999,999,999. The default value is 1.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGGER and NOTRIGGER

Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

TRIGGER

Triggering is active, and trigger messages are written to the initiation queue.

NOTRIGGER

Triggering is not active, and trigger messages are not written to the initiation queue. This is the default value.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

TRIGMPRI(integer)

The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see [“DISPLAY QMGR \(display queue manager settings\)” on page 860](#) for details. The default value is zero.

This parameter can also be changed using the MQSET API call.

TRIGTYPE

Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is named by the **INITQ** parameter.

This parameter is supported only on local and model queues.

FIRST

Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue. This is the default value.

EVERY

Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

DEPTH

When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPTH** parameter.

NONE

No trigger messages are written.

This parameter can also be changed using the MQSET API call.

USAGE

Queue usage.

This parameter is supported only on local and model queues.

NORMAL

The queue is not a transmission queue.

XMITQ

The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

 Additionally, on z/OS, do not specify **INDXTYPE**(MSGTOKEN) or **INDXTYPE**(GROUPID).

XMITQ(string)

The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **RQMNAME** is used as the transmission queue.

This parameter is ignored if the definition is being used as a queue manager alias and **RQMNAME** is the name of the local queue manager.

It is also ignored if the definition is used as a reply-to queue alias definition.

Related tasks

[Copying a local queue definition](#)

Related reference

[“ALTER queues \(alter queue settings\)” on page 453](#)

Use the MQSC **ALTER** command to alter the parameters of a queue. A queue might be a local queue (**ALTER QLOCAL**), alias queue (**ALTER QALIAS**), model queue (**ALTER QMODEL**), a remote queue, a queue manager alias, or a reply-to queue alias (**ALTER QREMOTE**).

[“CLEAR QLOCAL \(clear messages from local queue\)” on page 517](#)

Use the MQSC command **CLEAR QLOCAL** to clear the messages from a local queue.

[“DISPLAY QSTATUS \(display queue status\)” on page 890](#)

Use the MQSC command **DISPLAY QSTATUS** to display the status of one or more queues.

[“DISPLAY QUEUE \(display queue attributes\)” on page 903](#)

Use the MQSC command **DISPLAY QUEUE** to display the attributes of one or more queues of any type.

DEFINE QALIAS (define a new alias queue)

Use the MQSC command **DEFINE QALIAS** to define a new alias queue, and set its parameters.

Note: An alias queue provides a level of indirection to another queue or a topic object. If the alias refers to a queue, it must be another local or remote queue, defined at this queue manager, or a clustered alias queue defined on another queue manager. It cannot be another alias queue on this queue manager. If the alias refers to a topic, it must be a topic object defined at this queue manager.

- [“Syntax diagram for DEFINE QALIAS” on page 652](#)
- [“Usage notes for DEFINE queues” on page 625](#)
- [“Parameter descriptions for DEFINE queues” on page 626](#)

Syntax diagram for DEFINE QALIAS

Synonym: DEF QA

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Alias queue attrs

Notes:

¹ Valid only on z/OS.

² Valid only on z/OS when the queue manager is a member of a queue sharing group.

³ Valid only on AIX, Linux, and Windows.

⁴ Not valid on z/OS.

⁵ The TARGQ parameter, defined in IBM WebSphere MQ 6.0, is renamed to TARGET from version 7.0 and generalized to allow you to specify the name of either a queue or a topic.

The default value for TARGET is a queue, therefore TARGET(my_queue_name) is the same as TARGQ(my_queue_name). The TARGQ attribute is retained for compatibility with your existing programs.

[Changing local queue attributes](#)

DEFINE QMODEL (define a new model queue)

Use the MQSC command **DEFINE QMODEL** to define a new model queue, and set its parameters.

A model queue is not a real queue, but a collection of attributes that you can use when creating dynamic queues with the MQOPEN API call.

When it has been defined, a model queue (like any other queue) has a complete set of applicable attributes, even if some of these are defaults.

- [“Syntax diagram for DEFINE QMODEL” on page 657](#)
- [“Usage notes for DEFINE queues” on page 625](#)
- [“Parameter descriptions for DEFINE queues” on page 626](#)

Syntax diagram for DEFINE QMODEL

Synonym: DEF QM

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.
- ³ Not valid on z/OS.
- ⁴ Default for z/OS.
- ⁵ Default for Multiplatforms.

Related concepts

[Working with model queues](#)

DEFINE QREMOTE (define a new local remote queue definition)

Use the MQSC command **DEFINE QREMOTE** to define a new local definition of a remote queue, a queue manager alias, or a reply-to queue alias, and to set its parameters.

A remote queue is one that is owned by another queue manager that application processes connected to this queue manager need to access.

- [“Syntax diagram for DEFINE QREMOTE” on page 660](#)
- [“Usage notes for DEFINE queues” on page 625](#)
- [“Parameter descriptions for DEFINE queues” on page 626](#)

Syntax diagram for DEFINE QREMOTE

Synonym: DEF QR

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

DEFINE QREMOTE

Define attrs

Common queue attrs

Remote queue attrs

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.
- ³ Valid only on AIX, Linux, and Windows.
- ⁴ Not valid on z/OS.

Multi **DEFINE SERVICE (create a new service definition) on Multiplatforms**

Use the MQSC command **DEFINE SERVICE** to define a new IBM MQ service definition, and set its parameters.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- “Syntax diagram for DEFINE SERVICE” on page 662
- “Usage notes for DEFINE SERVICE” on page 663
- “Parameter descriptions for DEFINE SERVICE” on page 663

Syntax diagram for DEFINE SERVICE

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

Usage notes for DEFINE SERVICE

A service is used to define the user programs that are to be started and stopped when the queue manager is started and stopped. You can also start and stop these programs by issuing the **START SERVICE** and **STOP SERVICE** commands.

Attention: This command allows a user to run an arbitrary command with mqm authority. If granted rights to use this command, a malicious or careless user could define a service which damages your systems or data, for example, by deleting essential files.

For more information about services, see [Services](#).

Parameter descriptions for DEFINE SERVICE

The parameter descriptions apply to the **ALTER SERVICE** and **DEFINE SERVICE** commands, with the following exceptions:

- The **LIKE** parameter applies only to the **DEFINE SERVICE** command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the **DEFINE SERVICE** command.

(service-name)

Name of the IBM MQ service definition (see [Rules for naming IBM MQ objects](#)).

The name must not be the same as any other service definition currently defined on this queue manager (unless **REPLACE** is specified).

CONTROL(string)

Specifies how the service is to be started and stopped:

MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR

The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR(string)

Plain-text comment. It provides descriptive information about the service when an operator issues the **DISPLAY SERVICE** command (see [“DISPLAY SERVICE \(display service information\) on Multiplatforms”](#) on page 925).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

LIKE(service-name)

The name of a service the parameters of which are used to model this definition.

This parameter applies only to the **DEFINE SERVICE** command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.SERVICE)
```

A default service is provided but it can be altered by the installation of the default values required. See [Rules for naming IBM MQ objects](#).

REPLACE and NOREPLACE

Whether the existing definition is to be replaced with this one.

This parameter applies only to the **DEFINE SERVICE** command.

REPLACE

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

NOREPLACE

The definition should not replace any existing definition of the same name.

SERVTYPE

Specifies the mode in which the service is to run:

COMMAND

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the **DISPLAY SVSTATUS** command.

STARTARG(string)

Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD(string)

Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

STDERR(string)

Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

STDOUT(string)

Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

STOPARG(string)

Specifies the arguments to be passed to the stop program when instructed to stop the service.

STOPCMD(string)

Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the **STARTCMD**, **STARTARG**, **STOPCMD**, **STOPARG**, **STDOUT** or **STDERR** strings, for more information, see [Replaceable inserts on service definitions](#).

DEFINE STGCLASS (define storage class to page set mapping) on z/OS

Use the MQSC command **DEFINE STGCLASS** to define a storage class to page set mapping.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE STGCLASS” on page 665](#)
- [“Usage notes for DEFINE STGCLASS” on page 666](#)
- [“Parameter descriptions for DEFINE STGCLASS” on page 666](#)

Syntax diagram for DEFINE STGCLASS

Synonym: DEF STC

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

DEFINE STGCLASS

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DEFINE STGCLASS

1. The resultant values of **XCFGNAME** and **XCFMNAME** must either both be blank or both be nonblank.
2. You can change a storage class only if it is not being used by any queues. To determine whether any queues are using the storage class, you can use the following command:

```
DISPLAY QUEUE(*) STGCLASS(ABC) PSID(n)
```

where 'ABC' is the name of the storage class, and *n* is the identifier of the page set that the storage class is associated with.

This command gives a list of all queues that reference the storage class, and have an active association to page set *n*, and therefore identifies the queues that are actually preventing the change to the storage class. If you do not specify the PSID, you just get a list of queues that are potentially stopping the change.

See the **DISPLAY QUEUE PSID** command for more information about active association of a queue to a page set.

Parameter descriptions for DEFINE STGCLASS

(storage-class)

Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

Note: Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM Service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

•

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of specifying • is the same as entering the command on every queue manager in the queue sharing group.

DESCR(description)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY STGCLASS** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager

LIKE(stgclass-name)

The name of an object of the same type, with parameters that are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for this object.

Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEMST)
```

This default storage class definition can be altered by your installation to the default values required.

The queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP**(GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

PASSTKTA(application name)

The application name that is passed to RACF when authenticating the PassTicket specified in the MQIIH header.

PSID(integer)

The page set identifier that this storage class is to be associated with.

Note: No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC_PAGESET_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See “[DEFINE PSID \(define page set and buffer pool\) on z/OS](#)” on page 623.

QSGDISP

Specifies the disposition of the object in the group.

Table 194. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE STGCLASS(<i>storage_class_name</i>) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for an STGCLASS definition called <i>storage_class_name</i>. If a matching STGCLASS definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE STGCLASS(<i>storage_class_name</i>) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Whether the existing definition, and with the same disposition, is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

If you use the **REPLACE** parameter, all queues that use this storage class must be temporarily altered to use another storage class while the command is issued.

NOREPLACE

The definition does not replace any existing definition of the same name.

XCFGNAME(*group name*)

If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

XCFMNAME(*member name*)

If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in **XCFGNAME**. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

DEFINE SUB (create a durable subscription)

Use the MQSC command **DEFINE SUB** to allow an existing application to participate in a publish/subscribe application by allowing the administrative creation of a durable subscription.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DEFINE SUB” on page 669](#)
- [“Usage notes for DEFINE SUB” on page 671](#)
- [“Parameter descriptions for DEFINE SUB” on page 672](#)

Syntax diagram for DEFINE SUB**Synonym: DEF SUB**

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

DEFINE SUB

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ At least one of **TOPICSTR** and **TOPICOBJ** must be present on **DEFINE**.

Usage notes for **DEFINE SUB**

- You must provide the following information when you define a subscription:
 - The **SUBNAME**
 - A destination for messages
 - The topic to which the subscription applies
- You can provide the topic name in the following ways:

TOPICSTR

The topic is fully specified as the **TOPICSTR** attribute.

TOPICOBJ

The topic is obtained from the **TOPICSTR** attribute of the named topic object. The named topic object is retained as the **TOPICOBJ** attribute of the new subscription. This method is provided to help you enter long topic strings through an object definition.

TOPICSTR and TOPICOBJ

The topic is obtained by the concatenation of the **TOPICSTR** attribute of the named topic object and the value of **TOPICSTR** (see the MQSUB API specification for concatenation rules). The named topic object is retained as the **TOPICOBJ** attribute of the new subscription.

- If you specify **TOPICOBJ**, the parameter must name an IBM MQ topic object. The existence of the named topic object is checked at the time the command processes.
- You can explicitly specify the destination for messages through the use of the **DEST** and **DESTQMGR** keywords.

You must provide the **DEST** keyword for the default option of **DESTCLAS(PROVIDED)**; if you specify **DESTCLAS(MANAGED)**, a managed destination is created on the local queue manager, so you cannot specify either the **DEST** or **DESTQMGR** attribute. For more information, see [Managed queues and publish/subscribe](#).

-  On z/OS only, at the time the **DEF SUB** command processes, no check is performed that the named **DEST** or **DESTQMGR** exists.

These names are used at publishing time as the `ObjectName` and `ObjectQMgrName` for an `MQOPEN` call. These names are resolved according to the IBM MQ name resolution rules.

- When a subscription is defined administratively using MQSC or PCF commands, the selector is not validated for invalid syntax. The **DEFINE SUB** command has no equivalent to the `MQRC_SELECTION_NOT_AVAILABLE` reason code that can be returned by the MQSUB API call.
- **TOPICOBJ**, **TOPICSTR**, **WSHEMA**, **SELECTOR**, **SUBSCOPE**, **SUBLEVEL**, and **DESTCLAS** cannot be changed with **DEFINE REPLACE**.
- When a publication has been retained, it is no longer available to subscribers at higher levels because it is republished at PubLevel 1.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DEFINE SUB step in Checking that async commands for distributed networks have finished](#).
- When you create a subscription, the destination that you specify is validated. If the destination does not exist, the **DEFINE SUB** command fails with the following error:
AMQ8470E: The object DESTQ is not a valid subscription destination.

(string)

11

qmgr-name

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

You cannot use **CMDSCOPE** as a filter keyword.

The destination for messages published to this subscription; this parameter is the name of a queue.

System managed destination.

The destination is a queue.

The destination is managed.

The **CorrelId** used for messages published to this subscription.

If set to '00000000000000000000000000000000000000000000000000000' (48 zeros) the **CorrelId** set by the publishing application is maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

Note: You cannot set the **DESTCORL** property programmatically with JMS.

The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the **XMITQ**, and a sender channel. If you do not, messages do not arrive at the destination.

The time to expiry of the subscription object from the creation date and time.

The time to expiry, in tenths of a second, from the creation date and time.

There is no expiry time. This is the default option supplied with the product.

LIKE(subscription-name)

The name of a subscription, the parameters of which are used as a model for this definition.

This parameter applies only to the **DEFINE SUB** command.

If this field is not supplied, and you do not complete the parameter fields related to the command, the values are taken from the default definition for subscriptions on this queue manager. Not completing this parameter is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.SUB)
```

PSPROP

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE

Do not add publish subscribe properties to the message.

COMPAT

Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP

Publish/subscribe properties are added as message properties.

RFH2

Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(string)

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the AccountingToken field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(string)

Identity data passed by the subscriber, for propagation into messages published to this subscription in the ApplIdentityData field of the MQMD.

PUBPRTY

The priority of the message sent to this subscription.

AS PUB

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

ASQDEF

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)

An integer providing an explicit priority for messages published to this subscription.

REPLACE and NOREPLACE

This parameter controls whether any existing definition is to be replaced with this one.

REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

You cannot change **TOPICOBJ**, **TOPICSTR**, **WSHEMA**, **SELECTOR**, **SUBSCOPE**, or **DESTCLAS** with **DEFINE REPLACE**.

NOREPLACE

The definition does not replace any existing definition of the same name.

REQONLY

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO

All publications on the topic are delivered to this subscription. This is the default value.

YES

Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SELECTOR(string)

A selector that is applied to messages published to the topic.

SUBLEVEL(integer)

The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

SUBSCOPE

Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

ALL

The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

QMGR

The subscription forwards messages published on the topic only within this queue manager.

Note: Individual subscribers can only restrict **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

SUBNAME

The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

SUBUSER(string)

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

TOPICOBJ(string)

The name of a topic object used by this subscription.

TOPICSTR(string)

Specifies a fully qualified topic name, or a topic set using wildcard characters for the subscription.

USERDATA(string)

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see [Retrieval of user subscription data](#).

VARUSER

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY

Any user can connect to and takeover ownership of the subscription.

FIXED

Takeover by another USERID is not permitted.

WSHEMA

The schema to be used when interpreting any wildcard characters in the topic string.

CHAR

Wildcard characters represent portions of strings.

TOPIC

Wildcard characters represent portions of the topic hierarchy.

Syntax diagram for DEFINE TOPIC

Synonym: DEF TOPIC

Values shown above the main line in the syntax diagram are the defaults supplied with IBM MQ, but your installation might have changed them. For an explanation of how to use these diagrams, see [How to read syntax diagrams](#).

DEFINE TOPIC

►► DEFINE TOPIC — (— *topic-name* —) — TYPE — (— LOCAL —) — TOPICSTR — (→

Define attrs

Topic attrs

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

Usage notes for DEFINE TOPIC

- When an attribute has the value ASPARENT, the value is taken from the setting of the first parent administrative node that is found in the topic tree. Administered nodes are based on either locally defined topic objects or remotely defined cluster topics when participating in a publish/subscribe cluster. If the first parent topic object also has the value ASPARENT, the next object is looked for. If every object that is found, when looking up the tree, uses ASPARENT, the values are taken from the SYSTEM.BASE.TOPIC, if it exists. If SYSTEM.BASE.TOPIC does not exist, the values are the same as the values supplied with IBM MQ in the definition of the SYSTEM.BASE.TOPIC.
- The ASPARENT attribute is applied at each queue manager in the cluster collective by inspecting the set of local definitions and cluster definitions that is visible in the queue manager at the time.
- When a publication is sent to multiple subscribers, the attributes used from the topic object are used consistently for all subscribers that receive the publication. For example, inhibiting publication on a topic is applied for the next application MQPUT to the topic. A publication that is in progress to multiple subscribers completes to all subscribers. This publication does not take note of a change that has happened, part of the way through, to any attribute on the topic.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DEFINE TOPIC](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for DEFINE TOPIC

(topic-name)

Name of the IBM MQ topic definition (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless **REPLACE** is specified).

CAEXPRY(integer)

The maximum time, expressed in tenths of a second, which a message published to a topic, which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see [CAEXPRY: Limit message expiry time](#).

integer

The value must be in the range one through to 999 999 999.

NOLIMIT

There is no limit on the expiry time of messages put to this topic.

ASPARENT

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

Important:  You cannot specify the **CAEXPRY** attribute on a topic object with **QSGDISP(GROUP|COPY)**, which resides in a queue sharing group that contains queue managers running any version of IBM MQ for z/OS below 9.4.0. Attempting to do so results in CSQM532I and CSQM533I messages to identify which queue managers do not support **CAEXPRY**, and no modification to the object.

CLRROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

DIRECT

When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

TOPICHOST

When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to ' ') before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See [The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager](#). If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an MQRCCF_CLROUTE_NOT_ALTERABLE exception.

See also [Routing for publish/subscribe clusters: Notes on behavior](#) and [Designing publish/subscribe clusters](#).

CLUSTER

The name of the cluster to which this topic belongs. Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see [Distributed publish/subscribe networks](#).

• •

If no topic object above this topic in the topic tree has set this parameter to a cluster name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

string

The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics SYSTEM.BASE.TOPIC and SYSTEM.DEFAULT.TOPIC, except in special circumstances, for example to support migration.

➤ z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

The name of the Multicast communication information object associated with this topic object.

CUSTOM(*string*)

The **CUSTOM** attribute contains the values of attributes, as pairs of name and value, which are separated by at least one space. The attribute name-value pairs have the form NAME (VALUE).

Attribute names beginning with **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPYR**, **SQGETTMR**, and **PAGEVAL**. As an administrator, you can set and use other names for your own purposes.

The maximum length is defined by the IBM MQ constant **MQ_CUSTOM_LENGTH** and is set to 128 on all platforms.

The **CUSTOM** value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. The property names and values are case-sensitive, and must be specified in uppercase. The values can contain spaces, parentheses, and single quotation marks (which must be enclosed by another single-quote). Other characters, including nested parentheses (), can be included by enclosing them in two single quotation marks on either side. Examples of valid syntax are:

- CUSTOM('')
- CUSTOM('A(B)')
- CUSTOM('C(D) E(F)')
- CUSTOM('G(5000) H(''9.20.4.6(1415)'')')

The last syntax uses pairs of single quotation marks, not double quotation marks.

Note: **Deprecated** From IBM MQ 9.4.0, the **CAPEXPRT** queue attribute replaces the use of the **CAPEXPRT** option in the **CUSTOM** field. You cannot set the **CAPEXPRT** queue attribute if the **CUSTOM** attribute has the **CAPEXPRT** option defined in it already. You should alter existing topics to set the **CAPEXPRT** queue attribute and unset the **CAPEXPRT** option from the **CUSTOM** attribute. For example:

```
ALTER TOPIC(T1) CAPEXPY(1000) CAPEXPY('')
```

For more information about the permitted values, see CAPEXPY.

DEFPRESP

Specifies the put response to be used when applications specify the MQPMO_RESPONSE_AS_DEF option.

ASPARENT

The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

SYNC

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are issued as if MQPMO_SYNC_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

ASYNC

Put operations to the queue that specify MQPMO_RESPONSE_AS_Q_DEF are always issued as if MQPMO_ASYNC_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application; but an improvement in performance might be seen for messages put in a transaction and any non-persistent messages.

DEFPRTY(*integer*)

The default priority of messages published to the topic.

(*integer*)

The value must be in the range zero (the lowest priority), through to the **MAXPRTY** queue manager parameter (**MAXPRTY** is 9).

ASPARENT

The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

DEFPSIST

Specifies the message persistence to be used when applications specify the MQPER_PERSISTENCE_AS_TOPIC_DEF option.

ASPARENT

The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

NO

Messages on this queue are lost during a restart of the queue manager.

YES

Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

DESCR(*string*)

Plain-text comment. It provides descriptive information about the object when an operator issues the **DISPLAY TOPIC** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

Note: If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

DURSUB

Specifies whether applications are permitted to make durable subscriptions on this topic.

ASPARENT

Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

NO

Durable subscriptions cannot be made on this topic.

YES

Durable subscriptions can be made on this topic.

LIKE(*topic-name*)

The name of a topic. The topic parameters are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for topics on this queue manager.

Not completing this field is equivalent to specifying:

```
LIKE (SYSTEM.DEFAULT.TOPIC)
```

A default topic definition is provided, but it can be altered by the installation to the default values required. See [Rules for naming IBM MQ objects](#).

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the **LIKE** object is not copied to the object you are defining.

Note:

1. **QSGDISP** (GROUP) objects are not searched.
2. **LIKE** is ignored if **QSGDISP**(COPY) is specified.

MCAST

Specifies whether multicast is allowable in the topic tree. The values are:

ASPARENT

The multicast attribute of the topic is inherited from the parent.

DISABLED

No multicast traffic is allowed at this node.

ENABLED

Multicast traffic is allowed at this node.

ONLY

Only subscriptions from a multicast capable client are allowed.

MDURMDL(string)

The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

If **MDURMDL** is blank, it operates in the same way as **ASPARENT** values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MDURMDL**.

If you use **MDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of **SYSTEM.MANAGED.DURABLE**

MNDURMDL(string)

The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see [Rules for naming IBM MQ objects](#)). The maximum length is 48 characters.

If **MNDURMDL** is blank, it operates in the same way as **ASPARENT** values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for **MNDURMDL**.

If you use **MNDURMDL** to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of **SYSTEM.MANAGED.NDURABLE**.

NPMSGDLV

The delivery mechanism for non-persistent messages published to this topic:

ASPARENT

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL

Non-persistent messages must be delivered to all subscribers, irrespective of durability for the **MQPUT** call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the **MQPUT** call fails.

ALLAVAIL

Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR

Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the **MQPUT** call. If a

delivery failure to a durable subscriber occurs, no subscribers receive the message and the **MQPUT** call fails.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**.

Can be one of the following values:

ASPARENT

The default for everything other than **SYSTEM.BASE.TOPIC**, delegate to the parent topic's configuration.

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default for **SYSTEM.BASE.TOPIC**.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation. If the queue manager is in a queue sharing group, this value can only be set if all queue managers have been started at IBM MQ 9.4.5 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are published to this topic.

Can be one of the following values:

ASPARENT

The default for everything other than **SYSTEM.BASE.TOPIC**, delegate to the parent topic's configuration.

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default for **SYSTEM.BASE.TOPIC**.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PMSGDLV

The delivery mechanism for persistent messages published to this topic:

ASPARENT

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

ALL

Persistent messages must be delivered to all subscribers, irrespective of durability for the **MQPUT** call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the **MQPUT** call fails.

ALLAVAIL

Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

ALLDUR

Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the **MQPUT** call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the **MQPUT** calls fails.

PROXYSUB

Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see [Subscription performance in publish/subscribe networks](#).

FIRSTUSE

For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers in the following scenarios:

- When a local subscription is created.
- When a proxy subscription is received that must be propagated to further directly connected queue managers.

FORCE

A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

Note: The proxy subscription is sent when this value is set on **DEFINE** or **ALTER**. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

PUB

Controls whether messages can be published to this topic.

ASAPARENT

Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED

Messages can be published to the topic (by suitably authorized applications).

DISABLED

Messages cannot be published to the topic.

See also [Special handling for the **PUB** parameter](#).

PUBSCOPE

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a publication-by-publication basis, using `MQPMO_SCOPE_QMGR` on the Put Message options.

ASAPARENT

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster. This is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

QMGR

Publications for this topic are not propagated to connected queue managers.

ALL

Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 195. Object dispositions for QSGDISP options	
QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the LIKE object. For example, if you issue the following command, <pre>DEFINE TOPIC(topic_name) REPLACE QSGDISP(COPY)</pre> the queue manager searches the shared configuration repository for a TOPIC definition called <i>topic_name</i>. If a matching TOPIC definition is found, the queue manager creates a local copy of this definition on the queue manager page set. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
GROUP	The object definition resides in the shared configuration repository. QSGDISP(GROUP) is allowed only if the queue manager is in a queue sharing group. If the DEFINE for the QSGDISP(GROUP) object is successful, the DEFINE TOPIC(<i>topic_name</i>) REPLACE QSGDISP(COPY) command is generated and sent to all active queue managers in the queue sharing group to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

REPLACE and NOREPLACE

Determines whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** option and with *all* the other parameters specified.

(The difference between the **ALTER** command without the **FORCE** option, and the **DEFINE** command with the **REPLACE** option, is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets *all* the parameters. When you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** option, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.)

The command fails if both of the following statements are true:

- The command sets parameters that would require the use of the **FORCE** option if you were using the **ALTER** command.
- The object is open.

The **ALTER** command with the **FORCE** option succeeds in this situation.

Note: The **REPLACE** option does not replace the **TOPICSTR** properties of a topic. **TOPICSTR** is a property that is usefully varied in the example to test different topic trees. To change topics, delete the topic first.

NOREPLACE

The definition must not replace any existing definition of the object.

SUB

Controls whether applications are to be permitted to subscribe to this topic.

ASPARENT

Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

ENABLED

Subscriptions can be made to the topic (by suitably authorized applications).

DISABLED

Applications cannot subscribe to the topic.

SUBSCOPE

Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

Note: You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO_SCOPE_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**. Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO_SCOPE_QMGR** subscription option when creating a subscription.

ASPARENT

Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

QMGR

Only publications that are published on this queue manager reach the subscriber.

ALL

A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

TOPICSTR(string)

The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

Note: The **REPLACE** option does not replace the **TOPICSTR** properties of a topic. **TOPICSTR** is a property that is usefully varied in the example to test different topic trees. To change topics, delete the topic first.

TYPE(topic-type)

If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms  except z/OS.

LOCAL

A local topic object.

USEDLQ

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

ASPARENT

Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree. This value is the default supplied with IBM MQ, but your installation might have changed it.

NO

Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The MQPUT of an application to a topic fails in accordance with the settings of **NPMGDLV** and **PMSGDLV**.

YES

When the **DEADQ** queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

Note: When **PMSGDLV=ALL** and **NPMGDLV=ALL** are configured, along with **USEDLQ=YES**, even if the delivery to one of the subscribers fails, due to any issue such as **MAXDEPTH**, the message is always delivered to the other available subscribers. The failed subscriber message is placed in the dead-letter queue. The message is processed for all subscribers, either by successful delivery or by being routed to the dead-letter queue for the failed subscriber. As a result, this publication message is considered as a successful handling of the delivery attempt.

WILDCARD

The behavior of wildcard subscriptions with respect to this topic.

PASSTHRU

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

BLOCK

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the **WILDCARD** attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

DELETE AUTHINFO (delete authentication information)

Use the MQSC command **DELETE AUTHINFO** to delete an authentication information object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE AUTHINFO” on page 688](#)
- [“Parameter descriptions for DELETE AUTHINFO” on page 688](#)

Syntax diagram for DELETE AUTHINFO

Synonym: None

DELETE AUTHINFO

Notes:

- ¹ Valid only on z/OS.
- ² Valid only when the queue manager is a member of a queue sharing group. You can use queue sharing groups only on IBM MQ for z/OS.
- ³ Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE AUTHINFO

(*name*)

Name of the authentication information object. This is required.

The name must be that of an existing authentication information object.

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP**(QMGR), is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP**(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE AUTHINFO(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP**(COPY) fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

IGNSTATE

Specifies whether the command fails if the object does not exist. The value can be one of the following values:

NO

When the command is issued from **runmqsc** started with the **-n** parameter to run without connecting to a queue manager, the command succeeds regardless of whether the object exists.

In all other environments, the command fails if the object does not exist.

This is the default value.

YES

The command succeeds regardless of whether the object exists.

Multi **DELETE AUTHREC (delete authority records) on Multiplatforms**

Use the MQSC command **DELETE AUTHREC** to delete authority records associated with a profile name.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DELETE AUTHREC” on page 690](#)
- [“Parameter descriptions for DELETE AUTHREC” on page 691](#)

Syntax diagram for DELETE AUTHREC

DELETE AUTHREC

Notes:

¹ Valid only on AIX, Linux, and Windows.

² Default value is YES for QMGR, TOPIC, RQMNAME and QUEUE objects when set using the OBJTYPE parameter. Setting IGNSTATE to NO is not valid for these objects.

³ Default value is NO for objects apart from QMGR, TOPIC, RQMNAME and QUEUE.

Parameter descriptions for DELETE AUTHREC

PROFILE(*profile-name*)

The name of the object or generic profile for which to remove the authority record. This parameter is required unless the **OBJTYPE** parameter is QMGR, in which case it can be omitted.

OBJTYPE

The type of object referred to by the profile. Specify one of the following values:

AUTHINFO

Authentication information record

CHANNEL

Channel

CLNTCONN

Client connection channel

COMMINFO

Communication information object

LISTENER

Listener

NAMELIST

Namelist

PROCESS

Process

QUEUE

Queue

QMGR

Queue manager

RQMNAME

Remote queue manager

SERVICE

Service

TOPIC

Topic

PRINCIPAL(*principal-name*)

A principal name. This is the name of a user for whom to remove authority records for the specified profile. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: user@domain.

You must specify either **PRINCIPAL** or **GROUP**.

GROUP(*group-name*)

A group name. This is the name of the user group for which to remove authority records for the specified profile. You can specify one name only and it must be the name of an existing user group.

 **Windows** For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain  
domain\GroupName
```

You must specify either **PRINCIPAL** or **GROUP**.

ALW **IGNSTATE**

Specifies whether the command fails if the authority record does not exist. The value can be one of the following values:

NO

The command fails if the authority record does not exist.

This value is not valid for objects of type QUEUE, QMGR, RQMNAME, and TOPIC. This is the default value for all other object types.

YES

The command succeeds regardless of whether the authority record exists.

This is the default value for objects of type QUEUE, QMGR, RQMNAME, and TOPIC.

Use the MQSC command **SET AUTHREC** to set authority records associated with a profile name.

DELETE BUFFPOOL (delete a buffer pool) on z/OS

Use the MQSC command **DELETE BUFFPOOL** to delete a buffer pool that is used for holding messages in main storage.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE BUFFPOOL” on page 692](#)
- [“Usage note for DELETE BUFFPOOL” on page 692](#)
- [“Parameter descriptions for DELETE BUFFPOOL” on page 693](#)

Syntax diagram for DELETE BUFFPOOL

Synonym: DEL BP

DELETE BUFFPOOL

➤ **DELETE BUFFPOOL** — (— *integer* —) ➤

Usage note for DELETE BUFFPOOL

- Ensure there are no current page set definitions using the named buffer pool, otherwise the command will fail.
- **DELETE BUFFPOOL** cannot be issued from CSQINPT.

Parameter descriptions for DELETE BUFFPOOL

(integer)

This is the number of the buffer pool to be deleted. The value is an integer in the range zero through 99.

Related reference

[“DEFINE BUFFPOOL \(define a buffer pool\) on z/OS” on page 535](#)

Use the MQSC command **DEFINE BUFFPOOL** to define a buffer pool that is used for holding messages in main storage.

[“ALTER BUFFPOOL \(alter buffer pool settings\) on z/OS” on page 332](#)

Use the MQSC command **ALTER BUFFPOOL** to dynamically change the settings of a predefined buffer pool on z/OS.

DELETE CFSTRUCT (delete CF application structure) on z/OS

Use the MQSC command **DELETE CFSTRUCT** to delete a CF application structure definition.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE CFSTRUCT” on page 693](#)
- [“Usage notes for DELETE CFSTRUCT” on page 693](#)
- [“Keyword and parameter descriptions for DELETE CFSTRUCT” on page 693](#)

Syntax diagram for DELETE CFSTRUCT

Synonym: None

DELETE CFSTRUCT

➤ DELETE CFSTRUCT — (— *structure-name* —) ➤

Usage notes for DELETE CFSTRUCT

1. This command is valid only z/OS when the queue manager is a member of a queue sharing group.
2. The command fails if there are any queues in existence that reference this CF structure name that are not both empty and closed.
3. The command cannot specify the CF administration structure (CSQ_ADMIN).
4. The command deletes the Db2 CF structure record only. It does **not** delete the CF structure definition from the CFRM policy data set.
5. CF structures at CFLEVEL(1) are automatically deleted when the last queue on that structure is deleted.

Keyword and parameter descriptions for DELETE CFSTRUCT

(*structure-name*)

The name of the CF structure definition to be deleted. The name must be defined within the queue sharing group.

Related reference

[“ALTER CFSTRUCT \(alter CF application structure\) on z/OS” on page 334](#)

On z/OS, use the MQSC command **ALTER CFSTRUCT** to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.

[“BACKUP CFSTRUCT \(back up a CF application structure\) on z/OS” on page 516](#)

Use the MQSC command **BACKUP CFSTRUCT** to initiate a CF application structure backup.

[“DEFINE CFSTRUCT \(define coupling facility application structure\) on z/OS” on page 537](#)

Use the MQSC command **DEFINE CFSTRUCT** to define queue manager CF level capability, message offload environment, and backup and recovery parameters for a coupling facility application structure.

[“DISPLAY CFSTRUCT \(display CF application structure settings\) on z/OS” on page 747](#)

Use the MQSC command **DISPLAY CFSTRUCT** to display the attributes of one or more CF application structures. This command is valid only on z/OS when the queue manager is a member of a queue sharing group.

[“DISPLAY CFSTATUS \(display CF application structure status\) on z/OS” on page 739](#)

Use the MQSC command **DISPLAY CFSTATUS** to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

[“RECOVER CFSTRUCT \(recover CF application structure\) on z/OS” on page 992](#)

Use the MQSC command **RECOVER CFSTRUCT** to initiate recovery of CF application structures and associated shared message data sets. This command is valid only when the queue manager is a member of a queue sharing group.

[“RESET CFSTRUCT \(reset a CF application structure\) on z/OS” on page 1006](#)

Use the MQSC command **RESET CFSTRUCT** to modify the status of a specific application structure.

DELETE CHANNEL (delete a channel)

Use the MQSC command **DELETE CHANNEL** to delete a channel definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE CHANNEL” on page 694](#)
- [“Usage notes for DELETE CHANNEL” on page 695](#)
- [“Parameter descriptions for DELETE CHANNEL” on page 695](#)

Syntax diagram for DELETE CHANNEL

Synonym: DELETE CHL

DELETE CHANNEL

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.
- ³ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE CHANNEL

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DELETE CHANNEL](#) step in [Checking that async commands for distributed networks have finished](#).
- **z/OS** On z/OS systems, the command fails if the channel initiator and command server have not been started, or the channel status is RUNNING, except client-connection channels, which can be deleted without the channel initiator or command server running.
- **z/OS** On z/OS systems, you can only delete cluster-sender channels that have been created manually.

Parameter descriptions for DELETE CHANNEL

(channel-name)

The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

CHLTABLE

Specifies the channel definition table that contains the channel to be deleted. This is optional.

QMGRTBL

The channel table is that associated with the target queue manager. This table does not contain any channels of type CLNTCONN. This is the default.

CLNTTBL

The channel table for CLNTCONN channels. On z/OS, this is associated with the target queue manager, but separate from the main channel table. On all other platforms, this channel table is normally associated with a queue manager, but can be a system-wide, queue manager independent channel table if you set up a number of environment variables. For more information about setting up environment variables, see [Using IBM MQ environment variables](#).

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE CHANNEL(channel-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP(COPY)** fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

IGNSTATE

Specifies whether the command fails if the channel does not exist. The value can be one of the following values:

NO

When the command is issued from **runmqsc** started with the **-n** parameter to run without connecting to a queue manager, the command succeeds regardless of whether the channel exists.

In all other environments, the command fails if the channel does not exist.

This is the default value.

YES

The command succeeds regardless of whether the channel exists.

Use the MQSC command **DISPLAY CHANNEL** to display a channel definition.

[“PING CHANNEL \(test channel response\)” on page 985](#)

Use the MQSC command **PING CHANNEL** to test a channel by sending data as a special message to the remote queue manager, and checking that the data is returned. The data is generated by the local queue manager.

[“PURGE CHANNEL \(stop and purge a channel\) on AIX, Linux, and Windows” on page 990](#)

Use the MQSC command **PURGE CHANNEL** to stop and purge an IBM MQ Telemetry or AMQP channel. Purging an IBM MQ Telemetry or AMQP channel disconnects all the MQTT or AMQP clients connected to it, cleans up the state of the MQTT or AMQP clients, and stops the IBM MQ Telemetry or AMQP channel. Cleaning the state of a client deletes all the pending publications, including any last will and testament message required by the client, and removes all the subscriptions from the client.

[“RESET CHANNEL \(reset message sequence number for a channel\)” on page 1007](#)

Use the MQSC command **RESET CHANNEL** to reset the message sequence number for an IBM MQ channel with, optionally, a specified sequence number to be used the next time that the channel is started. This command is normally used when message AMQ9526E is received, where a channel is unable to start because of a sequence number error.

[“START CHANNEL \(start a channel\)” on page 1061](#)

Use the MQSC command **START CHANNEL** to start a channel.

[“STOP CHANNEL \(stop a channel\)” on page 1082](#)

Use the MQSC command **STOP CHANNEL** to stop a channel.

DELETE CHANNEL (delete a channel) MQTT

Use the MQSC command **DELETE CHANNEL** to delete an IBM MQ Telemetry channel definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

The **DELETE CHANNEL** (MQTT) command is only valid for IBM MQ Telemetry channels.

- [“Syntax diagram for DELETE CHANNEL \(MQTT\)” on page 697](#)
- [“Parameter descriptions for DELETE CHANNEL \(MQTT\)” on page 698](#)

Syntax diagram for DELETE CHANNEL (MQTT)

Synonym: DELETE CHL

DELETE CHANNEL

► DELETE CHANNEL — (— *channel-name* —) — CHLTYPE — (— MQTT —) ►

Parameter descriptions for DELETE CHANNEL (MQTT)

(*channel-name*)

The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

CHLTYPE

This parameter is required. There is only one possible value: MQTT.

Related reference

[“ALTER CHANNEL \(alter channel settings\) MQTT” on page 395](#)

Use the MQSC command **ALTER CHANNEL** to alter the parameters of a telemetry channel.

[“DEFINE CHANNEL \(define a new channel\) for MQTT” on page 599](#)

Use the MQSC command **DEFINE CHANNEL** to define a new IBM MQ Telemetry channel, and set its parameters.

[“DISPLAY CHANNEL \(display channel definition\) MQTT” on page 767](#)

Use the MQSC command **DISPLAY CHANNEL** (MQTT) to display an IBM MQ Telemetry channel definition.

[“START CHANNEL \(start a channel\) MQTT” on page 1065](#)

Use the MQSC command **START CHANNEL** to start an IBM MQ Telemetry channel.

[“STOP CHANNEL \(stop a channel\) MQTT” on page 1088](#)

Use the MQSC command **STOP CHANNEL** to stop an IBM MQ Telemetry channel.

DELETE COMMINFO (delete communications information) on Multiplatforms

Use the MQSC command **DELETE COMMINFO** to delete a communication information object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DELETE COMMINFO” on page 698](#)
- [“Parameter descriptions for DELETE COMMINFO” on page 698](#)

Syntax diagram for DELETE COMMINFO

Synonym: DEL COMMINFO

DELETE COMMINFO

Notes:

¹ Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE COMMINFO

(*comminfo_name*)

The name of the communications information object to be deleted. This parameter is required.

IGNSTATE

Specifies whether the command fails if the object does not exist. The value can be one of the following values:

NO

The command fails if the object does not exist. This is the default value.

YES

The command succeeds regardless of whether the object exists.

Related reference

[“ALTER COMMINFO \(alter communication information object\) on Multiplatforms” on page 399](#)

Use the MQSC command **ALTER COMMINFO** to alter the parameters of a communication information object.

[“DEFINE COMMINFO \(define a new communication information object\) on Multiplatforms” on page 603](#)

Use the MQSC command **DEFINE COMMINFO** to define a new communication information object. These objects contain the definitions required for Multicast messaging.

[“DISPLAY COMMINFO \(display communication information\) on Multiplatforms” on page 816](#)

Use the MQSC command **DISPLAY COMMINFO** to display the attributes of a communication information object.

DELETE LISTENER (delete a listener) on Multiplatforms

Use the MQSC command **DELETE LISTENER** to delete a listener definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DELETE LISTENER” on page 699](#)
- [“Usage notes for DELETE LISTENER” on page 699](#)
- [“Keyword and parameter descriptions for DELETE LISTENER” on page 699](#)

Syntax diagram for DELETE LISTENER

Synonym: DELETE LSTR

DELETE LISTENER

Notes:

- ¹ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE LISTENER

1. The command fails if an application has the specified listener object open, or if the listener is currently running.

Keyword and parameter descriptions for DELETE LISTENER

(listener-name)

The name of the listener definition to be deleted. This parameter is required. The name must be that of an existing listener defined on the local queue manager.

IGNSTATE

Specifies whether the command fails if the listener does not exist. The value can be one of the following values:

NO

The command fails if the listener does not exist. This is the default value.

YES

The command succeeds regardless of whether the listener exists.

Related reference

[“ALTER LISTENER \(alter an existing listener\) on Multiplatforms” on page 403](#)

Use MQSC command **ALTER LISTENER** to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

[“DEFINE LISTENER \(define a new listener\) on Multiplatforms” on page 608](#)

Use the MQSC command **DEFINE LISTENER** to define a new IBM MQ listener definition, and set its parameters.

[“DISPLAY LISTENER \(display listener information\) on Multiplatforms” on page 836](#)

Use the MQSC command **DISPLAY LISTENER** to display information about a listener.

[“DISPLAY LSSTATUS \(display listener status\) on Multiplatforms” on page 841](#)

Use the MQSC command **DISPLAY LSSTATUS** to display status information for one or more listeners.

[“START LISTENER \(start a channel listener\)” on page 1068](#)

Use the MQSC command **START LISTENER** to start a channel listener.

[“STOP LISTENER \(stop a channel listener\)” on page 1092](#)

Use the MQSC command **STOP LISTENER** to stop a channel listener.

DELETE NAMELIST (delete a name list)

Use the MQSC command **DELETE NAMELIST** to delete a namelist definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE NAMELIST” on page 700](#)
- [“Usage notes for DELETE NAMELIST” on page 701](#)
- [“Parameter descriptions for DELETE NAMELIST” on page 701](#)

Syntax diagram for DELETE NAMELIST

Synonym: DELETE NL

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE NAMELIST

Successful completion of the command does not mean that the action completed. To check for true completion, see the [DELETE NAMELIST](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for DELETE NAMELIST

You must specify which namelist definition you want to delete.

(name)

The name of the namelist definition to be deleted. The name must be defined to the local queue manager.

If an application has this namelist open, the command fails.

z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE NAMELIST(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP(COPY)** fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

ALW IGNSTATE

Specifies whether the command fails if the namelist does not exist. The value can be one of the following values:

NO

The command fails if the namelist does not exist. This is the default value.

YES

The command succeeds regardless of whether the namelist exists.

Related reference

[“ALTER NAMELIST \(alter a list of names\)” on page 406](#)

Use the MQSC command **ALTER NAMELIST** to alter a list of names. This list is most commonly a list of cluster names or queue names.

[“DEFINE NAMELIST \(define a list of names\)” on page 614](#)

Use the MQSC command **DEFINE NAMELIST** to define a list of names. This is most commonly a list of cluster names or queue names.

[“DISPLAY NAMELIST \(display a list of names\)” on page 846](#)

Use the MQSC command **DISPLAY NAMELIST** to display the names in a namelist.

Multi DELETE POLICY (delete a security policy) on Multiplatforms

Use the MQSC command **DELETE POLICY** to delete a security policy.

- [“Syntax diagram for DELETE POLICY” on page 702](#)
- [“Parameter descriptions for DELETE POLICY” on page 702](#)

Syntax diagram for DELETE POLICY

Parameter descriptions for DELETE POLICY

(policy-name)

Specifies the policy name to be deleted.

The name of the policy, or policies, to delete are the same as the name of the queue, or queues, that the policies control.

ALW IGNSTATE

Specifies whether the command fails if the policy does not exist. The value can be one of the following values:

NO

The command fails if the policy does not exist. This is the default value.

YES

The command succeeds regardless of whether the policy exists.

Related reference

[“DISPLAY POLICY \(display a security policy\) on Multiplatforms” on page 850](#)

Use the MQSC command **DISPLAY POLICY** to display a security policy.

[“SET POLICY \(set security policy\) on Multiplatforms” on page 1054](#)

Use the MQSC command **SET POLICY** to set a security policy.

[“setmqspl \(set security policy\)” on page 271](#)

Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy. **z/OS** On z/OS you use the command with the CSQOUTIL utility.

[“dspmqspl \(display security policy\)” on page 115](#)

Use the **dspmqspl** command to display a list of all policies and details of a named policy. **z/OS** On z/OS you use the command with the CSQOUTIL utility.

Related information

DELETE PROCESS (delete a process definition)

Use the MQSC command **DELETE PROCESS** to delete a process definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE PROCESS” on page 703](#)
- [“Parameter descriptions for DELETE PROCESS” on page 704](#)

Syntax diagram for DELETE PROCESS

Synonym: DELETE PRO

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ Valid only on AIX, Linux, and Windows.

Parameter descriptions for DELETE PROCESS

You must specify which process definition you want to delete.

(*process-name*)

The name of the process definition to be deleted. The name must be defined to the local queue manager.

If an application has this process open, the command fails.

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

▶ **z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE PROCESS(process-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP(COPY)** fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

ALW IGNSTATE

Specifies whether the command fails if the process definition does not exist. The value can be one of the following values:

NO

The command fails if the process definition does not exist. This is the default value.

YES

The command succeeds regardless of whether the process definition exists.

Related reference

[“DEFINE PROCESS \(create a new process definition\)” on page 618](#)

Use the MQSC command **DEFINE PROCESS** to define a new IBM MQ process definition, and set its parameters.

[“DISPLAY PROCESS \(display process information\)” on page 851](#)

Use the MQSC command **DISPLAY PROCESS** to display the attributes of one or more IBM MQ processes.

z/OS DELETE PSID (delete a page set) on z/OS

Use the MQSC command **DELETE PSID** to delete a page set. This command closes the page set and de-allocates it from the queue manager.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE PSID” on page 705](#)
- [“Usage notes for DELETE PSID” on page 705](#)
- [“Parameter descriptions for DELETE PSID” on page 706](#)

Syntax diagram for DELETE PSID

Synonym: DEL PSID

DELETE PSID

► DELETE PSID — (— *psid-number* —) ►

Usage notes for DELETE PSID

1. The identified page set must have no storage class (STGCLASS) referencing it.

2. If the page set still has buffers in the buffer pool when you issue this command, the command fails and an error message is issued. You cannot delete the page set until 3 checkpoints have been completed since the page set was emptied.
3. If the page set is not to be used again by the queue manager, update the queue manager started task procedure JCL, and remove the corresponding **DEFINE PSID** command from the CSQINP1 initialization data set. If the page set had a dedicated buffer pool, remove its definitions also from CSQINP1.
4. If you want to reuse the data set again as a page set, format it before doing so.

Parameter descriptions for DELETE PSID

(psid-number)

Identifier of the page set. This is required. You cannot delete page set 0.

Related reference

[“ALTER PSID \(change page set expansion method\) on z/OS” on page 414](#)

Use the MQSC command **ALTER PSID** to change the expansion method for a page set.

[“DEFINE PSID \(define page set and buffer pool\) on z/OS” on page 623](#)

Use the MQSC command **DEFINE PSID** to define a page set and associated buffer pool.

[“DISPLAY USAGE \(display usage information\) on z/OS” on page 981](#)

Use the MQSC command **DISPLAY USAGE** to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.

DELETE queues

Use the MQSC **DELETE** command to delete a queue definition for a local, model, or remote queue, or a queue alias.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagrams for DELETE queues” on page 706](#)
- [“Usage notes for DELETE queues” on page 706](#)
- [“Parameter descriptions for DELETE queues” on page 707](#)

Syntax diagrams for DELETE queues

There is a separate syntax diagram for each type of queue:

- [Syntax diagram for DELETE QALIAS](#)
- [Syntax diagram for DELETE QLOCAL](#)
- [Syntax diagram for DELETE QMODEL](#)
- [Syntax diagram for DELETE QREMOTE](#)

Usage notes for DELETE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DELETE queues](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for DELETE queues

(q-name)

The name of the queue must be defined to the local queue manager for all the queue types.

For an alias queue this is the local name of the alias queue to be deleted.

For a model queue this is the local name of the model queue to be deleted.

For a remote queue this is the local name of the remote queue to be deleted.

For a local queue this is the name of the local queue to be deleted. You must specify which queue you want to delete.

Note: A queue cannot be deleted if it contains uncommitted messages.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

If this queue has a **SCOPE** attribute of CELL, the entry for the queue is also deleted from the cell directory.

AUTHREC

This parameter does not apply to z/OS.

Specifies whether the associated authority record is also deleted:

YES

The authority record associated with the object is deleted. This is the default.

NO

The authority record associated with the object is not deleted.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

Blank

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

PURGE and NOPURGE

Specifies whether any existing committed messages on the queue named by the **DELETE** command are to be purged for the delete command to work. The default is **NOPURGE**.

PURGE

The deletion is to go ahead even if there are committed messages on the named queue, and these messages are also to be purged.

NOPURGE

The deletion is not to go ahead if there are any committed messages on the named queue.

QSGDISP

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves). If the object definition is shared, you do not need to delete it on every queue manager that is part of a queue sharing group. (Queue sharing groups are available only on IBM MQ for z/OS.)

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(GROUP)**. Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters **QSGDISP(SHARED)**, is not affected by this command.

If the deletion is successful, the following command is generated and sent to all active queue managers in the queue sharing group to make, or delete, local copies on page set zero:

```
DELETE queue(q-name) QSGDISP(COPY)
```

or, for a local queue only:

```
DELETE QLOCAL(q-name) NOPURGE QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP(COPY)** fails.

Note: You always get the **NOPURGE** option even if you specify **PURGE**. To delete messages on local copies of the queues, you must explicitly issue the command:

```
DELETE QLOCAL(q-name) QSGDISP(COPY) PURGE
```

for each copy.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(QMGR)**. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

SHARED

This option applies only to local queues.

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP(SHARED)**. Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters **QSGDISP(GROUP)**, is not affected by this command.

IGNSTATE

Specifies whether the command fails if the queue does not exist. The value can be one of the following values:

NO

The command fails if the queue does not exist. This is the default value.

YES

The command succeeds regardless of whether the queue exists.

DELETE QALIAS (delete an alias queue definition)

Use the MQSC command **DELETE QALIAS** to delete an alias queue definition.

- [“Syntax diagram for DELETE QALIAS” on page 709](#)
- [“Usage notes for DELETE queues” on page 706](#)
- [“Parameter descriptions for DELETE queues” on page 707](#)

Syntax diagram for DELETE QALIAS

Synonym: DELETE QA

DELETE QALIAS

Notes:

- ¹ Not valid on z/OS.
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only on AIX, Linux, and Windows.

Related concepts

[Working with alias queues](#)

DELETE QLOCAL (delete a local queue definition)

Use the MQSC command **DELETE QLOCAL** to delete a local queue definition. You can specify that the queue must not be deleted if it contains messages, or that it can be deleted even if it contains messages.

- [“Syntax diagram for DELETE QLOCAL” on page 709](#)
- [“Usage notes for DELETE queues” on page 706](#)
- [“Parameter descriptions for DELETE queues” on page 707](#)

Syntax diagram for DELETE QLOCAL

Synonym: DELETE QL

DELETE QLOCAL

Notes:

- ¹ Not valid on z/OS.
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only on AIX, Linux, and Windows.

Related tasks

[Deleting a local queue](#)

DELETE QMODEL (delete a model queue definition)

Use the MQSC command **DELETE QMODEL** to delete a model queue definition.

- [“Syntax diagram for DELETE QMODEL” on page 710](#)
- [“Usage notes for DELETE queues” on page 706](#)
- [“Parameter descriptions for DELETE queues” on page 707](#)

Syntax diagram for DELETE QMODEL

Synonym: DELETE QM

DELETE QMODEL

Notes:

- ¹ Not valid on z/OS.
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only on AIX, Linux, and Windows.

The parameters are described in [“DELETE queues” on page 706](#).

Related concepts

[Working with model queues](#)

DELETE QREMOTE (delete a local remote queue definition)

Use the MQSC command **DELETE QREMOTE** to delete a local definition of a remote queue. It does not affect the definition of that queue on the remote system.

- [“Syntax diagram for DELETE QREMOTE” on page 711](#)
- [“Usage notes for DELETE queues” on page 706](#)
- [“Parameter descriptions for DELETE queues” on page 707](#)

Syntax diagram for DELETE QREMOTE

Synonym: DELETE QR

DELETE QREMOTE

Notes:

- ¹ Not valid on z/OS.
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only on AIX, Linux, and Windows.

Multi DELETE SERVICE (delete a service definition) on Multiplatforms

Use the MQSC command **DELETE SERVICE** to delete a service definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DELETE SERVICE” on page 712](#)
- [“Usage notes for DELETE SERVICE” on page 712](#)
- [“Keyword and parameter descriptions for DELETE SERVICE” on page 713](#)

Syntax diagram for DELETE SERVICE

Synonym:

DELETE SERVICE

Notes:

- ¹ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE SERVICE

1. The command fails if an application has the specified service object open, or if the service is currently running.

Keyword and parameter descriptions for DELETE SERVICE

(*service-name*)

The name of the service definition to be deleted. This parameter is required. The name must be that of an existing service defined on the local queue manager.

ALW **IGNSTATE**

Specifies whether the command fails if the service does not exist. The value can be one of the following values:

NO

The command fails if the service does not exist. This is the default value.

YES

The command succeeds regardless of whether the service exists.

Related reference

Use the MQSC command **DEFINE SERVICE** to define a new IBM MQ service definition, and set its parameters.

[“DISPLAY SVSTATUS \(display services status\) on Multiplatforms” on page 946](#)

Use the MQSC command **DISPLAY SVSTATUS** to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

[“START SERVICE \(start a service\) on Multiplatforms” on page 1074](#)

Use the MQSC command **START SERVICE** to start a service. The identified service definition is started within the queue manager and inherits the environment and security variables of the queue manager.

[“STOP SERVICE \(stop a service\) on Multiplatforms” on page 1097](#)

Use the MQSC command **STOP SERVICE** to stop a service.

DELETE STGCLASS (delete a storage class) on z/OS

Use the MQSC command **DELETE STGCLASS** to delete a storage class definition.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE STGCLASS” on page 713](#)
- [“Parameter descriptions for DELETE STGCLASS” on page 714](#)

Syntax diagram for DELETE STGCLASS

Synonym: DELETE STC

DELETE STGCLASS

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for DELETE STGCLASS

You must specify which storage class definition you want to delete.

All queues that use this storage class must be altered to use another storage class.

(name)

The name of the storage class definition to be deleted. The name must be defined to the local queue manager.

The command fails unless all queues referencing the storage class are empty and closed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

QSGDISP

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP(COPY)**. Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP(QMGR)**, is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP**(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to delete local copies on page set zero:

```
DELETE STGCLASS(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP**(COPY) fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

DELETE SUB (delete a durable subscription)

Use the MQSC command **DELETE SUB** to remove a durable subscription from the system. For a managed destination, any unprocessed messages left on the destination are removed.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE SUB” on page 715](#)
- [Usage notes for DELETE SUB](#)
- [“Parameter descriptions for DELETE SUB” on page 716](#)

Syntax diagram for DELETE SUB

Synonym: **DEL SUB**

DELETE SUB

Notes:

- ¹ Valid only on z/OS.
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE SUB

- You can specify either the name, the identifier, or both, of the subscription you want to delete.

Examples of valid forms:

```
DELETE SUB(xyz)
DELETE SUB SUBID(123)
DELETE SUB(xyz) SUBID(123)
```

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DELETE SUB step in Checking that async commands for distributed networks have finished.](#)

Parameter descriptions for DELETE SUB

subscription-name

The local name of the subscription definition to be deleted.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

SUBID(string)

The internal, unique key identifying a subscription.

 IGNSTATE

Specifies whether the command fails if the subscription does not exist. The value can be one of the following values:

NO

The command fails if the subscription does not exist. This is the default value.

YES

The command succeeds regardless of whether the subscription exists.

Related tasks

Use the MQSC command **DISPLAY SUB** to display the attributes associated with a subscription.

DELETE TOPIC (delete an administrative topic node)

Use the MQSC command **DELETE TOPIC** to delete an IBM MQ administrative topic node.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DELETE TOPIC” on page 717](#)
- [“Usage notes for DELETE TOPIC” on page 718](#)
- [“Parameter descriptions for DELETE TOPIC” on page 718](#)

Syntax diagram for DELETE TOPIC

Synonym: None

DELETE TOPIC

Notes:

- ¹ Not valid on z/OS
- ² Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ³ Valid only on z/OS.
- ⁴ Valid only on AIX, Linux, and Windows.

Usage notes for DELETE TOPIC

- Successful completion of the command does not mean that the action completed. To check for true completion, see the [DELETE TOPIC](#) step in [Checking that async commands for distributed networks have finished](#).

Parameter descriptions for DELETE TOPIC

(topic-name)

The name of the administrative topic object to be deleted. This parameter is required.

The name must be that of an existing administrative topic object.

AUTHREC

This parameter does not apply to z/OS

Specifies whether the associated authority record is also deleted:

YES

The authority record associated with the object is deleted. This is the default.

NO

The authority record associated with the object is not deleted.

z/OS CMDSCOPE

This parameter applies to only z/OS and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

▶ **z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters **QSGDISP**(QMGR), is not affected by this command.

GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters **QSGDISP**(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue sharing group to make, or delete, local copies on page set zero:

```
DELETE TOPIC(topic-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with **QSGDISP**(COPY) fails.

QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters **QSGDISP**(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

▶ **ALW** **IGNSTATE**

Specifies whether the command fails if the topic does not exist. The value can be one of the following values:

NO

The command fails if the topic does not exist. This is the default value.

YES

The command succeeds regardless of whether the topic exists.

DISPLAY APSTATUS (display application status) on Multiplatforms

Use the MQSC command **DISPLAY APSTATUS** to display the status of one or more applications and application instances connected to a queue manager or a uniform cluster.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY APSTATUS” on page 720](#)
- [“Usage notes for DISPLAY APSTATUS” on page 721](#)
- [“Parameter descriptions for DISPLAY APSTATUS” on page 721](#)
- [“Application status parameters” on page 723](#)
- [“Queue manager status parameters” on page 723](#)
- [“Local status parameters” on page 724](#)

Syntax diagram for DISPLAY APSTATUS

Synonym: DIS APS

Usage notes for DISPLAY APSTATUS

The application name parameter of the **DISPLAY APSTATUS** command matches against application names set by applications. See [using the application name in supported programming languages](#) for more information.

Parameter descriptions for DISPLAY APSTATUS

The **DISPLAY APSTATUS** command requires an application name string value to determine which application details to return.

applicationnamestr

The application name string can have one of the following values:

- A specific application name string value. For example, `DIS APSTATUS('myapp')` returns details of just the 'myapp' application
- A string containing one or more wildcard characters. For example, `DIS APSTATUS('*put*')` returns all applications which have 'put' in their application names.

To return a list of all user applications, use `DIS APSTATUS('*')`

To filter the list of applications returned, use the WHERE parameter. For example, `DIS APSTATUS('*put*') TYPE(APPL) WHERE(BALANCED eq NO)` returns application information about all unbalanced applications with 'put' in their name.

WHERE

Specifies a filter condition to match only those applications or application instances that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that you can use with this **DISPLAY** command based on the **TYPE** option.

operator

Determines whether a keywords value satisfies a condition on the given filter value. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the *filter-keyword*, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can only use EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Use this parameter to display all attributes.

If you specify this parameter, any attributes that you request additionally have no effect; the command displays all attributes.

This value is the default, if you do not specify a generic name, and do not request any specific parameters.

TYPE

Specifies the type of status information required:

APPL

The command displays status information relating to each unique application name, which is the default if you do not provide a **TYPE** parameter. This represents a summary of the details from the local queue manager and any queue manager in the same uniform cluster.

QMGR

The command displays status information relating to applications at a queue manager level, including the local queue manager and any queue manager in the same uniform cluster.

LOCAL

The command displays status information for applications, for each application instance connected to the local queue manager.

Application status parameters

Application status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once:

BALANCED

If the local queue manager is a member of a uniform cluster, this field gives an indication as to whether the number of application instances across the cluster is currently balanced, based on the last information received from the other queue managers in the cluster.

If the queue manager is not a member of a uniform cluster, this field shows NOTAPPLIC.

The value can be any of the following values:

NO

This application is not considered balanced in the uniform cluster.

YES

This application is considered balanced in the uniform cluster.

NOTAPPLIC

This application is not shared across a uniform cluster.

UNKNOWN

This is a temporary state, representing an application that has not yet undergone a scan to calculate whether it is balanced or not, on at least one queue manager, across the uniform cluster.

CLUSTER

If the application details are being sent around a uniform cluster, this field displays the name of the uniform cluster, otherwise it shows a blank.

COUNT

This displays the sum of the number of application instances for this application from the local queue manager, and all queue managers in the uniform cluster that have shared their application instance counts.

A queue manager not in a uniform cluster displays the count of local application instances.

MOVCOUNT

This displays the sum of the number of movable application instances for this application from the local queue manager and all queue managers in the uniform cluster that have shared their application instance counts.

A queue manager not in a uniform cluster displays the count of local application instances that would be movable if put in a uniform cluster.

Queue manager status parameters

Queue manager status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once.

ACTIVE

Displays if the queue manager is considered active when balancing applications, which indicates whether information from that queue manager has been received recently.

YES

The queue manager is communicating with the uniform cluster. The local queue manager always shows **ACTIVE**(YES).

NO

No status has recently been received from this queue manager. This could indicate a communication problem, or that the queue manager has been suspended from the uniform cluster.

BALSTATE

Indicates the state of the application instances on this queue manager, compared to the other queue managers in a uniform cluster. The value can be :

HIGH

There is a surplus of application instances.

OK

There is a balanced number of application instances.

LOW

There are not enough application instances.

NOTAPPLIC

The queue manager is not in a uniform cluster.

UNKNOWN

This is a temporary state representing an application that is new to the uniform cluster, and which has not yet undergone a scan to calculate whether it is balanced or not.

COUNT

Represents the count of application instances for this application on the queue manager.

LMSGDATE

The local date on which the local queue manager last received a published message from this queue manager, containing its application instance details.

LMSGTIME

The local time on which the local queue manager last received a published message from this queue manager, containing its application instance details.

MOVCOUNT

This represents the count of movable application instances for this application on the queue manager. Only application instances which are movable will be considered for rebalancing in a uniform cluster.

QMID

The queue manager identifier of the queue manager, that this information originated from.

QMNAME

The queue manager name that this information originated from. There will be one entry for the local queue manager, and one from each queue manager that has distributed information about this application in a uniform cluster.

Local status parameters

Local status parameters define the data that the command displays. You can specify these parameters in any order, but you must not specify the same parameter more than once.

BALOPTS

The balancing options in effect for this application instance. Possible values are:

MQBNO_OPTIONS_NONE

No options are set.

MQBNO_OPTIONS_IGNORE_TRANS

This option allows applications to be re-balanced even if in the middle of a transaction.

BALTMOUT

The time out value in effect for this application instance. Possible values are:

NEVER

No time out occurs.

IMMEDIATE

Time out occurs immediately

value

The timeout value in seconds, up to a maximum of 999999999 seconds.

BALTYPE

The application type in effect for this application instance. Possible values are:

MQBNO_BALTYPE_SIMPLE

No specific rules should be applied beyond the defaults described in [Configuring the balancing behavior](#).

MQBNO_BALTYPE_REQREP

After each MQPUT call, a matching MQGET call is expected for a response message. Balancing is delayed until such a message is received, or the request message EXPIRY has been exceeded.

MQBNO_BALTYPE_RAMANAGED

Re-balancing requests are always dispatched immediately to the client, which re-balances at a point the client considers appropriate.

Note that different instances of the same application can provide different balancing options without causing any error.

CONNS

The number of connections (HCONNS) the application instance currently has.

CONNTAG

The connection tag of this application instance.

IMMCOUNT

The number of times this application instance has been asked to reconnect but has stayed connected. Any value higher than one indicates the application is not moving when requested.

IMMDATE

If the application instance is immovable for a fixed period, this indicates the date at which the instance will be eligible for moving again. If this has a value, the **IMMREASN** field should indicate why the connection is temporarily immovable. If the connection is not temporarily immovable, the value is blank.

IMMREASN

If the application instance is immovable, this indicates a reason as to why. If the application instance is movable, the value is blank. Only one **IMMREASN** is displayed even though multiple might apply; note that permanent statuses (such as NOTRECONN, NOTCLIENT) are displayed in preference to temporary values (such as MOVING, INTRANS).

The value can be any of the following values:

APPNAMECHG

This application instance cannot be moved as it is sharing a socket with a connection from an application instance which has a different application name.

INTRANS

The application instance has successfully performed at least one MQI operation within syncpoint, and the timeout specified to forcibly rebalance an instance has not been reached.

MOVING

This application instance cannot be moved as it has recently been requested to move, and has not yet disconnected.

This status should be temporary. **IMMDATE** and **IMMTIME** indicate when this application instance is considered eligible to move again if this state unexpectedly persists.

NONE

This application instance is currently considered movable.

NOREDIRECT

The client application has indicated that it cannot process redirect hints from the queue manager. This might be because the application isn't using a CCDT to connect to the queue manager.

NOTCLIENT

This application instance cannot be moved as it is not a client connection.

NOTRECONN

This application instance cannot be moved as it is not a reconnectable client connection.

REPLY

The application instance is of type REQREP and has sent at least one request message for which a corresponding response has not been received. The timeout specified to forcibly rebalance an instance has not been reached.

IMMTIME

If the application instance is immovable for a fixed period, this indicates the time at which the instance will be eligible for moving again. If this has a value, the **IMMREASN** field should indicate why the connection is temporarily immovable. If the connection is not temporarily immovable, the value is blank.

MOVABLE

This indicates whether this application instance is considered movable or not.

Related reference

[“DISPLAY CONN \(display application connection information\)” on page 819](#)

Use the MQSC command **DISPLAY CONN** to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

[“MQCMD_INQUIRE_APPL_STATUS \(inquire application status\) Response on Multiplatforms” on page 1291](#)

The response to the Inquire Application Status (**MQCMD_INQUIRE_APPL_STATUS**) PCF command consists of the response header followed by the *ApplicationName* structure and the requested combination of attribute parameter structures (where applicable) for the requested *ApplicationStatusInfoType*.

DISPLAY ARCHIVE (display archive system information) on z/OS

Use the MQSC command **DISPLAY ARCHIVE** to display archive system parameters and information.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY ARCHIVE” on page 727](#)
- [“Usage notes for DISPLAY ARCHIVE” on page 727](#)
- [“Parameter descriptions for DISPLAY ARCHIVE” on page 727](#)

Syntax diagram for DISPLAY ARCHIVE

Synonym: DIS ARC

Usage notes for DISPLAY ARCHIVE

1. **DISPLAY ARCHIVE** returns a report that shows the initial values for the archiving parameters, and the current values as changed by the **SET ARCHIVE** command.
 - Units in which primary and secondary space allocations are made (ALCUNIT).
 - Prefix for first archive log data set name (ARCPFX1).
 - Prefix for second archive log data set name (ARCPFX2).
 - The retention period of the archive log data set in days (ARCRETN).
 - List of route codes for messages to the operator about archive log data sets (ARCWRTC).
 - Whether to send message to operator and wait for reply before trying to mount an archive log data set (ARCWTOR).
 - Block size of archive log data set (BLKSIZE).
 - Whether archive log data sets are cataloged in the ICF (CATALOG).
 - Whether archive log data sets should be compacted (COMPACT).
 - Primary space allocation for DASD data sets (PRIQTY).
 - Whether archive log data sets are protected by ESM profiles when the data sets are created (PROTECT).
 - Maximum time, in seconds, allowed for quiesce when ARCHIVE LOG with MODE(QUIESCE) specified (QUIESCE).
 - Secondary space allocation for DASD data sets. See the ALCUNIT parameter for the units to be used (SECQTY).
 - Whether the archive data set name should include a time stamp (TSTAMP).
 - Device type or unit name on which the first copy of archive log data sets is stored (UNIT).
 - Device type or unit name on which the second copy of archive log data sets is stored (UNIT2).

It also reports the status of tape units used for archiving.

For more details of these parameters, see [“SET ARCHIVE \(change archive system settings\) on z/OS” on page 1030](#).

2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY ARCHIVE

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Related reference

[“ARCHIVE LOG \(back up the active log\) on z/OS” on page 513](#)

Use the MQSC command **ARCHIVE LOG** as part of your backup procedure. It takes a copy of the current active log (or both logs if you are using dual logging).

[“SET ARCHIVE \(change archive system settings\) on z/OS” on page 1030](#)

Use the MQSC command **SET ARCHIVE** to dynamically change certain archive system parameter values initially set by your system parameter module at queue manager startup.

DISPLAY AUTHINFO (display authentication information)

Use the MQSC command **DISPLAY AUTHINFO** to display the attributes of an authentication information object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY AUTHINFO” on page 728](#)
- [“Parameter descriptions for DISPLAY AUTHINFO” on page 730](#)
- [“Requested parameters” on page 733](#)

Syntax diagram for DISPLAY AUTHINFO

Synonym: DIS AUTHINFO

DISPLAY AUTHINFO

►► DISPLAY AUTHINFO — (— *generic-authentication-information-object-name* —) ►

Requested attrs

Parameter descriptions for DISPLAY AUTHINFO

(generic-authentication-information-object-name)

The name of the authentication information object to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all authentication information objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all authentication information objects.

WHERE

Specify a filter condition to display only those authentication information objects that satisfy the selection criterion of the filter condition. The filter condition is in three parts: filter-keyword, operator, and filter-value:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE** or **QSGDISP** parameters as filter keywords.

operator

This is used to determine whether an authentication information object satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
You can use any of the operators except LK and NL.
- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value with numeric values. Only a single trailing wildcard character (asterisk) is permitted.

You can only use operators LK or NL for generic values on the **DISPLAY AUTHINFO** command.

ALL

Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name and do not request any specific parameters.

 On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only requested attributes are displayed.

 CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

• •

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

AUTHTYPE

Specifies the authentication information type of the objects for which information is to be displayed. Values are:

ALL

This is the default value and displays information for objects defined with **AUTHTYPE**(CRLLDAP) and with **AUTHTYPE**(OCSP).

CRLLDAP

Displays information only for objects defined with **AUTHTYPE**(CRLLDAP).

IDPWLDAP

Displays information only for objects defined with **AUTHTYPE**(IDPWLDAP).

IDPWOS

Displays information only for objects defined with **AUTHTYPE**(IDPWOS).

OCSP

Displays information only for objects defined with **AUTHTYPE**(OCSP).

QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with **QSGDISP**(QMGR) or **QSGDISP**(COPY).

ALL

Displays information for objects defined with **QSGDISP**(QMGR) or **QSGDISP**(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP**(GROUP).

If **QSGDISP**(LIVE) is specified or defaulted, or if **QSGDISP**(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

COPY

Displays information only for objects defined with **QSGDISP**(COPY).

GROUP

Displays information only for objects defined with **QSGDISP**(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE

Displays information for objects defined with **QSGDISP**(QMGR) or **QSGDISP**(COPY).

Note: **QSGDISP**(PRIVATE) displays the same information as **QSGDISP**(LIVE).

QMGR

Displays information only for objects defined with **QSGDISP**(QMGR).

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP**(QMGR).

GROUP

The object was defined with **QSGDISP**(GROUP).

COPY

The object was defined with **QSGDISP**(COPY).

You cannot use **QSGDISP** as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the **ALL** parameter is not specified) is that the object names and their **AUTHTYPE**s, and, on z/OS, their **QSGDISP**s, are displayed.

ADOPTCTX

Displays the presented credentials as the context for this application.

ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd

ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss

AUTHENMD

Authentication method. Possible values are:

OS

Displays the traditional UNIX password verification method permissions.

PAM

Displays the Pluggable Authentication Method permissions.

You can set the PAM value only on AIX and Linux platforms.

AUTHORMD

Displays the authorization method. Possible values are:

OS

Use operating system groups to determine permissions associated with a user.

SEARCHGRP

A group entry in the LDAP repository contains an attribute listing the Distinguished Name of all users belonging to that group.

SEARCHUSR

A user entry in the LDAP repository contains an attribute listing the Distinguished Name of all the groups to which the specified user belongs.

SRCHGRPSN

A group entry in the LDAP repository contains an attribute listing the short user name of all users belonging to that group.

AUTHTYPE

The type of the authentication information

BASEDNG

Displays the Base DN for groups.

BASEDNU

Displays the base distinguished name to search for users within the LDAP server.

CHKLOCL or CHCKCLNT

These attributes are valid only for an **AUTHTYPE** of IDPWOS or IDPWLDAP. The possible values are:

NONE

Displays all locally bound applications that have no user ID and password authentication.

OPTIONAL

Displays the user IDs and passwords provided by an application. Note that it is not mandatory to provide these attributes. This option might be useful during migration, for example.

REQUIRED

Displays all applications providing a valid user ID and password.

REQDADM

Displays privileged users supplying a valid user ID and password, Non-privileged users are treated as with the OPTIONAL setting. See also the following note.  (This setting is not allowed on z/OS systems.)

CLASSGRP

Displays the LDAP object class for group records.

CLASSUSR

Displays the LDAP object class for user records within the LDAP repository.

CONNAME

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running. Applies only to objects with **AUTHTYPE(CRLLDAP)** or **AUTHTYPE(IDPWLDAP)**.

DESCR

Description of the authentication information object.

FAILDLAY

Delay in seconds before an authentication failure is returned to an application.

FINDGRP

Displays the name of the attribute within an LDAP entry to determine group membership.

GRPFIELD

Displays the LDAP attribute that represents a simple name for the group.

LDAPPWD

Password associated with the Distinguished Name of the user on the LDAP server. If not blank, this is displayed as asterisks  on all platforms except z/OS. Applies only to objects with **AUTHTYPE(CRLLDAP)** or **AUTHTYPE(IDPWLDAP)**.

LDAPUSER

Distinguished Name of the user on the LDAP server. Applies only to objects with **AUTHTYPE(CRLLDAP)** or **AUTHTYPE(IDPWLDAP)**.

NESTGRP

Displays whether a group is a member of another group..

OCSPURL

The URL of the OCSP responder used to check for certificate revocation. Applies only to objects with **AUTHTYPE(OCSP)**.

SECCOMM

Displays the method used to connect the LDAP server.

SHORTUSR

Displays the user record being used as a short name.

USRFIELD

Displays the user record being used in the LDAP user record, only if the user ID does not contain a qualifier.

For more information about individual parameters, see [“Usage notes for DEFINE AUTHINFO” on page 526.](#)

Related reference

[“ALTER AUTHINFO \(alter authentication information object\)” on page 319](#)

Use the MQSC command **ALTER AUTHINFO** to alter an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.

[“DEFINE AUTHINFO \(define an authentication information object\)” on page 521](#)

Use the MQSC command **DEFINE AUTHINFO** to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to check authentication credentials provided by applications.

[“DELETE AUTHINFO \(delete authentication information\)” on page 687](#)

Use the MQSC command **DELETE AUTHINFO** to delete an authentication information object.

DISPLAY AUTHREC (display authority records) on Multiplatforms

Use the MQSC command **DISPLAY AUTHREC** to display the authority records associated with a profile name.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY AUTHREC” on page 735](#)
- [“Parameter descriptions for DISPLAY AUTHREC” on page 736](#)
- [“Requested parameters” on page 738](#)

Syntax diagram for DISPLAY AUTHREC

Synonym: DIS AUTHREC

DISPLAY AUTHREC

Parameter descriptions for DISPLAY AUTHREC

PROFILE(*profile-name*)

The name of the object or generic profile for which to display the authority records. If you omit this parameter, all authority records that satisfy the values of the other parameters are displayed.

OBJTYPE

The type of object referred to by the profile. Specify one of the following values:

AUTHINFO

Authentication information record

CHANNEL

Channel

CLNTCONN

Client connection channel

COMMINFO

Communication information object

LISTENER

Listener

NAMELIST

Namelist

PROCESS

Process

QUEUE

Queue

QMGR

Queue manager

RQMNAME

Remote queue manager

SERVICE

Service

TOPIC

Topic

If you omit this parameter, authority records for all object types are displayed.

PRINCIPAL(*principal-name*)

A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

This parameter cannot be specified with **GROUP**.

GROUP(*group-name*)

A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

 **Windows** For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

This parameter cannot be specified with **PRINCIPAL**.

MATCH

Specify this parameter to control the set of authority records that is displayed. Specify one of the following values:

PROFILE

Return only those authority records which match the specified profile, principal, and group names. This means that a profile of ABCD results in the profiles ABCD, ABC*, and AB* being returned (if ABC* and AB* have been defined as profiles). If the profile name is a generic profile, only authority records which exactly match the specified profile name are returned. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profiles defined for the specified principal or group.

This is the default value.

MEMBERSHIP

Return only those authority records which match the specified profile, and the entity field of which matches the specified principal and the profiles pertaining to any groups in which the principal is a member that contribute to the cumulative authority for the specified entity.

If this option is specified, the **PROFILE** and **OBJTYPE** parameters must also be specified. In addition, either the **PRINCIPAL** or **GROUP** parameter must also be supplied. If **OBJTYPE (QMGR)** is specified, the profile name is optional.

EXACT

Return only those authority records which exactly match the specified profile name and EntityName. No matching generic profiles are returned unless the profile name is, itself, a generic profile. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profile defined for the specified principal or group.

SERVCOMP(service-component)

The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

ALL

Specify this parameter to display all of the authorization information available for the entity and the specified profile.

Requested parameters

You can request the following information about the authorizations:

AUTHLIST

Specify this parameter to display the list of authorizations.

ENTITY

Specify this parameter to display the entity name.

ENTTYPE

Specify this parameter to display the entity type.

Related reference

[“dmpmqaut \(dump MQ authorizations\)” on page 61](#)

Dump a list of current authorizations for a range of IBM MQ object types and profiles.

[“setmqaut \(grant or revoke authority\)” on page 248](#)

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

[“SET AUTHREC \(set authority records\) on Multiplatforms” on page 1035](#)

Use the MQSC command **SET AUTHREC** to set authority records associated with a profile name.

[“DELETE AUTHREC \(delete authority records\) on Multiplatforms” on page 690](#)

Use the MQSC command **DELETE AUTHREC** to delete authority records associated with a profile name.

DISPLAY AUTHSERV (display authorization services information) on AIX, Linux, and Windows

Use the MQSC command **DISPLAY AUTHSERV** to display information about the level of function supported by the installed authorization services.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Requested parameters” on page 739](#)

Syntax diagram for DISPLAY AUTHSERV

Synonym: DIS AUTHSERV

Parameter descriptions for DISPLAY AUTHSERV

ALL

Specify this parameter to display all the information for each authorization service.

Requested parameters

You can request the following information for the authorization service:

IFVER

Specify this parameter to display the current interface version of the authorization service.

UIDSUPP

Specify this parameter to display whether the authorization service supports user IDs.

DISPLAY CFSTATUS (display CF application structure status) on z/OS

Use the MQSC command **DISPLAY CFSTATUS** to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Summary status” on page 742](#)
- [“Connection status” on page 743](#)
- [“Backup status” on page 744](#)
- [“SMDS status” on page 745](#)

Syntax diagram for DISPLAY CFSTATUS

Synonym: DIS CFSTATUS

DISPLAY CFSTATUS

►► DISPLAY CFSTATUS — (— *generic-structure-name* —) ►

Notes:

¹ This option is only supported when the CFSTRUCT is defined with OFFLOAD(SMDS).

Keyword and parameter descriptions for DISPLAY CFSTATUS

The name of the application structure for the status information to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- Status information for all application structure definitions.
- Status information for one or more application structures that match the specified name .

The type of status information to be returned can also be specified. This can be:

- Summary status information for the application structure in the queue sharing group.
- Connection status information for each queue manager in the queue sharing group for each matching application structure name.
- Backup status information for each backup taken for each matching application structure defined in the queue sharing group.

(*generic-structure-name*)

The 12-character name of the CF application structure to be displayed. A trailing asterisk (*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all structure names.

The CF structure name must be defined within the queue sharing group.

The CFSTATUS generic name can be the administration CF structure name (CSQ_ADMIN) or any generic form of this name. Data for this structure, however, is only displayed when **TYPE** is set to SUMMARY.

WHERE

Specify a filter condition to display status information for those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that is returned by this **DISPLAY** command. However, you cannot use the **TYPE** parameter as a filter keyword.

operator

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, GE, only. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ACTIVE on the **STATUS** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string in the **QMNAME** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

TYPE

Specifies the type of status information required to be displayed. Values are:

SUMMARY

Display summary status information for each application structure. This is the default.

CONNECT

Display connection status information for each application structure for each active queue manager.

BACKUP

Display backup status information for each application structure.

SMDS

Display shared message data set information.

SMDS**qmgr-name**

Specifies the queue manager for which the shared message data set status is to be displayed.

Displays the status for all shared message data sets associated with the specified **CFSTRUCT** except those which have both **STATUS (NOTFOUND)** and **ACCESS (ENABLED)**.

Summary status

For summary status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

CFTYPE

The CF structure type. This is one of the following:

ADMIN

This is the CF administration structure.

APPL

This is a CF application structure.

STATUS

The status of the CF application structure. This is one of the following:

ACTIVE

The structure is active.

FAILED

The structure has failed.

NOTFOUND

The structure is not allocated in the CF, but has been defined to Db2. Check and resolve any messages in the job log about this structure.

INBACKUP

The structure is in the process of being backed-up.

INRECOVER

The structure is in the process of being recovered.

UNKNOWN

The status of the CF structure is not known because, for example, Db2 might be unavailable.

SIZEMAX (size)

The size in kilobytes of the application structure.

SIZEUSED (integer)

The percentage of the size of the application structure that is in use. Therefore **SIZEUSED(25)** would indicate that a quarter of the space allocated to this application structure is in use.

ENTSMAX (integer)

The number of CF list entries defined for this application structure.

Note: The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

ENTSUSED (*integer*)

The number of CF list entries for this application structure that are in use.

Note: The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

FAILTIME (*time*)

The time that this application structure failed. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE (*date*)

The date that this application-structure failed. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, then this is displayed as FAILDATE().

OFFLDUSE

This indicates whether offloaded large message data potentially exists in shared message data sets, Db2 or both.

When the offload method is switched, the previous offload method needs to remain available for retrieving and deleting old messages, so the **OFFLDUSE** status is changed to indicate **BOTH**. When a queue manager disconnects normally from a structure that has **OFFLDUSE (BOTH)** it checks whether there still are any messages which were stored using the old offload method. If not, it changes the **OFFLDUSE** status to match the current offload method and issues message CSQE245I to indicate that the switch is complete.

This parameter is one of the following:

NONE

No offloaded large messages are present.

SMDS

Offloaded large messages can exist in shared message data sets.

Db2

Offloaded large messages can exist in Db2.

BOTH

Offloaded large messages can exist both in shared message data sets and in Db2.

Connection status

For connection status, the following information is returned for each connection to each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

QMNAME (*qmgrname*)

The queue manager name.

SYSNAME (*systemname*)

The name of the z/OS image of the queue manager that last connected to the application structure. These can be different across queue managers depending on the customer configuration setup.

STATUS

A status indicating whether this queue manager is connected to this application structure. This is one of the following:

ACTIVE

The structure is connected to this queue manager.

FAILED

The queue manager connection to this structure has failed.

NONE

The structure has never been connected to this queue manager.

UNKNOWN

The status of the CF structure is not known.

FAILTIME (time)

The time that this queue manager lost connectivity to this application structure. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE (date)

The date that this queue manager lost connectivity to this application structure. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

Backup status

For backup status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

STATUS

The status of the CF application structure. This is one of the following:

ACTIVE

The structure is active.

FAILED

The structure has failed.

NONE

The structure is defined as **RECOVER(YES)**, but has never been backed up.

INBACKUP

The structure is in the process of being backed-up.

INRECOVER

The structure is in the process of being recovered.

UNKNOWN

The status of the CF structure is not known.

QMNAME (qmgrname)

The name of the queue manager that took the last successful backup for this application structure.

BKUPTIME (time)

The end time of the last successful backup taken for this application structure. The format of this field is hh.mm.ss.

BKUPDATE (date)

The date of the last successful backup taken for this application structure. The format of this field is yyyy-mm-dd.

BKUPSIZE (size)

The size in megabytes of the last successful backup taken for this application structure.

BKUPSRBA (hexadecimal)

This is the backup data set start RBA for the start of the last successful backup taken for this application structure.

BKUPERBA (hexadecimal)

This is the backup data set end RBA for the end of the last successful backup taken for this application structure.

LOGS (qmgrname-list)

This is the list of queue managers, the logs of which are required to perform a recovery.

FAILTIME (time)

The time that this CF structure failed. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

FAILDATE (date)

The date that this CF structure failed. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

SMDS status

The **DISPLAY CFSTATUS** command with **TYPE (SMDS)** displays status information relating to one or more shared message data sets associated with a specific application structure.

The following data is returned for each selected data set:

SMDS

The queue manager name which owns the shared message data set for which properties are being displayed

STATUS

The current status of the shared message data set. This is one of the following:

NOTFOUND

The data set has never been used, or the attempt to open it for the first time failed. Check and resolve any messages in the job log about this structure.

NEW

The data set is being opened and initialized for the first time, ready to be made active.

ACTIVE

The data set is available for normal use.

FAILED

The data set is in an unusable state and probably requires recovery.

INRECOVER

Data set recovery (using **RECOVER CFSTRUCT**) is in progress.

RECOVERED

The data set has been recovered or otherwise repaired, and is ready for use again, but requires some restart processing the next time it is opened. This restart processing ensures that obsolete references to any deleted messages have been removed from the coupling facility structure before the data set is made available again. The restart processing also rebuilds the data set space map.

EMPTY

The data set contains no messages. The data set is put into this state if it is closed normally by the owning queue manager at a time when it does not contain any messages. It can also be put into EMPTY state when the previous data set contents are to be discarded because the application structure has been emptied (using **RECOVER CFSTRUCT** with **TYPE PURGE** or, for a nonrecoverable structure only, by deleting the previous instance of the structure). The next time the data set is opened by its owning queue manager, the space map is reset to empty, and the status is changed to ACTIVE. As the previous data set contents are no longer required, a data set in this state can be replaced with a newly allocated data set, for example to change the space allocation or move it to another volume.

ACCESS

The current availability state of the shared message data set. This parameter is one of the following:

ENABLED

The data set can be used, and no error has been detected since the time that it was enabled. If the data set has **STATUS(Recovered)** it can only be opened by the owning queue manager for restart purposes, but if it has **STATUS(Active)** all queue managers can open it.

SUSPENDED

The data set is unavailable because of an error.

This occurs specifically when the **STATUS** is set to **FAILED** either because of an error accessing the data set, or using the **ALTER SMDS** command.

The queue manager can try to enable access again automatically if the error might no longer be present, for example when recovery completes, or if the status is manually set to RECOVERED. Otherwise, it can be enabled again by a command in order to retry the action which originally failed.

DISABLED

The shared message data set cannot be used because it has been explicitly disabled using a command. It can only be enabled again by using another command to enable it. For more information, see [“RESET SMDS \(reset shared message data sets\) on z/OS” on page 1018](#).

RCVDATE

The recovery start date.

If recovery is currently enabled for the data set, this indicates the date when it was activated, in the form *yyyy-mm-dd*. If recovery is not enabled, this is displayed as RCVDATE().

RCVTIME

The recovery start time.

If recovery is currently enabled for the data set, this indicates the time when it was activated, in the form *hh.mm.ss*. If recovery is not enabled, this is displayed as RCVTIME().

FAILDATE

The failure date.

If the data set was put into a failed state, and has not yet been restored to the active state, this indicates the date when the failure was indicated, in the form *yyyy-mm-dd*. If the data set is in the active state, this is displayed as FAILDATE().

FAILTIME

The failure time.

If the data set was put into a failed state and has not yet been restored to the active state, this indicates the time when the failure was indicated, in the form *hh.mm.ss*. If the data set is in the active state, this is displayed as FAILTIME().

Notes:

¹ For more information about this parameter, see [Planning your coupling facility and offload storage environment](#).

Usage notes for DISPLAY CFSTRUCT

1. The command cannot specify the CF administration structure (CSQ_ADMIN).

Keyword and parameter descriptions for DISPLAY CFSTRUCT

The name of the application structure to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- all application structure definitions
- one or more application structures that match the specified name

(*generic-structure-name*)

The 12-character name of the CF application structure to be displayed. A trailing asterisk (*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all structure names.

The CF structure name must be defined within the queue sharing group.

WHERE

Specify a filter condition to display only those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the **RECOVER** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values on the **DISPLAY CFSTRUCT** command.

ALL

Specify this to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

The default, if no parameters are specified (and the **ALL** parameter is not specified) is that the structure names are displayed.

ALTDAT

The date on which the definition was last altered, in the form yyyy-mm-dd.

ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss.

CFCONLOS

The action to be taken when the queue manager loses connectivity to the CF application structure.

CFLEVEL

Indicates the functional capability level for this CF application structure.

DESCR

Descriptive comment.

DSBLOCK

The logical block size, which is the unit in which shared message data set space is allocated to individual queues.

DSBUFS

The number of buffers allocated in each queue manager for accessing shared message data sets.

DSEXPA

Whether the queue manager expands a shared message data set.

DSGROUP

The generic data set name to be used for the group of shared message data sets.

OFFLD1SZ

Offload rule 1: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD1TH

Offload rule 1: The coupling facility structure percentage usage threshold value as an integer.

OFFLD2SZ

Offload rule 2: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD2TH

Offload rule 2: The coupling facility structure percentage usage threshold value as an integer.

OFFLD3SZ

Offload rule 3: The message size value specifying an integer followed by K, giving the number of kilobytes.

OFFLD3TH

Offload rule 3: The coupling facility structure percentage usage threshold value as an integer.

OFFLOAD

If the **CFLEVEL** is less than 4, the only value you can display is NONE.

If the **CFLEVEL** is 4, the only value can display is DB2.

If the **CFLEVEL** is 5, the values displayed are DB2, SMDS, or BOTH. These values depict whether offloaded message data is stored in a group of shared message data sets, or in Db2, or both.

In addition, the offload rules parameter values for **OFFLD1SZ**, **OFFLD1TH**, **OFFLD2SZ**, **OFFLD2TH**, **OFFLD3SZ**, and **OFFLD3TH** are displayed.

RECAUTO

Indicates whether automatic recovery action is taken when a queue manager detects that the structure is failed, or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values are:

YES

The structure and associated shared message data sets which also need recovery are automatically recovered.

NO

The structure is not automatically recovered.

RECOVER

Indicates whether CF recovery for the application structure is supported. Values are:

NO

CF application structure recovery is not supported.

YES

CF application structure recovery is supported.

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Not valid for z/OS client-connection channels.

³ Valid only on z/OS.

⁴ Valid only for RCVR, RQSTR, CLUSRCVR and (for z/OS only) SVRCONN channel types.

⁵ Not valid on z/OS.

⁶ Not valid on IBM i.

Usage notes for DISPLAY CHANNEL

You can only display cluster-sender channels if they were created manually. See [Cluster channels](#).

The values shown describe the current definition of the channel. If the channel has been altered since it was started, any currently running instance of the channel object might not have the same values as the current definition.

Parameter descriptions for DISPLAY CHANNEL

You must specify the name of the channel definition you want to display. It can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

(generic-channel-name)

The name of the channel definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions.

WHERE

Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, **QSGDISP**, or **MCANAME** parameters as filter keywords. You cannot use **TYPE** (or **CHLTYPE**) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

operator

This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the **TYPE** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL

Specify **ALL** to display the results of querying all the parameters. If **ALL** is specified, any request for a specific parameter is ignored. The result of querying with **ALL** is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

 On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms, only requested attributes are displayed.

If no parameters are specified (and the **ALL** parameter is not specified or defaulted), the default is that the channel names only are displayed.

 On z/OS, the **CHLTYPE** and **QSGDISP** values are also displayed.

 CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue sharing group.

..

The command is executed on the queue manager on which it was entered. This is the default value.

qmgr-name

The command is executed on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command is executed on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

 QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

Note: In the **QSGDISP(LIVE)** case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

In a shared queue manager environment, use

```
DISPLAY CHANNEL(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. Note that **QSGDISP(PRIVATE)** displays the same information as **QSGDISP(LIVE)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP(GROUP)**.

COPY

The object was defined with **QSGDISP(COPY)**.

You cannot use **QSGDISP** as a filter keyword.

TYPE

This is optional. It can be used to restrict the display to channels of one type.

The value is one of the following:

ALL

Channels of all types are displayed (this is the default).

SDR

Sender channels only are displayed.

SVR

Server channels only are displayed.

RCVR

Receiver channels only are displayed.

RQSTR

Requester channels only are displayed.

CLNTCONN

Client-connection channels only are displayed.

SVRCONN

Server-connection channels only are displayed.

CLUSSDR

Cluster-sender channels only are displayed.

CLUSRCVR

Cluster-receiver channels only are displayed.

AMQP

AMQP channels only are displayed.

CHLTYPE (*type*) can be used as a synonym for this parameter.

Requested parameters

Specify one or more **DISPLAY CHANNEL** parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

Note:

1.  **PUTAUT** is valid for a channel type of SVRCONN on z/OS only.

AFFINITY

The channel affinity attribute.

PREFERRED

Subsequent connections in a process attempt to use the same channel definition as the first connection.

NONE

All connections in a process select an applicable definition based on the weighting with any applicable **CLNTWGHT (0)** definitions selected first in alphabetical order.

ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd.

ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss.

AMQPKA

The keep alive time for an AMQP channel in milliseconds.

AUTOSTART

Whether an LU 6.2 responder process should be started for the channel.

BATCHHB

The batch heartbeating value being used.

BATCHINT

Minimum batch duration.

BATCHLIM

Batch data limit.

The limit of the amount of data that can be sent through a channel.

BATCHSZ

Batch size.

CERTLABL

Certificate labels.

CHLTYPE

Channel type.

The channel type is always displayed if you specify a generic channel name and do not request any other parameters.

 On z/OS, the channel type is always displayed.

 On [Multiplatforms](#), **TYPE** can be used as a synonym for this parameter.

CLNTWGHT

The client channel weighting.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. If random load balancing is performed the value is in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest.

CLUSTER

The name of the cluster to which the channel belongs.

CLUSNL

The name of the namelist that specifies the list of clusters to which the channel belongs.

CLWLPRTY

The priority of the channel for the purposes of cluster workload distribution.

CLWLRANK

The rank of the channel for the purposes of cluster workload distribution.

CLWLWGHT

The weighting of the channel for the purposes of cluster workload distribution.

COMPHDR

The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

COMPMSG

The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

CONNAME

Connection name.

CONVERT

Whether sender should convert application message data.

DEFCDISP

Specifies the default channel disposition of the channels for which information is to be returned. If this keyword is not present, channels of all default channel dispositions are eligible.

ALL

Channels of all default channel dispositions are displayed.

This is the default setting.

PRIVATE

Only channels where the default channel disposition is PRIVATE are displayed.

SHARED

Only channels where the default channel disposition is FIXSHARED or SHARED are displayed.

Note:  This does not apply to client-connection channel types on z/OS.

DESCR

Default client reconnection option.

DESCR

Description.

DISCINT

Disconnection interval.

HBINT

Heartbeat interval.

KAINT

KeepAlive timing for the channel.

LOCLADDR

Local communications address for the channel.

LONGRTY

Long retry count.

LONGTMR

Long retry timer.

MAXINST(*integer*)

The maximum number of instances of a server-connection channel that are permitted to run simultaneously.

MAXINSTC(*integer*)

The maximum number of instances of a server-connection channel, started from a single client, that are permitted to run simultaneously.

Note: In this context, connections originating from the same remote network address are regarded as coming from the same client.

MAXMSGL

Maximum message length for channel.

MCANAME

Message channel agent name.

You cannot use **MCANAME** as a filter keyword.

MCATYPE

Whether message channel agent runs as a separate process or a separate thread.

MCAUSER

Message channel agent user identifier.

MODENAME

LU 6.2 mode name.

MONCHL

Online monitoring data collection.

MRDATA

Channel message-retry exit user data.

MREXIT

Channel message-retry exit name.

MRRTY

Channel message-retry count.

MRTMR

Channel message-retry time.

MSGDATA

Channel message exit user data.

MSGEXIT

Channel message exit names.

NETPRTY

The priority for the network connection.

NPMSPEED

Nonpersistent message speed.

PASSWORD

Password for initiating LU 6.2 session. If nonblank, this is displayed as asterisks  on all platforms except z/OS.

PORT

The port number used to connect an AMQP channel.

PROPCTL

Message property control.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

COMPAT

This is the default value.

Table 197. Range of results, depending on which message properties are set, when PROPCTL value is COMPAT

Message properties	Result
The message contains a property with a prefix of mcd. , jms. , usr. or mqext.	All optional message properties (where the Support value is MQPD_SUPPORT_OPTIONAL), except those in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of mcd. , jms. , usr. or mqext.	All message properties, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the Support field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the Support field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the <i>content='properties'</i> attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

NONE

All properties of the message, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL then the message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.

ALL

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

PUTAUT

Put authority.

QMNAME

Queue manager name.

RESETSEQ

Pending reset sequence number.

This is the sequence number from an outstanding request and it indicates a user **RESET CHANNEL** command request is outstanding.

A value of zero indicates that there is no outstanding **RESET CHANNEL**. The value can be in the range 1 - 999999999.

 This parameter is not applicable on z/OS.

RCVDATA

Channel receive exit user data.

RCVEXIT

Channel receive exit names.

SCYDATA

Channel security exit user data.

SCYEXIT

Channel security exit names.

SENDDATA

Channel send exit user data.

SENDEXIT

Channel send exit names.

SEQWRAP

Sequence number wrap value.

SHARECNV

Sharing conversations value.

SHORTRTY

Specifies the maximum number of times that the channel is to try allocating a session to its partner.

SHORTTMR

Short retry timer.

 SPLPROT

SPLPROT (Security Policy Protection) specifies how a server-to-server Message Channel Agent should deal with message protection when AMS is active and an applicable policy exists.

SSLCAUTH

Whether TLS client authentication is required.

SSLCIPH

Cipher specification for the TLS connection.

SSLPEER

Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

SSLQS

Quantum safe algorithm.

SSLQSR

Whether quantum safe communications are required.

STATCHL

Statistics data collection.

TPNAME

LU 6.2 transaction program name.

TPROOT

The topic root for an AMQP channel.

TRPTYPE

Transport type.

USECLTID

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

USERID

User identifier for initiating LU 6.2 session.

XMITQ

Transmission queue name.

For more details of these parameters, see [“DEFINE CHANNEL \(define a new channel\)” on page 544](#).

Related reference

[“DISPLAY CHANNEL \(display channel definition\) MQTT” on page 767](#)

Use the MQSC command **DISPLAY CHANNEL** (MQTT) to display an IBM MQ Telemetry channel definition.

Use the MQSC command **DELETE CHANNEL** to delete a channel definition.

[“PING CHANNEL \(test channel response\)” on page 985](#)

Use the MQSC command **PING CHANNEL** to test a channel by sending data as a special message to the remote queue manager, and checking that the data is returned. The data is generated by the local queue manager.

[“PURGE CHANNEL \(stop and purge a channel\) on AIX, Linux, and Windows” on page 990](#)

Use the MQSC command **PURGE CHANNEL** to stop and purge an IBM MQ Telemetry or AMQP channel. Purging an IBM MQ Telemetry or AMQP channel disconnects all the MQTT or AMQP clients connected to it, cleans up the state of the MQTT or AMQP clients, and stops the IBM MQ Telemetry or AMQP channel. Cleaning the state of a client deletes all the pending publications, including any last will and testament message required by the client, and removes all the subscriptions from the client.

[“RESET CHANNEL \(reset message sequence number for a channel\)” on page 1007](#)

Use the MQSC command **RESET CHANNEL** to reset the message sequence number for an IBM MQ channel with, optionally, a specified sequence number to be used the next time that the channel is started. This command is normally used when message AMQ9526E is received, where a channel is unable to start because of a sequence number error.

[“START CHANNEL \(start a channel\)” on page 1061](#)

Use the MQSC command **START CHANNEL** to start a channel.

[“STOP CHANNEL \(stop a channel\)” on page 1082](#)

Use the MQSC command **STOP CHANNEL** to stop a channel.

ALW **DISPLAY CHANNEL (display channel definition) MQTT**

Use the MQSC command **DISPLAY CHANNEL** (MQTT) to display an IBM MQ Telemetry channel definition.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY CHANNEL \(MQTT\)” on page 767](#)
- [“Parameter descriptions for DISPLAY CHANNEL \(MQTT\)” on page 767](#)
- [“Requested parameters” on page 769](#)

Syntax diagram for DISPLAY CHANNEL (MQTT)

Synonym: DIS CHL

DISPLAY CHANNEL (MQTT) command is only valid for IBM MQ Telemetry channels.

Parameter descriptions for DISPLAY CHANNEL (MQTT)

You must specify the name of the channel definition you want to display. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

(*generic-channel-name*)

The name of the channel definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions.

CHLTYPE(*type*)

The value is always MQTT.

TYPE can be used as a synonym for this parameter.

WHERE

Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, **QSGDISP**, or **MCANAME** parameters as filter keywords. You cannot use **TYPE** (or **CHLTYPE**) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

operator

This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the TYPE parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL

Specify **ALL** to display the results of querying all the parameters. If **ALL** is specified, any request for a specific parameter is ignored. The result of querying with **ALL** is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

If no parameters are specified (and the ALL parameter is not specified or defaulted), the default is that the channel names only are displayed.

Requested parameters

Specify one or more **DISPLAY CHANNEL** parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

BACKLOG

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed. The value is in the range 0 - 999999999. The default value is 4096.

CHLTYPE

Channel type.

There is only one valid value for this parameter: MQTT.

JAASCFG

The name of a stanza in the JAAS configuration file.

LOCLADDR

The local communications address for the channel.

MCAUSER

The message channel agent user identifier.

PORT

The port number on which the telemetry (MQXR) service accepts client connections.

PROTOCOL

The communication protocol supported by the channel.

SSLCAUTH

Defines whether IBM MQ requires a certificate from the TLS client.

SSLCIPH

When **SSLCIPH** is used with a telemetry channel, it means TLS Cipher Suite.

SSLKEYP

The password for the key repository. If no passphrase is entered, you must use unencrypted connections.

SSLKEYR

The name of the TLS key repository. For full details, see the **SSLKEYR** parameter of the [ALTER QMGR](#) command.

TRPTYPE

The transmission protocol to be used. For a Telemetry channel, this is always TCP (that is, the TCP/IP protocol).

USECLTID

Indicates whether you want to use the MQTT client ID for the connection as the IBM MQ user ID for that connection.

For more information on these parameters, see [“DEFINE CHANNEL \(define a new channel\) for MQTT” on page 599](#).

- [“Usage notes for DISPLAY CHINIT” on page 771](#)
- [“Parameter descriptions for DISPLAY CHINIT” on page 771](#)

Syntax diagram for DISPLAY CHINIT

Synonym: DIS CHI or DIS DQM

DISPLAY CHINIT

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY CHINIT

1. The response to this command is a series of messages showing the current status of the channel initiator. This includes the following:
 - Whether the channel initiator is running or not
 - Which listeners are started, and information about them.
 - How many dispatchers are started, and how many were requested
 - How many adapter subtasks are started, and how many were requested
 - How many TLS subtasks are started, and how many were requested
 - The TCP system name
 - How many channel connections are current, and whether they are active, stopped, or retrying
 - The maximum number of current connections

Parameter descriptions for DISPLAY CHINIT

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

''

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Use the MQSC command **START CHINIT** to start a channel initiator.

[“STOP CHINIT \(stop channel initiator\) on z/OS” on page 1089](#)

Use the MQSC command **STOP CHINIT** to stop a channel initiator. The command server must be running.

DISPLAY CHLAUTH (display channel authentication record)

Use the MQSC command **DISPLAY CHLAUTH** to display the attributes of a channel authentication record.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- “Syntax diagram for DISPLAY CHLAUTH” on page 772
- “Parameters for DISPLAY CHLAUTH” on page 773

Syntax diagram for DISPLAY CHLAUTH

Synonym: DIS CHLAUTH

Parameters for DISPLAY CHLAUTH

generic-channel-name

The name of the channel or set of channels to display. You can use the asterisk (*) as a wildcard to specify a set of channels. When an asterisk is used on z/OS, single quotes must be used around the whole value. When **MATCH** is RUNCHECK this parameter must not be generic.

ADDRESS

The IP address to be matched.

This parameter is valid only when **MATCH** is RUNCHECK, must not be generic and must not be a host name.

ALL

Specify this parameter to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

CLNTUSER

The client asserted user ID to be mapped to a new user ID, allowed through unchanged, or blocked.

This can be the user ID flowed from the client indicating the user ID the client side process is running under, or the user ID presented by the client on an MQCONN call using MQCSP.

This parameter is valid only with **TYPE (USERMAP)** and when **MATCH** is RUNCHECK.

The maximum length of the string is MQ_CLIENT_USER_ID_LENGTH.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command is run when the queue manager is a member of a queue sharing group.

..

The command is run on the queue manager on which it was entered. This is the default value.

qmgr-name

The command is run on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command is run on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

MATCH

Indicates the type of matching to be applied.

RUNCHECK

Returns the record that is matched by a specific inbound channel at run time if it connects to this queue manager. The specific inbound channel is described by providing values that are not generic:

- Channel name.
- **ADDRESS** attribute containing an IP address, that is then reverse looked up as part of running the command to discover the host name, if the queue manager is configured with **REVDNS(ENABLED)**.
- **SSLCERTI** attribute, only if the inbound channel uses TLS.
- **SSLPEER** attribute, only if the inbound channel uses TLS.
- **QMNAME** or **CLNTUSER** attribute, depending on whether the inbound channel is a client or queue manager channel.

If the record discovered has **WARN** set to YES, a second record might also be displayed to show the actual record the channel will use at run time. This parameter must be combined with **TYPE(ALL)**.

EXACT

Return only those records which exactly match the channel profile name supplied. If there are no asterisks in the channel profile name, this option returns the same output as **MATCH(GENERIC)**.

GENERIC

Any asterisks in the channel profile name are treated as wildcards. If there are no asterisks in the channel profile name, this returns the same output as **MATCH(EXACT)**. For example, a profile of ABC* could result in records for ABC, ABC*, and ABCD being returned.

ALL

Return all possible records that match the channel profile name supplied. If the channel name is generic in this case, all records that match the channel name are returned even if more specific matches exist. For example, a profile of SYSTEM*.SVRCONN could result in records for SYSTEM.*, SYSTEM.DEF.*, SYSTEM.DEF.SVRCONN, and SYSTEM.ADMIN.SVRCONN being returned.

QMNAME

The name of the remote partner queue manager to be matched

This parameter is valid only when **MATCH** is **RUNCHECK** and must not be generic.

SSLCERTI

The Certificate issuer Distinguished Name of the certificate to be matched.

The **SSLCERTI** field, if not blank, is matched in addition to the **SSLPEER** value.

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

SSLPEER

The Subject Distinguished Name of the certificate to be matched.

The **SSLPEER** value is specified in the standard form used to specify a Distinguished Name.

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

TYPE

The type of Channel Authentication Record for which to display details. Possible values are:

- ALL
- BLOCKUSER
- BLOCKADDR
- SSLPEERMAP
- ADDRESSMAP
- USERMAP
- QMGRMAP

WHERE

Specify a filter condition to display only those channel authentication records that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this DISPLAY command.

operator

This is used to determine whether a channel authentication record satisfies the filter value on the given filter keyword. The operators are as follows:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, the value can be either explicit or generic:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ALL on the **MATCH** parameter), you can only use EQ or NE.

- A generic value. This is a character string with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

Note:  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

TYPE

The type of channel authentication record

SSLPEER

The Distinguished Name of the certificate.

ADDRESS

The IP address

CHCKCLNT

Whether a user ID and password are to be supplied by connections which match this rule.

CLNTUSER

The client asserted user ID

QMNAME

The name of the remote partner queue manager

MCAUSER

The user identifier to be used when the inbound connection matches the TLS DN, IP address, client asserted user ID or remote queue manager name supplied.

ADDRLIST

A list of IP address patterns which are banned from connecting into this queue manager on any channel.

USERLIST

A list of user IDs which are banned from use of this channel or set of channels.

ALTDAT

The date on which the channel authentication record was last altered, in the format *yyyy-mm-dd*.

ALTTIME

The time on which the channel authentication record was last altered, in the form *hh.mm.ss*.

DESCR

Descriptive information about the channel authentication record.

SSLCERTI

The Certificate issuer Distinguished Name of the certificate to be matched.

CUSTOM

Reserved for future use.

- [“Current-only status” on page 789](#)
- [“Short status” on page 797](#)
- [“Setting monitor values” on page 797](#)

Syntax diagram for DISPLAY CHSTATUS

Synonym: DIS CHS

DISPLAY CHSTATUS

►► DISPLAY CHSTATUS — (— *generic-channel-name* —) →

Common status

Current-only status

Short status

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.
- ³ Also displayed by selection of the MONITOR parameter.
- ⁴ Ignored if specified on z/OS.
- ⁵ Not valid on z/OS.
- ⁶ Not valid on IBM i.

Usage notes for DISPLAY CHSTATUS on z/OS

z/OS

1. The command fails if the channel initiator has not been started.
2. The command server must be running.
3. If you want to see the overall status of the channel (that is, the status of the queue sharing group) use the command **DISPLAY CHSTATUS SHORT**, which obtains the status information of the channel from Db2.
4. If any numeric parameter exceeds 999,999,999, it is displayed as 999999999.
5. The status information that is returned for various combinations of **CHLDISP**, **CMDScope**, and status type are summarized in Table 198 on page 780, Table 199 on page 780, and Table 200 on page 781.

Table 198. CHLDISP and CMDScope for DISPLAY CHSTATUS CURRENT			
CHLDISP	CMDScope() or CMDScope (local-qmgr)	CMDScope (qmgr-name)	CMDScope(*)
PRIVATE	Common and current-only status for current private channels on the local queue manager	Common and current-only status for current private channels on the named queue manager	Common and current-only status for current private channels on all queue managers
SHARED	Common and current-only status for current shared channels on the local queue manager	Common and current-only status for current shared channels on the named queue manager	Common and current-only status for current shared channels on all queue managers
ALL	Common and current-only status for current private and shared channels on the local queue manager	Common and current-only status for current private and shared channels on the named queue manager	Common and current-only status for current private and shared channels on all active queue managers

Table 199. CHLDISP and CMDScope for DISPLAY CHSTATUS SHORT			
CHLDISP	CMDScope() or CMDScope (local-qmgr)	CMDScope (qmgr-name)	CMDScope(*)
PRIVATE	STATUS and short status for current private channels on the local queue manager	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private channels on all active queue managers
SHARED	STATUS and short status for current shared channels on all active queue managers in the queue sharing group	Not permitted	Not permitted

Table 199. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT (continued)			
CHLDISP	CMDSCOPE() or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
ALL	STATUS and short status for current private channels on the local queue manager and current shared channels in the queue sharing group (“5.a” on page 781)	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private, and shared, channels on all active queue managers in the queue sharing group (“5.a” on page 781)

Note:

- a. In this case you get two separate sets of responses to the command on the queue manager where it was entered; one for PRIVATE and one for SHARED.

Table 200. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SAVED			
CHLDISP	CMDSCOPE() or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Common status for saved private channels on the local queue manager	Common status for saved private channels on the named queue manager	Common status for saved private channels on all active queue managers
SHARED	Common status for saved shared channels on all active queue managers in the queue sharing group	Not permitted	Not permitted
ALL	Common status for saved private channels on the local queue manager and saved shared channels in the queue sharing group	Common status for saved private channels on the named queue manager	Common status for saved private, and shared, channels on all active queue managers in the queue sharing group

Parameter descriptions for DISPLAY CHSTATUS on all platforms

You must specify the name of the channel for which you want to display status information. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

You can also specify whether you want the current status data (of current channels only), or the saved status data of all channels.

Status for all channels that meet the selection criteria is displayed, whether the channels were defined manually or automatically.

The classes of data available for channel status are **saved** and **current**, and (on z/OS only) **short**.

The status fields available for saved data are a subset of the fields available for current data and are called **common** status fields. Note that although the common data fields are the same, the data values might be different for saved and current status. The rest of the fields available for current data are called **current-only** status fields.

- **Saved** data consists of the common status fields noted in the syntax diagram.

- For a sending channel data is updated before requesting confirmation that a batch of messages has been received and when confirmation has been received.

- For a receiving channel data is reset just before confirming that a batch of messages has been received.
- For a server connection channel no data is saved.
- Therefore, a channel that has never been current cannot have any saved status.

Note: Status is not saved until a persistent message is transmitted across a channel, or a nonpersistent message is transmitted with a **NPMSPEED** of NORMAL. Because status is saved at the end of each batch, a channel does not have any saved status until at least one batch has been transmitted.

- **Current** data consists of the common status fields and current-only status fields as noted in the syntax diagram. The data fields are continually updated as messages are sent/received.
-  **Short** data consists of the STATUS current data item and the short status field as noted in the syntax diagram.

This method of operation has the following consequences:

- An inactive channel might not have any saved status - if it has never been current or has not yet reached a point where saved status is reset.
- The "common" data fields might have different values for saved and current status.
- A current channel always has current status and might have saved status.

Channels can either be current or inactive:

Current channels

These are channels that have been started, or on which a client has connected, and that have not finished or disconnected normally. They might not yet have reached the point of transferring messages, or data, or even of establishing contact with the partner. Current channels have **current** status and might also have **saved** status.

The term **Active** is used to describe the set of current channels that are not stopped.

Inactive channels

These are channels that are in one of the following states:

- Have not been started
- On which a client has not connected
- Have finished
- Have disconnected normally

Note: If a channel is stopped, it is not yet considered to have finished normally and is, therefore, still current. Inactive channels have either **saved** status or no status at all.

There can be more than one instance of the same named receiver, requester, cluster-receiver, or server-connection channel current at the same time (the requester is acting as a receiver). This occurs if several senders, at different queue managers, each initiate a session with this receiver, using the same channel name. For channels of other types, there can only be one instance current at any time.

For all channel types, however, there can be more than one set of saved status information available for a channel name. At most one of these sets relates to a current instance of the channel, the rest relate to previously current instances. Multiple instances arise if different transmission queue names or connection names have been used with the same channel. This can happen in the following cases:

- At a sender or server:
 - If the same channel has been connected to by different requesters (servers only)
 - If the transmission queue name has been changed in the definition
 - If the connection name has been changed in the definition
- At a receiver or requester:
 - If the same channel has been connected to by different senders or servers

- If the connection name has been changed in the definition (for requester channels initiating connection)

The number of sets that are displayed for a channel can be limited by using the **XMITQ**, **CONNAME**, and **CURRENT** parameters on the command.

(generic-channel-name)

The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

The parameter to be used to display attributes for this **DISPLAY** command.

 You cannot use the following parameters as filter keywords on Multiplatforms: **COMPRATE**, **COMPTIME**, **CURRENT**, **EXITTIME**, **JOBNAME**, **NETTIME**, **SAVED**, **SHORT**, **XBATCHSZ**, or **XQTIME**.

 You cannot use the following parameters as filter keywords on z/OS: **CHLDISP**, **CMDScope**, **MCASTAT**, or **MONITOR**.

You cannot use **CONNAME** or **XMITQ** as filter keywords if you also use them to select channel status.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator

This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the **CHLTYPE** parameter), you can only use EQ or NE.

- A generic value. This is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this to display all the status information for each relevant instance.

If **SAVED** is specified, this causes only common status information to be displayed, not current-only status information.

If this parameter is specified, any parameters requesting specific status information that are also specified have no effect; all the information is displayed.

CHLDISP

This parameter applies to z/OS only and specifies the disposition of the channels for which information is to be displayed, as used in the **START CHANNEL** and **STOP CHANNEL** commands, and **not** that set by **QSGDISP** for the channel definition. Values are:

ALL

This is the default value and displays requested status information for private channels.

If there is a shared queue manager environment and the command is being executed on the queue manager where it was issued, or if **CURRENT** is specified, this option also displays the requested status information for shared channels.

PRIVATE

Display requested status information for private channels.

SHARED

Display requested status information for shared channels. This is allowed only if there is a shared queue manager environment, and either:

- **CMDSCOPE** is blank or the local queue manager
- **CURRENT** is specified

CHLDISP displays the following values:

PRIVATE

The status is for a private channel.

SHARED

The status is for a shared channel.

FIXSHARED

The status is for a shared channel, tied to a specific queue manager.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

Note: See [Table 1](#), [Table 2](#), and [Table 3](#) for the permitted combinations of **CHLDISP** and **CMDSCOPE**.

CONNNAME(connection-name)

The connection name for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The value returned for **CONNNAME** might not be the same as in the channel definition, and might differ between the current channel status and the saved channel status. (Using **CONNNAME** for limiting the number of sets of status is therefore not recommended.)

For example, when using TCP, if **CONNNAME** in the channel definition:

- Is blank or is in "host name" format, the channel status value has the resolved IP address.
- Includes the port number, the current channel status value includes the port number (except on z/OS), but the saved channel status value does not.

 For SAVED or SHORT status, this value could also be the queue manager name, or queue sharing group name, on the remote system.

 For SAVED status, this value could also be:

1. The queue manager name on the remote system.
2. A combination of the queue manager name and QMID of the queue manager name on the remote system.

For the second option, the format is  QMNAME@QMID on AIX, Linux, and Windows or  QMNAME&QMID on IBM i, where QMNAME is the queue manager name, blank padded to the right, up to 48 characters.

To show this, in the following example there are 45 blank spaces between the character 2 (in QM2) and the @ character.

```
CONNNAME(QM2
```

```
@QM2_2023-07-18_12.24.06)
```

CURRENT

This is the default, and indicates that current status information as held by the channel initiator for current channels only is to be displayed.

Both common and current-only status information can be requested for current channels.

Short status information is not displayed if this parameter is specified.

SAVED

Specify this to display saved status information for both current and inactive channels.

Only common status information can be displayed. Short and current-only status information is not displayed for current channels if this parameter is specified.

SHORT

This indicates that short status information and the STATUS item for current channels only is to be displayed.

Other common status and current-only status information is not displayed for current channels if this parameter is specified.

MONITOR

Specify this to return the set of online monitoring parameters. These are **COMPRATE**, **COMPTIME**, **EXITTIME**, **MONCHL**, **NETTIME**, **XBATCHSZ**, **XQMSGSA**, and **XQTIME**. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

XMITQ(q-name)

The name of the transmission queue for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The following information is always returned, for each set of status information:

- The channel name
- The transmission queue name (for sender and server channels)
- The connection name
- The remote queue manager, or queue sharing group, name (only for current status, and for all channel types except server-connection channels)
- The remote partner application name (for server-connection channels)
- The type of status information returned (CURRENT, or SAVED , or on z/OS only, SHORT)
- STATUS  (except SAVED on z/OS)
-  On z/OS, **CHLDISP**
- STOPREQ (only for current status)
- SUBSTATE

If no parameters requesting specific status information are specified (and the **ALL** parameter is not specified), no further information is returned.

If status information is requested that is not relevant for the particular channel type, this is not an error.

Common status

The following information applies to sets of current status data and also to sets of saved status data. Some of this information does not apply to server-connection channels.

CHLTYPE

The channel type. This is one of the following:

SDR

A sender channel

SVR

A server channel

RCVR

A receiver channel

RQSTR

A requester channel

CLUSSDR

A cluster-sender channel

CLUSRCVR

A cluster-receiver channel

SVRCONN

A server-connection channel

AMQP

An AMQP channel

CURLUWID

The logical unit of work identifier associated with the current batch, for a sending or a receiving channel.

For a sending channel, when the channel is in doubt it is the LUWID of the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

It is updated with the LUWID of the next batch when this is known.

This parameter does not apply to server-connection channels.

CURMSG

For a sending channel, this is the number of messages that have been sent in the current batch. It is incremented as each message is sent, and when the channel becomes in doubt it is the number of messages that are in doubt.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the number of messages that have been received in the current batch. It is incremented as each message is received.

The value is reset to zero, for both sending and receiving channels, when the batch is committed.

This parameter does not apply to server-connection channels.

CURSEQNO

For a sending channel, this is the message sequence number of the last message sent. It is updated as each message is sent, and when the channel becomes in doubt it is the message sequence number of the last message in the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the message sequence number of the last message that was received. It is updated as each message is received.

This parameter does not apply to server-connection channels.

INDOUBT

Whether the channel is currently in doubt.

This is only YES while the sending Message Channel Agent is waiting for an acknowledgment that a batch of messages that it has sent has been successfully received. It is NO at all other times, including the period during which messages are being sent, but before an acknowledgment has been requested.

For a receiving channel, the value is always NO.

This parameter does not apply to server-connection channels.

LSTLUWID

The logical unit of work identifier associated with the last committed batch of messages transferred.

This parameter does not apply to server-connection channels.

LSTSEQNO

Message sequence number of the last message in the last committed batch. This number is not incremented by nonpersistent messages using channels with a **NPMSPEED** of FAST.

This parameter does not apply to server-connection channels.

STATUS

Current status of the channel. This is one of the following:

BINDING

Channel is performing channel negotiation and is not yet ready to transfer messages.

INITIALIZING

The channel initiator is attempting to start a channel.

▶ **z/OS** On z/OS, this is displayed as INITIALIZI.

PAUSED

The channel is waiting for the message-retry interval to complete before retrying an MQPUT operation.

REQUESTING

A local requester channel is requesting services from a remote MCA.

RETRYING

A previous attempt to establish a connection has failed. The MCA will reattempt connection after the specified time interval.

RUNNING

The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

STARTING

A request has been made to start the channel but the channel has not yet begun processing. A channel is in this state if it is waiting to become active.

STOPPED

This state can be caused by one of the following:

- Channel manually stopped
A user has entered a stop channel command against this channel.
- Retry limit reached

The MCA has reached the limit of retry attempts at establishing a connection. No further attempt will be made to establish a connection automatically.

A channel in this state can be restarted only by issuing the **START CHANNEL** command, or starting the MCA program in an operating-system dependent manner.

STOPPING

Channel is stopping or a close request has been received.

SWITCHING

The channel is switching transmission queues.

▶ **z/OS** On z/OS, **STATUS** is not displayed if saved data is requested.

▶ **Multi** On Multiplatforms, the value of the **STATUS** field returned in the saved data is the status of the channel at the time the saved status was written. Normally, the saved status value is RUNNING. To see the current status of the channel, you can use the **DISPLAY CHSTATUS CURRENT** command.

Note: For an inactive channel, **CURMSG**, **CURSEQNO**, and **CURLWID** have meaningful information only if the channel is INDOUBT. However they are still displayed and returned if requested.

Current-only status

The following information applies only to current channel instances. The information applies to all channel types, except where stated.

AMQPKA

The keep alive time for an AMQP channel in milliseconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type (**CHLTYPE**) of AMQP

BATCHES

Number of completed batches during this session (since the channel was started).

BATCHSZ

The batch size being used for this session.

This parameter does not apply to server-connection channels, and no values are returned; if specified on the command, this is ignored.

BUFSRCVD

Number of transmission buffers received. This includes transmissions to receive control information only.

BUFSSENT

Number of transmission buffers sent. This includes transmissions to send control information only.

BYTSRCVD

Number of bytes received during this session (since the channel was started). This includes control information received by the message channel agent.

If the value for **BYTSSENT** or **BYTSRCVD** exceeds 999999999, it wraps to zero.

BYTSSENT

Number of bytes sent during this session (since the channel was started). This includes control information sent by the message channel agent.

If the value for **BYTSSENT** or **BYTSRCVD** exceeds 999999999, it wraps to zero.

CHSTADA

Date when this channel was started (in the form *yyyy-mm-dd*).

CHSTATI

Time when this channel was started (in the form *hh.mm.ss*).

COMPHDR

The technique used to compress the header data sent by the channel. Two values are displayed:

- The default header data compression value negotiated for this channel.
- The header data compression value used for the last transmission segment that was eligible for compression, which might or might not carry a message. The header data compression value can be altered in a sending channels message exit. If no eligible transmission segment has been sent, the second value is blank.

COMPMSG

The technique used to compress the message data sent by the channel. Two values are displayed:

- The default message data compression value negotiated for this channel.
- The message data compression value used for the last message sent. The message data compression value can be altered in a sending channels message exit. If no message has been sent, the second value is blank.

COMPRATE

The compression rate achieved displayed to the nearest percentage; that is, a rate of 25 indicates messages are being compressed to 75% of their original length.

Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values are reset every time the channel is started and are displayed only when the **STATUS** of the channel is **RUNNING**. If monitoring data is not being collected, or if no messages have been sent by the channel, the values are shown as blank.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values”](#) on page 797.

COMPTIME

The amount of time for each message, displayed in microseconds, spent on compression or decompression. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

Note:  On z/OS, **COMPTIME** is the amount of time for each message, provided that the message does not have to be processed in segments. This segmenting of the message on z/OS occurs when the message is:

- 32 KB or larger, or
- 16 KB or larger, and the channel has TLS encryption.

On z/OS, if the message is split into segments, **COMPTIME** is the time spent compressing each segment. This means that a message that is split into 8 segments actually spends (**COMPTIME** * 8) microseconds during compression or decompression.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values”](#) on page 797.

CURSHCNV

The **CURSHCNV** value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the **CURSHCNV** output gives a count of the number of conversations currently running over that channel instance.

A value of zero indicates that the channel is running as it did in versions of the product earlier than IBM WebSphere MQ 7.0, regarding:

- Administrator stop-quiesce
- Heartbeating
- Read ahead
- Sharing conversations
- Client Asynchronous consumption

EXITTIME

Amount of time, displayed in microseconds, spent processing user exits per message. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the **STATUS** of the channel is **RUNNING**.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values”](#) on page 797.

HBINT

The heartbeat interval being used for this session.

JOBNAME

A name that identifies the IBM MQ process that is currently providing and hosting the channel.

Multi On Multiplatforms, this name is the concatenation of the process identifier and the thread identifier of the MCA program, displayed in hexadecimal.

z/OS This information is not available on z/OS. The parameter is ignored if specified.

z/OS You cannot use **JOBNAME** as a filter keyword on z/OS.

z/OS KAIN

The keepalive interval being used for this session. This is valid only on z/OS.

LOCLADDR

Local communications address for the channel. The value returned depends on the TRPTYPE of the channel (currently only TCP/IP is supported).

LONGRTS

Number of long retry wait start attempts left. This applies only to sender or server channels.

LSTMSGDA

Date when the last message was sent or MQI call was handled, see **LSTMSGTI**.

LSTMSGTI

Time when the last message was sent or MQI call was handled.

For a sender or server, this is the time the last message (the last part of it if it was split) was sent. For a requester or receiver, it is the time the last message was put to its target queue. For a server-connection channel, it is the time when the last MQI call completed.

In the case of a server-connection channel instance on which conversations are being shared, this is the time when the last MQI call completed on any of the conversations running on the channel instance.

z/OS MAXMSGL

The maximum message length being used for this session (valid only on z/OS).

MAXSHCNV

The **MAXSHCNV** value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the **MAXSHCNV** output gives the negotiated maximum of the number of conversations that can run over that channel instance.

A value of zero indicates that the channel is running as it did in versions earlier than IBM WebSphere MQ 7.0, regarding:

- Administrator stop-quiesce
- Heartbeating
- Read ahead
- Sharing conversations
- Client asynchronous consumption

Multi MCASTAT

Whether the Message Channel Agent is currently running. This is either "running" or "not running". Note that it is possible for a channel to be in stopped state, but for the program still to be running.

z/OS This information is not available on z/OS. The parameter is ignored if specified.

 You cannot use MCASTAT as a filter keyword on z/OS.

MCAUSER

The user ID used by the MCA. This can be the user ID set in the channel definition, the default user ID for message channels, a user ID transferred from a client if this is a server-connection channel, or a user ID specified by a security exit.

This parameter applies only to server-connection, receiver, requester, and cluster-receiver channels.

On server connection channels that share conversations, the **MCAUSER** field contains a user ID if all the conversations have the same MCA user ID value. If the MCA user ID in use varies across these conversations, the **MCAUSER** field contains a value of *.

 The maximum length on [Multiplatforms](#) is 64 characters.

 The maximum length on z/OS is 12 characters.

MONCHL

Current level of monitoring data collection for the channel.

This parameter is also displayed when you specify the **MONITOR** parameter.

MSGS

Number of messages sent or received (or, for server-connection channels, the number of MQI calls handled) during this session (since the channel was started).

In the case of a server-connection channel instance on which conversations are being shared, this is the total number of MQI calls handled on all of the conversations running on the channel instance.

NETTIME

Amount of time, displayed in microseconds, to send a request to the remote end of the channel and receive a response. This time only measures the network time for such an operation. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the **STATUS** of the channel is RUNNING.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values”](#) on page 797.

NPMSPEED

The nonpersistent message handling technique being used for this session.

PORT

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672.

RAPPLTAG

The remote partner application name. This is the name of the client application at the remote end of the channel.

For Managed File Transfer, **RAPPLTAG** displays Managed File Transfer Agent *agent name*.

This parameter applies only to server-connection channels.

Note: If multiple IBM MQ connections use the same channel instance, that is, the channel is defined with **SHARECNV** > 1 and the same process makes multiple connections to the queue manager, if the connections specify different application names the **RAPPLTAG** field displays an asterisk: RAPPLTAG (*).

RPRODUCT

The remote partner product identifier. This is the product identifier of the IBM MQ code running at the remote end of the channel. The possible values are shown in Table 201 on page 793.

Table 201. Product Identifier values	
Product Identifier	Description
MQMM	Queue manager on a distributed platform
  MQMV	Queue manager on z/OS
MQCC	IBM MQ C client
MQNM	IBM MQ .NET fully managed client
MQJB	IBM MQ Classes for JAVA
MQJF	Managed File Transfer Agent
MQJM	IBM MQ Classes for JMS (normal mode)
MQJN	IBM MQ Classes for JMS (migration mode)
MQJU	Common Java interface to the MQI
MQXC	XMS client C/C++ (normal mode)
MQXD	XMS client C/C++ (migration mode)
MQXN	XMS client .NET (normal mode)
MQXM	XMS client .NET (migration mode)
MQXU	IBM MQ .NET XMS client (unmanaged/XA)
MQNU	IBM MQ .NET unmanaged client

RQMNAME

The queue manager name, or queue sharing group name, of the remote system. This parameter does not apply to server-connection channels.

RVERSION

The remote partner version. This is the version of the IBM MQ code running at the remote end of the channel.

The remote version is displayed as *VVRRMMFF*, where

VV

Version

RR

Release

MM

Maintenance level

FF

Fix level

SECPROT

Defines the security protocol currently in use.

Does not apply to client-connection channels.

Set automatically, based on the value you set for *SSLCIPH* in **DEFINE CHANNEL**.

From IBM MQ 9.2.0, **SECPROT** is supported on z/OS.

Possible values are:

NONE

No security protocol

 SSLV3

SSL 3.0

This protocol is deprecated. See [Deprecated CipherSpecs](#)

 TLSV1

TLS 1.0

This protocol is deprecated. See [Deprecated CipherSpecs](#)

TLSV12

TLS 1.2

TLSV13

TLS 1.3

The product supports the TLS 1.3 security protocol on all platforms.  On IBM MQ for z/OS, TLS 1.3 is supported only on z/OS 2.4 or later.

SHORTRTS

Number of short retry wait start attempts left. This applies only to sender or server channels.

SSLCERTI

The full Distinguished Name of the issuer of the remote certificate. The issuer is the Certificate Authority that issued the certificate.

The maximum length is 256 characters, so longer Distinguished Names are truncated.

 SSLCERTU

The local user ID associated with the remote certificate. This is valid on z/OS only.

SSLCIPH

The CipherSpec being used by the connection.

This parameter, which already existed in **DEFINE CHANNEL**, is displayed by **DISPLAY CHSTATUS** from IBM MQ 9.2.0.

For more information, see [the SSLCIPH property in DEFINE CHANNEL](#).

The value for this parameter is also used to set the value of [SECPROT](#).

SSLKEYDA

Date on which the previous successful TLS secret key reset was issued.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

SSLKEYTI

Time at which the previous successful TLS secret key reset was issued.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

SSLPEER

Distinguished Name of the peer queue manager or client at the other end of the channel.

The maximum length is 256 characters, so longer Distinguished Names are truncated.

 SSLQS

The quantum safe algorithm that was used to secure this communication.

SSLRKEYS

Number of successful TLS key resets. The count of TLS secret key resets is reset when the channel instance ends.

Note: TLS 1.3 key resets are integral to TLS 1.3, and not communicated to applications. As a result, on z/OS queue managers, for receiver channels, this value will not be set when the channel is communicating using a TLS 1.3 CipherSpec. On distributed queue managers this value will not be accurate, and might even be set to zero at either end of a channel, when the channel is communicating using a TLS 1.3 CipherSpec.

STOPREQ

Whether a user stop request is outstanding. This is either YES or NO.

STATCHL

Current level of statistics data collection for the channel.

SUBSTATE

Action being performed by the channel when this command is issued. The following substates are listed in precedence order, starting with the substate of the highest precedence:

ENDBATCH

Channel is performing end-of-batch processing.

SEND

A request has been made to the underlying communication subsystem to send some data.

RECEIVE

A request has been made to the underlying communication subsystem to receive some data.

SERIALIZE

Channel is serializing its access to the queue manager. Valid on z/OS only.

RESYNCH

Channel is resynchronizing with the partner.

HEARTBEAT

Channel is heartbeating with the partner.

SCYEXIT

Channel is running the security exit.

RCVEXIT

Channel is running one of the receive exits.

SENDEXIT

Channel is running one of the send exits.

MSGEXIT

Channel is running one of the message exits.

MREXIT

Channel is running the message retry exit.

CHADEXIT

Channel is running through the channel auto-definition exit.

NETCONNECT

A request has been made to the underlying communication subsystem to connect a partner machine.

SSLHANDSHK

Channel is processing a TLS handshake.

NAMESERVER

A request has been made to the name server.

MQPUT

A request has been made to the queue manager to put a message on the destination queue.

MQGET

A request has been made to the queue manager to get a message from the transmission queue (if this is a message channel) or from an application queue (if this is an MQI channel).

MQICALL

A MQ API call, other than MQPUT and MQGET, is being executed.

COMPRESS

Channel is compressing or extracting data.

Not all substates are valid for all channel types or channel states. There are occasions when no substate is valid, at which times a blank value is returned.

For channels running on multiple threads, this parameter displays the substate of the highest precedence.

TPROOT

The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. To have AMQP clients publish and subscribe under a topic prefix, first create an MQ topic object with a topic string set to the prefix you want, then set **TPROOT** to the name of the IBM MQ topic object you created.

This parameter is valid only for channels with a channel type (CHLTYPE) of AMQP

XBATCHSZ

Size of the batches transmitted over the channel. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the **STATUS** of the channel is RUNNING.

This parameter does not apply to server-connection channels.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values” on page 797](#).

USECLTID

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the **MCAUSER** attribute value.

XQMSGSA

Number of messages queued on the transmission queue available to the channel for MQGETs.

This parameter has a maximum displayable value of 999. If the number of messages available exceeds 999, a value of 999 is displayed.

 On z/OS, if the transmission queue is not indexed by *CorrelId*, this value is shown as blank.

This parameter applies to cluster-sender channels only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values” on page 797](#).

XQTIME

The time, in microseconds, that messages remained on the transmission queue before being retrieved. The time is measured from when the message is put onto the transmission queue until

it is retrieved to be sent on the channel and, therefore, includes any interval caused by a delay in the putting application.

Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the **STATUS** of the channel is **RUNNING**.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONCHL** is set for this channel. See [“Setting monitor values” on page 797](#).

Short status

The following information applies only to current channel instances.

QMNAME

The name of the queue manager that owns the channel instance.

Setting monitor values

For auto-defined cluster sender channels, these are controlled with the queue manager **MONACLS** parameter. For more information, see [“ALTER QMGR \(alter queue manager settings\)” on page 415](#). You cannot display or alter auto-defined cluster sender channels. However you can get their status, or issue **DISPLAY CLUSQMGR**, as described here: [Working with auto-defined cluster-sender channels](#).

For other channels, including manually-defined cluster sender channels, these are controlled with the channel **MONCHL** parameter. For more information, see [“ALTER CHANNEL \(alter channel settings\)” on page 341](#).

The Inquire Channel Status (MQCMD_INQUIRE_CHANNEL_STATUS) PCF command inquires about the status of one or more channel instances.

[“MQCMD_INQUIRE_CHANNEL_STATUS \(Inquire Channel Status\) Response” on page 1366](#)

The response to the Inquire Channel Status (MQCMD_INQUIRE_CHANNEL_STATUS) PCF command consists of the response header followed by several structures.

[“START CHANNEL \(start a channel\)” on page 1061](#)

Use the MQSC command **START CHANNEL** to start a channel.

[“STOP CHANNEL \(stop a channel\)” on page 1082](#)

Use the MQSC command **STOP CHANNEL** to stop a channel.

[“DISPLAY CHSTATUS \(display channel status\) AMQP” on page 798](#)

Use the MQSC command **DISPLAY CHSTATUS** (AMQP) to display the status of one or more AMQP channels.

[“DISPLAY CHSTATUS \(display channel status\) MQTT” on page 802](#)

Use the MQSC command **DISPLAY CHSTATUS** (MQTT) to display the status of one or more IBM MQ Telemetry channels.

ALW DISPLAY CHSTATUS (display channel status) AMQP

Use the MQSC command **DISPLAY CHSTATUS** (AMQP) to display the status of one or more AMQP channels.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY CHSTATUS \(AMQP\)” on page 798](#)
- [“Parameter descriptions for DISPLAY CHSTATUS \(AMQP\)” on page 799](#)
- [“Summary attributes” on page 800](#)
- [“Client details mode” on page 801](#)
- [“Examples” on page 801](#)

Syntax diagram for DISPLAY CHSTATUS (AMQP)

Synonym: DIS CHS

Note:

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.

Parameter descriptions for **DISPLAY CHSTATUS (AMQP)**

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

generic-channel-name)

The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

The parameter to be used to display attributes for this **DISPLAY** command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator

This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the **CHLTYPE** parameter), you can use EQ or NE only.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

Summary attributes

When no **CLIENTID** parameter is added to the MQSC command **DISPLAY CHSTATUS** (AMQP), a summary of AMQP channel information is displayed. The number of connections is displayed as the **CONNS** attribute. The following attributes display a summary for each channel.

ALL

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for AMQP channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

CONNS

The number of current connections to this channel.

STATUS

The status of this channel.

Client details mode

CLIENTID

The identifier of the client.

STATUS

The status of the client.

CONNAME

The name of the remote connection (IP address)

AMQPKA

The client's keep alive interval.

MCAUSER

The user ID that the client is using to access IBM MQ resources.

CLNTUSER

The user ID that the client provided when it connected.

MSGSENT

Number of messages sent by the client since it connected last.

MSGRCVD

Number of messages received by the client since it connected last.

LSTMSGDA

Date last message was received or sent.

LSTMSGTI

Time last message was received or sent.

CHSTADA

Date channel started.

CHSTATI

Time channel was started.

PROTOCOL

The communication protocol used by the client. The value is AMQP.

Examples

The following command retrieves a status summary for the AMQP channel named MYAMQP:

```
dis chstatus(MYAMQP) chltype(AMQP) all
```

The command outputs the following status:

AMQ8417: Display Channel Status details.	
CHANNEL(MYAMQP)	CHLTYPE(AMQP)
CONNECTIONS(1)	STATUS(RUNNING)

The following command retrieves a full status for the AMQP channel named MYAMQP:

```
dis chstatus(*) chltype(AMQP) clientid(*) all
```

The command outputs the following status:

AMQ8417: Display Channel Status details.	
CHANNEL(MYAMQP)	CHLTYPE(AMQP)
CLIENTID(recv_cc2022b)	STATUS(RUNNING)
CONNAME(192.168.60.1)	AMQPKA(0)
MCAUSER(matt)	CLNTUSER()
MSGSENT(0)	MSGRCVD(0)
LSTMSGDA()	LSTMSGTI()
CHSTADA(2015-09-18)	CHSTATI(06.23.30)
PROTOCOL(AMQP)	

Related reference

[“DISPLAY CHSTATUS \(display channel status\)” on page 777](#)

Use the MQSC command **DISPLAY CHSTATUS** to display the status of one or more channels.

[“DISPLAY CHSTATUS \(display channel status\) MQTT” on page 802](#)

Use the MQSC command **DISPLAY CHSTATUS** (MQTT) to display the status of one or more IBM MQ Telemetry channels.

DISPLAY CHSTATUS (display channel status) MQTT

Use the MQSC command **DISPLAY CHSTATUS** (MQTT) to display the status of one or more IBM MQ Telemetry channels.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY CHSTATUS \(MQTT\)” on page 802](#)
- [“Parameter descriptions for DISPLAY CHSTATUS \(MQTT\)” on page 803](#)
- [“Summary attributes” on page 805](#)

Syntax diagram for DISPLAY CHSTATUS (MQTT)

Synonym: DIS CHS

Notes:

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.
- Either **CLIENTID**, **SUMMARY**, or neither may be specified, but not both at the same time.
- The **DISPLAY CHSTATUS** command for IBM MQ Telemetry has the potential to return a far larger number of responses than if the command was run for an IBM MQ channel. For this reason, the IBM MQ Telemetry server does not return more responses than fit on the reply-to queue. The number of responses is limited to the value of MAXDEPTH parameter of the `SYSTEM.MQSC.REPLY.QUEUE` queue. When RUNMQSC processes an IBM MQ Telemetry command that is truncated by the IBM MQ Telemetry server, the AMQ8492 message is displayed specifying how many responses are returned based on the size of MAXDEPTH.
- You can use this command to list disconnected clients. As these clients are not associated with a particular channel, you list them using the wildcard character. For example,

```
DIS CHS(*) CHLTYPE(MQTT) CLIENTID(*) WHERE(STATUS EQ DISCONNECTED).
```

You should take care using this command when there could be a large number of disconnected clients.

Parameter descriptions for DISPLAY CHSTATUS (MQTT)

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

(generic-channel-name)

The name of the channel definition for which status information is to be displayed. A trailing asterisk (*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all channel definitions. A value is required for all channel types.

WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

The parameter to be used to display attributes for this DISPLAY command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

operator

This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the **CHLTYPE** parameter), you can use EQ or NE only.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

Summary attributes

When **SUMMARY** is added to the MQSC command **DISPLAY CHSTATUS** (MQTT), the number of connections is displayed as the **CONNECTIONS** attribute. The following attributes display a summary for each channel.

ALL

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for MQTT channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

CONNECTIONS

The number of current connections to this channel.

STATUS

The status of this channel.

Client details mode

STATUS

The status of the client.

CLNTUSER

The user ID that the client provided when it connected.

CONNAME

The name of the remote connection (IP address)

KAINT

The client's keep alive interval.

MCAUSER

The user ID that the client is using to access IBM MQ resources. This is the client user ID selected by the process described in [MQTT client identity and authorization](#).

MSGSENT

Number of messages sent by the client since it connected last.

MSGRCVD

Number of messages received by the client since it connected last.

INDOUBTIN

Number of in doubt, inbound messages to the client.

INDOUBTOUT

Number of in doubt, outbound messages to the client.

PENDING

Number of outbound pending messages.

PROTOCOL

The communication protocol used by the client. This is MQTTV311, MQTTV3, or HTTP.

LMSGDATE

Date last message was received or sent.

LMSGTIME

Time last message was received or sent.

CHLSDATE

Date channel started.

CHLSTIME

Time channel was started.

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ Not valid on z/OS.

Usage notes for DISPLAY CLUSQMGR

Unlike the **DISPLAY CHANNEL** command, the **DISPLAY CLUSQMGR** command includes information about cluster channels that are auto-defined, and the status of cluster channels.

Note:  On z/OS, the command fails if the channel initiator is not started.

Parameter descriptions for DISPLAY CLUSQMGR

(generic-qmgr-name)

The name of the cluster queue manager for which information is to be displayed.

A trailing asterisk "*" matches all cluster queue managers with the specified stem followed by zero or more characters. An asterisk "*" on its own specifies all cluster queue managers.

WHERE

Specify a filter condition to display only those cluster channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the CMDSCOPE or MCANAME parameters as filter keywords. You cannot use CHANNEL or CLUSTER as filter keywords if you use them to select cluster queue managers.

operator

The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use CT to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use EX to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use CTG to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use EXG to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, *filter-value* can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. If the attribute value is a value from a possible set of values, you can use only EQ or NE. For example, the value STARTING on the **STATUS** parameter.

- A generic value. *filter-value* is a character string. An example is ABC*. If the operator is LK, all items where the attribute value begins with the string, ABC in the example, are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL

Specify ALL to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

ALL is the default if you do not specify a generic name and do not request any specific parameters.

 On z/OS ALL is also the default if you specify a filter condition using the WHERE parameter, but on other platforms, only requested attributes are displayed.

CHANNEL (*generic-name*)

This is optional, and limits the information displayed to cluster channels with the specified channel name. The value can be a generic name.

CLUSTER (*generic-name*)

This is optional, and limits the information displayed to cluster queue managers with the specified cluster name. The value can be a generic name.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

"

The command runs on the queue manager on which it was entered. ' ' is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can enter a different queue manager name, if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of * is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for cluster channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, and do not cause an error.

CLUSDATE

The date on which the definition became available to the local queue manager, in the form *yyyy-mm-dd*.

CLUSTIME

The time at which the definition became available to the local queue manager, in the form *hh.mm.ss*.

DEFTYPE

How the cluster channel was defined:

CLUSSDR

As a cluster-sender channel from an explicit definition.

CLUSSDRA

As a cluster-sender channel by auto-definition alone.

CLUSSDRB

As a cluster-sender channel by auto-definition and an explicit definition.

CLUSRCVR

As a cluster-receiver channel from an explicit definition.

QMID

The internally generated unique name of the cluster queue manager.

QMTYPE

The function of the cluster queue manager in the cluster:

REPOS

Provides a full repository service.

NORMAL

Does not provide a full repository service.

STATUS

The status of the channel for this cluster queue manager is one of the following values:

STARTING

The channel was started and is waiting to become active.

BINDING

The channel is performing channel negotiation and is not yet ready to transfer messages.

INACTIVE

The channel is not active.

INITIALIZING

The channel initiator is attempting to start a channel.

 On z/OS, INITIALIZING is displayed as INITIALIZI.

RUNNING

The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

STOPPING

The channel is stopping, or received a close request.

RETRYING

A previous attempt to establish a connection failed. The MCA attempts to connect again after the specified time interval.

PAUSED

The channel is waiting for the message-retry interval to complete before trying an MQPUT operation again.

STOPPED

This state can be caused by one of the following events:

- Channel manually stopped.

A user entered a stop channel command for this channel.

- The number of attempts to establish a connection reached the maximum number of attempts allowed for the channel.

No further attempt is made to establish a connection automatically.

A channel in this state can be restarted only by issuing the **START CHANNEL** command, or starting the MCA program in an operating-system dependent manner.

REQUESTING

A local requester channel is requesting services from a remote MCA.

SWITCHING

The channel is switching transmission queues.

SUSPEND

Specifies whether this cluster queue manager is suspended from the cluster or not (as a result of the **SUSPEND QMGR** command). The value of **SUSPEND** is either YES or NO.

VERSION

The version of the IBM MQ installation that the cluster queue manager is associated with.

The version has the format VVRRMMFF:

- VV: Version
- RR: Release
- MM: Maintenance level
- FF: Fix level

XMITQ

The cluster transmission queue.

Channel parameters**ALTDATE**

The date on which the definition or information was last altered, in the form *yyyy-mm-dd*.

ALTTIME

The time at which the definition or information was last altered, in the form *hh.mm.ss*.

BATCHHB

The batch heartbeat value being used.

BATCHINT

Minimum batch duration.

BATCHLIM

Batch data limit.

The limit of the amount of data that can be sent through a channel.

BATCHSZ

Batch size.

CLWLPRTY

The priority of the channel for the purposes of cluster workload distribution.

CLWLRANK

The rank of the channel for the purposes of cluster workload distribution.

CLWLWGHT

The weighting of the channel for the purposes of cluster workload distribution.

COMPHDR

The list of header data compression techniques supported by the channel.

COMPMSG

The list of message data compression techniques supported by the channel.

CONNAME

Connection name.

CONVERT

Specifies whether the sender converts application message data.

DESCR

Description.

DISCINT

Disconnection interval.

HBINT

Heartbeat interval.

KAINT

KeepAlive timing for the channel.

LOCLADDR

Local communications address for the channel.

LONGRTY

Limit of number of attempts to connect using the long duration timer.

LONGTMR

Long duration timer.

MAXMSG

Maximum message length for channel.

MCANAME

Message channel agent name.

You cannot use **MCANAME** as a filter keyword.

MCATYPE

Specifies whether the message channel agent runs as a separate process or a separate thread.

MCAUSER

Message channel agent user identifier.

MODENAME

LU 6.2 mode name.

MRDATA

Channel message-retry exit user data.

MREXIT

Channel message-retry exit name.

MRRTY

Channel message-retry count.

MRTMR

Channel message-retry time.

MSGDATA

Channel message exit user data.

MSGEXIT

Channel message exit names.

NETPRTY

The priority for the network connection.

NPMSPEED

Nonpersistent message speed.

PASSWORD

Password for initiating LU 6.2 session (if nonblank, PASSWORD is displayed as asterisks).

PROPCTL

Message property control.

PUTAUT

Put authority.

RCVDATA

Channel receive exit user data.

RCVEXIT

Channel receive exit names.

SCYDATA

Channel security exit user data.

SCYEXIT

Channel security exit name.

SENDDATA

Channel send exit user data.

SENDEXIT

Channel send exit names.

SEQWRAP

Sequence number wrap value.

SHORTRTY

Limit of number of attempts to connect using the short duration timer.

SHORTTMR

Short duration timer.

SSLCAUTH

Specifies whether TLS client authentication is required.

SSLCIPH

Cipher specification for the TLS connection.

SSLPEER

Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

TRPTYPE

Transport type.

TPNAME

LU 6.2 transaction program name.

USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

USERID

User identifier for initiating LU 6.2 session.

For more information about channel parameters, see [“DEFINE CHANNEL \(define a new channel\)”](#) on page 544

Related reference

[“REFRESH CLUSTER \(rebuild a cluster\)”](#) on page 994

Use the MQSC command **REFRESH CLUSTER** to discard all locally held cluster information and force it to be rebuilt. The command also processes any auto-defined channels that are in doubt. After the command completes processing, you can perform a "cold-start" on the cluster.

[“RESET CLUSTER \(remove a cluster member\)” on page 1010](#)

Use the MQSC command **RESET CLUSTER** on a full repository queue manager to remove a partial repository queue manager from a cluster. Only use this command in an emergency, where normal methods cannot be used.

DISPLAY CMDSERV (display command server status) on z/OS

Use the MQSC command **DISPLAY CMDSERV** to display the status of the command server.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY CMDSERV” on page 815](#)
- [“Usage notes for DISPLAY CMDSERV” on page 815](#)

Syntax diagram for DISPLAY CMDSERV

Synonym: DIS CS

DISPLAY CMDSERV

➡ DISPLAY CMDSERV →

Usage notes for DISPLAY CMDSERV

1. The command server takes messages from the system command input queue, and commands using **CMDSCOPE**, and processes them. **DISPLAY CMDSERV** displays the status of the command server.
2. The response to this command is a message showing the current status of the command server, which is one of the following:

ENABLED

Available to process commands

DISABLED

Not available to process commands

STARTING

START CMDSERV in progress

STOPPING

STOP CMDSERV in progress

STOPPED

STOP CMDSERV completed

RUNNING

Available to process commands, currently processing a message

WAITING

Available to process commands, currently waiting for a message

[“START CMDSERV \(start the command server\) on z/OS” on page 1067](#)

Use the MQSC command **START CMDSERV** to initialize the command server.

[“STOP CMDSERV \(stop the command server\) on z/OS” on page 1090](#)

Use the MQSC command **STOP CMDSERV** to stop the command server.

Multi **DISPLAY COMMINFO (display communication information) on Multiplatforms**

Use the MQSC command **DISPLAY COMMINFO** to display the attributes of a communication information object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY COMMINFO” on page 816](#)
- [“Parameter descriptions for DISPLAY COMMINFO” on page 817](#)
- [“Requested parameters” on page 818](#)

Syntax diagram for DISPLAY COMMINFO

Synonym: DIS COMMINFO

Parameter descriptions for DISPLAY COMMINFO

You must specify the name of the communication information object you want to display. This can be a specific communication information object name or a generic communication information object name. By using a generic communication information object name, you can display either:

- All communication information object definitions
- One or more communication information objects that match the specified name

(generic-comminfo-name)

The name of the communication information object definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all communication information objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all communication information objects. The names must all be defined to the local queue manager.

WHERE

Specify a filter condition to display only those communication information object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a communication information object definition satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DISABLED on the **COMMEV** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

ALL

Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

TYPE

Indicates the type of namelist to be displayed.

MULTICAST

Displays multicast communication information objects. This is the default.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the **ALL** parameter is not specified) is that the object names and **TYPE** parameters are displayed.

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*.

ALTTIME

The time at which the definition was last altered, in the form *hh.mm.ss*.

BRIDGE

Multicast bridging

CCSID

The coded character set identifier that messages are transmitted on.

COMMEV

Whether event messages are generated for Multicast.

DESCR(*string*)

Description

ENCODING

The encoding that the messages are transmitted in.

GRPADDR

The group IP address or DNS name.

MCHBINT

Multicast heartbeat interval.

MCPROP

Multicast property control

MONINT

Monitoring frequency.

MSGHIST

The amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

NSUBHIST

How much history a new subscriber joining a publication stream receives.

PORT

The port number to transmit on.

DISPLAY CONN (display application connection information)

Use the MQSC command **DISPLAY CONN** to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY CONN” on page 819](#)
- [“Usage notes for DISPLAY CONN” on page 821](#)
- [“Parameter descriptions for DISPLAY CONN” on page 821](#)
- [“Connection attributes” on page 824](#)
- [“Handle attributes” on page 829](#)
- [“Full attributes” on page 832](#)

Syntax diagram for DISPLAY CONN

Synonym: DIS CONN

Usage notes for DISPLAY CONN

1. **z/OS** This command is issued internally by IBM MQ on z/OS when taking a checkpoint, and when the queue manager is starting and stopping, so that a list of units of work that are in doubt at the time is written to the z/OS console log.
2. The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

z/OS On z/OS, these non-printable characters are displayed as blanks.

Multi On Multiplatforms using **runmqsc**, these non-printable characters are displayed as dots.

3. The state of asynchronous consumers, **ASTATE**, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

From IBM MQ 8.0, there is a change to the data that is returned in the EXTURID field on the results shown for the **DISPLAY CONN runmqsc** command when there is no XA transaction associated with the connection. Prior to IBM MQ 8.0, if there is no XA transaction associated with the connection then within the EXTURID attribute the XA_FORMATID field would be show as [00000000]. From IBM MQ 8.0, if there is no XA transaction associated with the connection, then the XA_FORMATID value is shown as the empty string [].

Parameter descriptions for DISPLAY CONN

You must specify a connection for which you want to display information. This can be a specific connection identifier or a generic connection identifier. A single asterisk (*) can be used as a generic connection identifier to display information for all connections.

(*generic-connid*)

The identifier of the connection definition for which information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed.

When an application connects to IBM MQ, it is given a unique 24-byte connection identifier (ConnectionId). The value for **CONN** is formed by converting the last eight bytes of the ConnectionId to its 16-character hexadecimal equivalent.

WHERE

Specify a filter condition to display only those connections that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, **EXTCONN**, **QSGDISP**, **TYPE**, and **EXTURID** parameters as filter keywords.

operator

This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item. You cannot use the **CONNOPTS** value MQCNO_STANDARD_BINDING with this operator.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item. You cannot use the **CONNOPTS** value MQCNO_STANDARD_BINDING with this operator.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the **UOWSTATE** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string in the **APPLTAG** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL,

all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

ALL

Specify this to display all the connection information of the requested type for each specified connection. This is the default if you do not specify a generic identifier, and do not request any specific parameters.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

EXTCONN

The value for **EXTCONN** is based on the first sixteen bytes of the ConnectionId converted to its 32-character hexadecimal equivalent.

Connections are identified by a 24-byte connection identifier. The connection identifier comprises a prefix, which identifies the queue manager, and a suffix which identifies the connection to that queue manager. By default, the prefix is for the queue manager currently being administered, but you can specify a prefix explicitly by using the **EXTCONN** parameter. Use the **CONN** parameter to specify the suffix.

When connection identifiers are obtained from other sources, specify the fully qualified connection identifier (both **EXTCONN** and **CONN**) to avoid possible problems related to non-unique **CONN** values.

Do not specify both a generic value for **CONN** and a non-generic value for **EXTCONN**.

You cannot use **EXTCONN** as a filter keyword.

TYPE

Specifies the type of information to be displayed. Values are:

CONN

Connection information for the specified connection.

 On z/OS, this includes threads which may be logically or actually disassociated from a connection, together with those that are in-doubt and for which external intervention is needed to resolve them. These latter threads are those that **DIS THREAD TYPE(INDOUBT)** would show.

HANDLE

Information relating to any objects opened by the specified connection.

*

Display all available information relating to the connection.

ALL

Display all available information relating to the connection.

► **z/OS** On z/OS, if you specify **TYPE**(ALL/*) and **WHERE**(xxxxx) you only get CONN or HANDLE information returned, based on the **WHERE** specification. That is, if the xxxxx is a condition relating to handle attributes then only handle attributes for the connection are returned.

URDISP

Specifies the unit of recovery disposition of connections to be displayed. Values are:

ALL

Display all connections. This is the default option.

GROUP

Display only those connections with a GROUP unit of recovery disposition.

QMGR

Display only those connections with a QMGR unit of recovery disposition.

Connection attributes

If **TYPE** is set to CONN, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (**CONN** parameter)
- Type of information returned (**TYPE** parameter)

The following parameters can be specified for **TYPE**(CONN) to request additional information for each connection. If a parameter is specified that is not relevant for the connection, operating environment, or type of information requested, that parameter is ignored.

APPLDESC

A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

APPLTAG

A string containing the tag of the application connected to the queue manager. It is one of the following:

- ► **z/OS** z/OS batch job name
- ► **z/OS** TSO USERID
- CICS APPLID
- ► **z/OS** IMS region name
- Channel initiator job name
- ► **IBM i** IBM i job name
- ► **Linux** ► **AIX** UNIX process

Notes:

- ► **Linux** On Linux, if the process name exceeds 15 characters, only the first 15 characters are shown.
- ► **AIX** On AIX, if the process name exceeds 28 characters, only the first 28 characters are shown.
- ► **Windows** Windows process

Note: This consists of the full program path and executable file name. If it is more than 28 characters long, only the last 28 characters are shown.

- Internal queue manager process name

APPLTYPE

A string indicating the type of the application that is connected to the queue manager. It is one of the following:

AIX

AIX application.

AMQP

Advanced Message Queuing Protocol (AMQP) application.

BATCH

Application using a batch connection.

BROKER

Broker application.

CHINIT

Channel initiator.

CICS

CICS application.

CICS_BRIDGE

CICS bridge application.

CICS_VSE

CICS/VSE application.

DEF

Default application type. See [DEFINE PROCESS \(create a new process definition\)](#).

DOS

MQI client application on PC DOS.

DQM

DQM application.

IMS

IMS application.

IMS_BRIDGE

IMS bridge application.

JAVA

Java application.

MVS

MVS or TSO application.

NOTES_AGENT

Lotus Notes Agent application.

OS2

OS/2 application.

OS390

OS/390® application.

 OS400

IBM i application.

QMGR

Queue manager application.

RRSBATCH

RRS batch application.

SYSTEM

Queue manager.

SYSTEMEXT

Application performing an extension of function that is provided by the queue manager.

A Linux or AIX application

UNKNOWN

Application of unknown type.

USER

User-defined application.

VMS

VMS application.

VOS

VOS application.

A Windows application

Represents a Windows NT application.

WLM

z/OS workload manager application.

XCF

XCF application.

ZOS

z/OS application.

A 4-character address-space identifier of the application identified by **APPLTAG**. It distinguishes duplicate values of **APPLTAG**.

This parameter is returned only on z/OS when the **APPLTYPE** parameter does not have the value SYSTEM.

This parameter is valid only on z/OS.

ASTATE

The state of asynchronous consumption on this connection handle.

Possible values are:

SUSPENDED

An MQCTL call with the Operation parameter set to MQOP_SUSPEND has been issued against the connection handle so that asynchronous message consumption is temporarily suspended on this connection.

STARTED

An MQCTL call with the Operation parameter set to MQOP_START has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

STARTWAIT

An MQCTL call with the Operation parameter set to MQOP_START_WAIT has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

STOPPED

An MQCTL call with the Operation parameter set to MQOP_STOP has been issued against the connection handle so that asynchronous message consumption cannot currently proceed on this connection.

NONE

No MQCTL call has been issued against the connection handle. Asynchronous message consumption cannot currently proceed on this connection.

CHANNEL

The name of the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

Multi

CLIENTID

The client ID of the client that is using the connection. If there is no client ID associated with the connection, this parameter is blank.

CONNAME

The connection name associated with the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

CONNOPTS

The connect options currently in force for this application connection. Possible values are:

- MQCNO_ACCOUNTING_MQI_DISABLED
- MQCNO_ACCOUNTING_MQI_ENABLED
- MQCNO_ACCOUNTING_Q_DISABLED
- MQCNO_ACCOUNTING_Q_ENABLED
- MQCNO_FASTPATH_BINDING
- MQCNO_HANDLE_SHARE_BLOCK
- MQCNO_HANDLE_SHARE_NO_BLOCK
- MQCNO_HANDLE_SHARE_NONE
- MQCNO_ISOLATED_BINDING
- MQCNO_RECONNECT
- MQCNO_RECONNECT_Q_MGR
- MQCNO_RESTRICT_CONN_TAG_Q_MGR
- MQCNO_RESTRICT_CONN_TAG_QSG
- MQCNO_SERIALIZE_CONN_TAG_Q_MGR
- MQCNO_SERIALIZE_CONN_TAG_QSG
- MQCNO_SHARED_BINDING
- MQCNO_STANDARD_BINDING

If you are using an IBM MQ 9.1.2 or later client, the values displayed for MQCNO_RECONNECT and MQCNO_RECONNECT_Q_MGR are the effective reconnect options. If you are using an earlier client version, the values displayed are whatever the application specifies, whether they are currently taking effect or not.

You cannot use the value MQCNO_STANDARD_BINDING as a filter value with the CT and EX operators on the **WHERE** parameter.

ALW

CONNTAG

The connection tag associated with this connection, formatted as a readable string in the local codepage for the RUNMQSC.

Note: The *CONNTAG* is treated as string data, so it can be filtered using the syntax WHERE (CONNTAG LK 'generic_tag*').

EXTURID

The external unit of recovery identifier associated with this connection. Its format is determined by the value of **URTYPE**.

You cannot use **EXTURID** as a filter keyword.

z/OS

NID

Origin identifier, set only if the value of **UOWSTATE** is UNRESOLVED. This is a unique token identifying the unit of work within the queue manager. It is of the form origin-node.origin-urid where

- **origin-node** identifies the originator of the thread, except in the case where **APPLTYPE** is set to RRSBATCH, when it is omitted.
- **origin-urid** is the hexadecimal number assigned to the unit of recovery by the originating system for the specific thread to be resolved.

This parameter is valid only on z/OS.

PID

Number specifying the process identifier of the application that is connected to the queue manager.

z/OS This parameter is not valid on z/OS.

z/OS PSBNAME

The 8-character name of the program specification block (PSB) associated with the running IMS transaction. You can use the **PSBNAME** and **PSTID** to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

z/OS PSTID

The 4-character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

QMURID

The queue manager unit of recovery identifier.

z/OS On z/OS, this is an 8-byte log RBA, displayed as 16 hexadecimal characters.

Multi On Multiplatforms, this is an 8-byte transaction identifier, displayed as m.n where m and n are the decimal representation of the first and last 4 bytes of the transaction identifier.

z/OS You can use **QMURID** as a filter keyword. On z/OS, you must specify the filter value as a hexadecimal string.

Multi On Multiplatforms, you must specify the filter value as a pair of decimal numbers separated by a period (.). You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

z/OS However, on z/OS, if log shunting has taken place, as indicated by message CSQR026I, instead of the RBA you have to use the URID from the message.

z/OS TASKNO

A 7-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

TID

Number specifying the thread identifier within the application process that has opened the specified queue.

z/OS This parameter is not valid on z/OS.

z/OS TRANSID

A 4-character CICS transaction identifier. This parameter is valid only on z/OS.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

Multi UOWLOG

The file name of the extent to which the transaction associated with this connection first wrote.

 This parameter is valid only on Multiplatforms.

UOWLOGDA

The date that the transaction associated with the current connection first wrote to the log.

UOWLOGTI

The time that the transaction associated with the current connection first wrote to the log.

UOWSTATE

The state of the unit of work. It is one of the following:

NONE

There is no unit of work.

ACTIVE

The unit of work is active.

PREPARED

The unit of work is in the process of being committed.

UNRESOLVED

The unit of work is in the second phase of a two-phase commit operation. IBM MQ holds resources on its behalf and external intervention is required to resolve it. This might be as simple as starting the recovery coordinator (such as CICS, IMS, or RRS) or it might involve a more complex operation such as using the **RESOLVE INDOUBT** command. The UNRESOLVED value can occur only on z/OS.

UOWSTDA

The date that the transaction associated with the current connection was started.

UOWSTTI

The time that the transaction associated with the current connection was started.

URTYPE

The type of unit of recovery as seen by the queue manager. It is one of the following:

-  CICS (valid only on z/OS)
- XA
-  RRS (valid only on z/OS)
-  IMS (valid only on z/OS)
- QMGR

URTYPE identifies the **EXTURID** type and not the type of the transaction coordinator. When **URTYPE** is QMGR, the associated identifier is in **QMURID** (and not **EXTURID**).

USERID

The user identifier associated with the connection.

This parameter is not returned when **APPLTYPE** has the value SYSTEM.

Handle attributes

If **TYPE** is set to HANDLE, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (**CONN** parameter)
- Read ahead status (**DEFREADA** parameter)
- Type of information returned (**TYPE** parameter)
- Handle status (**HSTATE**)
- Object name (**OBJNAME** parameter)
- Object type (**OBJTYPE** parameter)

The following parameters can be specified for **TYPE(HANDLE)** to request additional information for each queue. If a parameter is specified that is not relevant for the connection, operating environment, or type of status information requested, that parameter is ignored.

ASTATE

The state of the asynchronous consumer on this object handle.

Possible values are:

ACTIVE

An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

INACTIVE

An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

SUSPENDED

The asynchronous consumption callback has been suspended so that asynchronous message consumption cannot currently proceed on this object handle. This can be either because an MQCB call with Operation MQOP_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure that is passed to the callback function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP_RESUME.

SUSPTMP

The asynchronous consumption callback has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this object handle. As part of the process of suspending asynchronous message consumption, the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure passed to the callback function.

The callback function will be called again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

NONE

An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

DEST

The destination queue for messages that are published to this subscription. This parameter is only relevant for handles of subscriptions to topics. It is not returned for other handles.

DESTQMGR

The destination queue manager for messages that are published to this subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. If DEST is a queue that is hosted on the local queue manager, this parameter will contain the local queue manager name. If DEST is a queue that is hosted on a remote queue manager, this parameter will contain the name of the remote queue manager.

HSTATE

The state of the handle.

Possible values are:

ACTIVE

An API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when an MQGET WAIT call is in progress.

If there is an MQGET SIGNAL outstanding, then this does not mean, by itself, that the handle is active.

INACTIVE

No API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when no MQGET WAIT call is in progress.

OBJNAME

The name of an object that the connection has open.

OBJTYPE

The type of the object that the connection has open. If this handle is that of a subscription to a topic, then the **SUBID** parameter identifies the subscription. You can then use the **DISPLAY SUB** command to find all the details about the subscription.

It is one of the following:

- QUEUE
- PROCESS
- QMGR
-  STGCLASS (valid only on z/OS)
- NAMELIST
- CHANNEL
- AUTHINFO
- TOPIC

OPENOPTS

The open options currently in force for the connection for the object. This parameter is not returned for a subscription. Use the value in the **SUBID** parameter and the **DISPLAY SUB** command to find the details about the subscription.

Possible values are:

MQOO_INPUT_AS_Q_DEF

Open queue to get messages using queue-defined default.

MQOO_INPUT_SHARED

Open queue to get messages with shared access.

MQOO_INPUT_EXCLUSIVE

Open queue to get messages with exclusive access.

MQOO_BROWSE

Open queue to browse messages.

MQOO_OUTPUT

Open queue or topic to put messages.

MQOO_INQUIRE

Open queue to inquire attributes.

MQOO_SET

Open queue to set attributes.

MQOO_BIND_ON_OPEN

Bind handle to destination when queue is found.

MQOO_BIND_NOT_FIXED

Do not bind to a specific destination.

MQOO_SAVE_ALL_CONTEXT

Save context when message retrieved.

MQOO_PASS_IDENTITY_CONTEXT

Allow identity context to be passed.

MQOO_PASS_ALL_CONTEXT

Allow all context to be passed.

MQOO_SET_IDENTITY_CONTEXT

Allow identity context to be set.

MQOO_SET_ALL_CONTEXT

Allow all context to be set.

MQOO_ALTERNATE_USER_AUTHORITY

Validate with specified user identifier.

MQOO_FAIL_IF QUIESCING

Fail if queue manager is quiescing.

**QSGDISP**

Indicates the disposition of the object. It is valid on z/OS only. The value is one of the following:

QMGR

The object was defined with **QSGDISP(QMGR)**.

COPY

The object was defined with **QSGDISP(COPY)**.

SHARED

The object was defined with **QSGDISP(SHARED)**.

You cannot use **QSGDISP** as a filter keyword.

READA

The read ahead connection status.

Possible values are:

NO

Read ahead of non-persistent messages is not enabled for this object.

YES

Read ahead of non-persistent message is enabled for this object and is being used efficiently.

BACKLOG

Read ahead of non-persistent messages is enabled for this object. Read ahead is not being used efficiently because the client has been sent a large number of messages which are not being consumed.

INHIBITED

Read ahead was requested by the application but has been inhibited because of incompatible options specified on the first MQGET call.

SUBID

The internal, all-time unique identifier of the subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles.

Not all subscriptions show up in **DISPLAY CONN**; only those that have current handles open to the subscription show up. You can use the **DISPLAY SUB** command to see all subscriptions.

SUBNAME

The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

TOPICSTR

The resolved topic string. This parameter is relevant for handles with **OBJTYPE(TOPIC)**. For any other object type, this parameter is not returned.

Full attributes

If **TYPE** is set to *, or ALL, both Connection attributes and Handle attributes are returned for each connection that satisfies the selection criteria.

Related reference

“DISPLAY APSTATUS (display application status) on Multiplatforms” on page 720

Use the MQSC command **DISPLAY APSTATUS** to display the status of one or more applications and application instances connected to a queue manager or a uniform cluster.

DISPLAY ENTAUTH (display entity authorizations) on Multiplatforms

Use the MQSC command **DISPLAY ENTAUTH** to display the authorizations an entity has to a specified object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- “Syntax diagram for DISPLAY ENTAUTH” on page 833
- “Parameter descriptions for DISPLAY ENTAUTH” on page 834
- “Requested parameters” on page 835

Syntax diagram for DISPLAY ENTAUTH

Synonym: DIS ENTAUTH

Parameter descriptions for DISPLAY ENTAUTH

PRINCIPAL(*principal-name*)

A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: user@domain.

You must specify either **PRINCIPAL** or **GROUP**.

GROUP(*group-name*)

A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

 For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain  
domain\GroupName
```

You must specify either **PRINCIPAL** or **GROUP**.

OBJNAME(*object-name*)

The name of the object or generic profile for which to display the authorizations.

This parameter is required unless the **OBJTYPE** parameter is QMGR. This parameter can be omitted if the **OBJTYPE** parameter is QMGR.

OBJTYPE

The type of object referred to by the profile. Specify one of the following values:

AUTHINFO

Authentication information record

CHANNEL

Channel

CLNTCONN

Client connection channel

COMMINFO

Communication information object

LISTENER

Listener

NAMELIST

Namelist

PROCESS

Process

QUEUE

Queue

QMGR

Queue manager

RQMNAME

Remote queue manager

SERVICE

Service

TOPIC

Topic

SERVCOMP(*service-component*)

The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

ALL

Specify this value to display all of the authorization information available for the entity and the specified profile.

Requested parameters

You can request the following information about the authorizations:

AUTHLIST

Specify this parameter to display the list of authorizations.

ENTITY

Specify this parameter to display the entity name.

ENTTYPE

Specify this parameter to display the entity type.

OBJTYPE

Specify this parameter to display the object type.

DISPLAY GROUP (display QSG information) on z/OS

Use the MQSC command **DISPLAY GROUP** to display information about the queue sharing group to which the queue manager is connected. This command is valid only when the queue manager is a member of a queue sharing group.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY GROUP” on page 835](#)
- [“Usage notes for DISPLAY GROUP” on page 835](#)
- [“Parameter descriptions for DISPLAY GROUP” on page 836](#)

Syntax diagram for DISPLAY GROUP

Synonym: DIS GROUP

Usage notes for DISPLAY GROUP

1. The response to the **DISPLAY GROUP** command is a series of messages containing information about the queue sharing group to which the queue manager is connected.

The following information is returned:

- The name of the queue sharing group.
- Whether all the queue managers that belong to the group are active or inactive.

- The names of all the queue managers that belong to the group.
- The versions of the queue managers in the group. If ">10xx" is displayed this indicates that the queue manager is at a version that is greater than the displaying queue manager.
- If you specify **OBSMSGs (YES)**, whether queue managers in the group contain obsolete messages in Db2.

Parameter descriptions for DISPLAY GROUP

OBSMSGs

Specifies whether the command additionally looks for obsolete messages in Db2. This is optional. Possible values are:

NO

Obsolete messages in Db2 are not looked for. This is the default value.

YES

Obsolete messages in Db2 are looked for and messages containing information about any found are returned.

DISPLAY LISTENER (display listener information) on Multiplatforms

Use the MQSC command **DISPLAY LISTENER** to display information about a listener.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY LISTENER” on page 836](#)
- [“Usage notes for DISPLAY LISTENER” on page 837](#)
- [“Keyword and parameter descriptions for DISPLAY LISTENER” on page 837](#)
- [“Requested parameters” on page 838](#)

Syntax diagram for DISPLAY LISTENER

Synonym: DIS LSTR

Usage notes for **DISPLAY LISTENER**

The values displayed describe the current definition of the listener. If the listener has been altered since it was started, the currently running instance of the listener object may not have the same values as the current definition.

Keyword and parameter descriptions for **DISPLAY LISTENER**

You must specify a listener for which you want to display information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Information about all listener definitions, by using a single asterisk (*), or
- Information about one or more listeners that match the specified name.

(*generic-listener-name*)

The name of the listener definition for which information is to be displayed. A single asterisk (*) specifies that information for all listener identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

TRPTYPE

Transmission protocol. If you specify this parameter, it must follow directly after the *generic-listener-name* parameter. If you do not specify this parameter, a default of ALL is assumed. Values are:

ALL

This is the default value and displays information for all listeners.

LU62

Displays information for all listeners defined with a value of LU62 in their **TRPTYPE** parameter.

NETBIOS

Displays information for all listeners defined with a value of NETBIOS in their **TRPTYPE** parameter.

SPX

Displays information for all listeners defined with a value of SPX in their **TRPTYPE** parameter.

TCP

Displays information for all listeners defined with a value of TCP in their **TRPTYPE** parameter.

WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string, with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Specify this to display all the listener information for each specified listener. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ADAPTER

The adapter number on which NetBIOS listens.

ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd.

ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss.

BACKLOG

The number of concurrent connection requests that the listener supports.

COMMANDS

The number of commands that the listener can use.

CONTROL

How the listener is to be started and stopped:

MANUAL

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR

Descriptive comment.

IPADDR

The listener's IP address.

LOCLNAME

The NetBIOS local name that the listener uses.

NTBNAMES

The number of names that the listener can use.

PORT

The port number for TCP/IP.

SESSIONS

The number of sessions that the listener can use.

SOCKET

SPX socket.

TPNAME

The LU6.2 transaction program name.

For more information on these parameters, see [“DEFINE LISTENER \(define a new listener\) on Multiplatforms”](#) on page 608.

Related reference

[“ALTER LISTENER \(alter an existing listener\) on Multiplatforms”](#) on page 403

Use MQSC command **ALTER LISTENER** to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

[“DELETE LISTENER \(delete a listener\) on Multiplatforms”](#) on page 699

Use the MQSC command **DELETE LISTENER** to delete a listener definition.

[“DISPLAY LSSTATUS \(display listener status\) on Multiplatforms”](#) on page 841

Use the MQSC command **DISPLAY LSSTATUS** to display status information for one or more listeners.

[“START LISTENER \(start a channel listener\)”](#) on page 1068

Use the MQSC command **START LISTENER** to start a channel listener.

[“STOP LISTENER \(stop a channel listener\)” on page 1092](#)

Use the MQSC command **STOP LISTENER** to stop a channel listener.

DISPLAY LOG (display log information) on z/OS

Use the MQSC command **DISPLAY LOG** to display log system parameters and information.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY LOG” on page 840](#)
- [“Usage notes for DISPLAY LOG” on page 840](#)
- [“Parameter descriptions for DISPLAY LOG” on page 841](#)

Syntax diagram for DISPLAY LOG

Synonym: DIS LOG

Usage notes for DISPLAY LOG

1. **DISPLAY LOG** returns a report that shows the initial log parameters, and the current values as changed by the **SET LOG** command:

- Whether log compression is active (COMPLOG).
- Whether writes to the active logs are made with zHyperWrite being enabled (ZHYWRITE)
- Length of time that an allowed archive read tape unit remains unused before it is deallocated (DEALLCT).
- Size of input buffer storage for active and archive log data sets (INBUFF).
- Size of output buffer storage for active and archive log data sets (OUTBUFF).
- Maximum number of dedicated tape units that can be set to read archive log tape volumes (MAXRTU).
- Maximum number of archive log volumes that can be recorded (MAXARCH).
- Maximum number of concurrent log offload tasks (MAXCNOFF)
- Whether archiving is on or off (OFFLOAD).
- Whether single or dual active logging is being used (TWOACTV).
- Whether single or dual archive logging is being used (TWOARCH).

- Whether single or dual BSDS is being used (TWOBSDS).
- Number of output buffers to be filled before they are written to the active log data sets (WRTHRSH).
- Whether writes to the active logs are made with zHyperLink being enabled (ZHYLINK)

It also returns a report about the status of the logs.

2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY LOG

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

''

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

Related reference

[“DEFINE LOG \(define a new active log\) on z/OS” on page 611](#)

Use the MQSC command **DEFINE LOG** to add a new active log data set in the ring of active logs.

[“SET LOG \(change log system settings\) on z/OS” on page 1051](#)

On z/OS, use the MQSC command **SET LOG** to dynamically change certain log system parameter values that were initially set by your system parameter module at queue manager startup.

DISPLAY LSSTATUS (display listener status) on Multiplatforms

Use the MQSC command **DISPLAY LSSTATUS** to display status information for one or more listeners.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY LSSTATUS” on page 841](#)
- [“Keyword and parameter descriptions for DISPLAY LSSTATUS” on page 842](#)
- [“Requested parameters” on page 843](#)

Syntax diagram for DISPLAY LSSTATUS

Synonym: DIS LSSTATUS

Keyword and parameter descriptions for DISPLAY LSSTATUS

You must specify a listener for which you want to display status information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Status information for all listener definitions, by using a single asterisk (*), or
- Status information for one or more listeners that match the specified name.

(*generic-listener-name*)

The name of the listener definition for which status information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string, with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Display all the status information for each specified listener. This is the default if you do not specify a generic name, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ADAPTER

The adapter number on which NetBIOS listens.

BACKLOG

The number of concurrent connection requests that the listener supports.

CONTROL

How the listener is to be started and stopped:

MANUAL

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the **START LISTENER** and **STOP LISTENER** commands.

QMGR

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR

Descriptive comment.

IPADDR

The listener's IP address.

LOCLNAME

The NetBIOS local name that the listener uses.

NTBNAMES

The number of names that the listener can use.

PID

The operating system process identifier associated with the listener.

PORT

The port number for TCP/IP.

SESSIONS

The number of sessions that the listener can use.

SOCKET

SPX socket.

STARTDA

The date on which the listener was started.

STARTTI

The time at which the listener was started.

STATUS

The current status of the listener. It can be one of:

RUNNING

The listener is running.

STARTING

The listener is in the process of initializing.

STOPPING

The listener is stopping.

TPNAME

The LU6.2 transaction program name.

TRPTYPE

Transport type.

For more information on these parameters, see [“DEFINE LISTENER \(define a new listener\) on Multiplatforms” on page 608](#).

Related reference

[“ALTER LISTENER \(alter an existing listener\) on Multiplatforms” on page 403](#)

Use MQSC command **ALTER LISTENER** to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

[“DEFINE LISTENER \(define a new listener\) on Multiplatforms” on page 608](#)

Use the MQSC command **DEFINE LISTENER** to define a new IBM MQ listener definition, and set its parameters.

[“DELETE LISTENER \(delete a listener\) on Multiplatforms” on page 699](#)

Use the MQSC command **DELETE LISTENER** to delete a listener definition.

[“DISPLAY LISTENER \(display listener information\) on Multiplatforms” on page 836](#)

Use the MQSC command **DISPLAY LISTENER** to display information about a listener.

[“START LISTENER \(start a channel listener\)” on page 1068](#)

Use the MQSC command **START LISTENER** to start a channel listener.

[“STOP LISTENER \(stop a channel listener\)” on page 1092](#)

Use the MQSC command **STOP LISTENER** to stop a channel listener.

▶ **z/OS** **DISPLAY MAXSMGS (display maximum messages setting) on z/OS**

Use the MQSC command **DISPLAY MAXSMGS** to see the maximum number of messages that a task can get or put within a single unit of recovery.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY MAXSMGS” on page 845](#)
- [“Parameter descriptions for DISPLAY MAXSMGS” on page 845](#)
- [“Usage notes for DISPLAY MAXSMGS” on page 845](#)

Syntax diagram for DISPLAY MAXSMGS

Synonym: DIS MAXSM

DISPLAY MAXSMGS

Notes:

¹ Valid only on full function IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Usage notes for DISPLAY MAXSMGS

This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization data set. You should use the **MAXUMSGS** parameter of the **DISPLAY QMGR** command instead.

Parameter descriptions for DISPLAY MAXSMGS

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

“DEFINE MAXSMGS (define maximum messages setting) on z/OS” on page 613

Use the MQSC command **DEFINE MAXSMGS** to define the maximum number of messages that a task can get or put within a single unit of recovery.

DISPLAY NAMELIST (display a list of names)

Use the MQSC command **DISPLAY NAMELIST** to display the names in a namelist.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

➤ **z/OS** You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- “Syntax diagram for DISPLAY NAMELIST” on page 846
- “Parameter descriptions for DISPLAY NAMELIST” on page 847
- “Requested parameters” on page 850

Syntax diagram for DISPLAY NAMELIST

Synonym: DIS NL

Parameter descriptions for DISPLAY NAMELIST

You must specify the name of the namelist definition you want to display. This can be a specific namelist name or a generic namelist name. By using a generic namelist name, you can display either:

- All namelist definitions
- One or more namelists that match the specified name

(*generic-namelist-name*)

The name of the namelist definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all namelists with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all namelists.

WHERE

Specify a filter condition to display only those namelists that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE** or **QSGDISP** parameters as filter keywords. You cannot use **NLTYPE** as a filter keyword if you also use it to select namelists.

operator

This is used to determine whether a namelist satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

CTG

Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

EXG

Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the NLTYPE parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

ALL

Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all the parameters are displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

 On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only requested attributes are displayed.

 CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

► z/OS QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY NAMELIST(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

Note: **QSGDISP(PRIVATE)** displays the same information as **QSGDISP(LIVE)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP(GROUP)**.

COPY

The object was defined with **QSGDISP(COPY)**.

You cannot use **QSGDISP** as a filter keyword.

► z/OS NLTYPE

Indicates the type of namelist to be displayed.

This parameter is valid only on z/OS.

ALL

Displays namelists of all types. This is the default.

NONE

Displays namelists of type NONE.

QUEUE or Q

Displays namelists that hold lists of queue names.

CLUSTER

Displays namelists that are associated with clustering.

AUTHINFO

Displays namelists that contain lists of authentication information object names.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names, and, on z/OS, their **NLTYPES** and **QSGDISP** are displayed.

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*

ALTTIME

The time at which the definition was last altered, in the form *hh.mm.ss*

DESCR

Description

NAMCOUNT

Number of names in the list

NAMES

List of names

See [“DEFINE NAMELIST \(define a list of names\)” on page 614](#) for more information about the individual parameters.

Related reference

[“ALTER NAMELIST \(alter a list of names\)” on page 406](#)

Use the MQSC command **ALTER NAMELIST** to alter a list of names. This list is most commonly a list of cluster names or queue names.

[“DEFINE NAMELIST \(define a list of names\)” on page 614](#)

Use the MQSC command **DEFINE NAMELIST** to define a list of names. This is most commonly a list of cluster names or queue names.

[“DELETE NAMELIST \(delete a name list\)” on page 700](#)

Use the MQSC command **DELETE NAMELIST** to delete a namelist definition.

DISPLAY POLICY (display a security policy) on Multiplatforms

Use the MQSC command **DISPLAY POLICY** to display a security policy.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY POLICY” on page 851](#)
- [“Parameter descriptions for DISPLAY POLICY” on page 851](#)

Syntax diagram for DISPLAY POLICY

DISPLAY POLICY

► DISPLAY POLICY — (— *policy-name* —) ◄

Parameter descriptions for DISPLAY POLICY

(*policy-name*)

Specifies the policy name to be displayed.

The name of the policy to display is the same as the name of the queue that the policy controls. You can specify an asterisk to display all policy names.

Note: *policy-name* does not support wildcard characters to return multiple policies.

Display policy behavior with specific policy names

When executing a **DISPLAY POLICY** command for a specific policy, for example **DISPLAY POLICY (QUEUE.1)**, a policy object is always returned even if one does not exist. When a policy object does not exist, the policy object returned is a default policy object that specifies plain text protection, that is, no signing or encryption of message data.

To view policy objects that exist, a **DISPLAY POLICY (*)** command must be run. This command returns all policy objects that exist.

Related reference

[“DELETE POLICY \(delete a security policy\) on Multiplatforms” on page 702](#)

Use the MQSC command **DELETE POLICY** to delete a security policy.

[“SET POLICY \(set security policy\) on Multiplatforms” on page 1054](#)

Use the MQSC command **SET POLICY** to set a security policy.

[“setmqspl \(set security policy\)” on page 271](#)

Use the **setmqspl** command to define a new security policy, replace an already existing one, or remove an existing policy.  On z/OS you use the command with the CSQOUTIL utility.

[“dspmqspl \(display security policy\)” on page 115](#)

Use the **dspmqspl** command to display a list of all policies and details of a named policy.  On z/OS you use the command with the CSQOUTIL utility.

Related information

DISPLAY PROCESS (display process information)

Use the MQSC command **DISPLAY PROCESS** to display the attributes of one or more IBM MQ processes.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY PROCESS” on page 852](#)
- [“Parameter descriptions for DISPLAY PROCESS” on page 852](#)
- [“Requested parameters” on page 855](#)

Syntax diagram for DISPLAY PROCESS

Synonym: DIS PRO

DISPLAY PROCESS

►► DISPLAY PROCESS — (— *generic-process-name* —) ►

Requested attrs

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

Parameter descriptions for DISPLAY PROCESS

You must specify the name of the process you want to display. This can be a specific process name or a generic process name. By using a generic process name, you can display either:

- All process definitions
- One or more processes that match the specified name

(*generic-process-name*)

The name of the process definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all processes with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all processes. The names must all be defined to the local queue manager.

WHERE

Specify a filter condition to display only those process definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

 However, on z/OS, you cannot use the **CMDSCOPE** or **QSGDISP** parameters as filter keywords.

operator

This is used to determine whether a process definition satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DEF on the **APPLTYPE** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

ALL

Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

On the following platforms, this is the default if you do not specify a generic name and do not request any specific parameters:

-  AIX
-  IBM i
-  Linux
-  Windows

- **z/OS** z/OS

z/OS On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only requested attributes are displayed.

z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(LIVE)** is specified or defaulted, or if **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

Note: **QSGDISP(PRIVATE)** displays the same information as **QSGDISP(LIVE)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP (GROUP)**.

COPY

The object was defined with **QSGDISP (COPY)**.

You cannot use **QSGDISP** as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified and the **ALL** parameter is not specified, is that:

-  On Multiplatforms, the object names are displayed.
-  On z/OS, the object names and QSGDISP are displayed.

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*

ALTTIME

The time at which the definition was last altered, in the form *hh.mm.ss*

APPLICID

Application identifier

APPLTYPE

Application type. In addition to the values listed for this parameter in [“Parameter descriptions for DEFINE PROCESS”](#) on page 619, the value **SYSTEM** can be displayed. This indicates that the application type is a queue manager.

DESCR

Description

ENVRDATA

Environment data

USERDATA

User data

See [“DEFINE PROCESS \(create a new process definition\)”](#) on page 618 for more information about individual parameters.

Related reference

Use the MQSC command **DEFINE PROCESS** to define a new IBM MQ process definition, and set its parameters.

[“DELETE PROCESS \(delete a process definition\)”](#) on page 703

Use the MQSC command **DELETE PROCESS** to delete a process definition.

DISPLAY PUBSUB (display publish/subscribe status information)

Use the MQSC command **DISPLAY PUBSUB** to display publish/subscribe status information for a queue manager.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS.

- “Syntax diagram for DISPLAY PUBSUB” on page 856
- “Parameter descriptions for DISPLAY PUBSUB” on page 856
- “Returned parameters” on page 857

Syntax diagram for DISPLAY PUBSUB

Synonym: None

Parameter descriptions for DISPLAY PUBSUB

TYPE

The type of publish/subscribe connections.

ALL

Display the publish/subscribe status for this queue manager and for parent and child hierarchical connections.

CHILD

Display the publish/subscribe status for child connections.

LOCAL

Display the publish/subscribe status for this queue manager.

PARENT

Display the publish/subscribe status for the parent connection.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

Returned parameters

A group of parameters is returned, containing the attributes **TYPE**, **QMNAME**, **STATUS**, **SUBCOUNT**, and **TPCOUNT**. This group is returned for the current queue manager if you set **TYPE** to LOCAL or ALL, for the parent queue manager if you set **TYPE** to PARENT or ALL, and for each child queue manager if you set **TYPE** to CHILD or ALL.

TYPE

CHILD

A child connection.

LOCAL

Information for this queue manager.

PARENT

The parent connection.

QMNAME

The name of the current queue manager or the remote queue manager connected as a parent or a child.

STATUS

The status of the publish/subscribe engine or the hierarchical connection. The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster (has at least one CLUSRCVR defined), it remains in this state until the cluster cache is available.

 On IBM MQ for z/OS, this requires that the Channel Initiator is running.

When **TYPE** is CHILD, the following values can be returned:

ACTIVE

The connection with the child queue manager is active.

ERROR

This queue manager is unable to initialize a connection with the child queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific error. If you receive error message AMQ5821 or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814 or on z/OS systems CSQT814E, take the following actions:

- Check that the child queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the child broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the child queue manager name.
- A queue manager alias definition with the same name as the child queue manager name.
- A cluster with the child queue manager a member of the same cluster as this queue manager.
- A cluster queue manager alias definition with the same name as the child queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the child queue manager name to blank. Then set with the child queue manager name.

STARTING

Another queue manager is attempting to request that this queue manager become its parent.

If the child status remains in STARTING without progressing to ACTIVE, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

STOPPING

The queue manager is disconnecting.

If the child status remains in STOPPING, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

When **TYPE** is LOCAL, the following values can be returned:

ACTIVE

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

COMPAT

The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface. The queued publish/subscribe interface is not running. Therefore, any message that is put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

ERROR

The publish/subscribe engine has failed. Check your error logs to determine the reason for the failure.

INACTIVE

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe using the application programming interface. Any publish/subscribe messages that are put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

If inactive and you want to start the publish/subscribe engine use the command **ALTER QMGR PSMODE(ENABLED)**.

STARTING

The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster, that is, it has at least one **CLUSRCVR** defined, it remains in this state until the cluster cache is available.

On IBM MQ for z/OS, this requires that the Channel Initiator is running.

STOPPING

The publish/subscribe engine is stopping.

When **TYPE** is PARENT, the following values can be returned:

ACTIVE

The connection with the parent queue manager is active.

ERROR

This queue manager is unable to initialize a connection with the parent queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific error. If you receive error message AMQ5821 or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814 or error message CSQT814E on z/OS systems, take the following actions:

- Check that the parent queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the parent broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the parent queue manager name.
- A queue manager alias definition with the same name as the parent queue manager name.
- A cluster with the parent queue manager a member of the same cluster as this queue manager.
- A cluster queue manager alias definition with the same name as the parent queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the parent queue manager name to blank. Then set with the parent queue manager name.

REFUSED

The connection has been refused by the parent queue manager. This might be caused by the following:

- The parent queue manager already has a child queue manager with the same name as this queue manager.
- The parent queue manager has used the command `RESET QMGR TYPE(PUBSUB) CHILD` to remove this queue manager as one of its children.

STARTING

The queue manager is attempting to request that another queue manager become its parent.

If the parent status remains in STARTING without progressing to ACTIVE, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

STOPPING

The queue manager is disconnecting from its parent.

If the parent status remains in STOPPING, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

SUBCOUNT

When **TYPE** is LOCAL, the total number of subscriptions against the local tree is returned. When **TYPE** is CHILD or PARENT, queue manager relations are not inquired and the value NONE is returned.

TPCOUNT

When **TYPE** is LOCAL, the total number of topic nodes in the local tree is returned. When **TYPE** is CHILD or PARENT, queue manager relations are not inquired and the value NONE is returned.

DISPLAY QMGR (display queue manager settings)

Use the MQSC command **DISPLAY QMGR** to display the queue manager parameters for this queue manager.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY QMGR” on page 860](#)
- [“Parameter descriptions for DISPLAY QMGR” on page 864](#)
- [“Requested parameters” on page 865](#)

Syntax diagram for DISPLAY QMGR

Synonym: DIS QMGR

Event control attributes

Distributed queuing attributes for z/OS

Distributed queuing attributes for other platforms

Cluster attributes

Queue manager publish/subscribe attributes

Notes:

- ¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.
- ² Valid only on z/OS.
- ³ Not valid on z/OS.
- ⁴ Not valid on IBM i.
- ⁵ Valid only on AIX, Linux, and Windows.

Parameter descriptions for DISPLAY QMGR

ALL

Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically are ineffective; all parameters are still displayed.

 On [Multiplatforms](#), this parameter is the default if you do not request any specific parameters.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This command is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of running this command is the same as entering the command on every queue manager in the queue sharing group.

SYSTEM

Specify this parameter to display the set of queue manager system attributes that are available in the Queue manager system attrs list. See [“Requested parameters” on page 865](#) for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

EVENT

Specify this parameter to display the set of event control attributes that are available in the Event control attrs list. See [“Requested parameters” on page 865](#) for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

CHINIT

Specify this parameter to display the set of attributes relating to distributed queuing that are available in the Distributed queuing attrs list. You can also specify DQM to display the same set of attributes. See [“Requested parameters” on page 865](#) for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

CLUSTER

Specify this parameter to display the set of attributes relating to clustering that are available in the Cluster attrs list. See [“Requested parameters” on page 865](#) for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

PUBSUB

Specify this parameter to display the set of attributes relating to publish/subscribe that are available in the Queue manager pub/sub attrs list. See [“Requested parameters” on page 865](#) for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

Requested parameters

Note: If no parameters are specified (and the **ALL** parameter is not specified or defaulted), the queue manager name is returned.

You can request the following information for the queue manager:

ACCTCONO

Whether the settings of the **ACCTQMQI** and **ACCTQ** queue manager parameters can be overridden. This parameter is valid only on [Multiplatforms](#).

ACCTINT

The interval at which intermediate accounting records are written. This parameter is valid only on [Multiplatforms](#).

ACCTMQI

Whether accounting information is to be collected for MQI data. This parameter is valid only on [Multiplatforms](#).

ACCTQ

Whether accounting data collection is to be enabled for queues.

ACTCHL

The maximum number of channels that can be active at any time.

This parameter is valid only on z/OS.

ACTIVREC

Whether activity reports are to be generated if requested in the message.

ACTVCONO

Whether the settings of the **ACTVTRC** queue manager parameter can be overridden. This parameter is valid only on [Multiplatforms](#).

ACTVTRC

Whether IBM MQ MQI application activity tracing information is to be collected. See [Setting ACTVTRC to control collection of activity trace information](#). This parameter is valid only on [Multiplatforms](#).

ADOPTCHK

Which elements are checked to determine whether an MCA is adopted when a new inbound channel is detected with the same name as an already active MCA.

This parameter is valid only on z/OS.

ADOPTMCA

Whether an orphaned MCA instance is to be restarted when a new inbound channel request matching the **ADOPTCHK** parameters is detected.

This parameter is valid only on z/OS.

ADVCAP

Whether IBM MQ Advanced extended capabilities are available for a queue manager.

 On z/OS, the queue manager sets the value to be ENABLED, only if the value of **QMGRPROD** is ADVANCEDVUE. For any other value of **QMGRPROD**, or if **QMGRPROD** is not set, the queue manager sets the value to DISABLED. If **ADVCAP** is ENABLED you must be entitled to IBM MQ Advanced for z/OS Value Unit Edition (VUE). See [“START QMGR \(start queue manager\) on z/OS” on page 1071](#) and [Installing IBM MQ Advanced for z/OS Value Unit Edition](#) for more information.

Multi On other platforms, the queue manager sets the value to be **ENABLED**, only if you have installed Managed File Transfer, XR, Advanced Message Security or RDQM. If you have not installed Managed File Transfer, XR, Advanced Message Security or RDQM, **ADVCAP** is set to **DISABLED**. If **ADVCAP** is **ENABLED**, you must be entitled to IBM MQ Advanced. The list of installable components that enable **ADVCAP** might change in future releases. For more information, see [IBM MQ components and features](#) and [Installing IBM MQ Advanced for Multiplatforms](#).

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*.

ALTTIME

The time at which the definition was last altered, in the form *hh.mm.ss*.

AMQPCAP

Whether AMQP capabilities are available for a queue manager.

AUTHOREV

Whether authorization events are generated.

Multi **AUTHEVSC**

The scope of authorization events generated when authorization events are enabled.

This parameter is valid on Multiplatforms only.

z/OS **BRIDGEV**

On z/OS only, whether IMS bridge events are generated.

CCSID

Coded character set identifier. This parameter applies to all character string fields defined by the application programming interface (API), including the names of objects, and the creation date and time of each queue. It does not apply to application data carried as the text of messages.

CERTLABL

Specifies the certificate labels that this queue manager used.

z/OS **CERTQSG**

Specifies the queue sharing group (QSG) certificate label.

This parameter is valid only on z/OS.

ALW **CERTVPOL**

Specifies which TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards. For more information about certificate validation policies, see [Certificate validation policies in IBM MQ](#).

This parameter is valid only on AIX, Linux, and Windows.

z/OS **CFCONLOS**

Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with **CFCONLOS** set to **ASQMGR**.

This parameter is valid only on z/OS.

Multi **CHAD**

Whether auto-definition of receiver and server-connection channels is enabled.

z/OS **CHADEV**

Whether auto-definition events are enabled.

Multi **CHADEV**

Whether auto-definition events are enabled.

z/OS **CHADEV**

This parameter is not valid on z/OS.

CHADEXIT

The name of the channel auto-definition exit.

z/OS CHIADAPS

The number of adapter subtasks to use to process IBM MQ calls.

This parameter is valid only on z/OS.

z/OS CHDISPS

The number of dispatchers to use for the channel initiator.

This parameter is valid only on z/OS.

CHISERV

This field is reserved for IBM use only.

CHLAUTH

Whether channel authentication records are checked.

CHLEV

Whether channel events are generated.

CLWLEXIT

The name of the cluster workload exit.

CLWLDATA

The data passed to the cluster workload exit.

CLWLEN

The maximum number of bytes of message data that is passed to the cluster workload exit.

CLWLMRUC

The maximum number of outbound cluster channels.

CLWLUSEQ

The behavior of MQPUTs for queues where **CLWLUSEQ** has a value of QMGR.

CMDEV

Whether command events are generated.

CMDLEVEL

Command level. This indicates the level of system control commands supported by the queue manager.

COMMANDQ

The name of the system-command input queue. Suitably authorized applications can put commands on this queue.

CONFIGEV

Whether configuration events are generated.

CONNAUTH

The name of an authentication information object that is used to provide the location of user ID and password authentication.

CPILEVEL

Reserved, this value has no significance.

CRDATE

The date on which the queue manager was created (in the form *yyyy-mm-dd*).

CRTIME

The time at which the queue manager was created (in the form *hh.mm.ss*).

CUSTOM

This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form *NAME (VALUE)*.

DEADQ

The name of the queue to which messages are sent if they cannot be routed to their correct destination (the dead-letter queue or undelivered-message queue). The default is blanks.

For example, messages are put on this queue when:

- A message arrives at a queue manager, destined for a queue that is not yet defined on that queue manager
- A message arrives at a queue manager, but the queue for which it is destined cannot receive it because, possibly:
 - The queue is full
 - The queue is inhibited for puts
 - The sending node does not have authority to put the message on the queue
- An exception message must be generated, but the queue named is not known to that queue manager

Note: Messages that have passed their expiry time are not transferred to this queue when they are discarded.

If the dead-letter queue is not defined, or full, or unusable for some other reason, a message that would have been transferred to it by a message channel agent is retained instead on the transmission queue.

If a dead-letter queue or undelivered-message queue is not specified, all blanks are returned for this parameter.

DEFCLXQ

The **DEFCLXQ** attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

SCTQ

All cluster-sender channels send messages from `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. The `correlID` of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined. **DEFCLXQ** was not present.

CHANNEL

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`.

If the queue manager attribute, **DEFCLXQ**, is set to `CHANNEL`, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

DEFXMITQ

Default transmission queue name. This parameter is the transmission queue on which messages, destined for a remote queue manager, are put if there is no other suitable transmission queue defined.

DESCR

Description.

DISTL

Whether distribution lists are supported by the queue manager.

➤ **z/OS** This parameter is not valid on z/OS.

➤ **z/OS** **DNSGROUP**

This parameter is no longer used. See [z/OS: WLM/DNS no longer supported](#). This parameter is valid only on z/OS

➤ **z/OS** **DNSWLM**

This parameter is no longer used. See [z/OS: WLM/DNS no longer supported](#). This parameter is valid only on z/OS.

➤ **z/OS** **EXPRYINT**

On z/OS only, the approximate interval between scans for expired messages.

➤ **z/OS** **GROUPUR**

On z/OS only, whether XA client applications are allowed to connect to this queue manager with a GROUP unit of recovery disposition.

IMGINTVL

The target frequency with which the queue manager automatically writes media images.

➤ **z/OS** This parameter is not valid on z/OS.

IMGLOGLN

The target amount of recovery log written by which the queue manager automatically writes media images.

➤ **z/OS** This parameter is not valid on z/OS.

IMGRCOVO

Whether specified objects are recoverable from a media image, if linear logging is being used.

➤ **z/OS** This parameter is not valid on z/OS.

IMGRCOVQ

Whether a local or permanent dynamic queue object is recoverable from a media image, if linear logging is being used.

➤ **z/OS** This parameter is not valid on z/OS.

IMGSCHED

Whether the queue manager automatically writes media images.

➤ **z/OS** This parameter is not valid on z/OS.

➤ **z/OS** **IGQ**

On z/OS only, whether intra-group queuing is to be used.

➤ **z/OS** **IGQAUT**

On z/OS only, displays the type of authority checking used by the intra-group queuing agent.

➤ **z/OS** **IGQUSER**

On z/OS only, displays the user ID used by the intra-group queuing agent.

INHIBTEV

Whether inhibit events are generated.

➤ **Multi** **INITKEY**

Initial key for the password protection system. The value appears as ***** when set to a custom value. The value appears as ' ' when the default key is in use.

➤ **z/OS** This parameter is not valid on z/OS.

IPADDRV

Whether to use an IPv4 or IPv6 IP address for a channel connection in ambiguous cases.

ALW KEYRPWD

The password for the TLS key repository. The value appears as *****.

This parameter is valid only on AIX, Linux, and Windows.

LOCALEV

Whether local error events are generated.

Multi LOGGEREV

Whether recovery log events are generated. This parameter is valid only on [Multiplatforms](#).

z/OS LSTRTMR

The time interval, in seconds, between attempts by IBM MQ to restart the listener after an APPC or TCP/IP failure.

This parameter is valid only on z/OS.

z/OS LUGROUP

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue sharing group.

This parameter is valid only on z/OS.

z/OS LUNAME

The name of the LU to use for outbound LU 6.2 transmissions.

This parameter is valid only on z/OS.

z/OS LU62ARM

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC= xx is issued.

This parameter is valid only on z/OS.

z/OS LU62CHL

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol. If the value of LU62CHL is zero, the LU 6.2 transmission protocol is not used.

This parameter is valid only on z/OS.

MARKINT

The mark browse interval in milliseconds.

Attention: This value should not be below the default of 5000.

z/OS MAXCHL

The maximum number of channels that can be current (including server-connection channels with connected clients).

This parameter is valid only on z/OS.

MAXHANDS

The maximum number of open handles that any one connection can have at any one time.

MAXMSGL

The maximum message length that can be handled by the queue manager. Individual queues or channels might have a smaller maximum than the value of this parameter.

MAXPROPL (integer)

The maximum length of property data in bytes that can be associated with a message.

MAXPTY

The maximum priority. This value is 9.

MAXUMSGS

Maximum number of uncommitted messages within one sync point. The default value is 10000.

MAXUMSGS has no effect on IBM MQ Telemetry. IBM MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

MONACLS

Whether online monitoring data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

MONCHL

Whether online monitoring data is to be collected for channels, and, if so, the rate of data collection.

MONQ

Whether online monitoring data is to be collected for queues, and, if so, the rate of data collection.

▶ z/OS OPORTMAX

The maximum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

▶ z/OS OPORTMIN

The minimum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

▶ z/OS OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**, or from the message to the environment on **MQGET**. V 10.0.0 For IMS bridge queues, also controls whether the IMS bridge automatically propagates trace context from the messages it gets to IMS.

The **OTELPCTL** value on individual queues might override this value.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

▶ z/OS OTELTRAC

Whether the queue manager emits spans as messages are sent to or consumed from queues. V 10.0.0 For IMS bridge queues, also controls whether the IMS bridge emits spans when it sends the messages it gets to IMS.

The **OTELTRAC** value on individual queues might override this value, unless NONE is specified.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PARENT

The name of the queue manager to which this queue manager is connected hierarchically as its child.

PERFMEV

Whether performance-related events are generated.

PLATFORM

The architecture of the platform on which the queue manager is running. The value of this parameter is:

- ▶ z/OS MVS (for z/OS platforms)
- NSK
- OS2
- OS400
- APPLIANCE

- UNIX
- WINDOWSNT

PSCLUS

Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from ENABLED to DISABLED.

PSMODE

Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running, and therefore controls whether applications can publish or subscribe by using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

PSNPMMSG

If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue (depending on the report options of the input message). If the attempt to write the input message to the dead-letter queue fails, and the MQRO_DISCARD_MSG report option was specified on the input message or PSNPMMSG=DISCARD, the broker discards the input message. If PSNPMMSG=KEEP is specified, the interface only discards the input message if the MQRO_DISCARD_MSG report option was set in the input message.

PSNPRES

If the queued publish/subscribe interface attempts to generate a response message in response to a non-persistent input message, and the response message cannot be delivered to the reply-to queue, this attribute indicates whether the interface tries to write the undeliverable message to the dead-letter queue or whether to discard the message.

PSRTYCNT

When the queued publish/subscribe interface fails to process a command message under sync point (for example a publish message that cannot be delivered to a subscriber because the subscriber queue is full and it is not possible to put the publication on the dead letter queue), the unit of work is backed out and the command tries this number of times again before the broker attempts to process the command message according to its report options instead.

PSSYNCPT

If this attribute is set to IFPER, when the queued publish/subscribe interface reads a publish or delete publication messages from a stream queue during normal operation then it specifies MQGMO_SYNCPOINT_IF_PERSISTENT. This value makes the queued pubsub daemon receive non-persistent messages outside sync point. If the daemon receives a publication outside sync point, the daemon forwards that publication to subscribers known to it outside sync point.

QMID

The internally generated unique name of the queue manager.

QMNAME

The name of the local queue manager. See [Rules for naming IBM MQ objects](#).

z/OS QSGNAME

The name of the queue sharing group to which the queue manager belongs, or blank if the queue manager is not a member of a queue sharing group. You can use queue sharing groups only on z/OS.

z/OS RCVTIME

The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state. The value of this parameter is the numeric value qualified by **RCVTYPE**.

This parameter is valid only on z/OS.

z/OS RCVTMIN

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

This parameter is valid only on z/OS.

► **z/OS** **RCVTTTYPE**

The qualifier to apply to the value in **RCVTIME**.

This parameter is valid only on z/OS.

REMOTEEV

Whether remote error events are generated.

REPOS

The name of a cluster for which this queue manager is to provide a repository manager service.

REPOSNL

The name of a list of clusters for which this queue manager is to provide a repository manager service.

REVDNS

Whether reverse lookup of the host name from a Domain Name Server (DNS) is done for the IP address from which a channel has connected.

ROUTEREC

Whether trace-route information is to be recorded if requested in the message.

► **Multi** **SCHINIT**

Whether the channel initiator is to be started automatically when the queue manager starts.

► **z/OS** This parameter is not valid on z/OS.

► **Multi** **SCMDSERV**

Whether the command server is to be started automatically when the queue manager starts.

► **z/OS** This parameter is not valid on z/OS.

► **z/OS** **SCYCASE**

Whether the security profiles are uppercase or mixed case.

This parameter is valid only on z/OS.

If this parameter has been altered but the **REFRESH SECURITY** command has not yet been issued, the queue manager might not be using the case of profiles you expect. Use **DISPLAY SECURITY** to verify which case of profiles is actually in use.

SPLCAP

Indicates if Advanced Message Security (AMS) capabilities are available to the queue manager. If the AMS component is installed for the version of IBM MQ that the queue manager is running under, the attribute has a value **ENABLED**. If the AMS component is not installed, the value is **DISABLED**.

► **z/OS** **SQQMNAME**

When a queue manager makes an MQOPEN call for a shared queue and the queue manager that is specified in the **ObjectQmgrName** parameter of the MQOPEN call is in the same queue sharing group as the processing queue manager, the **SQQMNAME** attribute specifies whether the **ObjectQmgrName** is used or whether the processing queue manager opens the shared queue directly.

This parameter is valid only on z/OS.

SSLCRLNL

Indicates the namelist of AUTHINFO objects being used for the queue manager for certificate revocation checking.

Only authentication information objects with types of CRLLDAP or OCSP are allowed in the namelist referred to by **SSLCRLNL**. Any other type results in an error message when the list is processed and is subsequently ignored.

ALW SSLCRYP

Indicates the name of the parameter string being used to configure the cryptographic hardware present on the system. The PKCS #11 password appears as xxxxxx. This is valid only on AIX, Linux, and Windows.

SSLEV

Whether TLS events are generated.

SSLFIPS

Whether only FIPS certified algorithms are to be used if cryptography is processed in IBM MQ rather than in the cryptographic hardware itself.

SSLKEYR

Indicates the name of the Secure Sockets Layer key repository.

SSLRKEYC

Indicates the number of bytes to be sent and received within an TLS conversation before the secret key is renegotiated.

z/OS SSLTASKS

On z/OS only, indicates the number of server subtasks to use for processing TLS calls.

STATACLS

Whether statistics data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

STATCHL

It determines whether statistics data is to be collected for channels, and, if so, the rate of data collection.

Multi STATINT

The interval at which statistics monitoring data is written to the monitoring queue. This parameter is valid only on Multiplatforms.

Multi STATMQI

Whether statistics monitoring data is to be collected for the queue manager. This parameter is valid only on Multiplatforms.

STATQ

Whether statistics data is to be collected for queues.

STRSTPEV

Whether start and stop events are generated.

SUITEB

Whether Suite B compliant cryptography is used. For more information about Suite B configuration and its effect on TLS channels, see NSA Suite B Cryptography in IBM MQ.

SYNCPT

Whether sync point support is available with the queue manager. This is a read only queue manager attribute.

z/OS TCPCHL

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol. If zero, the TCP/IP transmission protocol is not used.

This parameter is valid only on z/OS.

z/OS TCPKEEP

Whether the KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

This parameter is valid only on z/OS.

➤ **z/OS** **TCPNAME**

The name of the preferred TCP/IP stack to be used in a CINET multiple stack environment. In INET single stack environments the channel initiator uses the only available TCP/IP stack.

This parameter is valid only on z/OS.

➤ **z/OS** **TCPSTACK**

Whether the channel initiator uses only the TCP/IP stack specified in TCPNAME, or can optionally bind to any of the TCP/IP stacks defined in a CINET multiple stack environment.

This parameter is valid only on z/OS.

➤ **z/OS** **TRAXSTR**

Whether channel initiator trace starts automatically.

This parameter is valid only on z/OS.

➤ **z/OS** **TRAXTBL**

The size, in megabytes, of the trace data space of the channel initiator.

This parameter is valid only on z/OS.

TREELIFE

The lifetime of non-administrative topics.

TRIGINT

The trigger interval.

VERSION

The version of the IBM MQ installation that the queue manager is associated with. The version has the format VVRRMMFF:

VV: Version

RR: Release

MM: Maintenance level

FF: Fix level

XRCAP

Whether IBM MQ Telemetry capability is supported by the queue manager.

For more information about these parameters, see [“ALTER QMGR \(alter queue manager settings\)” on page 415](#).

Related tasks

Use the MQSC command **STOP QMGR** to stop the queue manager.

Multi **DISPLAY QMSTATUS** (display queue manager status) on Multiplatforms

Use the MQSC command **DISPLAY QMSTATUS** to display status information associated with this queue manager.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY QMSTATUS” on page 876](#)
- [“Parameter descriptions for DISPLAY QMSTATUS” on page 879](#)
- [“Requested parameters for TYPE\(QMGR\)” on page 881](#)

Syntax diagram for DISPLAY QMSTATUS

Parameter descriptions for **DISPLAY QMSTATUS**

ALL

Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This parameter is the default for **TYPE(NATIVEHA)** if you do not request any specific parameters.

LOG

Specify this parameter to display all the **LOG** parameters. If this parameter is specified, any **LOG** parameters that are requested specifically have no effect; all parameters are still displayed.

TYPE

The type of status information to display. The value can be one of the following values:

QMGR

Status information that relates to the queue manager. This is the default value.

NATIVEHA

Status information that relates to Native HA instances and groups.

NHATYPE

Specify this parameter to select the Native HA information type that is displayed. This parameter can be specified only with **TYPE(NATIVEHA)**. The value can be one of the following values:

INSTANCE

Display information about all instances in the local group. This is the default setting.

GROUP

Display information about all Native HA groups.

ALL

Display information about all Native HA instances and groups.

WHERE

Use with the **TYPE(NATIVEHA)** parameter to specify a filter condition to display status information for queue managers that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command. You cannot use the **TYPE(NATIVEHA)** parameter itself as a filter keyword.

operator

The operator is used to determine whether a queue manager satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NO on the UNCOM parameter), you can only use EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The operator must be CT or EX. If it is a character value, it can be explicit or generic. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If ABC* is specified, all items where one of the attribute values begins with ABC are listed.

MQ Adv. For parameters for **DISPLAY QMSTATUS TYPE(NATIVEHA)**, see [“Requested parameters for TYPE\(NATIVEHA\)”](#) on page 886.

Requested parameters for TYPE (QMGR)

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

ARCHLOG

Name of the oldest log extent for which the queue manager is waiting for archive notification. This parameter is:

- Available only on queue managers using archive log management.
- Blank, if the queue manager is not using archive log management, or if the queue manager has no extents waiting for notification.

IBM i This parameter is not valid on IBM i.

ARCHSZ

The amount of space occupied, in megabytes, by log extents no longer required for restart or media recovery, but waiting to be archived.

Note that this value impacts the total space used by the queue manager for log extents.

This parameter is available only on queue managers using archive log management. If the queue manager is not using archive log management, this parameter is zero.

IBM i This parameter is not valid on IBM i.

AUTOCLUS

Whether the queue manager is a member of an automatic cluster. Is one of the following:

NONE

Does not belong to an automatic cluster.

UNIFORM

Is part of a uniform cluster.

See [Using automatic cluster configuration](#).

CHINIT

The status of the channel initiator reading SYSTEM.CHANNEL.INITQ. It is one of the following:

STOPPED

The channel initiator is not running.

STARTING

The channel initiator is in the process of initializing and is not yet operational.

RUNNING

The channel initiator is fully initialized and is running.

STOPPING

The channel initiator is stopping.

V1000 CHKPTCNT

The total number of checkpoints that have taken place on this queue manager.

CHKPTOPS

The number of operations checkpointed on this queue manager since the last checkpoint.

CHKPTSZ

The amount of data checkpointed on this queue manager since the last checkpoint, in MB, rounded up.

CMDSERV

The status of the command server. It is one of the following:

STOPPED

The command server is not running.

STARTING

The command server is in the process of initializing and is not yet operational.

RUNNING

The command server is fully initialized and is running.

STOPPING

The command server is stopping.

CONNS

The current number of connections to the queue manager.

CURRLOG

The name of the log extent being written to at the time that the **DISPLAY QMSTATUS** command is processed. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

DATFSSZ

The size of the dedicated queue manager data file system in MB, rounded up. If the queue manager data and recovery log are on the same file system, the value is **SHARED** (see QMFSSZ).

DATFSUSE

The percentage of the dedicated queue manager data file system that is full, rounded up to the nearest percent. If the queue manager data and recovery log are on the same file system, the value is **SHARED** (see QMFSUSE).

DATPATH

The path of the queue manager data directory.

DISKLSN

The LSN of the recovery log that has been written and forced to disk.

 This parameter is not valid on IBM i.

GRPLSN

Specifies the LSN that has been replicated between a quorum of instances in a Native HA group, in `<nnnnn:nnnnn:nnnnn:nnnnn>` format.

GRPNAME

Specifies the name of a Native HA group. Blank if a name has not been configured.

GRPROLE

Specifies the current role of a Native HA group and is one of:

LIVE

A live group

RECOVERY

A recovery group

PENDLIVE

A group waiting to become Live

PENDREC

A group waiting to become Recovery

UNKNOWN

The current role cannot be determined

NOTCONFIG

Native HA has not been configured

HOSTNAME

The name of the host that the queue manager is running on from the perspective of IBM MQ. Usually, this is the value reported by the O/S but it can be overridden by the MQS_IPC_HOST environment variable.

INSTANCE

The name of the local Native HA instance when the queue manager is part of a Native HA group. It is blank otherwise.

INSTDESC

Description of the installation associated with the queue manager.

INSTNAME

Name of the installation associated with the queue manager.

INSTPATH

Path of the installation associated with the queue manager.

LDAPCONN

The status of the connection to the LDAP server. It is one of the following:

CONNECTED

The queue manager currently has a connection to the LDAP server.

ERROR

The queue manager attempted to make a connection to the LDAP server and failed.

INACTIVE

The queue manager is not configured to use an LDAP server or has not yet made a connection to the LDAP server.

Note: The **LDAPCONN** status within **DISPLAY QMSTATUS** is a single status for the whole queue manager, reflecting only the most recent actions performed with the LDAP server. There are multiple connections to the LDAP server, one per queue manager agent process. **LDAPCONN** reflects the status from the most recent LDAP connection across the agents of the whole queue manager. If the error is temporary, and quickly clears, then the ERROR status will be short-lived. Always look in the [queue manager error logs](#) to see more details of any LDAP connectivity failures.

LOGEXTSZ

The size of each log file (or the threshold of the currently attached journal receiver on IBM i) in KB.

LOGFSSZ

The size of the dedicated recovery log file system in MB, rounded up. If the queue manager data and recovery log are on the same file system, the value is **SHARED** (see QMFSSZ).

LOGFSUSE

The percentage of the dedicated recovery log file system that is full, rounded up to the nearest percent. If the queue manager data and recovery log are on the same file system, the value is **SHARED** (see **QMFSUSE**).

LOGINUSE

The percentage of the primary log space in use for restart recovery at this point in time.

A value of 100 or greater indicates the queue manager might have allocated, and be using, secondary log files, probably due to long-lived transactions at this point in time.

 This parameter is not valid on IBM i.

LOGPATH

Identifies the directory where log files are created by the queue manager.

LOGPRIM

The number of primary log files.

 This parameter is not valid on IBM i.

LOGSEC

The maximum number of secondary log files.

 This parameter is not valid on IBM i.

LOGSTRDA

The date for the last log record recovered when the queue manager started.

 This parameter is not valid on IBM i.

LOGSTRL

The log sequence number (LSN) for the last log record recovered when the queue manager started, in `<nnnnn:nnnnn:nnnnn:nnnn>` format.

 This parameter is not valid on IBM i.

LOGSTRTI

The time for the last log record recovered when the queue manager was started.

 This parameter is not valid on IBM i.

LOGTYPE

The type of logging, is one of the following values:

CIRCULAR

Uses circular logging.

LINEAR

Uses linear logging.

REPLICATED

Uses replicated logging.

For information about logging types, see [Types of logging](#).

LOGUTIL

A percentage estimate of how well the queue manager workload is contained within the primary log space.

If the value is consistently above 100 you might want to investigate whether there are long-lived transactions, or if the number of primary files is not sufficient for the workload.

If the utilization continues to rise, eventually requests for most further operations requiring log activity will be refused, together with an MQRC_RESOURCE_PROBLEM return code being returned to the application. Transactions might be backed out.

 This parameter is not valid on IBM i.

MEDIALOG

The name of the oldest log extent required by the queue manager to perform media recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

MEDIASZ

Size of the log data required for media recovery in megabytes.

This value shows how much log that must be read for media recovery and directly impacts the time taken for this operation.

This is zero for a circular logging queue manager. The size is typically reduced by taking more frequent media images of objects.

 This parameter is not valid on IBM i.

QMFSENC

Indicates whether the queue manager file system is encrypted or not. Is set to one of the following values:

NO

The file system is not encrypted.

YES

The file system is encrypted.

UNKNOWN

The encryption status is not known.

 Returned on the IBM MQ Appliance only.

QMFSZ

The total size of the queue manager data and recovery log file systems in MB, rounded up. If the queue manager data and recovery log are on the same file system, the value is the size of that file system.

QMFSUSE

The percentage of the queue manager data and recovery log file systems that are full, rounded up to the nearest percent. If the queue manager data and recovery log are on the same file system, the value will be the usage of that file system.

QMNAME

The name of the queue manager. This parameter is always returned.

QUORUM

Two numeric values separated by a forward slash (X/Y) if the queue manager is part of a Native HA group, or blank otherwise. The two values give the following information:

- X is how many of the configured instances are in-sync with the active instance.
- Y is the total number of configured instances of the queue manager.

RECLOG

The name of the oldest log extent required by the queue manager to perform restart recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

RECSZ

Size of the log data required for restart recovery in megabytes.

This value shows how much log that must be read for restart recovery and directly impacts the time taken for this operation.

 This parameter is not valid on IBM i.

REUSESZ

This attribute is valid only on automatic or archive log management queue managers.

The amount of space occupied, in megabytes, by log extents available to be reused.

This value impacts the total space used by the queue manager for log extents.

The size is automatically managed by the queue manager, but if necessary you can request reductions using the **RESET QMGR TYPE(REDUCELOG)** command.

 This parameter is not valid on IBM i.

STANDBY

Whether a standby instance is permitted. It is one of the following:

NOPERMIT

Standby instances are not permitted.

PERMIT

Standby instances are permitted.

STARTDA

The date on which the queue manager was started (in the form yyyy-mm-dd).

STARTTI

The time at which the queue manager was started (in the form hh.mm.ss).

STATUS

The status of the queue manager. It is one of the following:

STARTING

The queue manager is in the process of initializing.

RUNNING

The queue manager is fully initialized and is running.

QUIESCING

The queue manager is quiescing.

UNICLUS

The name of the uniform cluster that the queue manager is a member of, or blank otherwise.

Requested parameters for TYPE(NATIVEHA)

When you specify **TYPE(NATIVEHA)** you can specify ALL to have all attributes returned, alternatively you can specify one or more of the following attributes. You can also use the **NHATYPE** attribute to select INSTANCE attributes, GROUP attributes (for Native HA cross-region replication configurations), or ALL attributes.

ACKLSN

Indicates the LSN that the instance has acknowledged as having been written to the recovery log, in <nnnnn:nnnnn:nnnnn:nnnnn> format. Blank if the LSN value is not known.

BACKLOG (for REPLICHA instances only)

How many KB of recovery log data the active instance has written that have not yet been acknowledged by the named instance. This is how 'out of sync' the named instance currently is. The value is rounded up to a 1 KB boundary. Set to **UNKNOWN** if the information is not available.

V 10.0.0 BACKLOG (for groups)

Native HA group backlog. Only for Recovery or Pending live groups in a Native HA cross-region replication configuration.

CONNECTV (for REPLICHA instances only)

Whether the instance currently has a pair of active connections to the active instance. Set to **YES** or **NO**.

V 10.0.0 CONNGRP

Indicates whether the group is connected to a live or pending recovery group. Only applies to recovery, pending live, or unknown groups in a Native HA cross-region replication configuration. Set to one of the following values:

YES

The group is connected.

NO

The group is disconnected.

SUSPENDED

The group is connected, but the group cannot replicate data until a configuration incompatibility between the groups is resolved. (This can occur if there is a version incompatibility, for example.)

V 10.0.0 GRPADDR

The IP address of the group.

V 10.0.0 GRSTATUS

Indicates the operational status of this group and is one of the following values:

NORMAL

The group is operating normally.

CHECKING

The group is being checked to ensure the consistency of the recovery log.

SYNC

The group is being sent data to bring it in sync.

REBASING

A new recovery log is being sent to the instance.

DISKFULL

The group has a full disk.

DISCONNECTED

Cannot communicate with the group.

PARTITIONED

Two groups believe they are the Live group (that is, a 'split brain' status).

V 10.0.0 V 10.0.0 SYNCFAILED

a Live group is configured to use synchronous replication, but is currently not in-sync.

UNKNOWN

The group status is unknown.

V 10.0.0 GRPVER

Indicates the version of the current group leader.

HAINITDA (for ACTIVE instances only)

The date of the last log record recovered when the Native HA group initially became active.

HAINITL (for ACTIVE instances only)

The log sequence number (LSN) of the last log record recovered when the Native HA group initially became active, in the format `<nnnnnn:nnnnnn:nnnnnn:nnnnnn>`.

HAINITTI (for ACTIVE instances only)

The time of the last log record recovered when the Native HA group initially became active.

V 10.0.0 HASTATUS

Indicates the operational status of this instance and is one of the following values:

NORMAL

The instance is operating normally.

CHECKING

The instance is being checked to ensure the consistency of the recovery log.

SYNC

The instance is being sent data to bring it in-sync.

REBASING

A new recovery log is being sent to the instance.

DISKFULL

The instance has a full disk.

DISCONNECTED

Cannot communicate with the instance.

UNKNOWN

The instance status is unknown.

V 10.0.0 INITLSN

The log sequence number (LSN) of the last log record recovered when the Native HA group initially became live, in the format `<nnnnnn:nnnnnn:nnnnnn:nnnnnn>`.

Only for live or pending recovery groups in a Native HA cross-region replication configuration.

INSTANCE

The name of the Native HA instance.

INSYNC (for REPLICA instances only)

Whether this instance is currently considered in-sync with the active instance. Is either **YES** or **NO**.

V 10.0.0 INSYNC (for groups)

Indicates whether the group could become Live with no loss of data if a failover occurred. (Note that a Recovery group might not be in-sync with the Live group very often because the log is replicated asynchronously. Use the RCOVLSN and RCOVTIME values to indicate if data loss might occur on an unplanned failover.) Only for recovery or pending live groups in a Native HA cross-region replication configuration.

V 10.0.0 INITTIME

The time of the last log record recovered when the Native HA group initially became live, in ISO 8601 format. Only for live or pending recovery groups in a Native HA cross-region replication configuration.

V 10.0.0 LIVETIME

The time the group first became the live group, in ISO 8601 format. Only for live or pending recovery groups in a Native HA cross-region replication configuration.

V 10.0.0 NHATYPE

Native HA information type. Can be one of the following values:

INSTANCE

Information about an instance in a Native HA group.

GROUP

Information about a Native HA group.

V 10.0.0 RCOVLSN

A log sequence number (LSN) that the group could recover to. Given in the format `<nnnnnn:nnnnn:nnnnn:nnnnn>`.

V 10.0.0 RCOVTIME

A time that the group could recover to, in ISO 8601 format.

REPLADDR

The network address and port to use when sending data to and from the specified instance.

ROLE

The current role of the instance in the Native HA group. Can be one of:

ACTIVE

An active instance is processing messages and writing to the recovery log.

REPLICA

A replica instance is writing replicated data to its own recovery log and updating its own queue data from the replicated recovery log.

V 10.0.0 LEADER

The leader in a Native HA CRR Recovery group.

UNKNOWN

The current role is not known.

See [Native HA](#) for a more detailed description of these roles.

V 10.0.0 SYNCTIME

Indicates the time when this group was last in-sync with the Live group, in ISO 8601 format. (Note that a Recovery group might not be in-sync with the Live group very often because the log is replicated asynchronously. Use the RCOVLSN and RCOVTIME values to indicate if data loss might occur on an unplanned failover.) Only for Recovery or Pending live groups in a Native HA cross-region replication configuration.

If you use the **DISPLAY QMSTATUS TYPE (NATIVEHA)** command in an environment where Native HA is not supported or configured, the following message is returned:

```
AMQ5708E: Native HA not available.
```

- [“Usage notes for DISPLAY QSTATUS” on page 892](#)
- [“Parameter descriptions for DISPLAY QSTATUS” on page 893](#)
- [“Queue status” on page 895](#)
- [“Handle status” on page 898](#)

Syntax diagram for DISPLAY QSTATUS

Synonym: DIS QS

Usage notes for DISPLAY QSTATUS

The state of asynchronous consumers, **ASTATE**, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

Parameter descriptions for **DISPLAY QSTATUS**

You must specify the name of the queue for which you want to display status information. This name can either be a specific queue name or a generic queue name. By using a generic queue name you can display either:

- Status information for all queues, or
- Status information for one or more queues that match the specified name and other selection criteria

You must also specify whether you want status information about:

- Queues
- Handles that are accessing the queues

Note: You cannot use the **DISPLAY QSTATUS** command to display the status of an alias queue or remote queue. If you specify the name of one of these types of queue, no data is returned. You can, however, specify the name of the local queue or transmission queue to which the alias queue or remote queue resolves.

(*generic-qname*)

The name of the queue for which status information is to be displayed. A trailing asterisk (*) matches all queues with the specified stem followed by zero or more characters. An asterisk (*) on its own matches all queues.

WHERE

Specify a filter condition to display status information for queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

However, you cannot use the **CMDSCOPE**, **MONITOR**, **OPENTYPE**, **QSGDISP**, **QTIME**, **TYPE**, or **URID** parameters as filter keywords.

operator

The operator is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

CT

Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

EX

Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NO on the UNCOM parameter), you can only use EQ or NE.

- A generic value. This value is a character string (such as the character string in the **APPLTAG** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The operator must be CT or EX. If it is a character value, it can be explicit or generic. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If ABC* is specified, all items where one of the attribute values begins with ABC are listed.

ALL

Display all the status information for each specified queue.

This value is the default if you do not specify a generic name, and do not request any specific parameters.

 On z/OS, this value is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only the requested attributes are displayed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group. It is valid on z/OS only.

..

The command runs on the queue manager on which it was entered. This value is the default.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this value is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

MONITOR

Specify this value to return the set of online monitoring parameters. These are **LGETDATE**, **LGETTIME**, **LPUTDATE**, **LPUTTIME**, **MONQ**, **MSGAGE**, and **QTIME**. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

OPENTYPE

Restricts the queues selected to queues which have handles with the specified type of access:

ALL

Selects queues that are open with any type of access. This value is the default if the **OPENTYPE** parameter is not specified.

INPUT

Selects queues that are open for input only. This option does not select queues that are open for browse.

OUTPUT

Selects queues that are open only for output.

The **OPENTYPE** parameter is valid only if **TYPE (HANDLE)** is also specified.

You cannot use **OPENTYPE** as a filter keyword.

TYPE

Specifies the type of status information required:

QUEUE

Status information relating to queues is displayed. This value is the default if the **TYPE** parameter is not specified.

HANDLE

Status information relating to the handles that are accessing the queues is displayed.

You cannot use **TYPE** as a filter keyword.

Queue status

For queue status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (**TYPE** parameter)
-  **Multi** Current queue depth (**CURDEPTH** parameter)
-  **z/OS** On z/OS only, the queue sharing group disposition (**QSGDISP** parameter)

The following parameters can be specified for **TYPE (QUEUE)** to request additional information for each queue. If a parameter is specified that is not relevant for the queue, operating environment, or type of status information requested, that parameter is ignored.

CURDEPTH

The current depth of the queue.

Messages put on a queue count toward the current depth as they are put. Messages got from a queue do not count toward the current depth. This is true whether operations are done under syncpoint or not. Commit has no effect on current depth. Therefore:

- Messages put under syncpoint (but not yet committed) are included in the current depth.
- Messages got under syncpoint (but not yet committed) are not included in the current depth.

 CURFSIZE

Indicates the current size of the queue file in megabytes, rounded up to the nearest megabyte.

For a new queue with default attributes, the value of **CURFSIZE** is 1.

 CURMAXFS

Indicates the current maximum size the queue file can grow to, rounded up to the nearest megabyte, given the current block size in use on a queue.

The use of this field is two fold:

- If you set **MAXFSIZE (DEFAULT)** for the current block size, **CURMAXFS** shows the actual value that **DEFAULT** equates to.

- If **CURMAXFS** does not match **MAXFSIZE**, you know the queue must be drained in order to adopt a bigger granularity.

IPPROCS

The number of handles that are currently open for input for the queue (either input-shared or input-exclusive). This number does not include handles that are open for browse.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue sharing group.

LGETDATE

The date on which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get date is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

 For queues with **QSGDISP (SHARED)**, the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than OFF for this queue.

LGETTIME

The time at which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get time is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

 For queues with **QSGDISP (SHARED)**, the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than **OFF** for this queue.

LPUTDATE

The date on which the last message was put to the queue since the queue manager started. When no put date is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

 For queues with **QSGDISP (SHARED)**, the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than OFF for this queue.

LPUTTIME

The time at which the last message was put to the queue since the queue manager started. When no put time is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

 For queues with **QSGDISP (SHARED)**, the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than OFF for this queue.

Note: Moving the system clock backwards should be avoided in case the **LPUTTIME** is being used to monitor the messages. The **LPUTTIME** of a queue is only updated when a message that arrives on the queue has a PutTime greater than the existing value of **LPUTTIME**. Because the PutTime of the message is less than the existing **LPUTTIME** of the queue in this case, the time is left unchanged.

Multi **MEDIALOG**

The log extent or journal receiver needed for media recovery of the queue. On queue managers on which circular logging is in place, **MEDIALOG** is returned as a null string.

This parameter is valid only on [Multiplatforms](#).

MONQ

Current level of monitoring data collection for the queue.

This parameter is also displayed when you specify the **MONITOR** parameter.

MSGAGE

Age, in seconds, of the oldest message on the queue. The maximum displayable value is 999999999; if the age exceeds this value, 999999999 is displayed.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than OFF for this queue.

OPPROCS

This is the number of handles that are currently open for output for the queue.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue sharing group.

z/OS **QSGDISP**

Indicates the disposition of the queue. The value displayed is one of the following:

QMGR

The object was defined with **QSGDISP(QMGR)**.

COPY

The object was defined with **QSGDISP(COPY)**.

SHARED

The object was defined with **QSGDISP(SHARED)**.

This parameter is valid on z/OS only.

For shared queues, if the CF structure used by the queue is unavailable or has failed, the status information might be unreliable.

You cannot use **QSGDISP** as a filter keyword.

QTIME

Interval, in microseconds, between messages being put on the queue and then being destructively read. The maximum displayable value is 999999999; if the interval exceeds this value, 999999999 is displayed.

The interval is measured from the time that the message is placed on the queue until it is destructively retrieved by an application and, therefore, includes any interval caused by a delay in committing by the putting application.

Two values are displayed and these are recalculated only when messages are processed:

- A value based on the last few messages processed
- A value based on a larger sample of the recently processed messages

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. For queues with **QSGDISP(SHARED)**, the values shown are for measurements collected on this queue manager only.

This parameter is also displayed when you specify the **MONITOR** parameter.

A value is only displayed for this parameter if **MONQ** is set to a value other than OFF for this queue.

UNCOM

Indicates whether there are any uncommitted changes (puts and gets) pending for the queue. The value displayed is one of the following:

YES

On z/OS, there are one or more uncommitted changes pending.

NO

There are no uncommitted changes pending.

n

 On Multiplatforms, an integer value indicating how many uncommitted changes are pending.

For shared queues, the value returned applies only to the queue manager generating the reply. The value does not apply to all the queue managers in the queue sharing group.

Handle status

For handle status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (**TYPE** parameter)
-  User identifier (**USERID** parameter) - not returned for **APPLTYPE (SYSTEM)**

Note:  Returned only if requested on z/OS

-  Application tag (**APPLTAG** parameter)
- Application type (**APPLTYPE** parameter)
-  On z/OS only, the queue sharing group disposition (QSGDISP parameter)

The following parameters can be specified for **TYPE (HANDLE)** to request additional information for each queue. If a parameter that is not relevant is specified for the queue, operating environment, or type of status information requested, that parameter is ignored.

APPLDESC

A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

APPLTAG

A string containing the tag of the application connected to the queue manager. It is one of the following:

-  z/OS batch job name
-  TSO USERID
- CICS APPLID
- IMS region name
- Channel initiator job name
-  IBM i job name
-   Linux or AIX process
-  Windows process

Note: The returned value consists of the full program path and executable file name. If it is more than 28 characters long, only the first 28 characters are shown.

- Internal queue manager process name

Application name represents the name of the process or job that has connected to the queue manager. In the instance that this process or job is connected via a channel, the application name represents the remote process or job rather than the local channel process or job name.

APPLTYPE

A string indicating the type of the application that is connected to the queue manager. It is one of the following:

BATCH

Application using a batch connection

RRSBATCH

RRS-coordinated application using a batch connection

CICS

CICS transaction

IMS

IMS transaction

CHINIT

Channel initiator

SYSTEM

Queue manager

SYSTEMEXT

Application performing an extension of function that is provided by the queue manager

USER

A user application

ASID

A four-character address-space identifier of the application identified by APPLTAG. It distinguishes duplicate values of **APPLTAG**.

This parameter is returned only when the queue manager owning the queue is running on z/OS, and the **APPLTYPE** parameter does not have the value SYSTEM.

ASTATE

The state of the asynchronous consumer on this queue.

Possible values are:

ACTIVE

An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

INACTIVE

An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

SUSPENDED

The asynchronous consumption call-back has been suspended so that asynchronous message consumption cannot currently proceed on this queue. This can be either because an MQCB call with Operation MQOP_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the call-back function is initiated with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure that is passed to the call-back function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP_RESUME.

SUSPTMP

The asynchronous consumption call-back has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this queue. As part of the

process of suspending asynchronous message consumption, the call-back function is called with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure passed to the call-back function.

The call-back function is initiated again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

NONE

An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

BROWSE

Indicates whether the handle is providing browse access to the queue. The value is one of the following:

YES

The handle is providing browse access.

NO

The handle is not providing browse access.

CHANNEL

The name of the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

CONNNAME

The connection name associated with the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

HSTATE

Whether an API call is in progress.

Possible values are:

ACTIVE

An API call from a connection is currently in progress for this object. For a queue, this condition can arise when an MQGET WAIT call is in progress.

If there is an MQGET SIGNAL outstanding, then this value does not mean, by itself, that the handle is active.

INACTIVE

No API call from a connection is currently in progress for this object. For a queue, this condition can arise when no MQGET WAIT call is in progress.

INPUT

Indicates whether the handle is providing input access to the queue. The value is one of the following:

SHARED

The handle is providing shared-input access.

EXCL

The handle is providing exclusive-input access.

NO

The handle is not providing input access.

INQUIRE

Indicates whether the handle currently provides inquire access to the queue. The value is one of the following:

YES

The handle provides inquire access.

NO

The handle does not provide inquire access.

OUTPUT

Indicates whether the handle is providing output access to the queue. The value is one of the following:

YES

The handle is providing output access.

NO

The handle is not providing output access.

PID

Number specifying the process identifier of the application that has opened the specified queue.

➤ **z/OS** This parameter is not valid on z/OS.

➤ **z/OS** **PSBNAME**

The eight characters long name of the program specification block (PSB) associated with the running IMS transaction. You can use the **PSBNAME** and **PSTID** to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

➤ **z/OS** **PSTID**

The four character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value IMS.

QMURID

The queue manager unit of recovery identifier.

- ➤ **z/OS** On z/OS, this value is an 8-byte log RBA, displayed as 16 hexadecimal characters.
- ➤ **Multi** On Multiplatforms, this value is an 8-byte transaction identifier, displayed as m.n where m and n are the decimal representation of the first and last 4 bytes of the transaction identifier.

You can use **QMURID** as a filter keyword.

- ➤ **z/OS** On z/OS, you must specify the filter value as a hexadecimal string.
- ➤ **Multi** On Multiplatforms, you must specify the filter value as a pair of decimal numbers separated by a period (.).

You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

➤ **z/OS** **QSGDISP**

Indicates the disposition of the queue. It is valid on z/OS only. The value is one of the following:

QMGR

The object was defined with **QSGDISP(QMGR)**.

COPY

The object was defined with **QSGDISP(COPY)**.

SHARED

The object was defined with **QSGDISP(SHARED)**.

You cannot use **QSGDISP** as a filter keyword.

SET

Indicates whether the handle is providing set access to the queue. The value is one of the following:

YES

The handle is providing set access.

NO

The handle is not providing set access.

► **z/OS TASKNO**

A seven-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

TID

Number specifying the thread identifier within the application process that has opened the specified queue.

► **z/OS** This parameter is not valid on z/OS.

An asterisk indicates that this queue was opened using a shared connection.

For further information about shared connections see [Shared \(thread independent\) connections with MQCONN](#).

► **z/OS TRANSID**

A four-character CICS transaction identifier. This parameter is valid on z/OS only.

This parameter is returned only when the **APPLTYPE** parameter has the value CICS.

URID

The external unit of recovery identifier associated with the connection. It is the recovery identifier known in the external syncpoint coordinator. Its format is determined by the value of **URTYPE**.

You cannot use **URID** as a filter keyword.

URTYPE

The type of unit of recovery as seen by the queue manager. It is one of the following:

- CICS (valid only on z/OS)
- XA
- RRS (valid only on z/OS)
- IMS (valid only on z/OS)
- QMGR

URTYPE identifies the **EXTURID** type and not the type of the transaction coordinator. When **URTYPE** is QMGR, the associated identifier is in **QMURID** (and not URID).

USERID

The user identifier associated with the handle.

This parameter is not returned when **APPLTYPE** has the value SYSTEM.

Notes:

¹ Valid only on z/OS.

² On z/OS, you cannot issue this from CSQINP2.

³ Valid only on z/OS when the queue manager is a member of a queue sharing group.

⁴ Valid only on an alias queue.

⁵ Not valid on z/OS.

⁶ Not valid on z/OS or IBM i.

Usage notes for DISPLAY QUEUE

1. You can use the following commands (or their synonyms) as an alternative way to display these attributes.

- **DISPLAY QALIAS**
- **DISPLAY QCLUSTER**
- **DISPLAY QLOCAL**
- **DISPLAY QMODEL**
- **DISPLAY QREMOTE**

These commands produce the same output as the **DISPLAY QUEUE TYPE** (*queue-type*) command. If you enter the commands this way, do not use the **TYPE** parameter.

2.  On z/OS, the channel initiator must be running before you can display information about cluster queues (using **TYPE** (**QCLUSTER**) or the **CLUSINFO** parameter).
3. The command might not show every clustered queue in the cluster when issued on a partial repository, because the partial repository only knows about a queue once it has tried to use it.

Parameter descriptions for DISPLAY QUEUE

You must specify the name of the queue definition you want to display. This can be a specific queue name or a generic queue name. By using a generic queue name, you can display either:

- All queue definitions
- One or more queues that match the specified name

queue-name

The local name of the queue definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk ***** matches all queues with the specified stem followed by zero or more characters. An asterisk (*****) on its own specifies all queues.

WHERE

Specify a filter condition to display only those queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the  **CMDSCOPE**, **QDPHIEV**, **QDPLOEV**, **QDPMAEV**, 

QSGDISP, or **QSVCI EV** parameters as filter keywords. You cannot use  **CFSTRUCT**,

CLUSTER,  **PSID**,  **STGCLASS**, or **CLUSNL** if these are also used to select queues. Queues of a type for which the filter keyword is not a valid attribute are not displayed.

operator

This is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the CLUSQT parameter), you can only use EQ or NE. For the parameters HARDENBO, SHARE, and TRIGGER, use either EQ YES or EQ NO.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Specify this to display all the attributes. If this parameter is specified, any attributes that are also requested specifically have no effect; all attributes are still displayed.

On all platforms, this is the default if you do not specify a generic name and do not request any specific attributes.

 On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

** **CFSTRUCT (*generic-name*)****

This parameter is optional and limits the information displayed to those queues where the value of the coupling facility structure is specified in brackets.

The value can be a generic name. If you do not enter a value for this parameter, **CFSTRUCT** is treated as a requested parameter.

CLUSINFO

This requests that, in addition to information about attributes of queues defined on this queue manager, information about these and other queues in the cluster that match the selection criteria is displayed. In this case, there might be multiple queues with the same name displayed. The cluster information is obtained from the repository on this queue manager.

 Note that, on z/OS, you cannot issue DISPLAY QUEUE CLUSINFO commands from CSQINP2.

CLUSNL (*generic-name*)

This is optional, and limits the information displayed if entered with a value in brackets:

- For queues defined on the local queue manager, only those with the specified cluster list. The value can be a generic name. Only queue types for which **CLUSNL** is a valid parameter are restricted in this way; other queue types that meet the other selection criteria are displayed.
- For cluster queues, only those belonging to clusters in the specified cluster list if the value is not a generic name. If the value is a generic name, no restriction is applied to cluster queues.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster list information is returned about all the queues displayed.

Note:  If the disposition requested is SHARED, CMDSCOPE must be blank or the local queue manager.

CLUSTER (*generic-name*)

This is optional, and limits the information displayed to queues with the specified cluster name if entered with a value in brackets. The value can be a generic name. Only queue types for which **CLUSTER** is a valid parameter are restricted in this way by this parameter; other queue types that meet the other selection criteria are displayed.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the queues displayed.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP or SHARED.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

PSID (*integer*)

The identifier of the page set where a queue resides. This is optional. Specifying a value limits the information displayed to queues that have an active association to the specified page set. The value consists of two numeric characters, in the range 00 - 99. An asterisk * on its own specifies all page set identifiers. If you do not enter a value, page set information is returned about all the queues displayed.

The page set identifier is displayed only if there is an active association of the queue to a page set, that is, after the queue has been the target of an MQPUT request. The association of a queue to a page set is not active when:

- The queue is just defined
- The STGCLASS attribute of the queue is altered, and there is no subsequent MQPUT request to the queue
- The queue manager is restarted and there are no messages on the queue

This parameter is valid only on z/OS.

QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, also display information for objects defined with QSGDISP(SHARED).

ALL

Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP) or QSGDISP(SHARED).

In a shared queue manager environment:

```
DISPLAY QUEUE(name) CMDSCOPE(*) QSGDISP(ALL)
```

The command lists objects matching name in the queue sharing group, without duplicating those in the shared repository.

COPY

Display information only for objects defined with QSGDISP(COPY).

GROUP

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

QMGR

Display information only for objects defined with QSGDISP(QMGR).

SHARED

Display information only for objects defined with QSGDISP(SHARED). This is allowed only in a shared queue manager environment.

Note: For cluster queues, this is always treated as a requested parameter. The value returned is the disposition of the real queue that the cluster queue represents.

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

Note: In the QSGDISP(LIVE) case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

QSGDISP displays one of the following values:

QMGR

The object was defined with QSGDISP(QMGR).

GROUP

The object was defined with QSGDISP(GROUP).

COPY

The object was defined with QSGDISP(COPY).

SHARED

The object was defined with QSGDISP(SHARED).

You cannot use **QSGDISP** as a filter keyword.

STGCLASS (generic-name)

This is optional, and limits the information displayed to queues with the storage class specified if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and storage class information is returned about all the queues displayed.

This parameter is valid only on z/OS.

TARGETTYPE (*target-type*)

This is optional and specifies the target type of the alias queue you want to be displayed.

TYPE (*queue-type*)

This is optional, and specifies the type of queues you want to be displayed. If you specify ALL, which is the default value, all queue types are displayed; this includes cluster queues if CLUSINFO is also specified.

As well as ALL, you can specify any of the queue types allowed for a **DEFINE** command: QALIAS, QLOCAL, QMODEL, QREMOTE, or their synonyms, as follows:

QALIAS

Alias queues

QLOCAL

Local queues

QMODEL

Model queues

QREMOTE

Remote queues

You can specify a queue type of QCLUSTER to display only cluster queue information. If QCLUSTER is specified, any selection criteria specified by the CFSTRUCT, STGCLASS, or PSID parameters are ignored. Note that you cannot issue **DISPLAY QUEUE TYPE(QCLUSTER)** commands from CSQINP2.

 On Multiplatforms, QTYPE (*type*) can be used as a synonym for this parameter.

The queue name and queue type  (and, on z/OS, the queue disposition) are always displayed.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most parameters are relevant only for queues of a particular type or types. Parameters that are not relevant for a particular type of queue cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of queue. There is a brief description of each parameter after the table, but for more information, see the **DEFINE** command for each queue type.

Table 202. Parameters that can be returned by the DISPLAY QUEUE command

ACCTQ

Whether accounting (on z/OS, thread-level and queue-level accounting) data collection is to be enabled for the queue.

ALTDATE

The date on which the definition or information was last altered, in the form yyyy-mm-dd.

ALTTIME

The time at which the definition or information was last altered, in the form hh.mm.ss.

BOQNAME

Backout requeue name.

BOTHRESH

Backout threshold.

CAEXPXY(integer)

The maximum time, expressed in tenths of a second, which a message put on an object handle opened, using this object in the resolution path, remains in the system until it becomes eligible for expiry processing.

CLCHNAME

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

CLUSDATE

The date on which the definition became available to the local queue manager, in the form yyyy-mm-dd.

CLUSNL

The namelist that defines the cluster that the queue is in.

CLUSQMGR

The name of the queue manager that hosts the queue.

CLUSQT

Cluster queue type. This can be:

QALIAS

The cluster queue represents an alias queue.

QLOCAL

The cluster queue represents a local queue.

QMGR

The cluster queue represents a queue manager alias.

QREMOTE

The cluster queue represents a remote queue.

CLUSTER

The name of the cluster that the queue is in.

CLUSTIME

The time at which the definition became available to the local queue manager, in the form hh.mm.ss.

CLWLPTY

The priority of the queue for the purposes of cluster workload distribution.

CLWLRANK

The rank of the queue for the purposes of cluster workload distribution.

CLWLUSEQ

Whether puts are allowed to other queue definitions apart from local ones.

CRDATE

The date on which the queue was defined (in the form yyyy-mm-dd).

CRTIME

The time at which the queue was defined (in the form hh.mm.ss).

CURDEPTH

Current depth of queue.

 On z/OS, **CURDEPTH** is returned as zero for queues defined with a disposition of GROUP. It is also returned as zero for queues defined with a disposition of SHARED if the CF structure that they use is unavailable or has failed.

Messages put on a queue count toward the current depth as they are put. Messages got from a queue do not count toward the current depth. This is true whether operations are done under syncpoint or not. Commit has no effect on current depth. Therefore:

- Messages put under syncpoint (but not yet committed) are included in the current depth.
- Messages got under syncpoint (but not yet committed) are not included in the current depth.

CUSTOM

This attribute contains name-value pairs that have the form NAME(VALUE). The value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. Attribute names beginning with **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPRT**, **SQGETTMR**, and **PAGEVAL**.

DEFBIND

Default message binding.

DEFPRESP

Default put response; defines the behavior that should be used by applications when the put response type in the **MQPMO** options has been set to **MQPMO_RESPONSE_AS_Q_DEF**.

DEFPRTY

Default priority of the messages put on the queue.

DEFPSIST

Whether the default persistence of messages put on this queue is set to NO or YES. NO means that messages are lost across a restart of the queue manager.

DEFREADA

This specifies the default read ahead behavior for non-persistent messages delivered to the client.

DEFSOPT

Default share option on a queue opened for input.

DEFTYPE

Queue definition type. This can be:

- **PREDEFINED** (Predefined)

The queue was created with a **DEFINE** command, either by an operator or by a suitably authorized application sending a command message to the service queue.

- **PERMDYN** (Permanent dynamic)

Either the queue was created by an application issuing **MQOPEN** with the name of a model queue specified in the object descriptor (**MQOD**), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

On z/OS the queue was created with **QSGDISP(QMGR)**.

- **TEMPDYN** (Temporary dynamic)

Either the queue was created by an application issuing **MQOPEN** with the name of a model queue specified in the object descriptor (**MQOD**), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

On z/OS the queue was created with **QSGDISP(QMGR)**.

- **SHAREDYN**

A permanent dynamic queue was created when an application issued an **MQOPEN** API call with the name of this model queue specified in the object descriptor (**MQOD**).

On z/OS, in a queue sharing group environment, the queue was created with **QSGDISP(SHARED)**.

DESCR

Descriptive comment.

DISTL

Whether distribution lists are supported by the partner queue manager. Supported only on Multiplatforms.

GET

Whether the queue is enabled for gets.

HARDENBO

Whether the back out count is hardened to ensure that the count of the number of times that a message has been backed out is accurate.

Note: This parameter affects only IBM MQ for z/OS. It can be set and displayed on other platforms but has no effect.

IMGRCOVQ

Whether a local or permanent dynamic queue object is recoverable from a media image if linear logging is being used.

Note:  This parameter is not valid on IBM MQ for z/OS.

INDXTYPE

Index type (supported only on z/OS).

INITQ

Initiation queue name.

IPPROCS

Number of applications that are currently connected to the queue to get messages from the queue.

 On z/OS, **IPPROCS** is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

MAXDEPTH

Maximum depth of queue.

MAXFSIZE

The size, in megabytes, of the queue file displayed.

The default value for this attribute is DEFQFS, which stands for *default queue file size* and equates to a hard-coded value of 2,088,960 MB.

MAXMSGL

Maximum message length.

MONQ

Online monitoring data collection.

MSGDLVSQ

Message delivery sequence.

NPMCLASS

Level of reliability assigned to non-persistent messages that are put to the queue.

OPPROCS

Number of applications that are currently connected to the queue to put messages on the queue.

 On z/OS, **OPPROCS** is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**, or from the message to the environment on **MQGET**.  For IMS bridge queues, also controls whether the IMS bridge automatically propagates trace context from the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation.

If the queue manager is in a queue sharing group, and the queue has a **QSGDISP** of SHARED, COPY or GROUP, this value can only be set if all queue managers have been started at IBM MQ 9.4.3 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are sent to or consumed from this queue. V 10.0.0
For IMS bridge queues, also controls whether the IMS bridge emits spans when it sends the messages it gets to IMS.

Can be one of the following values:

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PROCESS

Process name.

PROPTCL

Property control attribute.

This parameter is applicable to Local, Alias and Model queues.

This parameter is optional.

Specifies how message properties are handled when messages are retrieved from queues using the MQGET call with the MQGMO_PROPERTIES_AS_Q_DEF option.

Permissible values are:

ALL

To contain all the properties of the message, except those contained in the message descriptor (or extension), select ALL. The ALL value enables applications that cannot be changed to access all the message properties from MQRFH2 headers.

COMPAT

If the message contains a property with a prefix of **mcd.**, **jms.**, **usr.**, or **mqext.**, all message properties are delivered to the application in an MQRFH2 header. Otherwise all properties of the message, except those contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

This is the default value; it allows applications which expect JMS related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

FORCE

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the `MQGMO` structure on the `MQGET` call is ignored. Properties of the message are not accessible via the message handle.

NONE

All properties of the message, except those in the message descriptor (or extension), are removed from the message before the message is delivered to the application.

PUT

Whether the queue is enabled for puts.

QDEPTHHI

Queue Depth High event generation threshold.

QDEPTHLO

Queue Depth Low event generation threshold.

QDPHIEV

Whether Queue Depth High events are generated.

You cannot use **QDPHIEV** as a filter keyword.

QDPLOEV

Whether Queue Depth Low events are generated.

You cannot use **QDPLOEV** as a filter keyword.

QDPMAXEV

Whether Queue Full events are generated.

You cannot use **QDPMAXEV** as a filter keyword.

QMID

The internally generated unique name of the queue manager that hosts the queue.

QSVCI EV

Whether service interval events are generated.

You cannot use **QSVCI EV** as a filter keyword.

QSVCINT

Service interval event generation threshold.

QTYPE

Queue type.

The queue type is always displayed.

 On Multiplatforms, `TYPE(type)` can be used as a synonym for this parameter.

RETINTVL

Retention interval.

RNAME

Name of the local queue, as known by the remote queue manager.

RQMNAME

Remote queue manager name.

SCOPE

Scope of queue definition (not supported on z/OS).

SHARE

Whether the queue can be shared.

STATQ

Whether statistics data information is to be collected.

STGCLASS

Storage class.

STREAMQ

The name of a secondary queue where a copy of each message is put.

STRMQOS

The quality of service to use when delivering messages to the duplicate queue.

TARGET

This parameter requests that the base object name of an aliased queue is displayed.

TARGETTYPE

This parameter requests that the target (base) type of an aliased queue is displayed.

TPIPE

The **TPIPE** names used for communication with OTMA using the IBM MQ - IMS bridge if the bridge is active. This parameter is supported only on z/OS.

 For more information about TPIPEs, see [Controlling the IMS bridge](#).

TRIGDATA

Trigger data.

TRIGDPTH

Trigger depth.

TRIGGER

Whether triggers are active.

TRIGMPRI

Threshold message priority for triggers.

TRIGTYPE

Trigger type.

USAGE

Whether the queue is a transmission queue.

XMITQ

Transmission queue name.

For more details of these parameters, see [“DEFINE queues” on page 625](#).

Use the MQSC command **DISPLAY QSTATUS** to display the status of one or more queues.

DISPLAY SBSTATUS (display subscription status)

Use the MQSC command **DISPLAY SBSTATUS** to display the status of a subscription.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

z/OS You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- “Syntax diagram for DISPLAY SBSTATUS” on page 919
- “Parameter descriptions for DISPLAY SBSTATUS” on page 920
- “Requested parameters” on page 922

Syntax diagram for DISPLAY SBSTATUS

Synonym: **DIS SBSTATUS**

Parameter descriptions for DISPLAY SBSTATUS

You must specify the name of the subscription definition for which you want to display status information. This can be a specific subscription name or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions
- One or more subscriptions that match the specified name

(generic-name)

The local name of the subscription definition to be displayed. A trailing asterisk (*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all subscriptions.

WHERE

Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

▶ **z/OS** However, you cannot use the **CMDSCOPE** parameter as a filter keyword.

Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

operator

This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value USER on the **SUBTYPE** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **SUBUSER** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Display all the status information for each specified subscription definition. This is the default if you do not specify a generic name, and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only, requested attributes are displayed.

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

DURABLE

Specify this attribute to restrict the type of subscriptions which are displayed.

ALL

Display all subscriptions.

NO

Only information about nondurable subscriptions is displayed.

YES

Only information about durable subscriptions is displayed.

SUBTYPE

Specify this attribute to restrict the type of subscriptions which are displayed.

USER

Displays only **API** and **ADMIN** subscriptions.

PROXY

Only system created subscriptions relating to inter-queue manager subscriptions are selected.

ADMIN

Only subscriptions that have been created by an administration interface or modified by an administration interface are selected.

API

Only subscriptions created by applications using an IBM MQ API call are selected.

ALL

All subscription types are displayed (no restriction).

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

ACTCONN

Returns the *ConnId* of the *HConn* that currently has this subscription open.

DURABLE

A durable subscription is not deleted when the creating application closes its subscription handle.

NO

The subscription is removed when the application that created it is closed or disconnected from the queue manager.

YES

The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

LMSGDATE

The date on which a message was last published to the destination specified by this subscription.

LMSGTIME

The time on which a message was last published to the destination specified by this subscription.

MCASTREL

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, using the **COMMEV** parameter of the **COMMINFO** objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMMSGs

The number of messages put to the destination specified by this subscription since it was created, or since the queue manager was restarted, whichever is more recent. This number might not reflect the total number of messages that are, or have been, available to the consuming application. This is because it might also include publications that were partially processed but then undone by the queue manager due to a publication failure, or publications that were made within syncpoint that were rolled-back by the publishing application.

RESMDATE

The date of the most recent **MQSUB** API call that connected to the subscription.

RESMTIME

The time of the most recent **MQSUB** API call that connected to the subscription.

SUBID(*string*)

The internal, unique key identifying a subscription.

SUBUSER(*string*)

The owning user ID of the subscription.

SUBTYPE

Indicates how the subscription was created.

PROXY

An internally created subscription used for routing publications through a queue manager.

ADMIN

Created using the **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

API

Created using an **MQSUB** API call.

TOPICSTR

Returns the fully resolved topic string of the subscription.

For more details of these parameters, see [“DEFINE SUB \(create a durable subscription\)” on page 669](#).

DISPLAY SECURITY (display security settings) on z/OS

Use the MQSC command **DISPLAY SECURITY** to display the current settings for the security parameters.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [Syntax diagram](#)
- [“Parameter descriptions for DISPLAY SECURITY” on page 924](#)

Note: This command is not allowed to be issued from CSQINP1 or CSQINP2 on z/OS.

Syntax diagram for DISPLAY SECURITY

Synonym: DIS SEC

Parameter descriptions for DISPLAY SECURITY

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

ALL

Display the **TIMEOUT**, **INTERVAL**, and **SWITCHES** parameters. This is the default if no requested parameters are specified.

The command also outputs an additional message, either CSQH037I or CSQH038I, stating whether security is currently using upper or mixed case security classes.

The command also outputs messages CSQH040I through CSQH042I showing the connection authentication settings currently in use.

INTERVAL

Time interval between checks.

SWITCHES

Display the current setting of the switch profiles.

If the subsystem security switch is off, no other switch profile settings are displayed.

TIMEOUT

Timeout value.

See [“ALTER SECURITY \(alter security options\) on z/OS” on page 487](#) for details of the **TIMEOUT** and **INTERVAL** parameters.

Related tasks

[Displaying security status](#)

Related reference

Use the MQSC command **REFRESH SECURITY** to perform a security refresh.

[“RVERIFY SECURITY \(set a user reverification flag\) on z/OS” on page 1028](#)

Use the MQSC command **RVERIFY SECURITY** to set a reverification flag for all specified users. The user is reverified the next time that security is checked for that user.

DISPLAY SERVICE (display service information) on Multiplatforms

Use the MQSC command **DISPLAY SERVICE** to display information about a service.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY SERVICE” on page 925](#)
- [“Keyword and parameter descriptions for DISPLAY SERVICE” on page 926](#)
- [“Requested parameters” on page 927](#)

Syntax diagram for DISPLAY SERVICE

Synonym:

Keyword and parameter descriptions for DISPLAY SERVICE

You must specify a service for which you want to display information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Information about all service definitions, by using a single asterisk (*), or
- Information about one or more service that match the specified name.

(generic-service-name)

The name of the service definition for which information is to be displayed. A single asterisk (*) specifies that information for all service identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the **CONTROL** parameter), you can only use EQ or NE.

.

- A generic value. This is a character string, with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Specify this to display all the service information for each specified service. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only requested attributes are displayed.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*.

ALTIME

The time at which the definition was last altered, in the form *hh.mm.ss*.

CONTROL

How the service is to be started and stopped:

MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR

The service is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR

Descriptive comment.

SERVTYPE

Specifies the mode in which the service is to run:

COMMAND

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

SERVER

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the **DISPLAY SVSTATUS** command.

STARTARG

Specifies the arguments to be passed to the user program at queue manager startup.

STARTCMD

Specifies the name of the program which is to run.

STDERR

Specifies the path to the file to which the standard error (stderr) of the service program is to be redirected.

STDOUT

Specifies the path to the file to which the standard output (stdout) of the service program is to be redirected.

STOPARG

Specifies the arguments to be passed to the stop program when instructed to stop the service.

SMDS(*qmgr-name*|*)

Specifies the queue manager for which the shared message data set properties are to be displayed, or an asterisk to display the properties for all shared message data sets associated with the specified CFSTRUCT.

CFSTRUCT(*structure-name*)

Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be displayed.

WHERE

Specify a filter condition to display only the SMDS information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this DISPLAY command.

operator

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the **RECOVER** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values on the **DISPLAY SMDS** command.

ALL

Specify this keyword to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

Requested parameters for DISPLAY SMDS

The following information is returned for each selected data set:

SMDS

The queue manager name which owns the shared message data set for which properties are being displayed.

CFSTRUCT

The coupling facility application structure name.

DSBUFS

Displays the override value for the number of buffers to be used by the owning queue manager for accessing shared message data sets for this structure, or DEFAULT if the group value from the **CFSTRUCT** definition is being used.

DSEXPAND

Displays the override value (YES or NO) for the data set expansion option, or DEFAULT if the group value from the **CFSTRUCT** definition is being used.

Related reference

[“ALTER SMDS \(alter shared message data sets\) on z/OS” on page 492](#)

Use the MQSC command **ALTER SMDS** to alter the parameters of existing IBM MQ definitions relating to one or more shared message data sets associated with a specific application structure. It is only supported when the **CFSTRUCT** definition is using the option OFFLOAD (SMDS).

[“DISPLAY SMDSCONN \(display shared message data sets connection information\) on z/OS” on page 930](#)

Use the MQSC command **DISPLAY SMDSCONN** to display status and availability information about the connection between the queue manager and the shared message data sets for the specified **CFSTRUCT**.

[“RESET SMDS \(reset shared message data sets\) on z/OS” on page 1018](#)

Use the MQSC command **RESET SMDS** to modify availability or status information relating to one or more shared message data sets associated with a specific application structure.

[“START SMDSCONN \(restart a shared message data set connection\) on z/OS” on page 1075](#)

Use the MQSC command **START SMDSCONN** to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

[“STOP SMDSCONN \(stop shared message data sets connection\) on z/OS” on page 1098](#)

Use the MQSC command **STOP SMDSCONN** to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.

DISPLAY SMDSCONN (display shared message data sets connection information) on z/OS

Use the MQSC command **DISPLAY SMDSCONN** to display status and availability information about the connection between the queue manager and the shared message data sets for the specified **CFSTRUCT**.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY SMDSCONN” on page 931](#)
- [“Usage notes for DISPLAY SMDSCONN” on page 931](#)
- [“Parameter descriptions for DISPLAY SMDSCONN” on page 932](#)

Syntax diagram for DISPLAY SMDSCONN

Synonym:

Usage notes for DISPLAY SMDSCONN

This command is only supported when the **CFSTRUCT** definition is currently using the option **OFFLOAD(SMDS)**.

This information indicates whether the queue manager is currently able to allocate and open the data set.

The following results are returned for each selected connection:

SMDSCONN

The name of the queue manager which owns the shared message data set for this connection.

CFSTRUCT

The name of the coupling facility application structure.

OPENMODE

The mode in which the data set is currently open by this queue manager. This is one of the following:

NONE

The data set is not currently open.

READONLY

The data set is owned by another queue manager and is open for read-only access.

UPDATE

The data set is owned by this queue manager and is open for update access.

RECOVERY

The data set is open for recovery processing.

STATUS

The connection status as seen by this queue manager. This is one of the following:

CLOSED

This data set is not currently open.

OPENING

This queue manager is currently in the process of opening and validating this data set (including space map restart processing when necessary).

OPEN

This queue manager has successfully opened this data set and it is available for normal use.

CLOSING

This queue manager is currently in the process of closing this data set, including quiescing normal I/O activity and storing the saved space map if necessary.

NOTENABLED

The SMDS definition is not in the **ACCESS(ENABLED)** state so the data set is not currently available for normal use. This status is only set when the SMDSCONN status does not already indicate some other form of failure.

ALLOCFAIL

This queue manager was unable to locate or allocate this data set.

OPENFAIL

This queue manager was able to allocate the data set but was unable to open it, so it has now been deallocated.

STGFAIL

The data set could not be used because the queue manager was unable to allocate associated storage areas for control blocks, or for space map or header record processing.

DATAFAIL

The data set was successfully opened but the data was found to be invalid or inconsistent, or a permanent I/O error occurred, so it has now been closed and deallocated.

This may result in the shared message data set itself being marked as **STATUS(FAILED)**.

AVAIL

The availability of this data set connection as seen by this queue manager. This is one of the following:

NORMAL

The connection can be used and no error has been detected.

ERROR

The connection is unavailable because of an error.

The queue manager may try to enable access again automatically if the error may no longer be present, for example when recovery completes or the status is manually set to RECOVERED. Otherwise, it can be enabled again using the **START SMDSCONN** command in order to retry the action which originally failed.

STOPPED

The connection cannot be used because it has been explicitly stopped using the **STOP SMDSCONN** command. It can only be made available again by using a **START SMDSCONN** command to enable it.

EXPANDST

The data set automatic expansion status. This is one of the following:

NORMAL

No problem has been noted which would affect automatic expansion.

FAILED

A recent expansion attempt failed, causing the **DSEXPAND** option to be set to NO for this specific data set. This status is cleared when **ALTER SMDS** is used to set the **DSEXPAND** option back to YES or DEFAULT.

MAXIMUM

The maximum number of extents has been reached, so future expansion is not possible (except by taking the data set out of service and copying it to larger extents).

Note, that the command works only if the structure is currently connected, that is, some shared queues allocated to that structure have been opened.

Parameter descriptions for DISPLAY SMDSCONN

The parameter descriptions for the **DISPLAY SMDS** command.

SMDSCONN(*qmgr-name)**

Specify the queue manager which owns the SMDS for which the connection information is to be displayed, or an asterisk to display the connection information for all shared message data sets associated with the specified **CFSTRUCT**.

CFSTRUCT(*structure-name*)

Specify the structure name for which the shared message data set connection information is required.

WHERE

Specify a filter condition to display only the SMDS connection information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the **RECOVER** parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values on the **DISPLAY SMDSCONN** command.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered.

This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group. You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

DISPLAY STGCLASS (display storage class information) on z/OS

Use the MQSC command **DISPLAY STGCLASS** to display information about storage classes.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY STGCLASS” on page 934](#)
- [“Parameter descriptions for DISPLAY STGCLASS” on page 935](#)
- [“Requested parameters” on page 938](#)

Syntax diagram for DISPLAY STGCLASS

Synonym: DIS STC

DISPLAY STGCLASS

Notes:

¹ Valid only on IBM MQ for z/OS when the queue manager is a member of a queue sharing group.

Parameter descriptions for DISPLAY STGCLASS

You use **DISPLAY STGCLASS** to show the page set identifiers that are associated with each storage class.

(*generic-class*)

Name of the storage class. This is required.

This is 1 through 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

A trailing asterisk (*) matches all storage classes with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all storage classes.

WHERE

Specify a filter condition to display only those storage classes that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE** or **QSGDISP** parameters as filter keywords. You cannot use **PSID** as a filter keyword if you also use it to select storage classes.

operator

This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can only use EQ or NE.

- A generic value. This is a character string (such as the character string in the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string ABC are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Specify this to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms only requested attributes are displayed.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

If **QSGDISP** is set to GROUP, **CMDSCOPE** must be blank or the local queue manager.

''

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

PSID(integer)

The page set identifier that a storage class maps to. This is optional.

The string consists of two numeric characters, in the range 00 through 99. An asterisk (*) on its own specifies all page set identifiers. See [“DEFINE PSID \(define page set and buffer pool\) on z/OS” on page 623.](#)

QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

This is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY STGCLASS(generic-class) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

```
name
```

in the queue sharing group without duplicating those in the shared repository.

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP (GROUP)**.

COPY

The object was defined with **QSGDISP (COPY)**.

You cannot use **QSGDISP** as a filter keyword.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is the storage class names, their page set identifiers and queue sharing group dispositions are displayed.

ALTDATE

The date on which the definition was last altered, in the form *yyyy-mm-dd*.

ALTTIME

The time at which the definition was last altered, in the form *hh.mm.ss*.

DESCR

Descriptive comment.

PASSTKTA

The application name used to authenticate IMS bridge passtickets. A blank value indicates that the default batch job profile name is to be used.

XCFGNAME

The name of the XCF group that IBM MQ is a member of.

XCFMNAME

The XCF member name of the IMS system within the XCF group specified in **XCFGNAME**.

For more information on these parameters, see [“DEFINE STGCLASS \(define storage class to page set mapping\) on z/OS” on page 665](#).

Related reference

Syntax diagram for DISPLAY SUB

Synonym: **DIS SUB**

DISPLAY SUB

summary attributes

standard attributes

Usage notes for DISPLAY SUB

The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

z/OS On z/OS, these non-printable characters are displayed as blanks.

Multi On Multiplatforms using **runmqsc**, these non-printable characters are displayed as dots.

Parameter descriptions for DISPLAY SUB

You must specify either the name or the identifier of subscription you want to display. This can be a specific subscription name, or **SUBID**, or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions
- One or more subscriptions that match the specified name

The following forms are valid:

```
DIS SUB(xyz)
DIS SUB SUBID(123)
DIS SUB(xyz*)
```

(generic-name)

The local name of the subscription definition to be displayed. A trailing asterisk (*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all subscriptions.

WHERE

Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE** parameter as a filter keyword. Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

operator

This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the **CLUSQT** parameter), you can only use EQ or NE. For the parameters **HARDENBO**, **SHARE**, and **TRIGGER**, use either EQ YES or EQ NO.

- A generic value. This is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note:  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

SUMMARY

Specify this to display the set of summary attributes that you want displayed.

Specify this to display all the attributes.

This is the default if you do not specify a generic name and do not request any specific attributes.

ALTTIME(*string*)

• •

qmgr-name

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

You cannot use **CMDSCOPE** as a filter keyword.

The date of the first **MQSUB** or **DEF SUB** command that created this subscription.

The time of the first **MQSUB** or **DEF SUB** command that created this subscription.

The destination for messages published to this subscription; this parameter is the name of a queue.

System managed destination.

The destination is a queue.

The destination is managed.

The **CorrelId** used for messages published to this subscription.

If set to '0000000000000000000000000000000000000000000000000000000' (48 zeros) the **CorrelId** set by the publishing application is maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

Note: You cannot set the **DESTCORL** property programmatically with JMS.

DESTQMGR(string)

The destination queue manager for messages published to this subscription.

DISTYPE

Controls the output returned in the **TOPICSTR** and **TOPICOBJ** attributes.

RESOLVED

Returns the resolved (full) topic string in the **TOPICSTR** attribute. The value of the **TOPICOBJ** attribute is also returned. This is the default value.

DEFINED

Returns the values of the **TOPICOBJ** and **TOPICSTR** attributes provided when the subscription was created. The **TOPICSTR** attribute will contain the application part of the topic string only. You can use the values returned with **TOPICOBJ** and **TOPICSTR** to fully re-create the subscription by using **DISTYPE (DEFINED)**.

DURABLE

A durable subscription is not deleted when the creating application closes its subscription handle.

ALL

Display all subscriptions.

NO

The subscription is removed when the application that created it, is closed or disconnected from the queue manager.

YES

The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

EXPIRY

The time to expiry of the subscription object from the creation date and time.

(integer)

The time to expiry, in tenths of a second, from the creation date and time.

UNLIMITED

There is no expiry time. This is the default option supplied with the product.

PSPROP

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

NONE

Do not add publish subscribe properties to the message.

COMPAT

Publish/subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

MSGPROP

Publish/subscribe properties are added as message properties.

RFH2

Publish/subscribe properties are added within an MQRFH version 2 header.

PUBACCT(string)

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the AccountingToken field of the MQMD.

If this byte string is enclosed in quotation marks, characters in the range A-F must be specified in uppercase.

PUBAPPID(string)

Identity data passed by the subscriber, for propagation into messages published to this subscription in the ApplIdentityData field of the MQMD.

PUBPRTY

The priority of the message sent to this subscription.

AS PUB

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

AS QDEF

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(integer)

An integer providing an explicit priority for messages published to this subscription.

REQONLY

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

NO

All publications on the topic are delivered to this subscription. This is the default value.

YES

Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO_PUBLICATIONS_ON_REQUEST.

SELECTOR(string)

A selector that is applied to messages published to the topic.

SELTYPE

The type of selector string that has been specified.

NONE

No selector has been specified.

STANDARD

The selector references only the properties of the message, not its content, using the standard IBM MQ selector syntax. Selectors of this type are to be handled internally by the queue manager.

EXTENDED

The selector uses extended selector syntax, typically referencing the content of the message.

Selectors of this type cannot be handled internally by the queue manager; extended selectors can be handled only by another program such as IBM Integration Bus.

SUB(string)

The application's unique identifier for a subscription.

SUBID(string)

The internal, unique key identifying a subscription.

SUBLEVEL(integer)

The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

SUBSCOPE

Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

ALL

The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

QMGR

The subscription forwards messages published on the topic only within this queue manager.

Note: Individual subscribers can only restrict **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

SUBTYPE

Indicates how the subscription was created.

USER

Displays only **API** and **ADMIN** subscriptions.

PROXY

An internally created subscription used for routing publications through a queue manager.

Subscriptions of type PROXY are not modified to ADMIN when alterations are attempted.

ADMIN

Created using **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

API

Created using an **MQSUB** API request.

ALL

All.

SUBUSER(string)

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

TOPICOBJ(string)

The name of a topic object used by this subscription.

TOPICSTR(string)

Returns a topic string, that can contain wildcard characters to match a set of topic strings, for the subscription. The topic string is either the application provided portion only, or fully qualified, depending on the value of **DISTYPE**.

USERDATA(string)

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property. The **USERDATA** is stored in the RFH2 header in the mqps folder with the key Sud.

An IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant JMS_IBM_SUBSCRIPTION_USER_DATA. For more information, see [Retrieval of user subscription data](#).

VARUSER

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

ANY

Any user can connect to and takeover ownership of the subscription.

FIXED

Takeover by another USERID is not permitted.

WSHEMA

The schema to be used when interpreting any wildcard characters in the topic string.

CHAR

Wildcard characters represent portions of strings.

TOPIC

Wildcard characters represent portions of the topic hierarchy.

DISPLAY SVSTATUS (display services status) on Multiplatforms

Use the MQSC command **DISPLAY SVSTATUS** to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

- [“Syntax diagram for DISPLAY SVSTATUS” on page 946](#)
- [“Keyword and parameter descriptions for DISPLAY SVSTATUS” on page 947](#)
- [“Requested parameters” on page 948](#)

Syntax diagram for DISPLAY SVSTATUS

Synonym:

Keyword and parameter descriptions for **DISPLAY SVSTATUS**

You must specify a service for which you want to display status information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Status information for all service definitions, by using a single asterisk (*), or
- Status information for one or more services that match the specified name.

(generic-service-name)

The name of the service definition for which status information is to be displayed. A single asterisk (*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

WHERE

Specify a filter condition to display status information for those services that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Any parameter that can be used to display attributes for this **DISPLAY** command.

operator

This is used to determine whether a service satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the **CONTROL** parameter), you can only use EQ or NE.

- A generic value. This is a character string with an asterisk at the end, for example ABC*. If the operator is LT, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NE, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

ALL

Display all the status information for each specified service. This is the default if you do not specify a generic name, and do not request any specific parameters.

Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

CONTROL

How the service is to be started and stopped:

MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the **START SERVICE** and **STOP SERVICE** commands.

QMGR

The service is to be started and stopped at the same time as the queue manager is started and stopped.

STARTONLY

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

DESCR

Descriptive comment.

PID

The operating system process identifier associated with the service.

SERVTYPE

The mode in which the service runs. A service can have a **SERVTYPE** of SERVER or COMMAND, but only services with **SERVTYPE(SERVER)** are displayed by this command.

STARTARG

The arguments passed to the user program at startup.

STARTCMD

The name of the program being run.

STARTDA

The date on which the service was started.

STARTTI

The time at which the service was started.

STATUS

The status of the process:

RUNNING

The service is running.

STARTING

The service is in the process of initializing.

STOPPING

The service is stopping.

STDERR

Destination of the standard error (stderr) of the service program.

STDOUT

Destination of the standard output (stdout) of the service program.

STOPARG

The arguments to be passed to the stop program when instructed to stop the service.

STOPCMD

The name of the executable program to run when the service is requested to stop.

For more information about these parameters, see [“DEFINE SERVICE \(create a new service definition\) on Multiplatforms” on page 662](#).

DISPLAY SYSTEM (display system information) on z/OS

Use the MQSC command **DISPLAY SYSTEM** to display general system parameters and information.

Using MQSC commands on z/OS

For information on how you use MQSC commands on z/OS, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

You can issue this command from sources 12CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY SYSTEM” on page 949](#)
- [“Usage notes for DISPLAY SYSTEM” on page 950](#)
- [“Parameter descriptions for DISPLAY SYSTEM” on page 950](#)

Syntax diagram for DISPLAY SYSTEM

Synonym: DIS SYSTEM

Usage notes for DISPLAY SYSTEM

1. **DISPLAY SYSTEM** returns a report that shows the initial values of the system parameters and the current values as changed by the **SET SYSTEM** command:
 - The maximum size of the ACE storage pool in kilobytes (**ACELIM**).
 - The type of the cluster cache (**CLCACHE**).
 - Default user ID for command security checks (**CMDUSER**).
 - Time in seconds for which queue manager exits can execute during each invocation (**EXITLIM**).
 - How many started server tasks to use to run queue manager exits (**EXITTCB**).
 - Number of log records written by IBM MQ between the start of one checkpoint and the next (**LOGLOAD**).
 - The Measured Usage Pricing property for this queue manager (**MULCCAPT**). This property is only displayed if the **MULCCAPT** property is set to REFINED.
 - The OTMA connection parameters (OTMACON).
 - Whether queue manager restart waits until all indexes are built, or completes before all indexes are built (QINDXBLD).
 - Coded character set identifier for the queue manager (QMCCSID).
 - The queue sharing group parameters (QSGDATA).
 - The RESLEVEL auditing parameter (RESAUDIT).
 - The message routing code assigned to messages not solicited from a specific console (ROUTCDE).
 - Whether SMF accounting data is collected when IBM MQ is started (SMFACCT).
 - Whether SMF statistics are collected when IBM MQ is started (SMFSTAT).
 - Whether the Advanced Message Security (AMS) component is installed (**SPLCAP**).
 - From IBM MQ for z/OS 9.3.0, the time, in minutes and seconds, between consecutive gatherings of statistics data (**STATIME**). This value is also used for accounting data if **ACCTIME** is set to -1.
 - Time, in minutes and seconds, between each gathering of accounting data (**ACCTIME**).
 - Whether tracing is started automatically (**TRACSTR**).
 - Size of trace table, in 4 KB blocks, to be used by the global trace facility (**TRACTBL**).
 - Time between scanning the queue index for WLM-managed queues (**WLMTIME**).
 - **WLMTIMU** indicates whether **WLMTIME** is given in seconds or minutes.
 - A list of messages excluded from being written to any log (**EXCLMSG**).
 - It might also return a report about system status.
2. This command is issued internally by IBM MQ at the end of queue manager startup.

Parameter descriptions for DISPLAY SYSTEM

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

★

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect is the same as entering the command on every queue manager in the queue sharing group.

ACELIM

The maximum size of the ACE storage pool in kilobytes.

CLCACHE

The type of the cluster cache.

SPLCAP

Whether the AMS component is installed.

Related reference

[“SET SYSTEM \(change system settings\) on z/OS” on page 1057](#)

Use the MQSC command **SET SYSTEM** to dynamically change certain general system parameter values that were initially set from your system parameter module at queue manager startup. To permanently change these, either change the CSQ6SYSP parameters and regenerate the parameter module, or put the **SET SYSTEM** commands into a data set in the CSQINP2 concatenation.

DISPLAY TCLUSTER (display cluster topic attributes)

Use the MQSC command **DISPLAY TCLUSTER** to display the attributes of the IBM MQ cluster topic object.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

Attention: The **DISPLAY TCLUSTER** command produces the same output as the **DISPLAY TOPIC TYPE (CLUSTER)** command. See [“DISPLAY TOPIC \(display topic information\)” on page 959](#) for further information on all the attributes displayed.

- [“Syntax diagram for DISPLAY TCLUSTER” on page 951](#)
- [“Usage notes for DISPLAY TCLUSTER” on page 953](#)
- [“Parameter descriptions for DISPLAY TCLUSTER” on page 954](#)

Syntax diagram for DISPLAY TCLUSTER

Synonym: DIS TCLUSTER

DISPLAY TCLUSTER

►► DISPLAY TCLUSTER — (— *generic-topic-name* —) ►

Requested attrs

Usage notes for DISPLAY TCLUSTER

1. **z/OS** On z/OS, the channel initiator must be running before you can display information about cluster topics.
2. The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

z/OS On z/OS, these non-printable characters are displayed as blanks.

 On Multiplatforms using the **runmqsc** command, these non-printable characters are displayed as dots.

Parameter descriptions for DISPLAY TCLUSTER

You must specify the name of the cluster topic definition you want to display. This name can be a specific cluster topic name or a generic cluster topic name. By using a generic topic name, you can display either:

(*generic-topic-name*)

The name of the administrative cluster topic definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all administrative topic objects.

WHERE

Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

 However, you cannot use the **CMDSCOPE**, or **QSGDISP** parameters as filter keywords.

operator

This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note:  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

ALL

Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

..

The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this process is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

LIVE is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Display information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY TOPIC(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching name in the queue sharing group without duplicating those objects in the shared repository.

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.
QSGDISP(PRIVATE) displays the same information as **QSGDISP(LIVE)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP(GROUP)**.

COPY

The object was defined with **QSGDISP(COPY)**.

You cannot use **QSGDISP** as a filter keyword.

CLUSTER

Displays topics with the specified cluster name. The value can be a generic name.

Requested attributes**CLROUTE**

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

CLSTATE

The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

ACTIVE

The cluster topic is correctly configured and being adhered to by this queue manager.

PENDING

Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

INVALID

This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

ERROR

An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See [Routing for publish/subscribe clusters: Notes on behavior](#).

CLUSDATE

The date on which the information became available to the local queue manager, in the form *yyyy-mm-dd*.

CLUSQMGR

The name of the queue manager that hosts the topic.

CLUSTIME

The time at which the information became available to the local queue manager, in the form *hh.mm.ss*.

QMID

The internally generated unique name of the queue manager that hosts the topic.

Related reference

[“DISPLAY TPSTATUS \(display topic status\)” on page 969](#)

Parameter descriptions for DISPLAY THREAD

(*connection-name*)

List of one or more *connection-name* s (of 1 through 8 characters each).

- For batch connections, this name is the batch job name
- For CICS connections, this name is the CICS applid
- For IMS connections, this name is the IMS job name
- For TSO connections, this name is the TSO user ID
- For RRS connections, this is RRSBATCH for all RRSBATCH-type connections, or the batch job name

Threads are selected from the address spaces associated with these connections only.

(*)

Displays threads associated with all connections to IBM MQ.

CMDSCOPE

This parameter specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this is the same as entering the command on every queue manager in the queue sharing group.

TYPE

The type of thread to display. This parameter is optional.

ACTIVE

Display only active threads.

An active thread is one for which a unit of recovery has started but not completed. Resources are held in IBM MQ on its behalf.

This is the default if **TYPE** is omitted.

INDOUBT

Display only in-doubt threads.

An in-doubt thread is one that is in the second phase of the two-phase commit operation.

Resources are held in IBM MQ on its behalf. External intervention is needed to resolve the status of in-doubt threads. You might only have to start the recovery coordinator (CICS, IMS, or RRS), or you might need to do more. They might have been in doubt at the last restart, or they might have become in doubt since the last restart.

REGIONS

Display a summary of active threads for each active connection.

Note: Threads used internally by IBM MQ are excluded.

*

Display both active and in-doubt threads, but not regions.

If, during command processing, an active thread becomes in doubt, it might appear twice: once as active and once as in doubt.

QMNAME

Specifies that IBM MQ should check whether the designated queue manager is INACTIVE, and if so, report any shared units of work that were in progress on the designated and inactive queue manager.

This option is valid only for **TYPE (INDOUBT)**.

 For more information about the **DISPLAY THREAD** command and in-doubt recovery, see [Recovering units of recovery on another queue manager in the queue sharing group](#). Also, see messages CSQV401I through CSQV406I, and CSQV432I, in [Agent services messages \(CSQV...\)](#).

“DISPLAY CONN (display application connection information)” on page 819

Use the MQSC command **DISPLAY CONN** to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

DISPLAY TOPIC (display topic information)

Use the MQSC command **DISPLAY TOPIC** to display the attributes of one or more IBM MQ topic objects of any type.

Using MQSC commands

For information on how you use MQSC commands, see [Administering IBM MQ using MQSC commands](#).

 You can issue this command from sources 2CR. For an explanation of the source symbols, see [Sources from which you can issue MQSC and PCF commands on IBM MQ for z/OS](#).

- [“Syntax diagram for DISPLAY TOPIC” on page 959](#)
- [“Usage notes for DISPLAY TOPIC” on page 962](#)
- [“Parameter descriptions for DISPLAY TOPIC” on page 962](#)
- [“Requested parameters” on page 965](#)

Syntax diagram for DISPLAY TOPIC

Synonym: DIS TOPIC

DISPLAY TOPIC

Requested attrs

Notes:

¹ Valid only on z/OS when the queue manager is a member of a queue sharing group.

² Valid only on z/OS.

³ Not valid on z/OS.

Usage notes for DISPLAY TOPIC

1.  On z/OS, the channel initiator must be running before you can display information about cluster topics, using **TYPE (CLUSTER)** or the **CLUSINFO** parameter.
2. The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.

 On z/OS, these non-printable characters are displayed as blanks.

 On [Multiplatforms](#) using the runmqsc command, these non-printable characters are displayed as dots

3. You can use the following command (or synonym) as an alternative way to display these attributes.

```
DISPLAY TCLUSTER
```

This command produces the same output as the following command:

```
DISPLAY TOPIC TYPE(CLUSTER)
```

If you enter the command in this way, do not use the **TYPE** parameter.

Parameter descriptions for DISPLAY TOPIC

You must specify the name of the topic definition you want to display. This name can be a specific topic name or a generic topic name. By using a generic topic name, you can display either:

- All topic definitions
- One or more topic definitions that match the specified name

(generic-topic-name)

The name of the administrative topic definition to be displayed (see [Rules for naming IBM MQ objects](#)). A trailing asterisk (*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (*) on its own specifies all administrative topic objects.

WHERE

Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Almost any parameter that can be used to display attributes for this **DISPLAY** command. However, you cannot use the **CMDSCOPE**, or **QSGDISP** parameters as filter keywords.

operator

This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *filter-value*

NL

Does not match a generic string that you provide as a *filter-value*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string (such as the character string you supply for the **DESCR** parameter) with an asterisk at the end, for example ABC*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

Note:  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

ALL

Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

 CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

CMDSCOPE must be blank, or the local queue manager, if **QSGDISP** is set to GROUP.

..

The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name

The command runs on the queue manager you specify, providing the queue manager is active within the queue sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue sharing group environment and if the command server is enabled.

*

The command runs on the local queue manager and is also passed to every active queue manager in the queue sharing group. The effect of this process is the same as entering the command on every queue manager in the queue sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

 QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

LIVE

LIVE is the default value and displays information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

ALL

Display information for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**.

If there is a shared queue manager environment, and the command is being processed on the queue manager where it was issued, this option also displays information for objects defined with **QSGDISP(GROUP)**.

If **QSGDISP(ALL)** is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY TOPIC(name) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching name in the queue sharing group without duplicating those objects in the shared repository.

COPY

Display information only for objects defined with **QSGDISP(COPY)**.

GROUP

Display information only for objects defined with **QSGDISP(GROUP)**. This is allowed only if there is a shared queue manager environment.

PRIVATE

Display information only for objects defined with **QSGDISP(QMGR)** or **QSGDISP(COPY)**. **QSGDISP(PRIVATE)** displays the same information as **QSGDISP(LIVE)**.

QMGR

Display information only for objects defined with **QSGDISP(QMGR)**.

QSGDISP

QSGDISP displays one of the following values:

QMGR

The object was defined with **QSGDISP(QMGR)**.

GROUP

The object was defined with **QSGDISP(GROUP)**.

COPY

The object was defined with **QSGDISP(COPY)**.

You cannot use **QSGDISP** as a filter keyword.

CLUSINFO

Requests that, in addition to information about attributes of topics defined on this queue manager, information about these and other topics in the cluster, that match the selection criteria, is displayed. In this case, there might be multiple topics with the same topic string displayed. The cluster information is obtained from the repository on this queue manager.

▶ **z/OS** On z/OS, the channel initiator must be running before you can use the **CLUSINFO** parameter to display information about cluster topics.

CLUSTER

Limits the information displayed to topics with the specified cluster name if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the topics displayed.

▶ **z/OS** On z/OS, the channel initiator must be running before you can use the **CLUSINFO** parameter to display information about cluster topics.

TYPE

Specifies the type of topics that you want to be displayed. Values are:

ALL

Display all topic types, including cluster topics if you also specify **CLUSINFO**.

LOCAL

Display locally defined topics.

CLUSTER

Display topics that are defined in publish/subscribe clusters. Cluster attributes include:

CLUSDATE

The date on which the definition became available to the local queue manager, in the form *yyyy-mm-dd*.

CLUSQMGR

The name of the queue manager hosting the topic.

CLUSTIME

The time at which the definition became available to the local queue manager, in the form *hh.mm.ss*.

QMID

The internally generated, unique name of the queue manager hosting the topic.

Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most of the parameters are relevant for both types of topics, but parameters that are not relevant for a particular type of topic cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of topic. There is a brief description of each parameter after the table, but for more information, see [“DEFINE TOPIC \(define a new administrative topic\)”](#) on page 675.

WILDCARD	✓	✓

ALTDATE

The date on which the definition or information was last altered, in the form *yyyy-mm-dd*.

ALTTIME

The time at which the definition or information was last altered, in the form *hh.mm.ss*.

CAEXPRY

The maximum time, expressed in tenths of a second, which a message put on an object handle, opened using this object on the resolution path, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see **CAEXPRY: Limit message expiry time**.

integer

The value must be in the range one through to 999 999 999.

NOLIMIT

There is no limit on the expiry time of messages put to this topic.

ASPARENT

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

CLRROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

CLSTATE

The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

ACTIVE

The cluster topic is correctly configured and being adhered to by this queue manager.

PENDING

Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

INVALID

This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

ERROR

An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See [Routing for publish/subscribe clusters: Notes on behavior](#).

CLUSDATE

The date on which the information became available to the local queue manager, in the form *yyyy-mm-dd*.

CLUSQMGR

The name of the queue manager that hosts the topic.

CLUSTER

The name of the cluster that the topic is in.

CLUSTIME

The time at which the information became available to the local queue manager, in the form *hh.mm.ss*.

COMMINFO

The communication information object name.

CUSTOM

This attribute contains name-value pairs that have the form **NAME (VALUE)**. The value is a list of zero or more properties-value pairs, in MQSC-style syntax, separated by at least one space. Attribute names beginning with **IBM**, **AMQ**, **CSQ**, or **MQ** are reserved for IBM use only. The additional reserved attributes are **CAPEXPRT**, **SQGETTMR**, and **PAGEVAL**.

DEFPRTY

Default priority of the messages published to this topic.

DEFPSIST

Default persistence of messages published to this topic.

DEFPRESP

Default put response for this topic. This attribute defines the behavior that must be used by applications when the put response type in the MQPMO options has been set to **MQPMO_RESPONSE_AS_TOPIC_DEF**.

DESCR

Description of this administrative topic object.

DURSUB

Determines whether the topic permits durable subscriptions to be made.

MCAST

Specifies whether the topic is enabled for multicast.

MDURMDL

The name of the model queue for durable managed subscriptions.

MNDURMDL

The name of the model queue for non-durable managed subscriptions.

NPMSGDLV

The delivery mechanism for non-persistent messages.

 OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**.

Can be one of the following values:

ASPARENT

The default for everything other than SYSTEM.BASE.TOPIC, delegate to the parent topic's configuration.

QMGR

The value of **OTELPCTL** on the queue manager is used. This is the default for SYSTEM.BASE.TOPIC.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation. If the queue manager is in a queue sharing group, this value can only be set if all queue managers have been started at IBM MQ 9.4.5 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

 OTELTRAC

Whether the queue manager emits spans as messages are published to this topic.

Can be one of the following values:

ASPARENT

The default for everything other than SYSTEM.BASE.TOPIC, delegate to the parent topic's configuration.

QMGR

The value of **OTELTRAC** on the queue manager is used. This is the default for SYSTEM.BASE.TOPIC.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PMSGDLV

The delivery mechanism for persistent messages.

PROXYSUB

Determines whether a proxy subscription is forced for this subscription, even if no local subscriptions exist.

PUB

Determines whether the topic is enabled for publication.

PUBSCOPE

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

QMID

The internally generated unique name of the queue manager that hosts the topic.

SUB

Determines whether the topic is enabled for subscription.

SUBSCOPE

Determines whether this queue manager propagates subscriptions to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

TOPICSTR

The topic string.

TYPE

Specifies whether this object is a local topic or cluster topic.

USEDLQ

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

WILDCARD

The behavior of wildcard subscriptions with respect to this topic.

For more information on these parameters, except the **CLSTATE** parameter, see [“DEFINE TOPIC \(define a new administrative topic\)”](#) on page 675.

- [“Topic status parameters”](#) on page 973
- [“Sub status parameters”](#) on page 976
- [“Pub status parameters”](#) on page 977

Syntax diagram for DISPLAY TPSTATUS

Synonym: DIS TPS

DISPLAY TPSTATUS

Topic status

Sub status

Usage notes for DISPLAY TPSTATUS

1. The **TOPICSTR** parameter might contain characters that cannot be translated into printable characters when the command output is displayed.
 - ▶ **Multi** On Multiplatforms using the **runmqsc** command, these non-printable characters are displayed as dots.
 - ▶ **z/OS** On z/OS, these non-printable characters are displayed as blanks.
2. The topic-string input parameter on this command must match the topic you want to act on. Keep the character strings in your topic strings as characters that can be used from the location issuing the command. If you issue commands using MQSC, you have fewer characters available to you than if you are using an application that submits PCF messages, such as the IBM MQ Explorer.

Parameter descriptions for DISPLAY TPSTATUS

The **DISPLAY TPSTATUS** command requires a topic string value to determine which topic nodes the command returns.

topicstr)

The value of the topic string for which you want to display status information. You cannot specify the name of an IBM MQ topic object.

The topic string can have one of the following values:

- A specific topic string value. For example, `DIS TPS('Sports/Football')` returns just the 'Sports/Football' node.
- A topic string containing a "+" wildcard character. For example, `DIS TPS('Sports/Football/+')` returns all direct child nodes of the 'Sports/Football' node.
- A topic string containing a "#" wildcard character. For example, `DIS TPS('Sports/Football/#')` returns the 'Sports/Football' node and all its descendant nodes.
- A topic string containing more than one wildcard. For example, `DIS TPS('Sports/+Teams/#')` returns any direct child node of 'Sports' that also has a 'teams' child, with all descendants of the latter nodes.

The **DISPLAY TPSTATUS** command does not support the '*' wildcard. For more information about using wildcards, see the related topic.

- To return a list of all root-level topics, use `DIS TPS('')`
- To return a list of all topics in the topic tree, use `DIS TPS('#')`, but note that this command might return a large amount of data.
- To filter the list of topics returned, use the **WHERE** parameter. For example, `DIS TPS('Sports/Football/+') WHERE(TOPICSTR LK 'Sports/Football/L*')` returns all direct child nodes of the 'Sports/Football' node, that begin with the letter "L".

WHERE

Specifies a filter condition to display only those administrative topic definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

filter-keyword

Except for the **CMDSCOPE** parameter, any parameter that you can use with this **DISPLAY** command.

operator

Determines whether a topic string satisfies the filter value on the given filter keyword. The operators are:

LT

Less than

GT

Greater than

EQ

Equal to

NE

Not equal to

LE

Less than or equal to

GE

Greater than or equal to

LK

Matches a generic string that you provide as a *topicstr*

NL

Does not match a generic string that you provide as a *topicstr*

filter-value

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC*. If the operator is LK, the command lists all topic nodes that begin with the string (ABC in the example). If the operator is NL, the command lists all topic nodes that do not begin with the string.

You cannot use a generic *filter-value* for parameters with numeric values or with one of a set of values.

ALL

Use this parameter to display all attributes.

If this parameter is specified, any attributes that you request specifically have no effect; the command displays all attributes.

This parameter is the default parameter if you do not specify a generic name, and do not request any specific attributes.

 CMDSCOPE

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue sharing group.

..

The command runs on the queue manager on which it was entered. This value is the default value.

qmgr-name

The command runs on the named queue manager, if the queue manager is active within the queue sharing group.

You can specify a queue manager name other than the queue manager on which you enter the command, but only if you are using a queue sharing group environment and the command server is enabled.

*

The command runs on the local queue manager and on every active queue manager in the queue sharing group. The effect of this option is equivalent to entering the command on every queue manager in the queue sharing group.

TYPE**TOPIC**

The command displays status information relating to each topic node, which is the default if you do not provide a **TYPE** parameter.

PUB

The command displays status information relating to applications that have topic nodes open for publish.

SUB

The command displays status information relating to applications that subscribe to the topic node or nodes. The subscribers that the command returns are not necessarily the subscribers that would receive a message published to this topic node. The value of SelectionString or SubLevel determines which subscribers receive such messages.

Topic status parameters

Topic status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

Topic objects can be defined with attributes that have a value of ASPARENT. Topic status shows the resolved values that result in finding the setting of the closest parent administrative topic object in the topic tree, and so will never display a value of ASPARENT.

ADMIN

If the topic node is an admin-node, the command displays the associated topic object name containing the node configuration. If the field is not an admin-node the command displays a blank.

CAPEXPY(integer)

The maximum time, expressed in tenths of a second, which a message published to a topic, which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see [CAPEXPY: Limit message expiry time](#).

integer

The value must be in the range one through to 999 999 999.

NOLIMIT

There is no limit on the expiry time of messages put to this topic.

ASPARENT

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

CLROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

DIRECT

A publication on this topic string, originating from this queue manager, is sent direct to any queue manager in the cluster with a matching subscription.

TOPICHOST

A publication on this topic string, originating from this queue manager, is sent to one of the queue managers in the cluster that hosts a definition of the corresponding clustered topic object, and from there to any queue manager in the cluster with a matching subscription.

NONE

This topic node is not clustered.

CLUSTER

The name of the cluster to which this topic belongs.

..

This topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers.

COMMINFO

Displays the resolved value of the name of the communication information object to be used for this topic node.

DEFRESP

Displays the resolved default put response of messages published to the topic. The value can be SYNC or ASYNC.

DEFPTY

Displays the resolved default priority of messages published to the topic.

DEFPSIST

Displays the resolved default persistence for this topic string. The value can be YES or NO.

DURSUB

Displays the resolved value that shows whether applications can make durable subscriptions. The value can be YES or NO.

MCAST

Displays the resolved value that shows whether the topic could be transmittable via multicast or not. The value can be ENABLED, DISABLED, or ONLY.

MDURMDL

Displays the resolved value of the name of the model queue to be used for durable subscriptions.

MNDURMDL

Displays the resolved value of the name of the model queue used for non-durable subscriptions.

NPMMSGDLV

Displays the resolved value for the delivery mechanism for non-persistent messages published to this topic. The value can be ALL, ALLDUR, or ALLAVAIL.

OTELPCTL

Whether the queue manager automatically propagates trace context from the application environment to the message on **MQPUT**.

Can be one of the following values:

QMGR

The value of **OTELPCTL** on the queue manager is used.

MANUAL

Automatic propagation doesn't occur. If required, applications can manually propagate trace context properties.

AUTO

Automatic propagation occurs if the application is in an environment that supports automatic propagation. If the queue manager is in a queue sharing group, this value can only be set if all queue managers have been started at IBM MQ 9.4.5 or later. Otherwise, the command fails and messages CSQM532I and CSQM533I are issued in the queue manager job log, to identify the queue managers that do not support **OTELPCTL**.

For more information on automatic propagation, see [Trace propagation](#).

This parameter is valid only on z/OS.

OTELTRAC

Whether the queue manager emits spans as messages are published to this topic.

Can be one of the following values:

QMGR

The value of **OTELTRAC** on the queue manager is used.

OFF

Spans are not emitted even if messages have trace context.

ON

Spans are emitted if messages have trace context.

For more information on span emission, see [Span emission](#).

This parameter is valid only on z/OS.

PMSGDLV

Displays the resolved value for the delivery mechanism for persistent messages published to this topic. The value can be ALL, ALLDUR, or ALLAVAIL.

PUB

Displays the resolved value that shows whether publications are allowed for this topic. The values can be ENABLED or DISABLED.

PUBCOUNT

Displays the number of handles that are open for publish on this topic node.

PUBSCOPE

Determines whether this queue manager propagates publications, for this topic node, to other queue managers as part of a hierarchy or a cluster, or whether it restricts them to only subscriptions defined on the local queue manager. The value can be QMGR or ALL.

RETAINED

Displays whether there is a retained publication associated with this topic. The value can be YES or NO.

SUB

Displays the resolved value that shows whether subscriptions are allowed for this topic. The values can be ENABLED or DISABLED.

SUBCOUNT

Displays the number of subscribers to this topic node, including durable subscribers that are not currently connected.

SUBSCOPE

Determines whether this queue manager propagates subscriptions, for this topic node, to other queue managers as part of a cluster or hierarchy, or whether it restricts the subscriptions to only the local queue manager. The value can be QMGR or ALL.

USEDLQ

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue. The value can be YES or NO.

Sub status parameters

Sub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

ACTCONN

Detects local publications, returning the currently active ConnectionId (CONNID) that opened this subscription.

DURABLE

Indicates whether a durable subscription is not deleted when the creating application closes its subscription handle, and persists over queue manager restart. The value can be YES or NO.

LMSGDATE

The date on which an MQPUT call last sent a message to this subscription. The MQPUT call updates the date field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

LMSGTIME

The time at which an MQPUT call last sent a message to this subscription. The MQPUT call updates the time field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

MASTREL

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, use the **COMMEV** parameter of the COMMINFO objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMMSGs

Number of messages put to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

RESMDATE

Date of the most recent MQSUB call that connected to this subscription.

RESMTIME

Time of the most recent MQSUB call that connected to this subscription.

SUBID

An all time unique identifier for this subscription, assigned by the queue manager. The format of **SUBID** matches that of a CorrelId. For durable subscriptions, the command returns the **SUBID** even if the subscriber is not currently connected to the queue manager.

SUBTYPE

The type of subscription, indicating how it was created. The value can be ADMIN, API, or PROXY.

SUBUSER

The user ID that owns this subscription, which can be either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription.

Pub status parameters

Pub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

ACTCONN

The currently active ConnectionId (**CONNID**) associated with the handle that has this topic node open for publish.

LPUBDATE

The date on which this publisher last sent a message.

LPUBTIME

The time at which this publisher last sent a message.

MCASTREL

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues you can enable event message generation, using the **COMMEV** parameter of the **COMMINFO** objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

NUMPUBS

Number of publishes by this publisher. This value records the actual number of publishes, not the total number of messages published to all subscribers.
