If the programming language supports bit operations, perform the following steps:

1. Select one of the following values, according to the type of report to be checked:

- MQRO_COA_WITH_FULL_DATA for COA report
- MQRO_COD_WITH_FULL_DATA for COD report
- MQRO_EXCEPTION_WITH_FULL_DATA for exception report
- MQRO_EXPIRATION_WITH_FULL_DATA for expiration report

Call the value A.

On z/OS, use the MQRO_*_WITH_DATA values instead of the MQRO_*_WITH_FULL_DATA values.

2. Combine the *Report* field with A using the bitwise AND operation; call the result B.
3. Test B for equality with each value that is possible for that type of report.

For example, if A is MQRO_EXCEPTION_WITH_FULL_DATA, test B for equality with each of the following to determine what was specified by the sender of the message:

- MQRO_NONE
- MQRO_EXCEPTION
- MQRO_EXCEPTION_WITH_DATA
- MQRO_EXCEPTION_WITH_FULL_DATA

The tests can be performed in whatever order is most convenient for the application logic.

Use a similar method to test for the MQRO_PASS_MSG_ID or MQRO_PASS_CORREL_ID options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously.

Using arithmetic

If the programming language *does not* support bit operations, perform the following steps using integer arithmetic:

1. Select one of the following values, according to the type of report to be checked:

- MQRO_COA for COA report
- MQRO_COD for COD report
- MQRO_EXCEPTION for exception report
- MQRO_EXPIRATION for expiration report

Call the value A.

2. Divide the *Report* field by A ; call the result B.
3. Divide B by 8 ; call the result C.
4. Multiply C by 8 and subtract from B ; call the result D.
5. Multiply D by A ; call the result E.
6. Test E for equality with each value that is possible for that type of report.

For example, if A is MQRO_EXCEPTION, test E for equality with each of the following to determine what was specified by the sender of the message:

- MQRO_NONE
- MQRO_EXCEPTION
- MQRO_EXCEPTION_WITH_DATA
- MQRO_EXCEPTION_WITH_FULL_DATA

The tests can be performed in whatever order is most convenient for the application logic.

The following pseudocode illustrates this technique for exception report messages:

```
A = MQRO_EXCEPTION
B = Report/A
C = B/8
D = B - C*8
E = D*A
```

Use a similar method to test for the MQRO_PASS_MSG_ID or MQRO_PASS_CORREL_ID options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously, but replacing the value 8 in the previous steps by the value 2.

Structure of the message-flags field

This information describes the structure of the message-flags field.

The *MsgFlags* field is a 32-bit integer that is divided into three separate subfields. These subfields identify:

- Message flags that are rejected if the local queue manager does not recognize them
- Message flags that are always accepted, even if the local queue manager does not recognize them
- Message flags that are accepted only if certain other conditions are satisfied

Note: All subfields in *MsgFlags* are reserved for use by the queue manager.

Each subfield is identified by a bit mask that has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

MQMF_REJECT_UNSUP_MASK

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager cause the MQPUT or MQPUT1 call to fail with completion code MQCC_FAILED and reason code MQRC_MSG_FLAGS_ERROR.

This subfield occupies bit positions 20 through 31.

The following message flags are included in this subfield:

- MQMF_LAST_MSG_IN_GROUP
- MQMF_LAST_SEGMENT
- MQMF_MSG_IN_GROUP
- MQMF_SEGMENT
- MQMF_SEGMENTATION_ALLOWED
- MQMF_SEGMENTATION_INHIBITED

MQMF_ACCEPT_UNSUP_MASK

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls. The completion code is MQCC_OK.

This subfield occupies bit positions 0 through 11.

MQMF_ACCEPT_UNSUP_IF_XMIT_MASK

This mask identifies the bit positions within the *MsgFlags* field where message flags that are not supported by the local queue manager are nevertheless accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ObjectQMGrName* and *ObjectName* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code MQCC_OK is returned if these conditions are satisfied, and MQCC_FAILED with reason code MQRC_MSG_FLAGS_ERROR if not.

This subfield occupies bit positions 12 through 19.

If there are flags specified in the *MsgFlags* field that the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MsgFlags* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

Data-conversion exit

This collection of topics describes the interface to the data-conversion exit, and the processing performed by the queue manager when data conversion is required.

For more information about data conversion, see *Data Conversion under IBM MQ* at <https://www.ibm.com/support/docview.wss?uid=swg27005729>.

The data-conversion exit is invoked as part of the processing of the MQGET call in order to convert the application message data to the representation required by the receiving application. Conversion of the application message data is optional; it requires the MQGMO_CONVERT option to be specified on the MQGET call.

The following subjects are described:

- The processing performed by the queue manager in response to the MQGMO_CONVERT option; see [“Conversion processing” on page 870](#).
- Processing conventions used by the queue manager when processing a built-in format; these conventions are recommended for user-written exits too. See [“Processing conventions” on page 872](#).
- Special considerations for converting report messages; see [“Conversion of report messages” on page 876](#).
- The parameters passed to the data-conversion exit; see [“MQ_DATA_CONV_EXIT - Data conversion exit” on page 888](#).
- A call that can be used from the exit to convert character data between different representations; see [“MQXCNV - Convert characters” on page 882](#).
- The data-structure parameter that is specific to the exit; see [“MQDXP - Data-conversion exit parameter” on page 876](#).

Conversion processing

This information describes the processing performed by the queue manager in response to the MQGMO_CONVERT option.

The queue manager performs the following actions if the MQGMO_CONVERT option is specified on the MQGET call, and there is a message to be returned to the application:

1. If one or more of the following is true, no conversion is necessary:
 - The message data is already in the character set and encoding required by the application issuing the MQGET call. The application must set the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter of the MQGET call to the values required, before issuing the call.

- The length of the message data is zero.
- The length of the *Buffer* parameter of the MQGET call is zero.

In these cases the message is returned without conversion to the application issuing the MQGET call; the *CodedCharSetId* and *Encoding* values in the *MsgDesc* parameter are set to the values in the control information in the message, and the call completes with one of the following combinations of completion code and reason code:

Completion code	Reason code
MQCC_OK	MQRC_NONE
MQCC_WARNING	MQRC_TRUNCATED_MSG_ACCEPTED
MQCC_WARNING	MQRC_TRUNCATED_MSG_FAILED

The following steps are performed only if the character set or encoding of the message data differs from the corresponding value in the *MsgDesc* parameter, and there is data to be converted:

2. If the *Format* field in the control information in the message has the value MQFMT_NONE, the message is returned unconverted, with completion code MQCC_WARNING and reason code MQRC_FORMAT_ERROR.

In all other cases conversion processing continues.

3. The message is removed from the queue and placed in a temporary buffer that is the same size as the *Buffer* parameter. For browse operations, the message is copied into the temporary buffer, instead of being removed from the queue.
4. If the message has to be truncated to fit in the buffer, the following is done:
 - If the MQGMO_ACCEPT_TRUNCATED_MSG option was *not* specified, the message is returned unconverted, with completion code MQCC_WARNING and reason code MQRC_TRUNCATED_MSG_FAILED.
 - If the MQGMO_ACCEPT_TRUNCATED_MSG option was specified, the completion code is set to MQCC_WARNING, the reason code is set to MQRC_TRUNCATED_MSG_ACCEPTED, and conversion processing continues.
5. If the message can be accommodated in the buffer without truncation, or the MQGMO_ACCEPT_TRUNCATED_MSG option was specified, the following is done:
 - If the format is a built-in format, the buffer is passed to the queue-manager's data-conversion service.
 - If the format is not a built-in format, the buffer is passed to a user-written exit with the same name as the format. If the exit cannot be found, the message is returned unconverted, with completion code MQCC_WARNING and reason code MQRC_FORMAT_ERROR.

If no error occurs, the output from the data-conversion service or from the user-written exit is the converted message, plus the completion code and reason code to be returned to the application issuing the MQGET call.

6. If the conversion is successful, the queue manager returns the converted message to the application. In this case, the completion code and reason code returned by the MQGET call are one of the following combinations:

Completion code	Reason code
MQCC_OK	MQRC_NONE
MQCC_WARNING	MQRC_TRUNCATED_MSG_ACCEPTED

However, if the conversion is performed by a user-written exit, other reason codes can be returned, even when the conversion is successful.

If the conversion fails, the queue manager returns the unconverted message to the application, with the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter set to the values in the control information in the message, and with completion code MQCC_WARNING.

Processing conventions

When converting a built-in format, the queue manager follows the processing conventions described.

User-written exits should also follow these conventions, although this is not enforced by the queue manager. The built-in formats converted by the queue manager are:

- MQFMT_ADMIN
- MQFMT_CICS (z/OS only)
- MQFMT_COMMAND_1
- MQFMT_COMMAND_2
- MQFMT_DEAD_LETTER_HEADER
- MQFMT_DIST_HEADER
- MQFMT_EVENT version 1
- MQFMT_EVENT version 2
- MQFMT_IMS
- MQFMT_IMS_VAR_STRING
- MQFMT_MD_EXTENSION
- MQFMT_PCF
- MQFMT_REF_MSG_HEADER
- MQFMT_RF_HEADER
- MQFMT_RF_HEADER_2
- MQFMT_STRING
- MQFMT_TRIGGER
- MQFMT_WORK_INFO_HEADER (z/OS only)
- MQFMT_XMIT_Q_HEADER

1. If the message expands during conversion, and exceeds the size of the *Buffer* parameter, the following is done:

- If the MQGMO_ACCEPT_TRUNCATED_MSG option was *not* specified, the message is returned unconverted, with completion code MQCC_WARNING and reason code MQRC_CONVERTED_MSG_TOO_BIG.
- If the MQGMO_ACCEPT_TRUNCATED_MSG option *was* specified, the message is truncated, the completion code is set to MQCC_WARNING, the reason code is set to MQRC_TRUNCATED_MSG_ACCEPTED, and conversion processing continues.

2. If truncation occurs (either before or during conversion), the number of valid bytes returned in the *Buffer* parameter can be *less than* the length of the buffer.

This can occur, for example, if a 4-byte integer or a DBCS character straddles the end of the buffer. The incomplete element of information is not converted, and those bytes in the returned message do not contain valid information. This can also occur if a message that was truncated before conversion shrinks during conversion.

If the number of valid bytes returned is less than the length of the buffer, the unused bytes at the end of the buffer are set to nulls.

3. If an array or string straddles the end of the buffer, as much of the data as possible is converted; only the particular array element or DBCS character which is incomplete is not converted; preceding array elements or characters are converted.

4. If truncation occurs (either before or during conversion), the length returned for the *DataLength* parameter is the length of the *unconverted* message before truncation.
 5. When strings are converted between single-byte character sets (SBCS), double-byte character sets (DBCS), or multi-byte character sets (MBCS), the strings can expand or contract.
 - In the PCF formats MQFMT_ADMIN, MQFMT_EVENT, and MQFMT_PCF, the strings in the MQCFST and MQCFSL structures expand or contract as necessary to accommodate the string after conversion.

For the string-list structure MQCFSL, the strings in the list might expand or contract by different amounts. If this happens, the queue manager pads the shorter strings with blanks to make them the same length as the longest string after conversion.

 - In the format MQFMT_REF_MSG_HEADER, the strings addressed by the *SrcEnvOffset*, *SrcNameOffset*, *DestEnvOffset*, and *DestNameOffset* fields expand or contract as necessary to accommodate the strings after conversion.
 - In the format MQFMT_RF_HEADER, the *NameValueString* field expands or contracts as necessary to accommodate the name/value pairs after conversion.
 - In structures with fixed field sizes, the queue manager allows strings to expand or contract within their fixed fields, provided that no significant information is lost. In this regard, trailing blanks and characters following the first null character in the field are treated as insignificant.
 - If the string expands, but only insignificant characters need to be discarded to accommodate the converted string in the field, the conversion succeeds and the call completes with MQCC_OK and reason code MQRC_NONE (assuming no other errors).
 - If the string expands, but the converted string requires significant characters to be discarded in order to fit in the field, the message is returned unconverted and the call completes with MQCC_WARNING and reason code MQRC_CONVERTED_STRING_TOO_BIG.

Note: Reason code MQRC_CONVERTED_STRING_TOO_BIG results in this case whether or not the MQGMO_ACCEPT_TRUNCATED_MSG option was specified.

 - If the string contracts, the queue manager pads the string with blanks to the length of the field.
 6. For messages consisting of one or more MQ header structures followed by user data, one or more of the header structures might be converted, while the remainder of the message is not. However, (with two exceptions) the *CodedCharSetId* and *Encoding* fields in each header structure always correctly indicate the character set and encoding of the data that follows the header structure.
- The two exceptions are the MQCIH and MQIIH structures, where the values in the *CodedCharSetId* and *Encoding* fields in those structures are not significant. For those structures, the data following the structure is in the same character set and encoding as the MQCIH or MQIIH structure itself.
7. If the *CodedCharSetId* or *Encoding* fields in the control information of the message being retrieved, or in the *MsgDesc* parameter, specify values that are undefined or not supported, the queue manager might ignore the error if the undefined or unsupported value does not need to be used in converting the message.
- For example, if the *Encoding* field in the message specifies an unsupported float encoding, but the message contains only integer data, or contains floating-point data that does not require conversion (because the source and target float encodings are identical), the error might not be diagnosed.
- If the error is diagnosed, the message is returned unconverted, with completion code MQCC_WARNING and one of the MQRC_SOURCE_*_ERROR or MQRC_TARGET_*_ERROR reason codes (as appropriate); the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to the values in the control information in the message.
- If the error is not diagnosed and the conversion completes successfully, the values returned in the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are those specified by the application issuing the MQGET call.
8. In all cases, if the message is returned to the application unconverted the completion code is set to MQCC_WARNING, and the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter are set to the values appropriate to the unconverted data. This is done for MQFMT_NONE also.

The *Reason* parameter is set to a code that indicates why the conversion could not be carried out, unless the message also had to be truncated; reason codes related to truncation take precedence over reason codes related to conversion. (To determine if a truncated message was converted, check the values returned in the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter.)

When an error is diagnosed, either a specific reason code is returned, or the general reason code MQRC_NOT_CONVERTED. The reason code returned depends on the diagnostic capabilities of the underlying data-conversion service.

9. If completion code MQCC_WARNING is returned, and more than one reason code is relevant, the order of precedence is as follows:
 - a. The following reasons take precedence over all others; only one of the reasons in this group can arise:
 - MQRC_SIGNAL_REQUEST_ACCEPTED
 - MQRC_TRUNCATED_MSG_ACCEPTED
 - b. The order of precedence within the remaining reason codes is not defined.

10. On completion of the MQGET call:

- The following reason code indicates that the message was converted successfully:
 - MQRC_NONE
- The following reason codes indicate that the message *might* have been converted successfully (check the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter to find out):
 - MQRC_MSG_MARKED_BROWSE_CO_OP
 - MQRC_TRUNCATED_MSG_ACCEPTED
- All other reason codes indicate that the message was not converted.

The following processing is specific to the built-in formats; it does not apply to user-defined formats:

11. With the exception of the following formats:

- MQFMT_ADMIN
- MQFMT_COMMAND_1
- MQFMT_COMMAND_2
- MQFMT_EVENT
- MQFMT_IMS_VAR_STRING
- MQFMT_PCF
- MQFMT_STRING

none of the built-in formats can be converted from or to character sets that do not have SBCS characters for the characters that are valid in queue names. If an attempt is made to perform such a conversion, the message is returned unconverted, with completion code MQCC_WARNING and reason code MQRC_SOURCE_CCSID_ERROR or MQRC_TARGET_CCSID_ERROR, as appropriate.

The Unicode character set UCS-2 is an example of a character set that does not have SBCS characters for the characters that are valid in queue names.

12. If the message data for a built-in format is truncated, fields within the message that contain lengths of strings, or counts of elements or structures, are *not* adjusted to reflect the length of the data actually returned to the application; the values returned for such fields within the message data are the values applicable to the message *before truncation*.

When processing messages such as a truncated MQFMT_ADMIN message, ensure that the application does not attempt to access data beyond the end of the data returned.

13. If the format name is MQFMT_DEAD_LETTER_HEADER, the message data begins with an MQDLH structure, possibly followed by zero or more bytes of application message data. The format, character set, and encoding of the application message data are defined by the *Format*, *CodedCharSetId*, and *Encoding* fields in the MQDLH structure at the start of the message. Because the MQDLH

structure and application message data can have different character sets and encodings, one, other, or both of the MQDLH structure and application message data might require conversion.

The queue manager converts the MQDLH structure first, as necessary. If conversion is successful, or the MQDLH structure does not require conversion, the queue manager checks the *CodedCharSetId* and *Encoding* fields in the MQDLH structure to see if conversion of the application message data is required. If conversion is required, the queue manager invokes the user-written exit with the name given by the *Format* field in the MQDLH structure, or performs the conversion itself (if *Format* is the name of a built-in format).

If the MQGET call returns a completion code of MQCC_WARNING, and the reason code is one of those indicating that conversion was not successful, one of the following applies:

- The MQDLH structure could not be converted. In this case the application message data will not have been converted either.
- The MQDLH structure was converted, but the application message data was not.

The application can examine the values returned in the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter, and those in the MQDLH structure, in order to determine which of the previously applies.

14. If the format name is MQFMT_XMIT_Q_HEADER, the message data begins with an MQXQH structure, possibly followed by zero or more bytes of additional data. This additional data is usually the application message data (which may be of zero length), but there can also be one or more further MQ header structures present, at the start of the additional data.

The MQXQH structure must be in the character set and encoding of the queue manager. The format, character set, and encoding of the data following the MQXQH structure are given by the *Format*, *CodedCharSetId*, and *Encoding* fields in the MQMD structure contained *within* the MQXQH. For each subsequent MQ header structure present, the *Format*, *CodedCharSetId*, and *Encoding* fields in the structure describe the data that follows that structure; that data is either another MQ header structure, or the application message data.

If the MQGMO_CONVERT option is specified for an MQFMT_XMIT_Q_HEADER message, the application message data and certain of the MQ header structures are converted, *but the data in the MQXQH structure is not*. On return from the MQGET call, therefore:

- The values of the *Format*, *CodedCharSetId*, and *Encoding* fields in the *MsgDesc* parameter describe the data in the MQXQH structure, and *not* the application message data; the values are therefore *not* the same as those specified by the application that issued the MQGET call.

The effect of this is that an application that repeatedly gets messages from a transmission queue with the MQGMO_CONVERT option specified must reset the *CodedCharSetId* and *Encoding* fields in the *MsgDesc* parameter to the values required for the application message data, before each MQGET call.

- The values of the *Format*, *CodedCharSetId*, and *Encoding* fields in the last MQ header structure present describe the application message data. If there are no other MQ header structures present, the application message data is described by these fields in the MQMD structure within the MQXQH structure. If conversion is successful, the values will be the same as those specified in the *MsgDesc* parameter by the application that issued the MQGET call.

If the message is a distribution-list message, the MQXQH structure is followed by an MQDH structure (plus its arrays of MQOR and MQPMR records), which in turn might be followed by zero or more further MQ header structures and zero or more bytes of application message data. Like the MQXQH structure, the MQDH structure must be in the character set and encoding of the queue manager, and it is not converted on the MQGET call, even if the MQGMO_CONVERT option is specified.

The processing of the MQXQH and MQDH structures described previously is primarily intended for use by message channel agents when they get messages from transmission queues.

Conversion of report messages

In general a report message can contain varying amounts of application message data, according to the report options specified by the sender of the original message. However, an activity report can contain data but without the report option mentioning `*_WITH_DATA` in the constant.

In particular, a report message can contain either:

1. No application message data

2. Some of the application message data from the original message

This occurs when the sender of the original message specifies `MQRO_*_WITH_DATA` and the message is longer than 100 bytes.

3. All the application message data from the original message

This occurs when the sender of the original message specifies `MQRO_*_WITH_FULL_DATA`, or specifies `MQRO_*_WITH_DATA` and the message is 100 bytes or shorter.

When the queue manager or message channel agent generates a report message, it copies the format name from the original message into the *Format* field in the control information in the report message. The format name in the report message might therefore imply a length of data that is different from the length actually present in the report message (cases 1 and 2 previously).

If the `MQGMO_CONVERT` option is specified when the report message is retrieved:

- For case 1 previously, the data-conversion exit is not invoked (because the report message has no data).
- For case 3 previously, the format name correctly implies the length of the message data.
- But for case 2 previously, the data-conversion exit is invoked to convert a message that is *shorter* than the length implied by the format name.

In addition, the reason code passed to the exit is usually `MQRC_NONE` (that is, the reason code does not indicate that the message has been truncated). This happens because the message data was truncated by the *sender* of the report message, and not by the receiver's queue manager in response to the `MQGET` call.

Because of these possibilities, the data-conversion exit must *not* use the format name to deduce the length of data passed to it; instead the exit must check the length of data provided, and be prepared to convert *less* data than the length implied by the format name. If the data can be converted successfully, completion code `MQCC_OK` and reason code `MQRC_NONE` must be returned by the exit. The length of the message data to be converted is passed to the exit as the *InBufferLength* parameter.

Product-sensitive programming interface

MQDXP - Data-conversion exit parameter

The `MQDXP` structure is a parameter that the queue manager passes to the data-conversion exit when the exit is invoked to convert the message data as part of the processing of the `MQGET` call. See the description of the `MQ_DATA_CONV_EXIT` call for details of the data conversion exit.

Character data in `MQDXP` is in the character set of the local queue manager; this is given by the *CodedCharSetId* queue-manager attribute. Numeric data in `MQDXP` is in the native machine encoding; this is given by `MQENC_NATIVE`.

Only the *DataLength*, *CompCode*, *Reason*, and *ExitResponse* fields in `MQDXP` can be changed by the exit; changes to other fields are ignored. However, the *DataLength* field *cannot* be changed if the message being converted is a segment that contains only part of a logical message.

When control returns to the queue manager from the exit, the queue manager checks the values returned in `MQDXP`. If the values returned are not valid, the queue manager continues processing as though the exit had returned `MQXDR_CONVERSION_FAILED` in *ExitResponse*; however, the queue manager ignores the values of the *CompCode* and *Reason* fields returned by the exit in this case, and uses instead

the values those fields had on *input* to the exit. The following values in MQDXP cause this processing to occur:

- *ExitResponse* field not MQXDR_OK and not MQXDR_CONVERSION_FAILED
- *CompCode* field not MQCC_OK and not MQCC_WARNING
- *DataLength* field less than zero, or *DataLength* field changed when the message being converted is a segment that contains only part of a logical message.

The following table summarizes the fields in the structure.

Table 567. Fields in MQDXP		
Field	Description	Topic
<i>StrucId</i>	Structure identifier	StrucId
<i>Version</i>	Structure version number	Version
<i>AppOptions</i>	Application options	AppOptions
<i>Encoding</i>	Numeric encoding required by application	Encoding
<i>CodedCharSetId</i>	Character set required by application	CodedCharSetId
<i>DataLength</i>	Length in bytes of message data	DataLength
<i>CompCode</i>	Completion code	CompCode
<i>Reason</i>	Reason code qualifying <i>CompCode</i>	Reason
<i>ExitResponse</i>	Response from exit	ExitResponse
<i>Hconn</i>	Connection handle	Hconn
<i>pEntryPoints</i>	Address of the MQIEP structure	pEntryPoints

Fields

The MQDXP structure contains the following fields; the fields are described in alphabetical order.

AppOptions

Type: MQLONG

This is a copy of the *Options* field of the MQGMO structure specified by the application issuing the MQGET call. The exit might need to examine these to ascertain whether the MQGMO_ACCEPT_TRUNCATED_MSG option was specified.

This is an input field to the exit.

CodedCharSetId

Type: MQLONG

This is the coded character-set identifier of the character set required by the application issuing the MQGET call; see the *CodedCharSetId* field in the MQMD structure for more details. If the application specifies the special value MQCCSI_Q_MGR on the MQGET call, the queue manager changes this to the actual character-set identifier of the character set used by the queue manager, before invoking the exit.

If the conversion is successful, the exit must copy this to the *CodedCharSetId* field in the message descriptor.

This is an input field to the exit.

CompCode

Type: MQLONG

When the exit is invoked, this contains the completion code that is returned to the application that issued the MQGET call, if the exit does nothing. It is always MQCC_WARNING, because either the message was truncated, or the message requires conversion and this has not yet been done.

On output from the exit, this field contains the completion code to be returned to the application in the *CompCode* parameter of the MQGET call; only MQCC_OK and MQCC_WARNING are valid. See the description of the *Reason* field for suggestions on how the exit can set this field on output.

This is an input/output field to the exit.

DataLength

Type: MQLONG

When the exit is invoked, this field contains the original length of the application message data. If the message was truncated to fit into the buffer provided by the application, the size of the message provided to the exit is *smaller* than the value of *DataLength*. The size of the message provided to the exit is always given by the *InBufferLength* parameter of the exit, irrespective of any truncation that has occurred.

Truncation is indicated by the *Reason* field having the value MQRC_TRUNCATED_MSG_ACCEPTED on input to the exit.

Most conversions do not need to change this length, but an exit can do so if necessary; the value set by the exit is returned to the application in the *DataLength* parameter of the MQGET call. However, this length *cannot* be changed if the message being converted is a segment that contains only part of a logical message. This is because changing the length would cause the offsets of later segments in the logical message to be incorrect.

Note that, if the exit wants to change the length of the data, be aware that the queue manager has already decided whether the message data fits into the application's buffer, based on the length of the *unconverted* data. This decision determines whether the message is removed from the queue (or the browse cursor moved, for a browse request), and is not affected by any change to the data length caused by the conversion. For this reason it is recommended that conversion exits do not cause a change in the length of the application message data.

If character conversion does imply a change of length, a string can be converted into another string with the same length in bytes, truncating trailing blanks, or padding with blanks as necessary.

The exit is not invoked if the message contains no application message data; hence *DataLength* is always greater than zero.

This is an input/output field to the exit.

Encoding

Type: MQLONG

Numeric encoding required by application.

This is the numeric encoding required by the application issuing the MQGET call; see the *Encoding* field in the MQMD structure for more details.

If the conversion is successful, the exit copies this to the *Encoding* field in the message descriptor.

This is an input field to the exit.

ExitOptions

Type: MQLONG

This is a reserved field; its value is 0.

ExitResponse

Type: MQLONG

Response from exit. This is set by the exit to indicate the success or otherwise of the conversion. It must be one of the following:

MQXDR_OK

Conversion was successful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *CompCode* field on output from the exit
- The value of the *Reason* field on output from the exit
- The value of the *DataLength* field on output from the exit
- The contents of the exit's output buffer *OutBuffer*. The number of bytes returned is the lesser of the exit's *OutBufferLength* parameter, and the value of the *DataLength* field on output from the exit.

If the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter are *both* unchanged, the queue manager returns:

- The value of the *Encoding* and *CodedCharSetId* fields in the MQDXP structure on *input* to the exit.

If one or both of the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter has been changed, the queue manager returns:

- The value of the *Encoding* and *CodedCharSetId* fields in the exit's message descriptor parameter on output from the exit

MQXDR_CONVERSION_FAILED

Conversion was unsuccessful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *CompCode* field on output from the exit
- The value of the *Reason* field on output from the exit
- The value of the *DataLength* field on *input* to the exit
- The contents of the exit's input buffer *InBuffer*. The number of bytes returned is given by the *InBufferLength* parameter

If the exit has altered *InBuffer*, the results are undefined.

ExitResponse is an output field from the exit.

Hconn

Type: MQHCONN

This is a connection handle which can be used on the MQXCNVC call. This handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

pEntryPoints

Type: PMQIEP

The address of an MQIEP structure through which MQI and DCI calls can be made.

Reason

Type: MQLONG

Reason code qualifying *CompCode*.

When the exit is invoked, this contains the reason code that is returned to the application that issued the MQGET call, if the exit chooses to do nothing. Among possible values are MQRC_TRUNCATED_MSG_ACCEPTED, indicating that the message was truncated in order fit into the buffer provided by the application, and MQRC_NOT_CONVERTED, indicating that the message requires conversion but that this has not yet been done.

On output from the exit, this field contains the reason to be returned to the application in the *Reason* parameter of the MQGET call; the following is recommended:

- If *Reason* had the value MQRC_TRUNCATED_MSG_ACCEPTED on input to the exit, the *Reason* and *CompCode* fields must not be altered, irrespective of whether the conversion succeeds or fails.

(If the *CompCode* field is not MQCC_OK, the application which retrieves the message can identify a conversion failure by comparing the returned *Encoding* and *CodedCharSetId* values in the message descriptor with the values requested; in contrast, the application cannot distinguish a truncated message from a message that fitted the buffer. For this reason, MQRC_TRUNCATED_MSG_ACCEPTED must be returned in preference to any of the reasons that indicate conversion failure.)

- If *Reason* had any other value on input to the exit:
 - If the conversion succeeds, *CompCode* must be set to MQCC_OK and *Reason* set to MQRC_NONE.
 - If the conversion fails, or the message expands and has to be truncated to fit in the buffer, *CompCode* must be set to MQCC_WARNING (or left unchanged), and *Reason* set to one of the values listed, to indicate the nature of the failure.

Note if the message after conversion is too large for the buffer, it must be truncated only if the application that issued the MQGET call specified the MQGMO_ACCEPT_TRUNCATED_MSG option:

- If it did specify that option, reason MQRC_TRUNCATED_MSG_ACCEPTED is returned.
- If it did not specify that option, the message is returned unconverted, with reason code MQRC_CONVERTED_MSG_TOO_BIG.

The reason codes listed are recommended for use by the exit to indicate the reason that conversion failed, but the exit can return other values from the set of MQRC_* codes if deemed appropriate. In addition, the range of values MQRC_APPL_FIRST through MQRC_APPL_LAST are allocated for use by the exit to indicate conditions that the exit wants to communicate to the application issuing the MQGET call.

Note: If the message cannot be converted successfully, the exit *must* return MQXDR_CONVERSION_FAILED in the *ExitResponse* field, in order to cause the queue manager to return the unconverted message. This is true regardless of the reason code returned in the *Reason* field.

MQRC_APPL_FIRST

(900, X'384') Lowest value for application-defined reason code.

MQRC_APPL_LAST

(999, X'3E7') Highest value for application-defined reason code.

MQRC_CONVERTED_MSG_TOO_BIG

(2120, X'848') Converted data too large for buffer.

MQRC_NOT_CONVERTED

(2119, X'847') Message data not converted.

MQRC_SOURCE_CCSID_ERROR

(2111, X'83F') Source coded character set identifier not valid.

MQRC_SOURCE_DECIMAL_ENC_ERROR

(2113, X'841') Packed-decimal encoding in message not recognized.

MQRC_SOURCE_FLOAT_ENC_ERROR

(2114, X'842') Floating-point encoding in message not recognized.

MQRC_SOURCE_INTEGER_ENC_ERROR

(2112, X'840') Source integer encoding not recognized.

MQRC_TARGET_CCSID_ERROR

(2115, X'843') Target coded character set identifier not valid.

MQRC_TARGET_DECIMAL_ENC_ERROR

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

MQRC_TARGET_FLOAT_ENC_ERROR

(2118, X'846') Floating-point encoding specified by receiver not recognized.

MQRC_TARGET_INTEGER_ENC_ERROR

(2116, X'844') Target integer encoding not recognized.

MQRC_TRUNCATED_MSG_ACCEPTED

(2079, X'81F') Truncated message returned (processing completed).

This is an input/output field to the exit.

StrucId

Type: MQCHAR4

Structure identifier. The value must be:

MQDXP_STRUC_ID

Identifier for data conversion exit parameter structure.

For the C programming language, the constant MQDXP_STRUC_ID_ARRAY is also defined; this has the same value as MQDXP_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the exit.

Version

Type: MQLONG

Structure version number. The value must be:

MQDXP_VERSION_1

Version number for data-conversion exit parameter structure.

The following constant specifies the version number of the current version:

MQDXP_CURRENT_VERSION

Current version of data-conversion exit parameter structure.

Note: When a new version of this structure is introduced, the layout of the existing part is not changed. The exit must therefore check that the *Version* field is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

C declaration

```
typedef struct tagMQDXP MQDXP;
struct tagMQDXP {
    MQCHAR4  StrucId;           /* Structure identifier */
    MQLONG   Version;          /* Structure version number */
    MQLONG   ExitOptions;      /* Reserved */
    MQLONG   AppOptions;       /* Application options */
    MQLONG   Encoding;         /* Numeric encoding required by
                               application */
    MQLONG   CodedCharSetId;    /* Character set required by application */
    MQLONG   DataLength;        /* Length in bytes of message data */
    MQLONG   CompCode;         /* Completion code */
    MQLONG   Reason;           /* Reason code qualifying CompCode */
    MQLONG   ExitResponse;      /* Response from exit */
    MQHCONN  Hconn;            /* Connection handle */
    PMQIEP   pEntryPoints;     /* Address of the MQIEP structure */
};
```

```

MQXCNVC - Convert characters

The MQXCNVC call converts characters from one character set to another using the C programming language.

This call is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

Note: The call can be used from both application, and data-conversion exit environments.

Syntax

MQXCNVC (*Hconn*, *Options*, *SourceCCSID*, *SourceLength*, *SourceBuffer*, *TargetCCSID*, *TargetLength*, *TargetBuffer*, *DataLength*, *CompCode*, *Reason*)

Parameters

Hconn

Type: MQHCONN - input

This handle represents the connection to the queue manager.

In a data-conversion exit, *Hconn* is normally the handle that is passed to the data-conversion exit in the *Hconn* field of the MQDXP structure; this handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

On IBM i, the following special value can be specified for *Hconn*:

MQHC_DEF_HCONN

Default connection handle.

If you run a CICS TS 3.2 or higher application, ensure that the character conversion exit program, which invokes the MQXCNVC call, is defined as OPENAPI. This definition prevents the 2018 MQRC_HCONN_ERROR error caused by from an incorrect connection, and allows the MQGET to complete.

Options

Type: MQLONG - input

Options that control the action of MQXCNCV.

Zero or more of the options described can be specified. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

Default-conversion option: The following option controls the use of default character conversion:

MQDCC_DEFAULT_CONVERSION

Default conversion.

This option specifies that default character conversion can be used if one or both of the character sets specified on the call is not supported. This allows the queue manager to use an installation-specified default character set that approximates the specified character set, when converting the string.

Note: The result of using an approximate character set to convert the string is that some characters can be converted incorrectly. This can be avoided by using in the string only characters which are common to both the specified character set and the default character set.

The default character sets are defined by a configuration option when the queue manager is installed or restarted.

If MQDCC_DEFAULT_CONVERSION is not specified, the queue manager uses only the specified character sets to convert the string, and the call fails if one or both of the character sets is not supported.

This option is supported in the following environments: AIX, HP-UX, IBM i, Solaris, Linux, Windows.

Padding option: The following option allows the queue manager to pad the converted string with blanks or discard insignificant trailing characters, in order to make the converted string fit the target buffer:

MQDCC_FILL_TARGET_BUFFER

Fill target buffer.

This option requests that conversion take place in such a way that the target buffer is filled completely:

- If the string contracts when it is converted, trailing blanks are added in order to fill the target buffer.
- If the string expands when it is converted, trailing characters that are not significant are discarded to make the converted string fit the target buffer. If this can be done successfully, the call completes with MQCC_OK and reason code MQRC_NONE.

If there are too few insignificant trailing characters, as much of the string as can fit is placed in the target buffer, and the call completes with MQCC_WARNING and reason code MQRC_CONVERTED_MSG_TOO_BIG.

Insignificant characters are:

- Trailing blanks
- Characters following the first null character in the string (but excluding the first null character itself)
- If the string, *TargetCCSID* , and *TargetLength* are such that the target buffer cannot be set completely with valid characters, the call fails with MQCC_FAILED and reason code MQRC_TARGET_LENGTH_ERROR. This can occur when *TargetCCSID* is a pure DBCS character set (such as UCS-2, but *TargetLength* specifies a length that is an odd number of bytes.
- *TargetLength* can be less than or greater than *SourceLength* . On return from MQXCNCV, *DataLength* has the same value as *TargetLength* .

If this option is not specified:

- The string is allowed to contract or expand within the target buffer as required. Insignificant trailing characters are not added or discarded.

If the converted string fits in the target buffer, the call completes with MQCC_OK and reason code MQRC_NONE.

If the converted string is too large for the target buffer, as much of the string as fits is placed in the target buffer, and the call completes with MQCC_WARNING and reason code MQRC_CONVERTED_MSG_TOO_BIG. Note fewer than *TargetLength* bytes can be returned in this case.

- *TargetLength* can be less than or greater than *SourceLength*. On return from MQXCNCV, *DataLength* is less than or equal to *TargetLength*.

This option is supported in the following environments: AIX, HP-UX, IBM i, Solaris, Linux, Windows.

Encoding options: The options described can be used to specify the integer encodings of the source and target strings. The relevant encoding is used *only* when the corresponding character set identifier indicates that the representation of the character set in main storage is dependent on the encoding used for binary integers. This affects only certain multibyte character sets (for example, UCS-2 character sets).

The encoding is ignored if the character set is a single-byte character set (SBCS), or a multibyte character set with representation in main storage that is not dependent on the integer encoding.

Only one of the MQDCC_SOURCE_* values must be specified, combined with one of the MQDCC_TARGET_* values:

MQDCC_SOURCE_ENC_NATIVE

Source encoding is the default for the environment and programming language.

MQDCC_SOURCE_ENC_NORMAL

Source encoding is normal.

MQDCC_SOURCE_ENC_REVERSED

Source encoding is reversed.

MQDCC_SOURCE_ENC_UNDEFINED

Source encoding is undefined.

MQDCC_TARGET_ENC_NATIVE

Target encoding is the default for the environment and programming language.

MQDCC_TARGET_ENC_NORMAL

Target encoding is normal.

MQDCC_TARGET_ENC_REVERSED

Target encoding is reversed.

MQDCC_TARGET_ENC_UNDEFINED

Target encoding is undefined.

The encoding values defined previously can be added directly to the *Options* field. However, if the source or target encoding is obtained from the *Encoding* field in the MQMD or other structure, the following processing must be done:

1. The integer encoding must be extracted from the *Encoding* field by eliminating the float and packed-decimal encodings; see [“Analyzing encodings” on page 865](#) for details of how to do this.
2. The integer encoding resulting from step 1 must be multiplied by the appropriate factor before being added to the *Options* field. These factors are:
 - MQDCC_SOURCE_ENC_FACTOR for the source encoding
 - MQDCC_TARGET_ENC_FACTOR for the target encoding

The following example code illustrates how this might be coded in the C programming language:

```
Options = (MsgDesc.Encoding & MQENC_INTEGER_MASK)
          * MQDCC_SOURCE_ENC_FACTOR
          + (DataConvExitParms.Encoding & MQENC_INTEGER_MASK)
          * MQDCC_TARGET_ENC_FACTOR;
```

If not specified, the encoding options default to undefined (MQDCC_*_ENC_UNDEFINED). In most cases, this does not affect the successful completion of the MQXCNVC call. However, if the corresponding character set is a multibyte character set with representation that is dependent on the encoding (for example, a UCS-2 character set), the call fails with reason code MQRC_SOURCE_INTEGER_ENC_ERROR or MQRC_TARGET_INTEGER_ENC_ERROR as appropriate.

The encoding options are supported in the following environments: AIX, HP-UX, z/OS, IBM i, Solaris, Linux, Windows.

Default option: If none of the options described previously is specified, the following option can be used:

MQDCC_NONE

No options specified.

MQDCC_NONE is defined to aid program documentation. It is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

SourceCCSID

Type: MQLONG - input

This is the coded character set identifier of the input string in *SourceBuffer*.

SourceLength

Type: MQLONG - input

This is the length in bytes of the input string in *SourceBuffer* ; it must be zero or greater.

SourceBuffer

Type: MQCHARxSourceLength - input

This is the buffer containing the string to be converted from one character set to another.

TargetCCSID

Type: MQLONG - input

This is the coded character set identifier of the character set to which *SourceBuffer* is to be converted.

TargetLength

Type: MQLONG - input

This is the length in bytes of the output buffer *TargetBuffer* ; it must be zero or greater. It can be less than or greater than *SourceLength*.

TargetBuffer

Type: MQCHARxTargetLength - output

This is the string after it has been converted to the character set defined by *TargetCCSID*. The converted string can be shorter or longer than the unconverted string. The *DataLength* parameter indicates the number of valid bytes returned.

DataLength

Type: MQLONG - output

This is the length of the string returned in the output buffer *TargetBuffer*. The converted string can be shorter or longer than the unconverted string.

CompCode

Type: MQLONG - output

It is one of the following:

MQCC_OK

Successful completion.

MQCC_WARNING

Warning (partial completion).

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_WARNING:

MQRC_CONVERTED_MSG_TOO_BIG

(2120, X'848') Converted data too large for buffer.

If *CompCode* is MQCC_FAILED:

MQRC_DATA_LENGTH_ERROR

(2010, X'7DA') Data length parameter not valid.

MQRC_DBCS_ERROR

(2150, X'866') DBCS string not valid.

MQRC_HCONN_ERROR

(2018, X'7E2') Connection handle not valid.

MQRC_OPTIONS_ERROR

(2046, X'7FE') Options not valid or not consistent.

MQRC_RESOURCE_PROBLEM

(2102, X'836') Insufficient system resources available.

MQRC_SOURCE_BUFFER_ERROR

(2145, X'861') Source buffer parameter not valid.

MQRC_SOURCE_CCSID_ERROR

(2111, X'83F') Source coded character set identifier not valid.

MQRC_SOURCE_INTEGER_ENC_ERROR

(2112, X'840') Source integer encoding not recognized.

MQRC_SOURCE_LENGTH_ERROR

(2143, X'85F') Source length parameter not valid.

MQRC_STORAGE_NOT_AVAILABLE

(2071, X'817') Insufficient storage available.

MQRC_TARGET_BUFFER_ERROR

(2146, X'862') Target buffer parameter not valid.

MQRC_TARGET_CCSID_ERROR

(2115, X'843') Target coded character set identifier not valid.

MQRC_TARGET_INTEGER_ENC_ERROR

(2116, X'844') Target integer encoding not recognized.

MQRC_TARGET_LENGTH_ERROR

(2144, X'860') Target length parameter not valid.

MQRC_UNEXPECTED_ERROR

(2195, X'893') Unexpected error occurred.

For detailed information about these codes, see [Messages and reason codes](#).

C invocation

```
MQXCNCV (Hconn, Options, SourceCCSID, SourceLength, SourceBuffer,  
         TargetCCSID, TargetLength, TargetBuffer, &DataLength,  
         &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONN  Hconn;           /* Connection handle */  
MQLONG   Options;         /* Options that control the action of  
                           MQXCNCV */  
MQLONG   SourceCCSID;     /* Coded character set identifier of string  
                           before conversion */  
MQLONG   SourceLength;    /* Length of string before conversion */  
MQCHAR   SourceBuffer[n]; /* String to be converted */  
MQLONG   TargetCCSID;     /* Coded character set identifier of string  
                           after conversion */  
MQLONG   TargetLength;    /* Length of output buffer */  
MQCHAR   TargetBuffer[n]; /* String after conversion */  
MQLONG   DataLength;      /* Length of output string */  
MQLONG   CompCode;        /* Completion code */  
MQLONG   Reason;          /* Reason code qualifying CompCode */
```

COBOL declaration (IBM i only)

```
CALL 'MQXCNCV' USING HCONN, OPTIONS, SOURCECCSID, SOURCELENGTH,  
                     SOURCEBUFFER, TARGETCCSID, TARGETLENGTH,  
                     TARGETBUFFER, DATALENGTH, COMPCODE, REASON.
```

Declare the parameters as follows:

```
** Connection handle  
01 HCONN          PIC S9(9) BINARY.  
** Options that control the action of MQXCNCV  
01 OPTIONS        PIC S9(9) BINARY.  
** Coded character set identifier of string before conversion  
01 SOURCECCSID    PIC S9(9) BINARY.  
** Length of string before conversion  
01 SOURCELENGTH   PIC S9(9) BINARY.  
** String to be converted  
01 SOURCEBUFFER    PIC X(n).  
** Coded character set identifier of string after conversion  
01 TARGETCCSID    PIC S9(9) BINARY.  
** Length of output buffer  
01 TARGETLENGTH   PIC S9(9) BINARY.  
** String after conversion  
01 TARGETBUFFER    PIC X(n).  
** Length of output string  
01 DATALENGTH    PIC S9(9) BINARY.  
** Completion code  
01 COMPCODE        PIC S9(9) BINARY.  
** Reason code qualifying COMPCODE  
01 REASON          PIC S9(9) BINARY.
```

S/390 assembler declaration

```
CALL MQXCNCV, (HCONN, OPTIONS, SOURCECCSID, SOURCELENGTH,      X  
               SOURCEBUFFER, TARGETCCSID, TARGETLENGTH, TARGETBUFFER, X  
               DATALENGTH, COMPCODE, REASON)
```

Declare the parameters as follows:

```
HCONN      DS F      Connection handle  
OPTIONS     DS F      Options that control the action of MQXCNCV  
SOURCECCSID DS F      Coded character set identifier of string before  
* conversion  
SOURCELENGTH DS F      Length of string before conversion  
SOURCEBUFFER DS CL(n) String to be converted  
TARGETCCSID DS F      Coded character set identifier of string after  
* conversion  
TARGETLENGTH DS F      Length of output buffer  
TARGETBUFFER DS CL(n) String after conversion
```

DATALENGTH	DS	F	Length of output string
COMPCODE	DS	F	Completion code
REASON	DS	F	Reason code qualifying COMPCODE

MQ_DATA_CONV_EXIT - Data conversion exit

The MQ_DATA_CONV_EXIT call describes the parameters that are passed to the data-conversion exit.

No entry point called MQ_DATA_CONV_EXIT is provided by the queue manager (see usage note [11](#)).

This definition is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

Syntax

MQ_DATA_CONV_EXIT (*DataConvExitParms*, *MsgDesc*, *InBufferLength*, *InBuffer*, *OutBufferLength*, *OutBuffer*)

Parameters

DataConvExitParms

Type: MQDXP - input/output

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate the outcome of the conversion. See [“MQDXP - Data-conversion exit parameter”](#) on page 876 for details of the fields in this structure.

MsgDesc

Type: MQMD - input/output

On input to the exit, this is the message descriptor associated with the message data passed to the exit in the *InBuffer* parameter.

Note: The *MsgDesc* parameter passed to the exit is always the most-recent version of MQMD supported by the queue manager which invokes the exit. If the exit is intended to be portable between different environments, the exit will check the *Version* field in *MsgDesc* to verify that the fields that the exit needs to access are present in the structure.

In the following environments, the exit is passed a version-2 MQMD: AIX, HP-UX, IBM i, Solaris, Linux, Windows. In all other environments that support the data conversion exit, the exit is passed a version-1 MQMD.

On output, the exit will change the *Encoding* and *CodedCharSetId* fields to the values requested by the application, if conversion was successful; these changes are reflected back to the application. Any other changes that the exit makes to the structure are ignored; they are not reflected back to the application.

If the exit returns MQXDR_OK in the *ExitResponse* field of the MQDXP structure, but does not change the *Encoding* or *CodedCharSetId* fields in the message descriptor, the queue manager returns for those fields the values that the corresponding fields in the MQDXP structure had on input to the exit.

InBufferLength

Type: MQLONG - input

Length in bytes of *InBuffer*.

This is the length of the input buffer *InBuffer*, and specifies the number of bytes to be processed by the exit. *InBufferLength* is the lesser of the length of the message data before conversion, and the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

InBuffer

Type: MQBYTEInBufferLength - input

Buffer containing the unconverted message.

This contains the message data before conversion. If the exit is unable to convert the data, the queue manager returns the contents of this buffer to the application after the exit has completed.

Note: The exit should not alter *InBuffer* ; if this parameter is altered, the results are undefined.

In the C programming language, this parameter is defined as a pointer-to-void.

OutBufferLength

Type: MQLONG - input

Length in bytes of *OutBuffer*.

This is the length of the output buffer *OutBuffer*, and is the same as the length of the buffer provided by the application on the MQGET call.

The value is always greater than zero.

OutBuffer

Type: MQBYTEOutBufferLength - output

Buffer containing the converted message.

On output from the exit, if the conversion was successful (as indicated by the value MQXDR_OK in the *ExitResponse* field of the *DataConvExitParms* parameter), *OutBuffer* contains the message data to be delivered to the application, in the requested representation. If the conversion was unsuccessful, any changes that the exit has made to this buffer are ignored.

In the C programming language, this parameter is defined as a pointer-to-void.

Usage notes

1. A data-conversion exit is a user-written exit which receives control during the processing of an MQGET call. The function performed by the data-conversion exit is defined by the provider of the exit; however, the exit must conform to the rules described here, and in the associated parameter structure MQDXP.

The programming languages that can be used for a data-conversion exit are determined by the environment.

2. The exit is invoked only if *all* of the following are true:

- The MQGMO_CONVERT option is specified on the MQGET call
- The *Format* field in the message descriptor is not MQFMT_NONE
- The message is not already in the required representation; that is, one or both of the message's *CodedCharSetId* and *Encoding* is different from the value specified by the application in the message descriptor supplied on the MQGET call
- The queue manager has not already done the conversion successfully
- The length of the application's buffer is greater than zero
- The length of the message data is greater than zero
- The reason code so far during the MQGET operation is MQRC_NONE or MQRC_TRUNCATED_MSG_ACCEPTED

3. When an exit is being written, consider coding the exit in a way that allows it to convert messages that have been truncated. Truncated messages can arise in the following ways:

- The receiving application provides a buffer that is smaller than the message, but specifies the MQGMO_ACCEPT_TRUNCATED_MSG option on the MQGET call.

In this case, the *Reason* field in the *DataConvExitParms* parameter on input to the exit has the value MQRC_TRUNCATED_MSG_ACCEPTED.

- The sender of the message truncated it before sending it. This can happen with report messages, for example (see [“Conversion of report messages”](#) on page 876 for more details).

In this case, the *Reason* field in the *DataConvExitParms* parameter on input to the exit has the value MQRC_NONE (if the receiving application provided a buffer that was large enough for the message).

Thus the value of the *Reason* field on input to the exit cannot always be used to decide whether the message has been truncated.

The distinguishing characteristic of a truncated message is that the length provided to the exit in the *InBufferLength* parameter is *less than* the length implied by the format name contained in the *Format* field in the message descriptor. The exit should therefore check the value of *InBufferLength* before attempting to convert any of the data; the exit *should not* assume that the full amount of data implied by the format name has been provided.

If the exit has *not* been written to convert truncated messages, and *InBufferLength* is less than the value expected, the exit will return MQXDR_CONVERSION_FAILED in the *ExitResponse* field of the *DataConvExitParms* parameter, with the *CompCode* and *Reason* fields set to MQCC_WARNING and MQRC_FORMAT_ERROR.

If the exit *has* been written to convert truncated messages, the exit will convert as much of the data as possible (see next usage note), taking care not to attempt to examine or convert data beyond the end of *InBuffer*. If the conversion completes successfully, the exit will leave the *Reason* field in the *DataConvExitParms* parameter unchanged. This returns MQRC_TRUNCATED_MSG_ACCEPTED if the message was truncated by the receiver's queue manager, and MQRC_NONE if the message was truncated by the sender of the message.

It is also possible for a message to expand *during* conversion, to the point where it is bigger than *OutBuffer*. In this case the exit must decide whether to truncate the message; the *AppOptions* field in the *DataConvExitParms* parameter indicates whether the receiving application specified the MQGMO_ACCEPT_TRUNCATED_MSG option.

4. Generally, all the data in the message provided to the exit in *InBuffer* is converted, or that none of it is. An exception to this, however, occurs if the message is truncated, either before conversion or during conversion; in this case there can be an incomplete item at the end of the buffer (for example: 1 byte of a double-byte character, or 3 bytes of a 4-byte integer). In this situation, consider omitting the incomplete item and set the unused bytes in the *OutBuffer* to nulls. However, complete elements or characters within an array or string *should* be converted.
5. When an exit is needed for the first time, the queue manager attempts to load an object that has the same name as the format (apart from extensions). The object loaded must contain the exit that processes messages with that format name. Consider making the exit name, and the name of the object that contains the exit identical, although not all environments require this.
6. A new copy of the exit is loaded when an application attempts to retrieve the first message that uses that *Format* since the application connected to the queue manager. For CICS or IMS applications, this means when the CICS or IMS subsystem connected to the queue manager. A new copy can also be loaded at other times, if the queue manager has discarded a previously loaded copy. For this reason, an exit must not attempt to use static storage to communicate information from one invocation of the exit to the next - the exit can be unloaded between the two invocations.
7. If there is a user-supplied exit with the same name as one of the built-in formats supported by the queue manager, the user-supplied exit does not replace the built-in conversion routine. The only circumstances in which such an exit is invoked are:
 - If the built-in conversion routine cannot handle conversions to or from either the *CodedCharSetId* or *Encoding* involved, or
 - If the built-in conversion routine has failed to convert the data (for example, because there is a field or character which cannot be converted).
8. The scope of the exit is environment-dependent. *Format* names must be chosen to minimize the risk of clashes with other formats. Consider starting with characters that identify the application defining the format name.

9. The data-conversion exit runs in an environment like that of the program which issued the MQGET call; environment includes address space and user profile (where applicable). The program could be a message channel agent sending messages to a destination queue manager that does not support message conversion. The exit cannot compromise the queue manager's integrity, since it does not run in the queue manager's environment.
10. The only MQI call which can be used by the exit is MQXCNVC; attempting to use other MQI calls fails with reason code MQRC_CALL_IN_PROGRESS, or other unpredictable errors.
11. No entry point called MQ_DATA_CONV_EXIT is provided by the queue manager. However, a typedef is provided for the name MQ_DATA_CONV_EXIT in the C programming language, and this can be used to declare the user-written exit, to ensure that the parameters are correct. The name of the exit must be the same as the format name (the name contained in the *Format* field in MQMD), although this is not required in all environments.

The following example illustrates how the exit that processes the format MYFORMAT can be declared in the C programming language:

```
#include "cmqc.h"
#include "cmqxc.h"

MQ_DATA_CONV_EXIT MYFORMAT;

void MQENTRY MYFORMAT(
    PMQDXP  pDataConvExitParms, /* Data-conversion exit parameter
                                block */
    PMQMD   pMsgDesc,           /* Message descriptor */
    MQLONG  InBufferLength,     /* Length in bytes of InBuffer */
    PMQVOID pInBuffer,          /* Buffer containing the unconverted
                                message */
    MQLONG  OutBufferLength,    /* Length in bytes of OutBuffer */
    PMQVOID pOutBuffer)         /* Buffer containing the converted
                                message */
{
    /* C language statements to convert message */
}
```

12. On z/OS, if an API-crossing exit is also in force, it is called after the data-conversion exit.

C invocation

```
exitname (&DataConvExitParms, &MsgDesc, InBufferLength,
          InBuffer, OutBufferLength, OutBuffer);
```

The parameters passed to the exit are declared as follows:

```
MQDXP  DataConvExitParms; /* Data-conversion exit parameter block */
MQMD   MsgDesc;           /* Message descriptor */
MQLONG InBufferLength;    /* Length in bytes of InBuffer */
MQBYTE InBuffer[n];       /* Buffer containing the unconverted
                             message */
MQLONG OutBufferLength;   /* Length in bytes of OutBuffer */
MQBYTE OutBuffer[n];      /* Buffer containing the converted
                             message */
```

COBOL declaration (IBM i only)

```
CALL 'exitname' USING DATACONVEXITPARMS, MSGDESC, INBUFFERLENGTH,
                     INBUFFER, OUTBUFFERLENGTH, OUTBUFFER.
```

The parameters passed to the exit are declared as follows:

```
** Data-conversion exit parameter block
01 DATACONVEXITPARMS.
   COPY CMQDXPV.
** Message descriptor
01 MSGDESC.
   COPY CMQMDV.
** Length in bytes of INBUFFER
01 INBUFFERLENGTH PIC S9(9) BINARY.
```

```

** Buffer containing the unconverted message
01 INBUFFER          PIC X(n).
** Length in bytes of OUTBUFFER
01 OUTBUFFERLENGTH   PIC S9(9) BINARY.
** Buffer containing the converted message
01 OUTBUFFER          PIC X(n).

```

System/390 assembler declaration

```

CALL EXITNAME, (DATACONVEXITPARMS, MSGDESC, INBUFFERLENGTH,      X
                INBUFFER, OUTBUFFERLENGTH, OUTBUFFER)

```

The parameters passed to the exit are declared as follows:

```

DATACONVEXITPARMS  CMQDXPA  ,      Data-conversion exit parameter block
MSGDESC            CMQMDA   ,      Message descriptor
INBUFFERLENGTH     DS       F      Length in bytes of INBUFFER
INBUFFER           DS       CL(n)  Buffer containing the unconverted
*                  message
OUTBUFFERLENGTH     DS       F      Length in bytes of OUTBUFFER
OUTBUFFER          DS       CL(n)  Buffer containing the converted
*                  message

```

Properties specified as MQRFH2 elements

Non-message descriptor properties can be specified as elements in MQRFH2 header folders. Overview of MQRFH2 elements being specified as properties.

This retains compatibility with the previous versions of the IBM MQ JMS and XMS clients. This section describes how to specify properties in MQRFH2 headers.

To use MQRFH2 elements as properties, specify the elements as described in [Using IBM MQ classes for Java](#). This information supplements the information described in “MQRFH2 - Rules and formatting header 2” on page 502.

Mapping property data types to MQRFH2 data types

This topic provides information on message property types mapped to their corresponding MQRFH2 data types.

Table 568. Supported MQRFH2 data types	
Message property type	MQRFH2 data type
MQBYTE[]	bin.hex
MQBOOL	boolean
MQINT8	i1
MQINT16	i2
MQINT32	i4
MQINT64	i8
MQFLOAT32	r4
MQFLOAT64	r8
MQCHAR[]	string

Any element without a data type is assumed to be of type "string".

An MQRFH2 data type of `int`, meaning an integer of unspecified size, is treated as if it were an `i8`.

A null value is indicated by the element attribute `xsi:nil='true'`. Do not use the attribute `xsi:nil='false'` for non-null values.

For example, the following property has a null value:

```
<NullProperty xsi:nil='true'></NullProperty>
```

A byte or character string property can have an empty value. This is represented by an MQRFH2 element with a zero length element value.

For example, the following property has an empty value:

```
<EmptyProperty></EmptyProperty>
```

Supported MQRFH2 folders

Overview of the use of message descriptor fields as properties.

The folders `<jms>`, `<mcd>`, `<mqext>`, and `<usr>` are described in [The MQRFH2 header and JMS](#). The `<usr>` folder is used to transport any JMS application-defined properties that are associated with a message. Groups are not allowed in the `<usr>` folder.

[The MQRFH2 header and JMS](#) supports the following additional folders:

- `<mq>`

This folder is used and reserved for MQ-defined properties that are used by IBM MQ.

- `<mq_usr>`

This folder can be used to transport any application-defined properties that are not exposed as JMS user-defined properties, as the properties might not meet the requirements of a JMS property. This folder can contain groups that the `<usr>` folder cannot.

- Any folder marked with the `content='properties'` attribute.

Such a folder is equivalent to the `<mq_usr>` folder in content.

- `<mpps>`

This folder is used for IBM MQ publish/subscribe properties.

IBM MQ also supports the following folders that are already in use by WAS/SIB:

- `<sib>`

This folder is used and reserved for WAS/SIB system message properties that are not exposed as JMS properties, or are mapped to `JMS_IBM_*` properties, but are exposed to WAS/SIB applications; these include forward and reverse routing paths properties.

At least some cannot be exposed as JMS properties, because they are byte arrays. If your application adds properties to this folder, the value is either ignored or removed.

- `<sib_usr>`

This folder is used and reserved for WAS/SIB user message properties that cannot be exposed as JMS user properties because they are not of supported types; they are exposed to WAS/SIB applications.

These are user properties, that you can get or set through the `SIMessage` interface, but the content of the byte array is mapped to the required property value.

If your IBM MQ application writes an arbitrary `bin.hex` element to the folder, the application probably receives an `IOException`, as it is not of the format expected to restore. If you add anything other than a `bin.hex` element you receive a `ClassCastException`.

Do not attempt to make properties available to WAS/SIB by using this folder; instead user the `<usr>` folder for that purpose.

- `<sib_context>`

This folder is used for WAS/SIB system message properties that are not exposed to WAS/SIB user applications or as JMS properties. These include security and transactional properties that are used for web services and similar.

Your application must not add properties to this folder.

- <mqema>

This folder was used by WAS/SIB instead of the <mqext> folder.

MQRFH2 folder names are case-sensitive.

The following folders are reserved, in any mixture of lowercase or uppercase characters:

- Any folder prefixed by mq or wmq ; reserved for use by IBM MQ.
- Any folder prefixed by sib ; reserved for use by WAS/SIB.
- <Root> and <Body> folders; reserved but not used.

The following folders are not recognized as containing message properties:

- <psc>

Used by IBM Integration Bus to convey publish/subscribe command messages to the broker.

- <pscr>

Used by IBM Integration Bus to contain information from the broker, in response to publish/subscribe command messages.

- Any folder not defined by IBM, that is not marked with the content= 'properties' attribute.

Do not specify content= 'properties' on the <psc> or <pscr> folders. If you do so, these folders are treated as properties and IBM Integration Bus is likely to stop functioning as expected.

If your application is building messages with properties, in MQRFH2 headers to be recognized as an MQRFH2 header containing properties, the header must be in the list of headers that can be chained at the head of the message.

The MQRFH2 can be preceded by any number of MQH standard headers, or an MQCIH, an MQDLH, an MQIIH, an MQTM, an MQTMC2, or an MQXQH. A string or an MQCFH ends parsing because they cannot be chained.

It is possible for a message to contain multiple MQRFH2 headers all carrying message properties. Folders with the same name can coexist in different headers unless otherwise restricted, for example by WAS/SIB. The folders are treated as one logical folder, if they are all in significant headers.

While folders from the significant headers cannot be merged with those folders in nonsignificant headers, folders with the same name within the significant headers can be merged, removing any conflicting properties. Your applications must not depend on the layout of properties within their message.

MQRFH2 groups are parsed for properties in user-defined folders, that is, not the <wmq>, <jms>, <mcd>, <usr>, <mqext>, <sib>, <sib_usr>, <sib_context>, and <mqema> folders.

Groups in the IBM-defined properties folders, except for the <wmq> and <mq> folders, are parsed for properties.

An MQRFH2 folder cannot contain mixed content; a folder or group can contain either groups or properties, or a value, but not both.

A segment of a message, either the first or a subsequent segment, cannot contain IBM MQ -defined properties other than those properties in the message descriptor. Therefore putting a message containing such properties with either MQMF_SEGMENT or MQMF_SEGMENTATION_ALLOWED set causes the put to fail with MQRC_SEGMENTATION_NOT_ALLOWED.

However, message groups can contain IBM MQ -defined properties.

Generation of MQRFH2 headers

If IBM MQ converts message properties to their MQRFH2 representation, it must add the MQRFH2 to the message. It adds the MQRFH2 either as a separate header, or merges it with an existing header.

Generation of new MQRFH2 headers by IBM MQ might disrupt existing headers in a message. Applications that parse a message buffer for headers must be aware that the number and position of headers in

a buffer might change in some circumstances. IBM MQ attempts to minimize the impact of adding properties to a message by merging message properties into an existing MQRFH2 header, where it can. It also attempts to minimize the impact by inserting a generated MQRFH2 into a fixed position relative to other headers in the message buffer.

A generated MQRFH2 header is placed following the MQMD, and any number of MQXQH, MQRFH, and MQDLH headers, whatever order they are in. The generated MQRFH2 header is placed immediately before the first header that is not an MQMD, MQXQH, MQDLH, or MQRFH header.

 On z/OS systems, the generated MQRFH2 header is created in the application's CCSID. This is defined as follows:

- For batch LE applications using the DLL interface, the CCSID is the CODESET associated with the current locale at the time **MQCONN** is issued (default value is 1047).
- For batch LE applications bound with one of the batch MQ stubs, the CCSID is the CODESET associated with the current locale at the time of the first MQI call issued after **MQCONN** (default value is 1047).
- For batch non-LE applications running on a USS thread, the CCSID is the value of THLICCSID at the time of the first MQI call issued after **MQCONN** (default value is 1047).
- For other batch applications, the CCSID is the CCSID of the queue manager.

For LE applications, the locale can be changed using the `setlocale()` / `CEESETL` LE callable service. For non-LE applications running on USS threads, the value of THLICCSID can be changed using USS mapping macro **BPXYTHLI**.

Rules for merging generated MQRFH2

The following rules apply to merging a generated MQRFH2 with an existing MQRFH2. The generated MQRFH2 header is merged with an existing MQRFH2 header, if:

1. The existing MQRFH2 is in the same position IBM MQ would place a generated MQRFH2, or earlier in the header chain.
2. The CCSID of the generated properties is the same as the NameValueCCSID of the existing MQRFH2.

Otherwise, the generated header is placed separately in the buffer, in the position described before.

Rules for merging folders in an existing MQRFH2

If message properties are merged into an existing MQRFH2, then the existing MQRFH2 is scanned for folders that match the message properties, and merges them. If a matching folder does not exist a new folder is added to the end of the existing folders. If a matching folder does exist, the folder is searched. Any matching properties are overwritten. Any new ones are added at the end of the folder.

MQRFH2 folder restrictions

Overview of folder restrictions in MQRFH2 headers

The MQRFH2 restrictions apply to the following folders:

- Element names in the `<usr>` folder must not begin with the prefix JMS ; such property names are reserved for use by JMS and are not valid for user-defined properties.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

- Element names in the `<usr>` folder must not be, in any mixture of lower or uppercase, NULL, TRUE, FALSE, NOT, AND, OR, BETWEEN, LIKE, IN, IS and ESCAPE. These names match SQL keywords and make parsing selectors harder, because `<usr>` is the default folder used when no folder is specified for a particular property in a selector.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

- The content model of the <usr> folder is as follows:
 - Any valid XML name can be used as an element name, providing that it does not contain a colon.
 - Only simple elements, not nested folders, are allowed.
 - All elements take the default type of string, unless modified by a dt="xxx" attribute.
 - All elements are optional, but should occur no more than once in a folder.
- Element names in any folder considered to contain message properties must not contain a period (.) (Unicode character U+002E), because this is used in property names to indicate the hierarchy.

Such an element name does not cause parsing of the MQRFH2 to fail, but is not accessible to the IBM MQ message property APIs.

In general, MQRFH2 headers that contain valid XML-style data can be parsed by IBM MQ without failure, although certain elements of the MQRFH2 are not accessible through the IBM MQ message property APIs.

MQRFH2 element name conflicts

Overview of conflicts within MQRFH2 element names.

Only one value can be attached to a message property. If an attempt to access a property leads to a conflict of values, one is chosen in preference over another.

The IBM MQ syntax for accessing MQRFH2 elements allows unique identification of an element, if a folder contains no elements with the same name. If a folder contains more than one element with the same name, the value of the property used is the one closest to the head of the message.

This applies if two or more folders of the same name are contained in different significant MQRFH2 headers within the same message.

A conflict can result when the MQGET call is processed after a non-message descriptor property has been set twice: both through an MQSETMP call and directly in the raw MQRFH2 header.

If this happens, the property associated with the message by an API call takes preference over one in the message data, that is, the one in the raw MQRFH2 header. If a conflict occurs, it is considered to come logically before the message data.

Mapping from property names to MQRFH2 folder and element names

Overview of the differences between property names and element names in the MQRFH2 header.

When using any of the defined APIs that ultimately generate MQRFH2 headers, in order to specify message properties (for example, MQ JMS), the property name is not necessarily the element name in the MQRFH2 folder.

Therefore, a mapping occurs from the property name to the MQRFH2 element, and in the reverse way, taking into account both the folder name that contains the element, and the element name. Some examples from IBM MQ classes for JMS are already documented in [Using Java](#).

Property name	MQRFH2 folder name	MQRFH2 element name
JMSDestination	jms	Dst
JMSType	mcd	Type, Set, Fmt
xxx (user defined, where xxx does not begin with JMS)	usr	xxx

Therefore, when a JMS application accesses the JMSDestination property this maps to the Dst element in the <jms> folder.

When specifying properties as MQRFH2 elements, IBM MQ defines its elements as follows:

Property name	MQRFH2 folder name	MQRFH2 group name	MQRFH2 element name
<Property>	<usr>	n/a	<Property>
<folder>.<Property>	<folder>	n/a	<Property>
<folder>.<group>.<Property>	<folder>	<group>	<Property>

For example, when an IBM MQ application attempts to access the Property1 property, this maps to the Property1 element in the <usr> folder. The wmq.Property2 property maps to the Property2 property in the <wmq> folder.

If the property name contains more than one . character, the MQRFH2 element name used is the one following the final . character, and MQRFH2 groups are used to form a hierarchy; nested MQRFH2 groups are permitted.

The JMS header and provider-specific properties that are contained in an MQRFH2 in the <mcd>, <jms>, and <mqext> folders are accessed by an IBM MQ application using the short names defined in [Using IBM MQ classes for Java](#).

JMS user-defined properties are accessed from the <usr> folder. An IBM MQ application can use the <usr> folder for its application properties if it is acceptable for the property to appear to JMS applications as one of its user-defined properties.

If it is not acceptable, choose another folder; the <wmq_usr> folder is provided as a standard location for such non-JMS properties.

Your applications can specify and use any MQRFH2 folder with a well-defined use, not documented in “Properties specified as MQRFH2 elements” on page 892 if you note the following:

1. The folder might already be in use, or might be used in the future, by another application providing undefined access to properties contained inside it; see [Property names](#) for the suggested naming convention for property names.
2. The properties are not accessible to previous versions of the IBM MQ classes for JMS or XMS client that can only access the <usr> folder for user-defined properties
3. The folder must be marked with the attribute content with the value set to properties, for example, content='properties'.

“MQSETMP - Set message property” on page 750 automatically adds this attribute as required. This attribute must not be added to any of the IBM-defined folders, for example, <jms> and <usr>. Doing so, causes the message to be rejected by the IBM MQ classes for JMS client before Version 7.0. with a MessageFormatException.

Because the <usr> folder is the default location for properties of the <Property> syntax, an IBM MQ application and a JMS application to access the same user-defined property value using the same name.

Reserved folder names

There are several reserved folder names. You cannot use such names as your folder prefixes; for example, Root.Property1 does not access a valid property because Root is reserved. The following list contains reserved folder names:

- Root
- Body
- Properties
- Environment
- LocalEnvironment
- DestinationList
- ExceptionList

- InputBody
- InputRoot
- InputProperties
- InputLocalEnvironment
- InputDestinationList
- InputExceptionList
- OutputRoot
- OutputLocalEnvironment
- OutputDestinationList
- OutputExceptionList

Mapping property descriptor fields into MQRFH2 headers

When a property is translated into an MQRFH2 element the following element attributes are used to specify the significant fields of the property descriptor: This describes how MQPD fields are translated to MQRFH2 element attributes.

Support

The Support property descriptor field is split into three element attributes

- The **sr** element attribute specifies values in the MQPD_REJECT_UNSUP_MASK bit mask.
- The **sa** element attribute specifies values in the MQPD_ACCEPT_UNSUP_MASK bit mask.
- The **sx** element attribute specifies values in the MQPD_ACCEPT_UNSUP_IF_XMIT_MASK bit mask.

These element attributes are only valid in the <mq> folder and are ignored if set on elements in the other folders containing properties.

Support value	MQRFH2 element attribute	MQRFH2 attribute value
MQPD_SUPPORT_OPTIONAL	sa	optional This is the default value.
MQPD_SUPPORT_REQUIRED	sr	required
MQPD_SUPPORT_REQUIRED_IF_LOCAL	sx	local

Context

Use the **context** element attribute to indicate the message context to which a property belongs. Use one value only. This element attribute is valid on a property in any folder containing properties.

Context value	MQRFH2 attribute value
MQPD_NO_CONTEXT	none This is the default value.
MQPD_USER_CONTEXT	user

CopyOptions

Use the **copy** element attribute to indicate messages into which a property should be copied. More than one value is acceptable; separate multiple values with a comma. For example **copy='reply'** and **copy='publish,report'** are both valid. This element attribute is valid on a property in any folder containing properties.

Note: In the attribute definition, single quotation marks or double quotation marks are valid use, for example **copy='reply'** or **copy="report"**

CopyOption value	MQRFH2 attribute value
MQPD_COPY_FORWARD	forward
MQPD_COPY_REPLY	reply
MQPD_COPY_REPORT	report
MQPD_COPY_PUBLISH	publish
MQPD_COPY_ALL	all Do not specify this with any other value. When used with another value, this takes precedence over any value except none .
MQPD_COPY_DEFAULT	default This is the default value. It is equivalent to specifying the three values MQCOPY_FORWARD, MQCOPY_REPORT and MQCOPY_PUBLISH. Do not specify this with any other value.
MQPD_COPY_NONE	none Do not specify this with any other value. When used with another value, this takes precedence.

Restrictions to the <mq> MQRFH2 folder

When a message is put on to a queue, it is searched for an <mq> folder so that the message can be processed according to its MQ-defined properties. To allow the efficient parsing of MQ-defined properties, the following restrictions apply to the folder:

- Only properties in the first significant <mq> folder in the message are acted upon by MQ; properties in any other <mq> folder in the message are ignored.
- If the folder is in UTF-8, only single-byte UTF-8 characters are allowed in the folder. A multi-byte character in the folder, can cause parsing to fail, and the message to be rejected.
- Do not include MQRFH2 groups in the <mq> folder. The presence of Unicode character U+003C in a property value will cause the message to be rejected.
- Do not use escape strings in the folder. An escape string is treated as the actual value of the element.
- Only Unicode character U+0020 is treated as white space within the folder. All other characters are treated as significant and can cause parsing of the folder to fail, and the message to be rejected.

If parsing of the <mq> folder fails, or if the folder does not observe these restrictions, the message is rejected with CompCode **MQCC_FAILED** and Reason **MQRC_RFH_RESTRICTED_FORMAT_ERR**.

MQRFH2 headers that are not valid

At the time an MQPUT, MQPUT1, or MQGET call processes, a partial parsing of any MQRFH2 headers in the message can occur to check what folders are included, and to determine if the folders contain properties. Overview of MQRFH2 headers that are not valid.

If the partial parsing of the message cannot complete successfully because the structure is not valid, for example, the StrucLength field is too small, then:

- The MQPUT or MQPUT1 call fails with reason code MQRC_RFH_ERROR, if it can be determined that the application includes some IBM MQ Version 7 option, so that existing applications do not fail.

- The MQGET call returns successfully, and the MQRFH2 containing the error is returned in the buffer you provided.

If the partial parsing fails because it cannot be detected whether a particular folder contains properties or not, for example, the folder begins <<jms, so parsing fails before the folder name is determined, then:

- The MQPUT or MQPUT1 call fails with reason code MQRC_RFH_FORMAT_ERROR, if it can be determined that the application includes some IBM MQ Version 7 option, so that existing applications do not fail.
- The MQGET call returns successfully, and the MQRFH2 containing the error is returned in the buffer you provided.
- While internally within the queue manager, the message is not rejected due to the badly formatted folder, but the folder is always treated as if no properties were contained inside it.

A message can flow through the queue manager network with a folder containing such a syntax error, but never being parsed and detected, while one or more folders in the message are:

- Valid
- Successfully parsed
- Used in the processing of the message

Therefore, detection is not guaranteed.

If one of your applications uses [“MQSETMP - Set message property”](#) on page 750, or MQINQMP to access a property, and in so doing this causes an MQRFH2 folder to be fully parsed, detecting an error such that parsing cannot complete, this is indicated by an appropriate return code to the API call. No properties in the folder are made available to the application.

If an attempt is made to fully parse an MQRFH2 folder and the parser finds unrecognized element attributes, or an unrecognized data type, parsing continues and complete successfully with no warnings being issued; this does not constitute a parsing error.

Code page conversion

This section describes codeset names and CCSIDs, national language, z/OS conversion, IBM i conversion, and Unicode conversion support.

Each national language section lists the following information:

- The native CCSIDs supported
- The code page conversions that are **not** supported

The following terms are used in the information:

-8

Indicates for HP-UX that the CCSID is for the HP-UX defined codeset *roman8*

AIX

Indicates IBM MQ for AIX

HP-UX

Indicates IBM MQ for HP-UX

Linux

Indicates IBM MQ for Linux for Intel and IBM MQ for Linux for zSeries

HP Integrity NonStop Server

Indicates IBM WebSphere MQ for HP Integrity NonStop Server

OS/400

Indicates IBM MQ for IBM i

Solaris

Indicates IBM MQ for Solaris

Windows

Indicates IBM MQ for Windows

z/OS

Indicates IBM MQ for z/OS

The default for data conversion is for the conversion to be performed at the target (receiving) system.

If the source product supports the conversion a channel can be set up and data exchanged by setting the channel attribute CONVERT to YES at the source.

Note:

1. Conversion for IBM MQ MQI client information takes place in the server, so the server must support conversion from the client CCSID to the server CCSID.
2. The conversion might include support added by CSD/PTF to the latest version of IBM MQ. Check the content of the latest service level to see if you need to install a CSD/PTF to enable this conversion.
3. The IBM MQ queue manager CCSID must be Mixed or SBCS.
4. Some CCSIDs, for example 850 on AIX, that are not supported by the operating system can still be used by the application and also can be set as the IBM MQ queue manager CCSID. This is allowed for backward compatibility purpose only and the conversion will fail if the relevant conversion tables are not installed.

See [Table 569 on page 901](#) for a cross reference between some of the CCSID numbers and some industry codeset names.

Codeset names and CCSIDs

IBM MQ for z/OS provides more conversion than is listed in the language specific tables.

<i>Table 569. Codeset names and CCSIDs</i>	
Codeset names	CCSIDs
ISO 8859-1	819
ISO 8859-2	912
ISO 8859-3	913

US English

Details of CCSIDs and CCSID conversion for US English.

The following table shows the native CCSIDs for US English on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	37, 924, 1140
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 1252, 5348, 858
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

37

Does not convert to code pages 923, 858

924

Does not convert to code pages 437, 858, 1051, 1140, 1252, 1275, 5348

1140

Does not convert to code pages 924, 1051, 1275

German

Details of CCSIDs and CCSID conversion for German.

The following table shows the native CCSIDs for German on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	273, 924, 1141
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

273

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 273, 437, 858, 1051, 1141, 1252, 1275, 5348

1141

Does not convert to code pages 924, 1051, 1275

Danish and Norwegian

Details of CCSIDs and CCSID conversion for Danish and Norwegian.

The following table shows the native CCSIDs for Danish and Norwegian on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	277, 924, 1142
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	850, 858, 865, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

277

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 277, 858, 865, 1051, 1142, 1252, 1275, 5348

1142

Does not convert to code pages 924, 865, 1051, 1275

AIX

Code page:

819

Does not convert to code page 865

HP-UX

Code page:

1051

Does not convert to code page 865

Windows

Code page:

865

Does not convert to code pages 1051, 1275

Finnish and Swedish

Details of CCSIDs and CCSID conversion for Finnish and Swedish.

The following table shows the native CCSIDs for Finnish and Swedish on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	278, 924, 1143
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 865, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

278

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 278, 437, 858, 865, 1051, 1143, 1252, 1275, 5348

1143

Does not convert to code pages 865, 924, 1051, 1275

AIX

Code page:

819

Does not convert to code page 865

850

Does not convert to code page 865

HP-UX

Code page:

1051

Does not convert to code page 865

Windows

Code page:

865

Does not convert to code pages 1051, 1275

Italian

Details of CCSIDs and CCSID conversion for Italian.

The following table shows the native CCSIDs for Italian on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	280, 924, 1144
AIX	819, 923, 5348
HP-UX	819, 923, 1051

Platform	Native CCSIDs
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

280

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 280, 437, 858, 1051, 1144, 1252, 1275, 5348

1144

Does not convert to code pages 924, 1051, 1275

Spanish

Details of CCSIDs and CCSID conversion for Spanish.

The following table shows the native CCSIDs for Spanish on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	284, 924, 1145
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

284

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 284, 437, 858, 1051, 1145, 1252, 1275, 5348

1145

Does not convert to code pages 924, 1051, 1275

UK English /Gaelic

Details of CCSIDs and CCSID conversion for UK English/Gaelic.

The following table shows the native CCSIDs for UK English / Gaelic on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	285, 924, 1146
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

285

Does not convert to code pages 858, 923, 924, 1275

924

Does not convert to code pages 285, 437, 858, 1051, 1146, 1252, 1275, 5348

1146

Does not convert to code pages 924, 1051, 1275

French

Details of CCSIDs and CCSID conversion for French.

The following table shows the native CCSIDs for French on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	297, 924, 1147
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

297

Does not convert to code pages 858, 923, 924, 1275, 5348

924

Does not convert to code pages 297, 437, 858, 1051, 1147, 1252, 1275, 5348

1147

Does not convert to code pages 924, 1051, 1275

Multilingual

Details of CCSIDs and CCSID conversion for Multilingual.

The following table shows the native CCSIDs for multilingual conversion on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	500, 924, 1148
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	437, 850, 858, 1252, 5348
HP Integrity NonStop Server, SINIX, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

500

Does not convert to code pages 858, 923

924

Does not convert to code pages 437, 858, 1051, 1148, 1252, 1275, 5348

1148

Does not convert to code pages 924, 1051, 1275

Portuguese

Details of CCSIDs and CCSID conversion for Portuguese.

The following table shows the native CCSIDs for Portuguese on supported platforms:

Platform	Native CCSIDs
IBM i	37, 500, 924, 1140
z/OS	500, 924, 1140
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	850, 858, 860, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

37

Does not convert to code pages 858, 923, 1275

500

Does not convert to code pages 858, 923, 1275

924

Does not convert to code pages 858, 860, 1051, 1140, 1252, 1275, 5348

1140

Does not convert to code pages 860, 924, 1051, 1275

HP-UX

Code page:

1051

Does not convert to code page 860

Windows

Code page:

860

Does not convert to code pages 1051, 1275

Icelandic

Details of CCSIDs and CCSID conversion for Icelandic.

The following table shows the native CCSIDs for Icelandic on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	871, 924, 1149
AIX	819, 923, 5348
HP-UX	819, 923, 1051
Windows	850, 858, 861, 1252, 5348
HP Integrity NonStop Server, Solaris, Linux	819, 923
Apple client	1275

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

IBM i

Code page:

871

Does not convert to code pages 858, 923, 924, 1275, 5348

924

Does not convert to code pages 858, 861, 871, 1051, 1149, 1252, 1275, 5348

1149

Does not convert to code pages 924, 1051, 1275

HP-UX

Code page:

1051

Does not convert to code page 861

Windows

Code page:

861

Does not convert to code pages 1051, 1275

Eastern European languages

Details of CCSIDs and CCSID conversion for Eastern European Languages. The typical languages using these CCSIDs include Albanian, Croatian, Czech, Hungarian, Polish, Romanian, Serbian, Slovak, and Slovenian.

The following table shows the native CCSIDs for Eastern European languages on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	870, 1153
Windows	852, 1250, 5346, 9044
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux	912
Eastern European Apple client	1282
Romanian Apple client	1285
Croatian Apple client	1284

All non-client platforms support conversion between their native CCSIDs and the native CCSIDs of the other platforms, with the following exceptions.

z/OS

Does not convert to code page 5350

Hebrew

Details of CCSIDs and CCSID conversion for Hebrew.

The following table shows the native CCSIDs for Hebrew on supported platforms:

Platform	Native CCSIDs
z/OS	424, 803, 4899, 12712
IBM i	424
AIX	916, 9048
HP-UX	916 (see note)
Windows	1255, 5351
HP Integrity NonStop Server, Solaris, Linux	916

Note: Only the ISO codeset is supported on HP-UX. The HP-UX proprietary greek8 codeset has no registered CCSID and is not supported.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

424

Does not convert to code pages 867, 4899, 9048, 12712

803

Does not convert to code pages 867, 4899, 5351, 9048, 12712

4899

Does not convert to code pages 424, 803, 856, 862, 916, 1255

12712

Does not convert to code pages 424, 803, 856, 916, 1255

IBM i

Code page:

424

Does not convert to code pages 803, 867, 4899, 5351, 9048, 12712

Code page 424 also converts to and from CCSID 4952, which is a variant of 856.

AIX

Code page:

916

Does not convert to code pages 867, 4899, 9048, 12712

9048

Does not convert to code pages 424, 803, 856, 862, 916, 1255

Windows

Code page:

1255

Does not convert to code pages 867, 4899, 9048, 12712

5351

Does not convert to code page 803

Arabic

Details of CCSIDs and CCSID conversion for Arabic

The following table shows the native CCSIDs for Arabic on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	420
AIX	1046, 1089
HP-UX	1089 (see note)
Windows	720, 864, 1256, 5352
HP Integrity NonStop Server, Solaris, Linux	1089

Note: Only the ISO codeset is supported on HP-UX. The HP-UX proprietary arabic8 codeset has no registered CCSID and is not supported.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

IBM i

Code page:

420

Does not convert to code page 5352

HP-UX, Solaris, Linux, HP Integrity NonStop Server, Tru64

Code page:

1089

Does not convert to code page 720

Windows

Code page:

720

Does not convert to code pages 1089, 5352

5352

Does not convert to code page 720

Farsi

Details of CCSIDs and CCSID conversion for Farsi.

The following table shows the native CCSIDs for Farsi on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	1097
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux Windows	1098 (see note)

Note: The native CCSID for these platforms has not been standardized and might change.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

Urdu

Details of CCSIDs and CCSID conversion for Urdu.

The following table shows the native CCSIDs for Urdu on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	918
Windows	868
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux	1006

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

IBM i

Code page:

918

Does not convert to code page 1006

Thai

Details of CCSIDs and CCSID conversion for Thai.

The following table shows the native CCSIDs for Thai on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	838
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux Windows	874 (see note)

Note: The native CCSID for these platforms has not been standardized and might change.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

Lao

Details of CCSIDs and CCSID conversion for Lao.

The following table shows the native CCSIDs for Lao on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	1132
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux Windows	1133

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms.

Vietnamese

Details of CCSIDs and CCSID conversion for Vietnamese.

The following table shows the native CCSIDs for Vietnamese on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	1130
Windows	1258, 5354
AIX, HP-UX, HP Integrity NonStop Server, Solaris, Linux	1129

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

IBM i

Code page:

1130

Does not convert to code pages 1129, 5354

Japanese Latin SBCS

Details of CCSIDs and CCSID conversion for Japanese Latin SBCS.

The following table shows the native CCSIDs for Japanese Latin SBCS on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	1027
AIX	932, 5050, 33722 (see Note 1)
Windows	932, 943 (see Notes 2 and 3)

Platform	Native CCSIDs
Linux, HP Integrity NonStop Server, Solaris	943, 5050
HP-UX	Not known

Note:

1. 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
2. Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 943.

3. IBM MQ does not support code pages based on the JIS X 0213 (JIS2004) standard.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

1027

Japanese Katakana SBCS

Details of CCSIDs and CCSID conversion for Japanese Katakana SBCS.

The following table shows the native CCSIDs for Japanese Katakana SBCS on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	290
HP-UX	897
AIX	932, 5050, 33722 (see Note 1)
Windows	932, 943 (see Notes 2 and 3)
Linux, HP Integrity NonStop Server, Solaris	943, 5050

Note:

1. 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
2. Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.
On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file `.. / conv/table/ccsid.tbl` can be made which changes the CCSID used to 943.
3. IBM MQ does not support code pages based on the JIS X 0213 (JIS2004) standard.
4. In addition to the previous conversions, the IBM MQ products on AIX, HP-UX, Solaris, Linux and Tru64 support conversion from CCSID 897 to CCSIDs 37, 273, 277, 278, 280, 284, 285, 290, 297, 437, 500, 819, 850, 1027, and 1252.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

290

Does not convert to code pages 932, 943, 954, 5050, 33722

5050

Does not convert to code pages 290, 897

Japanese Kanji/ Latin Mixed

Details of CCSIDs and CCSID conversion for Japanese Kanji/Latin Mixed.

The following table shows the native CCSIDs for Japanese Kanji/ Latin Mixed on supported platforms:

Platform	Native CCSIDs
IBM i, z/OS	1399, 5035 (see Note 1)
AIX	932, 5050, 33722 (see Note 2)
HP-UX	932, 954, 5039 (see Note 3)
Windows	932, 943 (see Notes 4 and 5)
Linux, HP Integrity NonStop Server, Solaris	943, 5050

Note:

1. 5035 is a CCSID related to code page 939
2. 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
3. Code sets japan15 and SJIS on HP-UX are represented by CCSID 932. These have a few DBCS characters having different representations in SJIS so 932 may be converted incorrectly if the conversion is not performed on an HP-UX system. IBM MQ for HP-UX supports 5039, the correct CCSID for HP SJIS. A change to file `/var/mqm/conv/ccsid.tbl` can be made to change the CCSID used from 932 to 5039.
4. Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 943.
5. IBM MQ does not support code pages based on the JIS X 0213 (JIS2004) standard.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

1399

Does not convert to code pages 954, 5035, 5050, 33722

5035

Does not convert to code pages 954, 1399, 5050, 33722

Japanese Kanji/ Katakana Mixed

Details of CCSIDs and CCSID conversion for Japanese Kanji/Katakana Mixed.

Table 570. Native CCSIDs for Japanese Kanji/ Katakana Mixed on supported platforms	
Platform	Native CCSIDs
z/OS	1390, 5026 (see Note 1)
IBM i	5026 (see Note 1)
AIX	932, 5050, 33722 (see Note 2)
HP-UX	932, 954, 5039 (see Note 3)
Windows	932, 943 (see Notes 4 and 5)
Linux, HP Integrity NonStop Server, Solaris	943, 5050

Note:

1. The single-byte mode of CCSIDs 1390 and 5026 in EBCDIC contain lower-case characters in different locations to the typical/invariant layout for basic Latin and care must be taken to ensure data is not lost when message data is being converted to other CCSIDs. In addition, the use of these CCSIDs as a queue manager's default CCSID may cause issues when communicating with other queue managers, for example, channel names using lower case characters may not be correctly interpreted on the remote system. 5026 is a CCSID related to code page 930. CCSID 5026 is the CCSID reported on IBM i when the Japanese Katakana (DBCS) feature is selected.
2. 5050 and 33722 are CCSIDs related to base code page 954 on AIX. The CCSID reported by the operating system is 33722.
3. Code sets japan15 and SJIS on HP-UX are represented by CCSID 932. These have a few DBCS characters having different representations in SJIS so 932 may be converted incorrectly if the conversion is not performed on an HP-UX system. IBM MQ for HP-UX supports 5039, the correct CCSID for HP SJIS. A change to file `/var/mqm/conv/ccsid.tbl` can be made to change the CCSID used from 932 to 5039.
4. Windows NT uses code page 932 but this is best represented by the CCSID of 943. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows, CCSID 932 is used to represent code page 932, but a change to file `./conv/table/ccsid.tbl` can be made that changes the CCSID used to 943.
5. IBM MQ does not support code pages based on the JIS X 0213 (JIS2004) standard.

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

1390

Does not convert to code pages 954, 5026, 5050, 33722

Does not accept lowercase characters.

Korean

Details of CCSIDs and CCSID conversion for Korean.

The following table shows the native CCSIDs for Korean on supported platforms:

Platform	Native CCSIDs
z/OS, IBM i	933, 1364
AIX, HP-UX, Linux, HP Integrity NonStop Server, Solaris	970
Windows	949, 1363

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

933

Does not convert to code page 970

1364

Does not convert to code page 970

HP-UX

Code page:

970

Does not convert to code pages 949, 1363, 1364

Simplified Chinese

Details of CCSIDs and CCSID conversion for Simplified Chinese.

The following table shows the native CCSIDs for Simplified Chinese on supported platforms:

Platform	Native CCSIDs
z/OS	935, 1388
IBM i	935, 1388

Platform	Native CCSIDs
AIX	1383, 1386
HP-UX	1381 (see Note 1)
Windows	1381, 1386(see Note 2)
Linux, HP Integrity NonStop Server, Solaris	1383

Note:

1. Code sets prc15 and hp15CN on HP-UX are represented by CCSID 1381.
2. Windows uses code page 936 but this is best represented by the CCSID of 1386. However, not all platforms of IBM MQ support this CCSID.

On IBM MQ for Windows CCSID 1381 is used to represent code page 936, but a change to file `./conv/table/ccsid.tbl` can be made which changes the CCSID used to 1386.

3. IBM MQ supports phase one of the Chinese GB18030 standard.

On z/OS, Linux, Windows, and Solaris, conversion support is provided between Unicode (UTF-8 and UCS-2) and CCSID 1388 (EBCDIC with GB18030 extensions), Unicode (UTF-8 and UCS-2) and CCSID 5488 (GB18030 phase one), and between CCSID 1388 and CCSID 5488.

Note:

On IBM i, support is provided by the operating system for conversion between Unicode (UTF-8 and UCS-2) and CCSID 1388 (EBCDIC with GB18030 extensions).

On HP-UX there is currently no support available on the HP11 operating system for GB18030.

On HP11i, patch PHCO_26456 provides conversion support between GB18030 (CCSID 5488) and Unicode. Support is not provided for the conversion between GB18030 and 1388 (EBCDIC).

All platforms support conversion between their native CCSIDs and the native CCSIDs of other platforms, with the following exceptions.

z/OS

Code page:

935

Does not convert to code page 1383

1388

Does not convert to code page 1383

33699	930-932, 939, 942-943, 1390, 1399, 5026, 5028, 5035, 5038-5039, 9122, 9124, 9131, 9135, 13218-13219, 13231, 17314, 25508, 25518, 29614, 33698, 33700, 37796
33700	930-932, 939, 942-943, 1390, 1399, 5026, 5028, 5035, 5038-5039, 9122, 9124, 9131, 9135, 13218-13219, 13231, 17314, 25508, 25518, 29614, 33698-33699, 37796
33717	933-934, 944, 949, 1363-1364, 5029, 5045, 5460, 9125, 9555, 13221, 13651, 17317, 25510, 25520, 25525, 29616, 29621, 37813
37796	930-932, 939, 942-943, 1390, 1399, 5026, 5028, 5035, 5038-5039, 9122, 9124, 9131, 9135, 13218-13219, 13231, 17314, 25508, 25518, 29614, 33698-33700
37813	933-934, 944, 949, 1363-1364, 5029, 5045, 5460, 9125, 9555, 13221, 13651, 17317, 25510, 25520, 25525, 29616, 29621, 33717

IBM i conversion support

A full list of CCSIDs, and conversions supported by IBM i, can be found in the appropriate IBM i publication.

The supported code pages are listed in [Supported CCSID mappings](#).

Unicode conversion support

Some platforms support the conversion of user data to or from Unicode encoding. The two forms of Unicode encoding supported are UCS-2 (CCSIDs 1200, 13488, and 17584) and UTF-8 (CCSID 1208).

The term *UCS-2* is often used interchangeably but incorrectly with *UTF-16*. UCS-2 is a fixed-width encoding where each character occupies 2 bytes. UTF-16 is variable-width encoding that is a superset of

UCS-2. In addition to the 2-byte UCS-2 characters, UTF-16 contains characters, known as surrogate pairs, that are 4 bytes in length. IBM MQ does not support surrogate pairs. The support for UTF-16 and UTF-8 in IBM MQ is therefore limited to those Unicode characters that can be encoded in UCS-2.

Note: IBM MQ does not support UCS-2 queue manager CCSIDs so message header data cannot be encoded in UCS-2.

IBM MQ AIX support for Unicode

On IBM MQ for AIX conversion to and from Unicode CCSIDs is supported for the CCSIDs in the following table.

037	273	278	280	284	285
297	423	437	500	813	819
850	852	856	857	858	860

IBM MQ HP-UX support for Unicode

On IBM MQ for HP-UX conversion to and from Unicode CCSIDs is supported for the CCSIDs listed in the following table.

437	737	813	819	850	852
855	857	861	864	865	866
869	874	912	915	916	920
932	938	950	954	964	970
1051	1089	1140	1141	1142	1143
1144	1145	1146	1147	1148	1149
1200	1208	1250	1251	1252	1253
1254	1255	1256	1257	1258	1381
5050	5488	13488	33722		

IBM MQ for Windows, Solaris, and Linux support for Unicode

On IBM MQ for Windows, IBM MQ for Solaris, and IBM MQ for Linux conversion to, and from, Unicode CCSIDs is supported for the CCSIDs in the following table.

037	277	278	280	284	285
290	297	300	301	420	424
437	500	813	819	833	835
836	837	838	850	852	855
856	857	858	860	861	862
863	864	865	866	867	868
869	870	871	874	875	878
880	891	897	901	902	903
904	912	913 (5)	915	916	918
920	921	922	923	924	927
928	930	931 (1)	932 (2)	933	935
937	938 (3)	939	941	942	943
947	948	949	950	951	954 (4)
964	970	1006	1025	1026	1027
1040	1041	1042	1043	1046	1047
1051	1088	1089	1097	1098	1112
1114	1115	1122	1123	1124	1129
1130	1132	1133	1140	1141	1142
1143	1144	1145	1146	1147	1148
1149	1153	1156	1157	1200	1208
1250	1251	1252	1253	1254	1255
1256	1257	1258	1275	1280	1281
1282	1283	1363	1364	1380	1381
1383	1386	1388	4899	5050	5346
5347	5348	5349	5350	5351	5352
5353	5354	5488 (5)	9044	9048	9449
12712	13488	17584	33722 (4)		

Notes:

1. 931 uses 939 for conversion.
2. 932 uses 942 for conversion.
3. 938 uses 948 for conversion.
4. 954 and 33722 use 5050 for conversion.
5. On Windows, Linux, and Solaris only.

IBM i support for Unicode

For details on UNICODE support refer to the appropriate IBM i publication relating to your operating system.

IBM MQ for z/OS support for Unicode

On IBM MQ for z/OS conversion to and from the Unicode CCSIDs is supported for the following CCSIDs:

37	256	259	273	275	277
278	280	282	284	285	290
293	297	300	301	367	420
423	424	437	500	720	737
775	803	806	808	813	819
833	834	835	836	837	838
848	849	850	851	852	855
856	857	858	859	860	861
862	863	864	865	866	867

Coding standards on 64-bit platforms

Use this information to learn about coding standards on 64-bit platforms and the preferred data types.

Preferred data types

These types never change size and are available on both 32-bit and 64-bit IBM MQ platforms:

Name	Length
MQLONG	4 bytes
MQULONG	4 bytes
MQINT32	4 bytes
MQUINT32	4 bytes
MQINT64	8 bytes
MQUINT64	8 bytes

Standard data types

Learn about standard data types on 32-bit UNIX, 64-bit UNIX, and 64-bit Windows applications.

32-bit UNIX applications

This section is included for comparison and is based on Solaris. Any differences with other UNIX platforms are noted:

Name	Length
char	1 byte
short	2 bytes
int	4 bytes
long	4 bytes
float	4 bytes
double	8 bytes
long double	16 bytes
Note that on AIX and Linux PPC a long double is 8 bytes.	
pointer	4 bytes
ptrdiff_t	4 bytes

Name	Length
size_t	4 bytes
time_t	4 bytes
clock_t	4 bytes
wchar_t	4 bytes

Note that on AIX a wchar_t is 2 bytes.

64-bit UNIX applications

This section is based on Solaris. Any differences with other UNIX platforms are noted:

Name	Length
char	1 byte
short	2 bytes
int	4 bytes
long	8 bytes
float	4 bytes
double	8 bytes
long double	16 bytes

Note that on AIX and Linux PPC a long double is 8 bytes.

pointer	8 bytes
ptrdiff_t	8 bytes
size_t	8 bytes
time_t	8 bytes
clock_t	8 bytes

Note that on the other UNIX platforms a clock_t is 4 bytes.

wchar_t	4 bytes
---------	---------

Note that on AIX a wchar_t is 2 bytes.

Windows 64-bit applications

Name	Length
char	1 byte
short	2 bytes
int	4 bytes
long	4 bytes
float	4 bytes
double	8 bytes
long double	8 bytes

Name	Length
pointer	8 bytes
	Note that all pointers are 8 bytes.
ptrdiff_t	8 bytes
size_t	8 bytes
time_t	8 bytes
clock_t	4 bytes
wchar_t	2 bytes
WORD	2 bytes
DWORD	4 bytes
HANDLE	8 bytes
HFILE	4 bytes

Coding considerations on Windows

HANDLE hf;

Use

```
hf = CreateFile((LPCTSTR) FileName,
                Access,
                ShareMode,
                xihSecAttsNTRestrict,
                Create,
                AttrAndFlags,
                NULL);
```

Do not use

```
HFILE hf;
hf = (HFILE) CreateFile((LPCTSTR) FileName,
                        Access,
                        ShareMode,
                        xihSecAttsNTRestrict,
                        Create,
                        AttrAndFlags,
                        NULL);
```

as this produces an error.

size_t len fgets

Use

```
size_t len
while (fgets(string1, (int) len, fp) != NULL)
len = strlen(buffer);
```

Do not use

```
int len;

while (fgets(string1, len, fp) != NULL)
len = strlen(buffer);
```

printf

Use

```
printf("My struc pointer: %p", pMyStruc);
```

Do not use

```
printf("My struc pointer: %x", pMyStruc);
```

If you need hexadecimal output, you have to print the upper and lower 4 bytes separately.

char *ptr

Use

```
char * ptr1;
char * ptr2;
size_t buflen;

buflen = ptr2 - ptr1;
```

Do not use

```
char *ptr1;
char *ptr2;
UINT32 buflen;

buflen = ptr2 - ptr1;
```

alignBytes

Use

```
alignBytes = (unsigned short) ((size_t) address % 16);
```

Do not use

```
void *address;
unsigned short alignBytes;

alignBytes = (unsigned short) ((UINT32) address % 16);
```

len

Use

```
len = (UINT32) ((char *) address2 - (char *) address1);
```

Do not use

```
void *address1;
void *address2;
UINT32 len;

len = (UINT32) ((char *) address2 - (char *) address1);
```

sscanf

Use

```
MQLONG SBCSprt;

sscanf(line, "%d", &SBCSprt);
```

Do not use

```
MQLONG SBCSprt;

sscanf(line, "%1d", &SBCSprt);
```

%1d tries to put an 8-byte type into a 4-byte type; only use %1 if you are dealing with an actual long data type. MQLONG, UINT32 and INT32 are defined to be four bytes, the same as an int on all IBM MQ platforms:

Application programming for IBM i

Use the following topics to help you develop applications for IBM i:

- [“Data type descriptions” on page 958](#)
- [“Function calls” on page 1206](#)
- [“Attributes of objects” on page 1324](#)
- [“Applications” on page 1369](#)
- [“Return codes for IBM i \(ILE RPG\)” on page 1381](#)
- [“Rules for validating MQI options for IBM i \(ILE RPG\)” on page 1382](#)
- [“Machine encodings on IBM i” on page 1385](#)
- [“Report options and message flags” on page 1388](#)

Compatibility mode for RPG applications on IBM i

This mode of operation was needed for applications that are written before MQSeries Version 5.1. Subsequent versions of the product provide a compatible runtime environment for these applications, even though the copybooks needed for compiling them were removed in IBM WebSphere MQ 6.0. Although dynamic linkage (compatibility mode) is provided in library QMQM for versions of the product after MQSeries Version 5.1, applications that use this compatibility mode of operation, need to be recompiled to use the static bound MQ calls that are provided by the LIBMQM and LIBMQM_R service programs, instead.

Related tasks

[Developing applications](#)

Data type descriptions

This collection of topics provides descriptions of data types used in IBM i programming.

Conventions used in the description of data types

For each elementary data type, this information gives a description of its usage, in a form that is independent of the programming language. This is followed by typical declarations in the ILE version of the RPG programming language. The definitions of elementary data types are included here to provide consistency. RPG uses 'D' specifications where working fields can be declared using whatever attributes you need. You can, however, do this in the calculation specifications where the field is used.

To use the elementary data types, you create:

- A /COPY member containing all the data types, or
- An external data structure (PF) containing all the data types. You then need to specify your working fields with attributes 'LIKE' the appropriate data type field.

The benefits of the second option are that the definitions can be used as a 'FIELD REFERENCE FILE' for other IBM i objects. If an IBM MQ data type definition changes, it is a relatively simple matter to re-create these objects.

Elementary data types

All of the other data types described in this section equate either directly to these elementary data types, or to aggregates of these elementary data types (arrays or structures).

<i>Table 572. Elementary data types</i>	
Data type	Representation
MQBOOL	10-digit signed integer
MQBYTE	1-byte alphanumeric field
MQBYTE16	16-byte alphanumeric field
MQBYTE24	24-byte alphanumeric field
MQBYTE32	32-byte alphanumeric field
MQBYTE64	64-byte alphanumeric field
MQCHAR	1-byte alphanumeric field
MQCHAR4	4-byte alphanumeric field
MQCHAR8	8-byte alphanumeric field
MQCHAR12	12-byte alphanumeric field
MQCHAR16	16-byte alphanumeric field
MQCHAR20	20-byte alphanumeric field
MQCHAR28	28-byte alphanumeric field
MQCHAR32	32-byte alphanumeric field
MQCHAR48	48-byte alphanumeric field
MQCHAR64	64-byte alphanumeric field
MQCHAR128	128-byte alphanumeric field
MQCHAR256	256-byte alphanumeric field
MQFLOAT32	4-byte floating-point number
MQFLOAT64	8-byte floating-point number
MQHCONFIG	Configuration handle
MQHCONN	10-digit signed integer
MQHMSG	Message handle that gives access to a message
MQHOBJ	10-digit signed integer
MQINT8	8-bit signed integer
MQINT16	16-bit signed integer
MQINT32	32-bit signed integer
MQINT64	64-bit signed integer
MQLONG	32-bit signed integer
MQPID	Process identifier
MQPTR	Pointer

Table 572. Elementary data types (continued)

Data type	Representation
MQTID	Thread identifier
MQUINT8	8-bit unsigned integer
MQUINT16	16-bit unsigned integer
MQUINT32	32-bit unsigned integer
MQUINT64	64-bit unsigned integer
MQULONG	32-bit unsigned integer
PMQACH	Pointer to a data structure of type MQACH
PMQAIR	Pointer to a data structure of type MQAIR
PMQAXC	Pointer to a data structure of type MQAXC
PMAXP	Pointer to a data structure of type MAXP
PMQBMHO	Pointer to a data structure of type MQBMHO
PMQBO	Pointer to a data structure of type MQBO
PMQBOOL	Pointer to data of type MQBOOL
PMQBYTE	Pointer to data of type MQBYTE
PMQBYTEn	Pointer to data of type MQBYTEn
PMQCBC	Pointer to a data structure of type MQCBC
PMQCBD	Pointer to a data structure of type MQCBD
PMQCHAR	Pointer to a data structure of type MQCHAR
PMQCHARV	Pointer to a data structure of type MQCHARV
PMQCHARn	Pointer to data of type MQCHARn
PMQCIH	Pointer to a data structure of type MQCIH
PMQCMHO	Pointer to a data structure of type MQCMHO
PMQCNO	Pointer to a data structure of type MQCNO
PMQCSP	Pointer to a data structure of type MQCSP
PMQCTLO	Pointer to a data structure of type MQCTLO
PMQDH	Pointer to a data structure of type MQDH
PMQDHO	Pointer to a data structure of type MQDHO
PMQDLH	Pointer to a data structure of type MQDLH
PMQDMHO	Pointer to a data structure of type MQDMHO
PMQDMPO	Pointer to a data structure of type MQDMPO
PMQEPH	Pointer to a data structure of type MQEPH
PMQFLOAT32	Pointer to data of type MQFLOAT32
PMQFLOAT64	Pointer to data of type MQFLOAT64
PMQFUNC	Pointer to a function

Table 572. Elementary data types (continued)

Data type	Representation
PMQGM0	Pointer to a data structure of type MQGM0
PMQHCONFIG	Pointer to data of type MQHCONFIG
PMQHCONN	Pointer to data of type MQHCONN
PMQHMSG	Pointer to data of type MQHMSG
PMQHOBj	Pointer to data of type MQHOBj
PMQIIH	Pointer to a data structure of type MQIIH
PMQIMPO	Pointer to a data structure of type MQIMPO
PMQINT8	Pointer to data of type MQINT8
PMQINT16	Pointer to data of type MQINT16
PMQINT32	Pointer to data of type MQINT32
PMQINT64	Pointer to data of type MQINT64
PMQLONG	Pointer to data of type MQLONG

PMQMDE	Pointer to a data structure of type MQMDE
PMQMD1	Pointer to a data structure of type MQMD1
PMQMD2	Pointer to a data structure of type MQMD2
PMQMHBO	Pointer to a data structure of type MQMHBO
PMQOD	Pointer to a data structure of type MQOD
PMQOR	Pointer to a data structure of type MQOR
PMQPD	Pointer to a data structure of type MQPD
PMQPID	Pointer to a process identifier MQPID
PMQPMO	Pointer to a data structure of type MQPMO
PMQPTR	Pointer to data of type MQPTR
PMQRFH	Pointer to a data structure of type MQRFH
PMQRFH2	Pointer to a data structure of type MQRFH2
PMQRMH	Pointer to a data structure of type MQRMH
PMQRR	Pointer to a data structure of type MQRR
PMQSCO	Pointer to a data structure of type MQSCO
PMQSD	Pointer to a data structure of type MQSD
PMQSMPO	Pointer to a data structure of type MQSMPO
PMQSRO	Pointer to a data structure of type MQSRO
PMQSTS	Pointer to a data structure of type MQSTS
PMQTID	Pointer to a thread identifier MQTID
PMQTM	Pointer to a data structure of type MQTM

Table 572. Elementary data types (continued)

Data type	Representation
PMQPMC2	Pointer to a data structure of type MQPMC2
PMQUINT8	Pointer to data of type MQUINT8
PMQUINT16	Pointer to data of type MQUINT16
PMQUINT32	Pointer to data of type MQUINT32
PMQUINT64	Pointer to data of type MQUINT64
PMQULONG	Pointer to data of type MQULONG
PMQVOID	Pointer
PMQWIH	Pointer to a data structure of type MQWIH
PMQXQH	Pointer to a data structure of type MQXQH

MQBOOL

The MQBOOL data type represents a boolean value. The value 0 represents false. Any other value represents true.

An MQBOOL must be aligned as for the MQLONG data type.

MQBYTE - Byte

The MQBYTE data type represents a single byte of data.

No particular interpretation is placed on the byte—it is treated as a string of bits, and not as a binary number or character. No special alignment is required.

An array of MQBYTE is sometimes used to represent an area of main storage with a nature that is not known to the queue manager. For example, the area might contain application message data or a structure. The boundary alignment of this area must be compatible with the nature of the data contained within it.

MQBYTEN - String of *n* bytes

Each MQBYTEN data type represents a string of *n* bytes.

Where *n* can take one of the following values:

- 16, 24, 32, or 64.

Each byte is described by the MQBYTE data type. No special alignment is required.

If the data in the string is shorter than the defined length of the string, the data must be padded with nulls to fill the string.

When the queue manager returns byte strings to the application (for example, on the MQGET call), the queue manager always pads with nulls to the defined length of the string.

Constants are available that define the lengths of byte string fields.

MQCHAR - character

The MQCHAR data type represents a single character.

The coded character set identifier of the character is that of the queue manager (see the *CodedCharSetId* attribute in topic [CodedCharSetId](#)). No special alignment is required.

Note: Application message data specified on the MQGET, MQPUT, and MQPUT1 calls is described by the MQBYTE data type, not the MQCHAR data type.

MQCHARn - String of n characters

Each MQCHARn data type represents a string of n characters.

Where n can take one of the following values:

- 4, 8, 12, 16, 20, 28, 32, 48, 64, 128, or 256

Each character is described by the MQCHAR data type. No special alignment is required.

If the data in the string is shorter than the defined length of the string, the data must be padded with blanks to fill the string. In some cases a null character can be used to end the string prematurely, instead of padding with blanks; the null character and characters following it are treated as blanks, up to the defined length of the string. The places where a null can be used are identified in the call and data type descriptions.

When the queue manager returns character strings to the application (for example, on the MQGET call), the queue manager always pads with blanks to the defined length of the string; the queue manager does not use the null character to delimit the string.

Constants are available that define the lengths of character string fields.

MQFLOAT32

The MQFLOAT32 data type is a 32-bit floating-point number represented using the standard IEEE floating-point format.

An MQFLOAT32 must be aligned on a 4-byte boundary.

MQFLOAT64

The MQFLOAT64 data type is a 64-bit floating-point number represented using the standard IEEE floating-point format.

An MQFLOAT64 must be aligned on an 8-byte boundary.

MQHCONFIG - configuration handle

The MQHCONFIG data type represents a configuration handle, that is, the component that is being configured for a particular installable service. A configuration handle must be aligned on its natural boundary.

Note: Applications must test variables of this type for equality only.

MQHCONN - Connection handle

The MQHCONN data type represents a connection handle, that is, the connection to a particular queue manager.

A connection handle must be aligned on its natural boundary.

Note: Applications must test variables of this type for equality only.

MQHMSG - Message handle

The MQHMSG data type represents a message handle that gives access to a message.

A message handle must be aligned on an 8-byte boundary.

Note: Applications must test variables of this type for equality only.

MQHOBJ - Object handle

The MQHOBJ data type represents an object handle that gives access to an object.

An object handle must be aligned on its natural boundary.

Note: Applications must test variables of this type for equality only.

MQINT8 - 8-bit signed integer

The MQINT8 data type is an 8-bit signed integer that can take any value in the range -128 to +127, unless otherwise restricted by the context.

MQINT16 - 16-bit signed integer

The MQINT16 data type is a 16-bit signed integer that can take any value in the range -32 768 to +32 767, unless otherwise restricted by the context.

An MQINT16 must be aligned on a 2-byte boundary.

MQINT32 - 32-bit integer

The MQINT32 data type is a 32-bit signed integer.

It is equivalent to MQLONG.

MQINT64 - 64-bit integer

The MQINT64 data type is a 64-bit signed integer that can take any value in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, unless otherwise restricted by the context.

For COBOL, the valid range is limited to -999 999 999 999 999 999 through +999 999 999 999 999 999. An MQINT64 should be aligned on an 8-byte boundary.

MQLONG - Long integer

The MQLONG data type is a 32-bit signed binary integer that can take any value in the range -2 147 483 648 through +2 147 483 647, unless otherwise restricted by the context, aligned on its natural boundary.

MQPID - process identifier

The IBM MQ process identifier.

This is the same identifier used in IBM MQ trace and FFST dumps, but might be different from the operating system process identifier.

MQPTR - pointer

The MQPTR data type is the address of data of any type. A pointer must be aligned on its natural boundary; this is a 16-byte boundary on IBM i.

Some programming languages support typed pointers; the MQI also uses these in a few cases.

MQTID - thread identifier

The MQ thread identifier.

This is the same identifier used in MQ trace and FFST dumps, but might be different from the operating system thread identifier.

MQUINT8 - 8-bit unsigned integer

The MQUINT8 data type is an 8-bit unsigned integer that can take any value in the range 0 to +255, unless otherwise restricted by the context.

MQUINT16 - 16-bit unsigned integer

The MQUINT16 data type is a 16-bit unsigned integer that can take any value in the range 0 through +65 535, unless otherwise restricted by the context.

An MQUINT16 must be aligned on a 2-byte boundary.

MQUINT32 - 32-bit unsigned integer

The MQUINT32 data type is a 32-bit unsigned integer. It is equivalent to MQULONG.

MQUINT64 - 64-bit unsigned integer

The MQUINT64 data type is a 64-bit unsigned integer that can take any value in the range 0 through +18 446 744 073 709 551 615 unless otherwise restricted by the context.

For COBOL, the valid range is limited to 0 through +999 999 999 999 999 999. An MQUINT64 should be aligned on a 8-byte boundary.

MQULONG - 32-bit unsigned integer

The MQULONG data type is a 32-bit unsigned binary integer that can take any value in the range 0 through +4 294 967 294, unless otherwise restricted by the context.

An MQULONG must be aligned on a 4-byte boundary.

PMQACH - pointer to a data structure of type MQACH

A pointer to a data structure of type MQACH.

PMQAIR - pointer to a data structure of type MQAIR

A pointer to a data structure of type MQAIR.

PMQAXC - pointer to a data structure of type MQAXC

A pointer to a data structure of type MQAXC.

PMQAXP - pointer to a data structure of type MQAXP

A pointer to a data structure of type MQAXP.

PMQBMHO - pointer to a data structure of type MQBMHO

A pointer to a data structure of type MQBMHO.

PMQBO - pointer to a data structure of type MQBO

A pointer to a data structure of type MQBO.

PMQBOOL - pointer to data of type MQBOOL

A pointer to data of type MQBOOL.

A pointer to data of type MQBOOL.

PMQBYTE - pointer to a data type of MQBYTE

A pointer to a data type of MQBYTE.

PMQBYTEn - pointer to a data structure of type MQBYTEn

A pointer to a data structure of type MQBYTEn, where n can be 8, 12, 16, 24, 32, 40, 48 or 128.

PMQCBC - pointer to a data structure of type MQCBC

A pointer to a data structure of type MQCBC.

PMQCBD - pointer to a data structure of type MQCBD

A pointer to a data structure of type MQCBD.

PMQCHAR - pointer to data of type MQCHAR

A pointer to data of type MQCHAR.

PMQCHARV - pointer to a data structure of type MQCHARV

A pointer to a data structure of type MQCHARV.

PMQCHARn - pointer to a data type of MQCHARn

A pointer to a data type of MQCHARn, where n can be 4, 8, 12, 20, 28, 32, 64, 128, 256, 264.

PMQCIH - pointer to a data structure of type of MQCIH

A pointer to a data structure of type of MQCIH.

PMQCMHO - pointer to a data structure of type MQCMHO

A pointer to a data structure of type MQCMHO.

PMQCNO - pointer to a data structure of type of MQCNO

A pointer to a data structure of type of MQCNO.

PMQCSP - pointer to a data structure of type MQCSP

A pointer to a data structure of type MQCSP.

PMQCTLO - pointer to a data structure of type MQCTLO

A pointer to a data structure of type MQCTLO.

PMQDH - pointer to a data structure of type MQDH

A pointer to a data structure of type MQDH.

PMQDHO - pointer to a data structure of type MQDHO

A pointer to a data structure of type MQDHO.

PMQDLH - pointer to a data structure of type of MQDLH

A pointer to a data structure of type of MQDLH.

PMQDMHO - pointer to a data structure of type MQDMHO

A pointer to a data structure of type MQDMHO.

PMQDMPO - pointer to a data structure of type MQDMPO

A pointer to a data structure of type MQDMPO.

A pointer to a data structure of type MQDMPO.

PMQEPPH - pointer to a data structure of type MQEPPH

A pointer to a data structure of type MQEPPH.

PMQFLOAT32 - pointer to data of type MQFLOAT32

A pointer to data of type MQFLOAT32.

PMQFLOAT64 - pointer to data of type MQFLOAT64

A pointer to data of type MQFLOAT64.

PMQFUNC - pointer to a function

A pointer to a function.

PMQGMPO - pointer to a data structure of type MQGMPO

A pointer to a data structure of type MQGMPO.

PMQHCONFIG - pointer to a data type of MQHCONFIG

A pointer to a data type of MQHCONFIG.

PMQHCONN - pointer to a data type of MQHCONN

A pointer to a data type of MQHCONN.

PMQHMSG - pointer to a data type of MQHMSG

A pointer to a data type of MQHMSG.

PMQHOBJS - pointer to data of type MQHOBJS

A pointer to data of type MQHOBJS.

PMQIIH - pointer to a data structure of type MQIIH

A pointer to a data structure of type MQIIH.

PMQIMPO - pointer to a data structure of type MQIMPO

A pointer to a data structure of type MQIMPO.

PMQINT8 - pointer to data of type MQINT8

A pointer to data of type MQINT8.

PMQINT16 - pointer to data of type MQINT16

A pointer to data of type MQINT16.

PMQINT32 - Pointer to data of type MQINT32

The PMQINT32 data type is a pointer to data of type MQINT32. It is equivalent to PMQLONG.

PMQINT64 - Pointer to data of type MQINT64

The PMQINT64 data type is a pointer to data of type MQINT64.

PMQLONG - pointer to data of type MQLONG

A pointer to data of type MQLONG.

PMQMD - pointer to structure of type MQMD

A pointer to structure of type MQMD.

PMQMDE - pointer to a data structure of type MQMDE

A pointer to a data structure of type MQMDE.

PMQMDI - pointer to a data structure of type MQMDI

A pointer to a data structure of type MQMDI.

PMQMD2 - pointer to a data structure of type MQMD2

A pointer to a data structure of type MQMD2

PMQMHBO - pointer to a data structure of type MQMHBO

A pointer to a data structure of type MQMHBO.

PMQOD - pointer to a data structure of type MQOD

A pointer to a data structure of type MQOD.

PMQOR - pointer to a data structure of type MQOR

A pointer to a data structure of type MQOR.

PMQPD - pointer to a data structure of type MQPD

A pointer to a data structure of type MQPD.

PMQPID - pointer to a process identifier

A pointer to a process identifier.

MQPMO - pointer to a data structure of type MQPMO

A pointer to a data structure of type MQPMO.

MQPTR - pointer to data of type MQPTR

A pointer to data of type MQPTR.

MQRFH - pointer to a data structure of type MQRFH

A pointer to a data structure of type MQRFH.

MQRFH2 - pointer to a data structure of type MQRFH2

A pointer to a data structure of type MQRFH2.

.

MQRMH - pointer to a data structure of type MQRMH

A pointer to a data structure of type MQRMH.

MQRR - pointer to a data structure of type MQRR

A pointer to a data structure of type MQRR.

MQSCO - pointer to a data structure of type MQSCO

A pointer to a data structure of type MQSCO.

.

MQSD - pointer to a data structure of type MQSD

A pointer to a data structure of type MQSD.

PMQSMPO - pointer to a data structure of type MQSMPO

A pointer to a data structure of type MQSMPO.

PMQSRO - pointer to a data structure of type MQSRO

A pointer to a data structure of type MQSRO.

PMQSTS - pointer to a data structure of type MQSTS

A pointer to a data structure of type MQSTS.

PMQTID - pointer to a data structure of type MQTID

A pointer to a data structure of type MQTID.

PMQTM - pointer to a data structure of type MQTM

A pointer to a data structure of type MQTM.

PMQTM2 - pointer to a data structure of type MQTM2

A pointer to a data structure of type MQTM2.

PMQUINT8 - pointer to data of type MQUINT8

A pointer to data of type MQUINT8.

PMQUINT16 - pointer to data of type MQUINT16

A pointer to data of type MQUINT16.

PMQUINT32 - Pointer to data of type MQUINT32

The PMQUINT32 data type is a pointer to data of type MQUINT32. It is equivalent to PMQULONG.

PMQUINT64 - Pointer to data of type MQUINT64

The PMQUINT64 data type is a pointer to data of type MQUINT64.

PMQULONG - pointer to data of type MQULONG

A pointer to data of type MQULONG.

PMQVOID - pointer

A pointer.

PMQWIH - pointer to a data structure of type MQWIH

A pointer to a data structure of type MQWIH.

PMQXQH - pointer to a data structure of type MQXQH

A pointer to a data structure of type MQXQH.

Language considerations

This topic contains information to help you use the MQI from the RPG programming language.

Some of these language considerations are:

- [“COPY files” on page 971](#)
- [“Calls” on page 973](#)
- [“Call parameters” on page 973](#)
- [“Structures” on page 973](#)
- [“Named constants” on page 973](#)
- [“MQI procedures” on page 974](#)
- [“Threading considerations” on page 974](#)
- [“Commitment control” on page 974](#)
- [“Coding the bound calls” on page 974](#)
- [“Notational conventions” on page 976](#)

COPY files

Various COPY files are provided to assist with the writing of RPG application programs that use message queuing. There are three sets of COPY files:

- COPY files with names ending with the letter *G* are for use with programs that use static linkage. These files are initialized with the exceptions stated in [“Structures” on page 973](#).
- COPY files with names ending with the letter *H* are for use with programs that use static linkage, but are **not** initialized.
- COPY files with names ending with the letter *R* are for use with programs that use dynamic linkage. These files are initialized with the exceptions stated in [“Structures” on page 973](#).

The COPY files reside in QRPGLSRC in the QMQM library.

For each set of COPY files, there are two files containing named constants, and one file for each of the structures. The COPY files are summarized in [Table 573 on page 971](#).

<i>Table 573. RPG COPY files</i>			
File name (static linkage, initialized, CMQ*G)	File name (static linkage, not initialized, CMQ*H)	File name (dynamic linkage, initialized, CMQ*R)	Contents
CMQBOG	CMQBOH	-	Begin options structure
CMQCDG	CMQCDH	CMQCDR	Channel definition structure
CMQCFBFG	CMQCFBFH	-	PCF bit filter parameter
CMQCFG	-	-	Constants for PCF and events
CMQCFBSG	CMQCFBSH	-	PCF byte string

Table 573. RPG COPY files (continued)

File name (static linkage, initialized, CMQ*G)	File name (static linkage, not initialized, CMQ*H)	File name (dynamic linkage, initialized, CMQ*R)	Contents
CMQCFGRG	CMQCFGRH	-	PCF group parameter
CMQCFIFG	CMQCFIFH	-	PCF integer filter parameter
CMQCFHG	CMQCFHH	-	PCF header
CMQCFILG	CMQCFILH	-	PCF integer list parameter structure
CMQCFING	CMQCFINH	-	PCF integer parameter structure
CMQCFSFG	CMQCFSFH	-	PCF string filter parameter
CMQCFSLG	CMQCFSLH	-	PCF string list parameter structure
CMQCFSTG	CMQCFSTH	-	PCF string parameter structure
CMQCFXLG	CMQCFXLH	-	PCF short name for CFIL64
CMQCFXNG	CMQCFXNH	-	PCF short name for CFIN64
CMQCIHG	CMQCIHH	-	CICS information header structure
CMQCNORG	CMQCNOH	-	Connect options structure
CMQCSPG	CMQCSPH	-	Security parameters
CMQCXPG	CMQCXPH	CMQCXPR	Channel exit parameter structure
CMQDHG	CMQDHH	CMQDHR	Distribution header structure
CMQDLHG	CMQDLHH	CMQDLHR	Dead letter header structure
CMQDXPG	CMQDXPH	CMQDXPR	Data conversion exit parameter structure
CMQEPHG	CMQEPHH	-	Embedded PCF header structure
CMQG	-	CMQR	Named constants for main MQI
CMQGMORG	CMQGMOH	CMQGMOR	Get message options structure
CMQIIHG	CMQIIHH	CMQIIHR	IMS information header structure
CMQMDEG	CMQMDEH	CMQMDER	Message descriptor extension structure
CMQMDG	CMQMDH	CMQMDR	Message descriptor structure
CMQMD1G	CMQMD1H	CMQMD1R	Message descriptor structure version 1
CMQMD2G	CMQMD2H	-	Message descriptor structure version 2
CMQODG	CMQODH	CMQODR	Object descriptor structure
CMQORG	CMQORH	CMQORR	Object record structure
CMQPMORG	CMQPMOH	CMQPMOR	Put message options structure
CMQPSG	-	-	Constants for publish/subscribe
CMQRFHG	CMQRFHH	-	Rules and formatting header structure
CMQRFH2G	CMQRFH2H	-	Rules and formatting header 2 structure
CMQRMHG	CMQRMHH	CMQRMHR	Reference message header structure

Table 573. RPG COPY files (continued)

File name (static linkage, initialized, CMQ*G)	File name (static linkage, not initialized, CMQ*H)	File name (dynamic linkage, initialized, CMQ*R)	Contents
CMQRRG	CMQRRH	CMQRRR	Response record structure
CMQTMCG	CMQTMCH	CMQTMCR	Trigger message structure (character format)
CMQTMCG	CMQTMCH	CMQTMCR	Trigger message structure (character format) version 2
CMQTMG	CMQTMH	CMQTMR	Trigger message structure
CMQWIHG	CMQWIHH	-	Work information header structure
CMQXG	-	CMQXR	Named constants for data conversion exit
CMQXQHG	CMQXQHH	CMQXQHR	Transmission queue header structure

Calls

Calls are described using their individual names.

Call parameters

Some parameters passed to the MQI can have more than one concurrent function. This is because the integer value passed is often tested on the setting of individual bits within the field, and not on its total value. This allows you to 'add' several functions together and pass them as a single parameter.

Structures

All IBM MQ structures are defined with initial values for the fields, with the following exceptions:

- Any structure with a suffix of H.
- MQTMC
- MQTMC2

These initial values are defined in the relevant table for each structure.

The structure declarations do not contain DS statements. This allows the application to declare either a single data structure or a multiple-occurrence data structure, by coding the DS statement and then using the /COPY statement to copy in the remainder of the declaration:

```
D*.1.....2.....3.....4.....5.....6.....7
D* Declare an MQMD data structure with 5 occurrences
DMYMD      DS              5
D/COPY CMQMDR
```

Named constants

There are many integer and character values that provide data interchange between your application program and the queue manager. To facilitate a more readable and consistent approach to using these values, named constants are defined for them. You can use these named constants and not the values they represent, as this improves the readability of the program source code.

When the COPY file CMQG is included in a program to define the constants, the RPG compiler will issue many severity-zero messages for the constants that are not used by the program; these messages are benign, and can safely be ignored.

MQI procedures

When using the ILE bound calls, you must bind to the MQI procedures when you create your program. These procedures are exported from the following service programs as appropriate:

QMQM/AMQZSTUB

This service program provides compatibility bindings for applications written before MQSeries V5.1 that do not require access to any of the new capabilities provided in version 5.1. The signature of this service program matches that contained in version 4.2.1.

QMQM/LIBMQM

This service program contains the single-threaded bindings for version 5.1 and above. See the following section for special considerations when writing threaded applications.

QMQM/LIBMQM_R

This service program contains the multi-threaded bindings for version 5.1 and above. See the following section for special considerations when writing threaded applications.

QMQM/LIBMQIC

This service program is for binding non-threaded client applications.

QMQM/LIBMQIC_R

This service program is for binding threaded client applications.

Use the CRTPGM command to create your programs. For example, the following command creates a single-threaded program that uses the ILE bound calls:

```
CRTPGM PGM(MYPROGRAM) BNDSRVPGM(QMQM/LIBMQM)
```

Threading considerations

The RPG compiler used for IBM i is part of the WebSphere Development Toolset and WebSphere Development Studio for IBM i and is known as the ILE RPG IV Compiler.

In general, RPG programs should not use the multi-threaded service programs. Exceptions are RPG programs created using the ILE RPG IV Compiler, and containing the THREAD(*SERIALIZE) keyword in the control specification. However, even though these programs are thread safe, careful consideration must be given to the overall application design, as THREAD(*SERIALIZE) forces serialization of RPG procedures at the module level, and this might have an adverse affect on overall performance.

Where RPG programs are used as data-conversion exits, they must be made thread-safe, and should be recompiled using the version 4.4 ILE RPG compiler or above, with THREAD(*SERIALIZE) specified in the control specification.

For further information about threading, see the *IBM i IBM MQ Development Studio: ILE RPG Reference*, and the *IBM i IBM MQ Development Studio: ILE RPG Programmer's Guide*.

Commitment control

The MQI syncpoint functions MQCMIT and MQBACK are available to ILE RPG programs running in normal mode; these calls allow the program to commit and back out changes to MQ resources.

The MQCMIT and MQBACK calls are not available to ILE RPG programs running in compatibility mode. For these programs, you should use the operation codes COMMIT and ROLBK.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

Coding the bound calls

MQI ILE procedures are listed in [Table 574 on page 975](#).

Table 574. ILE RPG bound calls supported by each service program

Name of call	LIBMQM and LIBMQM_R	AMQZSTUB	AMQVSTUB	LIBMQIC and LIBMQIC_R
MQBACK	Y			Y
MQBEGIN	Y			Y
MQCMIT	Y			Y
MQCLOSE	Y	Y		Y
MQCONN	Y	Y		Y
MQCONNX	Y			Y
MQDISC	Y	Y		Y
MQGET	Y	Y		Y
MQINQ	Y	Y		Y
MQOPEN	Y	Y		Y
MQPUT	Y	Y		Y
MQPUT1	Y	Y		Y
MQSET	Y	Y		Y
MQXCNVC	Y		Y	Y

To use these procedures you need to:

1. Define the external procedures in your 'D' specifications. These are all available within the COPY file member CMQG containing the named constants.
2. Use the CALLP operation code to call the procedure along with its parameters.

For example the MQOPEN call requires the inclusion of the following code:

```

D*****
D**  MQOPEN Call -- Open Object (From COPY file CMQG)      **
D*****
D*
D*..1....:....2....:....3....:....4....:....5....:....6....:....7..
DMQOPEN          PR          EXTPROC('MQOPEN')
D* Connection handle
D HCONN          10I 0 VALUE
D* Object descriptor
D OBJDSC          224A
D* Options that control the action of MQOPEN
D OPTS          10I 0 VALUE
D* Object handle
D HOBJ          10I 0
D* Completion code
D CMPCOD          10I 0
D* Reason code qualifying CMPCOD
D REASON          10I 0
D*

```

To call the procedure, after initializing the various parameters, you need the following code:

```

...+... 1 ...+... 2 ...+... 3 ...+... 4 ...+... 5 ...+... 6 ...+... 7 ...+... 8
  C          CALLP      MQOPEN(HCONN : MQOD : OPTS : HOBJ :
  C          CMPCOD : REASON)

```

Here, the structure MQOD is defined using the COPY member CMQODG which breaks it down into its components.

Notational conventions

The latter topics in this section show how the:

- Calls should be invoked
- Parameters should be declared
- Various data types should be declared

In a number of cases, parameters are arrays or character strings with a size that is not fixed. For these, a lowercase "n" is used to represent a numeric constant. When the declaration for that parameter is coded, the "n" must be replaced by the numeric value required.

MQAIR - Authentication information record

The MQAIR structure represents the authentication information record.

Overview

Purpose: The MQAIR structure allows an application running as an IBM MQ client to specify information about an authenticator that is to be used for the client connection. The structure is an input parameter on the MQCONN call.

Character set and encoding: Data in MQAIR must be in the character set given by the *CodedCharSetId* queue-manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 976](#)
- [“Initial values” on page 978](#)
- [“RPG declaration” on page 978](#)

Fields

The MQAIR structure contains the following fields; the fields are described in **alphabetical order**:

AICN (10-digit signed integer)

This is either the host name or the network address of a host on which the LDAP server is running. This can be followed by an optional port number, enclosed in parentheses.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the value is not valid, the call fails with reason code RC2387.

The default port number is 389.

This is an input field. The length of this field is given by LNAICN. The initial value of this field is blank characters.

AITYP (10-digit signed integer)

This is the type of authentication information contained in the record.

The value must be:

AITLDP

Certificate revocation using LDAP server.

If the value is not valid, the call fails with reason code RC2386.

This is an input field. The initial value of this field is AITLDP.

AIPW (10-digit signed integer)

This is the password needed to access the LDAP CRL server.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the LDAP server does not require a password, or you omit the

LDAP user name, *AIPW* must be null or blank. If you omit the LDAP user name and *AIPW* is not null or blank, the call fails with reason code RC2390.

This is an input field. The length of this field is given by *LNLDPW*. The initial value of this field blank characters.

AILUL (10-digit signed integer)

This is the length in bytes of the LDAP user name addressed by the *AILUP* or *AILUO* field. The value must be in the range zero through *LNDISN*. If the value is not valid, the call fails with reason code RC2389.

If the LDAP server involved does not require a user name, set this field to zero.

This is an input field. The initial value of this field is 0.

AILUO (10-digit signed integer)

This is the offset in bytes of the LDAP user name from the start of the MQAIR structure.

The offset can be positive or negative. The field is ignored if *LDAPUserNameLength* is zero.

You can use either *LDAPUserNamePtr* or *LDAPUserNameOffset* to specify the LDAP user name, but not both; see the description of the *LDAPUserNamePtr* field for details.

This is an input field. The initial value of this field is 0.

AILUP (10-digit signed integer)

This is the LDAP user name.

It consists of the Distinguished Name of the user who is attempting to access the LDAP CRL server. If the value is shorter than the length specified by *AILUL*, terminate the value with a null character, or pad it with blanks to the length *AILUL*. The field is ignored if *AILUL* is zero.

You can supply the LDAP user name in one of two ways:

- By using the pointer field *AILUP*

In this case, the application can declare a string that is separate from the MQAIR structure, and set *AILUP* to the address of the string.

Consider using *AILUP* for programming languages that support the pointer data type in a fashion that is portable to different environments (for example, the C programming language).

- By using the offset field *AILUO*

In this case, the application must declare a compound structure containing the MQSCO structure followed by the array of MQAIR records followed by the LDAP user name strings, and set *AILUO* to the offset of the appropriate name string from the start of the MQAIR structure. Ensure that this value is correct, and has a value that can be accommodated within an MQLONG (the most restrictive programming language is COBOL, for which the valid range is -999 999 999 through +999 999 999).

Consider using *AILUO* for programming languages that do not support the pointer data type, or that implement the pointer data type in a fashion that might not be portable to different environments (for example, the COBOL programming language).

Whichever technique is chosen, use only one of *AILUP* and *AILUO* ; the call fails with reason code RC2388.

This is an input field. The initial value of this field is the null pointer in those programming languages that support pointers, and an all-null byte string otherwise.

Note: On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

AISID (10-digit signed integer)

The value must be:

AISIDV

Identifier for the authentication information record.

This is always an input field. The initial value of this field is AISIDV.

AIVER (10-digit signed integer)

The value must be:

AIVER1

Version-1 authentication information record.

The following constant specifies the version number of the current version:

AIRVERC

Current version of authentication information record.

This is always an input field. The initial value of this field is AIVER1.

Initial values

Table 575. Initial values of fields in MQAIR for MQAIR		
Field name	Name of constant	Value of constant
<i>AISID</i>	AISIDV	'AIR↵'
<i>AIVER</i>	AIVERC	1
<i>AITYP</i>	AITLDP	1
<i>AICN</i>	None	Null string or blanks
<i>AILUP</i>	None	Null pointer or null bytes
<i>AILUO</i>	None	0
<i>AILUL</i>	None	0
<i>AIPW</i>	None	Null string or blanks

Notes:

1. The symbol ↵ represents a single blank character.

RPG declaration

```

D*.1.....2.....3.....4.....5.....6.....7..
D* MQAIR Structure
D*
D* Structure identifier
D  AISID          1      4      INZ('AIR ')
D* Structure version number
D  AIVER          5      8I 0  INZ(1)
D* Type of authentication information
D  AITYP          9     12I 0  INZ(1)
D* Connection name of CRL LDAP server
D  AICN         13     276      INZ
D* Address of LDAP user name
D  AILUP        277     292*    INZ(*NULL)
D* Offset of LDAP user name from start of MQAIR structure

D  AIPW        301     332      INZ

```

MQBMHO - Buffer to message handle options

Structure defining the buffer to message handle options.

Overview

Purpose: The MQBMHO structure allows applications to specify options that control how message handles are produced from buffers. The structure is an input parameter on the MQBUFMH call.

Character set and encoding: Data in MQBMHO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 979](#)
- [“Initial values” on page 980](#)
- [“RPG declaration” on page 980](#)

Fields

The MQBMHO structure contains the following fields; the fields are described in **alphabetical order**:

BMSID (10-digit signed integer)

Buffer to message handle structure - StrucId field.

This is the structure identifier. The value must be:

BMSIDV

Identifier for buffer to message handle structure.

This is always an input field. The initial value of this field is BMSIDV.

BMVER (10-digit signed integer)

Buffer to message handle structure - Version field.

This is the structure version number. The value must be:

BMVER1

Version number for buffer to message handle structure.

The following constant specifies the version number of the current version:

BMVERVC

Current version of buffer to message handle structure.

This is always an input field. The initial value of this field is BMVER1.

BMOPT (10-digit signed integer)

Buffer to message handle structure - Options field.

The value can be:

BMDLPR

Properties that are added to the message handle are deleted from the buffer. If the call fails no properties are deleted.

Default options: If you do not need the option described, use the following option:

BMNONE

No options specified.

This is always an input field. The initial value of this field is BMDLPR.

MQBO - Begin options

The MQBO structure allows the application to specify options relating to the creation of a unit of work.

Overview

Purpose: The structure is an input/output parameter on the MQBEGIN call.

Character set and encoding: Data in MQBO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 980](#)
- [“Initial values” on page 981](#)
- [“RPG declaration” on page 981](#)

Fields

The MQBO structure contains the following fields; the fields are described in **alphabetical order**:

BOOPT (10-digit signed integer)

Options that control the action of MQBEGIN.

The value must be:

BONONE

No options specified.

This is always an input field. The initial value of this field is BONONE.

BOSID (4-byte character string)

Structure identifier.

The value must be:

BOSIDV

Identifier for begin-options structure.

This is always an input field. The initial value of this field is BOSIDV.

BOVER (10-digit signed integer)

Structure version number.

The value must be:

BOVER1

Version number for begin-options structure.

The following constant specifies the version number of the current version:

BOVERC

Current version of begin-options structure.

This is always an input field. The initial value of this field is BOVER1.

Initial values

Table 577. Initial values of fields in MQBO		
Field name	Name of constant	Value of constant
BOSID	BOSIDV	'B0 ' (B followed by a blank)
BOVER	BOVER1	1
BOOPT	BONONE	0

Notes:

1. The symbol – represents a single blank character.

MQCBC - Callback context

Structure describing the callback routine.

Overview

Purpose

The MQCBC structure is used to specify context information that is passed to a callback function.

The structure is an input/output parameter on the call to a message consumer routine.

Version

The current version of MQCBC is CBCV2.

Character set and encoding

Data in MQCBC is in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure is in the character set and encoding of the client.

- [“Fields” on page 982](#)
- [“Initial values” on page 987](#)
- [“RPG declaration” on page 987](#)

Fields

The MQCBC structure contains the following fields; the fields are described in alphabetical order:

CBCBUFFLEN (10 digit signed integer)

The buffer can be larger than both the MaxMsgLength value defined for the consumer and the ReturnedLength value in the MQGMO.

Callback context structure - BufferLength field.

This is the length in bytes of the message buffer that has been passed to this function.

The actual message length is supplied in DataLength field.

The application can use the entire buffer for its own purposes for the duration of the callback function.

This is an input field to the message consumer function; it is not relevant to an exception handler function.

CBCCALLBA (10 digit signed integer)

Callback context structure - CallbackArea field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the CBDCALLBA field in the MQCBD structure, which is a parameter on the MQCB call used to define the callback function.

Changes to the *CBCCALLBA* are preserved across the invocations of the callback function for an *CBCHOBJ*. This field is not shared with callback functions for other handles.

This is an input/output field to the callback function. The initial value of this field is a null pointer or null bytes.

CBCCALLT (10 digit signed integer)

Callback Context structure - CallType field.

Field containing information about why this function has been called; the following are defined.

Message delivery call types: These call types contain information about a message. The *CBCLLEN* and *CBCBUFFLEN* parameters are valid for these call types.

CBCTMR

The message consumer function has been invoked with a message that has been destructively removed from the object handle.

If the value of *CBCCC* is CCWARN, the value of the *Reason* field is RC2079 or one of the codes indicating a data conversion problem.

CBCTMN

The message consumer function has been invoked with a message that has not yet been destructively removed from the object handle. The message can be destructively removed from the object handle using the *MsgToken*.

The message might not have been removed because:

- The MQGMO options requested a browse operation, GMBR*
- The message is larger than the available buffer and the MQGMO options do not specify *gmatm*

If the value of *CBCCC* is CCWARN, the value of the *Reason* field is RC2080 or one of the codes indicating a data conversion problem.

Callback control call types: These call types contain information about the control of the callback and do not contain details about a message. These call types are requested using CBDOPT in the MQCBD structure.

The *CBCLLEN* and *CBCBUFFLEN* parameters are not valid for these call types.

CBCTRC

The purpose of this call type is to allow the callback function to perform some initial setup.

The callback function is invoked immediately after the callback is registered, that is, upon return from an MQCB call using a value for the *Operation* field of CBREG.

This call type is used both for message consumers and event handlers.

If requested, this is the first invocation of the callback function.

The value of the *CBCREA* field is RCNONE.

CBCTSC

The purpose of this call type is to allow the callback function to perform some setup when it is started, for example, reinstating resources that were cleaned up when it was previously stopped.

The callback function is invoked when the connection is started using either CTLSR or CTLSW.

If a callback function is registered within another callback function, this call type is invoked when the callback returns.

This call type is used for message consumers only.

The value of the *CBCREA* field is RCNONE.

CBCTTC

The purpose of this call type is to allow the callback function to perform some cleanup when it is stopped for a while, for example, cleaning up additional resources that have been acquired during the consuming of messages.

The callback function is invoked when an MQCTL call is issued using a value for the *Operation* field of CTLSP.

This call type is used for message consumers only.

The value of the *CBCREA* field is set to indicate the reason for stopping.

CBCTDC

The purpose of this call type is to allow the callback function to perform final cleanup at the end of the consume process. The callback function is invoked when the:

- Callback function is deregistered using an MQCB call with BCUNR.
- Queue is closed, causing an implicit deregister. In this instance the callback function is passed HOUNUH as the object handle.
- MQDISC call completes - causing an implicit close and, therefore, a deregister. In this case the connection is not disconnected immediately, and any ongoing transaction is not yet committed.

If any of these actions are taken inside the callback function itself, the action is invoked once the callback returns.

This call type is used both for message consumers and event handlers.

If requested, this is the last invocation of the callback function.

The value of the *CBCREA* field is set to indicate the reason for stopping.

CBCTEC

Event handler function

The event handler function has been invoked without a message when:

- An MQCTL call is issued with a value for the *Operation* field of CTLSP, or
- The queue manager or connection stops or quiesces.

This call can be used to take appropriate action for all callback functions.

- **Message consumer function**

The message consumer function has been invoked without a message when an error (*CBCCC* = *CCFAIL*) has been detected that is specific to the object handle; for example *CBCREA* code = *RC2016* .

The value of the *CBCREA* field is set to indicate the reason for the call.

This is an input field. *CBCTMR* and *CMCTMN* are applicable only to message consumer functions.

CBCCC (10 digit signed integer)

Callback context structure - *CompCode* field.

This is the completion code. It indicates whether there were any problems consuming the message; it is one of the following:

CCOK

Successful completion

CCWARN

Warning (partial completion)

CCFAIL

Call failed

This is an input field. The initial value of this field is *CCOK*.

CBCCONNAREA (10 digit signed integer)

Callback context structure - *ConnectionArea* field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the *ConnectionArea* field in the *MQCTLO* structure, which is a parameter on the *MQCTL* call used to control the callback function.

Any changes made to this field by the callback functions are preserved across the invocations of the callback function. This area can be used to pass information that is to be shared by all callback functions. Unlike *CallbackArea*, this area is common across all callbacks for a connection handle.

This is an input and output field. The initial value of this field is a null pointer or null bytes.

CBCLLEN (10 digit signed integer)

This is the length in bytes of the application data in the message. If the value is zero, it means that the message contains no application data.

The *CBCLLEN* field contains the length of the message but not necessarily the length of the message data passed to the consumer. It could be that the message was truncated. Use the *GMRL* field in the *MQGMO* to determine how much data has been passed to the consumer.

If the reason code indicates the message has been truncated, you can use the *CBCLLEN* field to determine how large the actual message is. This allows you to determine the size of the buffer required to accommodate the message data, and then issue an *MQCB* call to update the *CBDMML* in the *MQCBD* with an appropriate value.

If the *GMCONV* option is specified, the converted message could be larger than the value returned for *DataLength*. In such cases, the application probably needs to issue an *MQCB* call to update the *CBDMML* in the *MQCBD* to be greater than the value returned by the queue manager for *DataLength*.

To avoid message truncation problems, specify *MaxMsgLength* as *CBDLFM*. This causes the queue manager to allocate a buffer for the full message length after data conversion. Be aware, however, that even if this option is specified, it is still possible that sufficient storage is not available to correctly process the request. Applications should always check the returned reason code. For example, if it is not possible to allocate sufficient storage to convert the message, the message is returned to the application unconverted.

This is an input field to the message consumer function; it is not relevant to an event handler function.

CBCFLG (10 digit signed integer)

Flags containing information about this consumer.

The following option is defined:

CBCFBE

This flag can be returned if a previous MQCLOSE call using the COQSC option failed with a reason code of RC2458.

This code indicated that the last read ahead message is being returned and that the buffer is now empty. If the application issues another MQCLOSE call using the COQSC option, it succeeds.

Note, that an application is not guaranteed to be given a message with this flag set, as there might still be messages in the read-ahead buffer that do not match the current selection criteria. In this instance, the consumer function is invoked with the reason code RC2019 .

If the read ahead buffer is empty, the consumer is invoked with the CBCFBE flag and the reason code RC2518.

This is an input field to the message consumer function; it is not relevant to an event handler function.

CBCHOBJ (10 digit signed integer)

Callback context structure - CBCHOBJ field.

For a call to a message consumer, this is the handle for the object relating to the message consumer.

For an event handler, this value is HONONE

The application can use this handle and the message token in the Get Message Options block to get the message if a message has not been removed from the queue.

This is always an input field. The initial value of this field is HOUNUH

CBCRCD (10 digit signed integer)

CBCRCD indicates how long the queue manager waits before trying to reconnect. The field can be modified by an event handler to change the delay or stop reconnection altogether.

Use the **CBCRCD** field only if the value of the **Reason** field in the Callback Context is RC2545.

On entry to the event handler the value of **CBCRCD** is the number of milliseconds the queue manager is going to wait before making a reconnection attempt. [Table 578 on page 985](#) lists the values that you can set to modify the behavior of the queue manager on return from the event handler.

Table 578. CBCRCD values	
Value	Description
-1	Make no more reconnection attempts. An error is returned to the application.
0	Try to reconnect immediately.
>0	Wait for this many milliseconds before trying the connection again.

CBCREA (10 digit signed integer)

Callback context structure - Reason field.

This is the reason code qualifying the CBCCC

This is an input field. The initial value of this field is RCNONE.

CBCSTATE (10 digit signed integer)

An indication of the state of the current consumer. This field is of most value to an application when a nonzero reason code is passed to the consumer function.

You can use this field to simplify application programming because you do not need to code behavior for each reason code.

This is an input field. The initial value of this field is CSNONE

State	Queue manager action	Value of constant
<i>CSNONE</i> This reason code represents a normal call with no additional reason information	None; this is the normal operation.	0
<i>CSSUST</i> These reason codes represent temporary conditions.	The callback routine is called to report the condition and then suspended. After a period the system might attempt the operation again, which can lead to the same condition being raised again.	1
<i>CSSUSU</i> These reason codes represent conditions where the callback needs to act to resolve the condition.	The consumer is suspended and the callback routine is called to report the condition. The callback routine should resolve the condition if possible and either RESUME or close down the connection.	2
<i>CSSUS</i> These reason codes represent failures that prevent further message callbacks.	The queue manager automatically suspends the callback function. If the callback function is resumed it is likely to receive the same reason code again.	3
<i>CSSTOP</i> These reason codes represent the end of message consumption.	Delivered to the exception handler and to callbacks that specified CBDTC. No further messages can be consumed.	4

CBCSID (10 digit signed integer)

Callback context structure - StrucId field.

This is the structure identifier; the value must be:

CBCSI

Identifier for callback context structure.

This is always an input field. The initial value of this field is CBCSI.

CBCVER (10 digit signed integer)

Callback context structure - Version field.

This is the structure version number; the value must be:

CBCV1

Version-1 callback context structure.

The following constant specifies the version number of the current version:

CBCCV

Current version of the callback context structure.

This is always an input field. The initial value of this field is CBCV1.

Initial values

Table 579. Initial values of fields in MQCBC		
Field name	Name of constant	Value of constant
<i>CBCSID</i>	CBCSI	'CBC~'
<i>CBCVER</i>	CBCV1	1
<i>CBCCALLT</i>	None	0
<i>CBCHOBJ</i>	HOUNUH	-1
<i>CBCCALLBA</i>	None	Null pointer or null bytes
<i>CBCCONNAREA</i>	None	Null pointer or null bytes
<i>CBCCC</i>	CCOK	0
<i>CBCREA</i>	RCNONE	0
<i>CBCSTATE</i>	CSNONE	0
<i>CBCLLEN</i>	None	0
<i>CBCBUFFLEN</i>	None	0
<i>CBCFLG</i>	None	0
<i>CBRCRD</i>	none	0

MQCBD - Callback descriptor

Structure specifying the callback function.

Overview

Purpose: The MQCBD structure is used to specify a callback function and the options controlling its use by the queue manager.

The structure is an input parameter on the MQCB call.

Version: The current version of MQCBD is CBDV1.

Character set and encoding: Data in MQCBD must be in the character set and encoding of the local queue manager; these are given by the *CodedCharSetId* queue-manager attribute and ENNAT. However, if the application is running as an IBM MQ MQI client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 988](#)
- [“Initial values” on page 992](#)
- [“RPG declaration” on page 992](#)

Fields

The MQCBD structure contains the following fields; the fields are described in **alphabetical order**:

CBDSCALLBA (10-digit signed integer)

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the field in the MQCBD structure, which is a parameter on the callback function declaration.

The value is used only on an *Operation* having a value CBREG, with no currently defined callback, it does not replace a previous definition.

This is an input and output field to the callback function. The initial value of this field is a null pointer or null bytes.

CBDSCALLBF (10-digit signed integer)

The callback function is invoked as a function call.

Use this field to specify a pointer to the callback function.

You *must* specify either *CallbackFunction* or *CallbackName*. If you specify both, the reason code RC2486 is returned.

If neither *CallbackName* nor *CallbackFunction* is not set, the call fails with the reason code RC2486.

This option is not supported in the following environments:

- CICS on z/OS
- Programming languages and compilers that do not support function-pointer references

In such situations, the call fails with the reason code RC2486.

This is an input field. The initial value of this field is a null pointer or null bytes.

CBDSCALLBN (10-digit signed integer)

The callback function is invoked as a dynamically linked program.

You *must* specify either *CallbackFunction* or *CallbackName*. If you specify both, the reason code RC2486 is returned.

If either *CallbackName* or *CallbackFunction* is not true, the call fails with the reason code RC2486.

The module is loaded when the first callback routine to use is registered, and unloaded when the last callback routine to use it deregisters.

Except where noted in the following text, the name is left-aligned within the field, with no embedded blanks; the name itself is padded with blanks to the length of the field. In the descriptions that follow, square brackets ([]) denote optional information:

IBMi

The callback name can be one of the following formats:

- Library "/" Program
- Library "/" ServiceProgram "("FunctionName")"

For example, MyLibrary/MyProgram(MyFunction).

The library name can be *LIBL. Both the library and program names are limited to a maximum of 10 characters.

UNIX systems

The callback name is the name of a dynamically loadable module or library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path:

```
[path]library(function)
```

If the path is not specified the system search path is used.

The name is limited to a maximum of 128 characters.

Windows

The callback name is the name of a dynamic-link library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path and drive:

```
[d:][path]library(function)
```

If the drive and path are not specified the system search path is used.

The name is limited to a maximum of 128 characters.

z/OS

The callback name is the name of a load module that is valid for specification on the EP parameter of the LINK or LOAD macro.

The name is limited to a maximum of 8 characters.

z/OS CICS

The callback name is the name of a load module that is valid for specification on the PROGRAM parameter of the EXEC CICS LINK command macro.

The name is limited to a maximum of 8 characters.

The program can be defined as remote using the REMOTESYTEM option of the installed PROGRAM definition or by the dynamic routing program.

The remote CICS region must be connected to IBM MQ if the program is to use IBM MQ API calls. Note, however, that the field in the MQCBC structure is not valid in a remote system.

If a failure occurs trying to load *CallbackName*, one of the following error codes is returned to the application:

- RC2495
- RC2496
- RC2497

A message is also written to the error log containing the name of the module for which the load was attempted, and the failing reason code from the operating system.

This is an input field. The initial value of this field is a null string or blanks.

CBDSCALLBT (10-digit signed integer)

This is the type of the callback function. The value must be one of:

CBTMC

Defines this callback as a message consumer function.

A message consumer callback function is called when a message, meeting the selection criteria specified, is available on an object handle and the connection is started.

CBTEH

Defines this callback as the asynchronous event routine; it is not driven to consume messages for a handle.

Hobj is not required on the MQCB call defining the event handler and is ignored if specified.

The event handler is called for conditions that affect the whole message consumer environment. The consumer function is invoked without a message when an event, for example, a queue manager or connection stopping, or quiescing, occurs. It is not called for conditions that are specific to a single message consumer, for example, RC2016.

Events are delivered to the application, regardless of whether the connection is started or stopped, except in the following environments:

- CICS on z/OS environment
- nonthreaded applications

If the caller does not pass one of these values, the call fails with a reason code of RC2483

This is always an input field. The initial value of this field is CBTMC.

CBDMML (10-digit signed integer)

This is the length in bytes of the longest message that can be read from the handle and given to the callback routine. If a message has a longer length, the callback routine receives *MaxMsgLength* bytes of the message, and reason code:

- RC2080 or
- RC2079 if you specified GMATM.

The actual message length is supplied in the [“CBCLEN \(10 digit signed integer\)”](#) on page 984 field of the MQCBC structure.

The following special value is defined:

CBDFFM

The buffer length is adjusted by the system to return messages without truncation.

If insufficient memory is available to allocate a buffer to receive the message, the system calls the callback function with an RC2071 reason code.

If, for example, you request data conversion, and there is insufficient memory available to convert the message data, the unconverted message is passed to the callback function.

This is an input field. The initial value of the *MaxMsgLength* field is CBDFM.

CBDOPT (10-digit signed integer)

Callback descriptor structure - Options field.

Any one, or all, of the following can be specified. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations). Combinations that are not valid are noted; any other combinations are valid.

CBDFQ

The MQCB call fails if the queue manager is in the quiescing state.

On z/OS, this option also forces the MQCB call to fail if the connection (for a CICS or IMS application) is in the quiescing state.

Specify GMFIQ, in the MQGMO options passed on the MQCB call, to cause notification to message consumers when they are quiescing.

Control options: The following options control whether the callback function is called, without a message, when the state of the consumer changes:

CBDRRC

The callback function is invoked with call type CBCTRC

.

CBDSRC

The callback function is invoked with call type CBCTSC.

CBDTTC

The callback function is invoked with call type CBCTTC.

CBDDC

The callback function is invoked with call type CBCTDC.

See [“CBCCALLT \(10 digit signed integer\)” on page 982](#) for further details about these call types.

Default option: If you do not need any of the options described, use the following option:

CBDNO

Use this value to indicate that no other options have been specified; all options assume their default values.

CBDNO is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *Options* field is CBDNO.

CBDSID (10-digit signed integer)

Callback descriptor structure - StrucId field.

This is the structure identifier; the value must be:

CBDSI

Identifier for callback descriptor structure.

This is always an input field. The initial value of this field is CBDSI.

CBDVER (10-digit signed integer)

Callback descriptor structure - Version field.

This is the structure version number; the value must be:

CBDV1

Version-1 callback descriptor structure.

The following constant specifies the version number of the current version:

CBDV

Current version of callback descriptor structure.

This is always an input field. The initial value of this field is CBDV1.

Initial values

Table 580. Initial values of fields in MQCBD

MQCHARV - Variable Length String

Use the MQCHARV structure to describe a variable length string.

Overview

Character set and encoding: Data in the MQCHARV must be in the encoding of the local queue manager that is given by ENNAT and the character set of the VCHRC field within the structure. If the application

is running as an IBM MQ MQI client, the structure must be in the encoding of the client. Some character sets have a representation that depends on the encoding. If VCHRC is one of these character sets, the encoding used is the same encoding as that of the other fields in the MQCHARV. The character set identified by VSCCSID can be a double-byte character set (DBCS).

Usage: The MQCHARV structure addresses data that might be discontinuous with the structure containing it. To address this data, fields declared with the pointer data type can be used.

- [“Fields” on page 993](#)
- [“Initial values” on page 994](#)
- [“RPG declaration” on page 994](#)
- [“Redefinition of CSAPL” on page 994](#)

Fields

The MQCHARV structure contains the following fields; the fields are described in **alphabetical order**:

VCHRC (10-digit signed integer)

This is the character set identifier of the variable length string addressed by the VCHRP or VCHRO field.

The initial value of this field is CSAPL. This is defined by IBM MQ to indicate that it should be changed by the queue manager to the true character set identifier of the queue manager. This is in the same way as CSQM behaves. As a result, the value CSAPL is never associated with a variable length string. The initial value of this field can be changed by defining a different value for the constant CSAPL for your compile unit by the appropriate means for your application's programming language.

VCHRL (10-digit signed integer)

The length in bytes of the variable length string addressed by the VCHRP or VCHRO field.

The initial value of this field is 0. The value must be either greater than or equal to zero or the following special value which is recognized:

VSNTL

If VSNTL is not specified, VCHRL bytes are included as part of the string. If null characters are present they do not delimit the string.

If VSNTL is specified, the string is delimited by the first null encountered in the string. The null itself is not included as part of that string.

Note: The null character used to terminate a string if VSNTL is specified is a null from the code set specified by VCHRC.

For example, in UTF-16 (UCS-2 CCSIDs 1200 and 13488), this is the 2-byte Unicode encoding where a null is represented by a 16 bit number of all zeros. In UTF-16 it is common to find single bytes set to all zero which are part of characters (7-bit ASCII characters for example), but the strings will only be null terminated when two 'zero' bytes are found on an even byte boundary. It is possible to get two 'zero' bytes on an odd boundary when they are each part of valid characters. For example, x'01' x'00' x'00' x'30' represents two valid Unicode characters and does not null terminate the string.

VCHRO (10-digit signed integer)

The offset in bytes of the variable length string from the start of the MQCHARV, or the structure containing it.

When the MQCHARV structure is embedded within another structure, this value is the offset in bytes of the variable length string from the start of the structure that contains this MQCHARV structure. When the MQCHARV structure is not embedded within another structure, for example, if it is specified as a parameter on a function call, the offset is relative to the start of the MQCHARV structure.

The offset can be positive or negative. You can use either the VCHRP or VCHRO field to specify the variable length string, but not both.

The initial value of this field is 0.

VCHRP (pointer)

This is a pointer to the variable length string.

You can use either the VCHRP or VCHRO field to specify the variable length string, but not both.

The initial value of this field is a null pointer or null bytes.

VCHRS (10-digit signed integer)

The size in bytes of the buffer addressed by the VCHRP or VCHRO field.

When the MQCHARV structure is used as an output field on a function call, this field must be initialized with the length of the buffer provided. If the value of VCHRL is greater than VCHRS then only VCHRS bytes of data will be returned to the caller in the buffer.

The value must be greater than or equal to zero or the following special value which is recognized:

VSUSL

If VSUSL is specified, the length of the buffer is taken from the VCHRL field in the MQCHARV structure. This special value is not appropriate when the structure is used as an output field and a buffer is provided. This is the initial value of this field.

Initial values

Field name	Name of constant	Value of constant
VCHRP	None	Null pointer or null bytes.
VCHRO	None	0
VCHRS	VSUSL	-1
VCHRL	None	0
VCHRC	CSAPL	-3

RPG declaration

```
D*..1.....2.....3.....4.....5.....6.....7..
D* MQCHARV Structure
D*
D* Address of variable length string
D VCHRP          1      16*
D* Offset of variable length string
D VCHRO          17      20I 0
D* Size of buffer
D VCHRS          21      24I 0
D* Length of variable length string
D VCHRL          25      28I 0
D* CCSID of variable length string
D VCHRC          29      32I 0
```

Redefinition of CSAPL

Unlike the programming languages supported on other platforms, RPG does not have a way of redefining a defined constant, so you must set each VCHRC specifically if you want to use a value other than CSAPL.

MQCIH - CICS bridge header

The MQCIH structure describes the information that can be present at the start of a message sent to the CICS bridge through IBM MQ for z/OS.

Overview

Format name: FMCICS.

Version: The current version of MQCIH is CIVER2. Fields that exist only in the more-recent version of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQCIH, with the initial value of the *CIVER* field set to CIVER2.

Character set and encoding: Special conditions apply to the character set and encoding used for the MQCIH structure and application message data:

- Applications that connect to the queue manager that owns the CICS bridge queue must provide an MQCIH structure that is in the character set and encoding of the queue manager. This is because data conversion of the MQCIH structure is not performed in this case.
- Applications that connect to other queue managers can provide an MQCIH structure that is in any of the supported character sets and encodings; conversion of the MQCIH is performed by the receiving message channel agent connected to the queue manager that owns the CICS bridge queue.

Note: There is one exception to this. If the queue manager that owns the CICS bridge queue is using CICS for distributed queuing, the MQCIH must be in the character set and encoding of the queue manager that owns the CICS bridge queue.

- The application message data following the MQCIH structure must be in the same character set and encoding as the MQCIH structure. The *CICSI* and *CIENC* fields in the MQCIH structure cannot be used to specify the character set and encoding of the application message data.

A data-conversion exit must be provided by the user to convert the application message data if the data is not one of the built-in formats supported by the queue manager.

Usage: If the values required by the application are the same as the initial values shown in [Table 582 on page 1004](#), and the bridge is running with AUTH=LOCAL or AUTH=IDENTIFY, the MQCIH structure can be omitted from the message. In all other cases, the structure must be present.

The bridge accepts either a version-1 or a version-2 MQCIH structure, but for 3270 transactions a version-2 structure must be used.

The application must ensure that fields documented as "request" fields have appropriate values in the message sent to the bridge; these fields are input to the bridge.

Fields documented as "response" fields are set by the CICS bridge in the reply message that the bridge sends to the application. Error information is returned in the *CIRET*, *CIFNC*, *CICC*, *CIREA*, and *CIAC* fields, but not all of them are set in all cases. [Table 581 on page 995](#) shows which fields are set for different values of *CIRET*.

Table 581. Contents of error information fields in MQCIH structure				
<i>CIRET</i>	<i>CIFNC</i>	<i>CICC</i>	<i>CIREA</i>	<i>CIAC</i>
CRC000	-	-	-	-
CRC003	-	-	FBC*	-
CRC002 CRC008	IBM MQ call name	IBM MQ <i>CMPCOD</i>	IBM MQ <i>REASON</i>	-
CRC001 CRC006 CRC007 CRC009	CICS EIBFN	CICS EIBRESP	CICS EIBRESP2	-
CRC004 CRC005	-	-	-	CICS ABCODE

- [“Fields” on page 996](#)
- [“Initial values” on page 1004](#)
- [“RPG declaration” on page 1005](#)

Fields

The MQCIH structure contains the following fields; the fields are described in **alphabetical order**:

CIAC (4-byte character string)

Abend code.

The value returned in this field is significant only if the *CIRET* field has the value CRC005 or CRC004. If it does, *CIAC* contains the CICS ABCODE value.

This is a response field. The length of this field is given by LNABNC. The initial value of this field is 4 blank characters.

This is an indicator specifying whether ADS descriptors should be sent on SEND and RECEIVE BMS requests. The following values are defined:

ADNONE

Do not send or receive ADS descriptor.

ADSEND

Send ADS descriptor.

ADRECV

Receive ADS descriptor.

ADMSGF

Use message format for the ADS descriptor.

This causes the ADS descriptor to be sent or received using the long form of the ADS descriptor. The long form has fields that are aligned on 4-byte boundaries.

The *CIADS* field should be set as follows:

- If ADS descriptors are *not* being used, set the field to ADNONE.
- If ADS descriptors *are* being used, and with the *same* CCSID in each environment, set the field to the sum of ADSEND and ADRECV.
- If ADS descriptors *are* being used, but with *different* CCSIDs in each environment, set the field to the sum of ADSEND, ADRECV, and ADMSGF.

This is a request field used only for 3270 transactions. The initial value of this field is ADNONE.

CIADS (10-digit signed integer)

Send/receive ADS descriptor.

This is an indicator specifying whether ADS descriptors should be sent on SEND and RECEIVE BMS requests. The following values are defined:

ADNONE

Do not send or receive ADS descriptor.

ADSEND

Send ADS descriptor.

ADRECV

Receive ADS descriptor.

ADMSGF

Use message format for the ADS descriptor.

This causes the ADS descriptor to be sent or received using the long form of the ADS descriptor. The long form has fields that are aligned on 4-byte boundaries.

The *CIADS* field should be set as follows:

- If ADS descriptors are *not* being used, set the field to ADNONE.
- If ADS descriptors *are* being used, and with the *same* CCSID in each environment, set the field to the sum of ADSEND and ADRECV.
- If ADS descriptors *are* being used, but with *different* CCSIDs in each environment, set the field to the sum of ADSEND, ADRECV, and ADMSGF.

This is a request field used only for 3270 transactions. The initial value of this field is ADNONE.

CIAI (4-byte character string)

AID key.

This is the initial value of the AID key when the transaction is started. It is a 1-byte value, left-aligned.

This is a request field used only for 3270 transactions. The length of this field is given by LNATID. The initial value of this field is 4 blanks.

CIAUT (8-byte character string)

Password or passticket.

This is a password or passticket. If user-identifier authentication is active for the CICS bridge, *CIAUT* is used with the user identifier in the MQMD identity context to authenticate the sender of the message.

This is a request field. The length of this field is given by LNAUTH. The initial value of this field is 8 blanks.

CICC (10-digit signed integer)

IBM MQ completion code or CICS EIBRESP.

The value returned in this field is dependent on *CIRET*; see [Table 581 on page 995](#).

This is a response field. The initial value of this field is CCOK.

CICNC (4-byte character string)

Abend transaction code.

This is the abend code to be used to terminate the transaction (normally a conversational transaction that is requesting more data). Otherwise this field is set to blanks.

This is a request field used only for 3270 transactions. The length of this field is given by LNCNCL. The initial value of this field is 4 blanks.

CICP (10-digit signed integer)

Cursor position.

This is the initial cursor position when the transaction is started. Later, for conversational transactions, the cursor position is in the RECEIVE vector.

This is a request field used only for 3270 transactions. The initial value of this field is 0. This field is not present if *CIVER* is less than CIVER2.

CICSI (10-digit signed integer)

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

CICT (10-digit signed integer)

Whether task can be conversational.

This is an indicator specifying whether the task should be allowed to issue requests for more information, or should abend. The value must be one of the following:

CTYES

Task is conversational.

CTNO

Task is not conversational.

This is a request field used only for 3270 transactions. The initial value of this field is CTNO.

CIENC (10-digit signed integer)

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

CIEO (10-digit signed integer)

Offset of error in message.

This is the position of invalid data detected by the bridge exit. This field provides the offset from the start of the message to the location of the invalid data.

This is a response field used only for 3270 transactions. The initial value of this field is 0. This field is not present if *CIVER* is less than *CIVER2*.

CIFAC (8-byte bit string)

Bridge facility token.

This is an 8-byte bridge facility token. The purpose of a bridge facility token is to allow multiple transactions in a pseudoconversation to use the same bridge facility (virtual 3270 terminal). In the first, or only, message in a pseudoconversation, a value of FCNONE should be set; this tells CICS to allocate a new bridge facility for this message. A bridge facility token is returned in response messages when a nonzero *CIFKT* is specified on the input message. Subsequent input messages can then use the same bridge facility token.

The following special value is defined:

FCNONE

No BVT token specified.

This is both a request and a response field used only for 3270 transactions. The length of this field is given by LNFAAC. The initial value of this field is FCNONE.

CIFKT (10-digit signed integer)

Bridge facility release time.

This is the length of time in seconds that the bridge facility will be kept after the user transaction has ended. For nonconversational transactions, the value should be zero.

This is a request field used only for 3270 transactions. The initial value of this field is 0.

CIFL (4-byte character string)

Terminal emulated attributes.

This is the name of an installed terminal that is to be used as a model for the bridge facility. A value of blanks means that *CIFL* is taken from the bridge transaction profile definition, or a default value is used.

This is a request field used only for 3270 transactions. The length of this field is given by LNFAAC. The initial value of this field is 4 blanks.

CIFLG (10-digit signed integer)

Flags.

The value must be:

CIFNON

No flags.

This is a request field. The initial value of this field is CIFNON.

CIFMT (8-byte character string)

IBM MQ format name of data that follows MQCIH.

This specifies the IBM MQ format name of the data that follows the MQCIH structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

This format name is also used for the reply message, if the *CIRFM* field has the value FMNONE.

- For DPL requests, *CIFMT* must be the format name of the COMMAREA.
- For 3270 requests, *CIFMT* must be CSQCBDCI, and *CIRFM* must be CSQCBDCO.

The data-conversion exits for these formats must be installed on the queue manager where they are to run.

If the request message results in the generation of an error reply message, the error reply message has a format name of FMSTR.

This is a request field. The length of this field is given by LNFMT. The initial value of this field is FMNONE.

CIFNC (4-byte character string)

IBM MQ call name or CICS EIBFN function.

The value returned in this field is dependent on *CIRET*; see [Table 581 on page 995](#). The following values are possible when *CIFNC* contains an IBM MQ call name:

CFCONN

MQCONN call.

CFGET

MQGET call.

CFINQ

MQINQ call.

CFOPEN

MQOPEN call.

CFPUT

MQPUT call.

CFPUT1

MQPUT1 call.

CFNONE

No call.

This is a response field. The length of this field is given by LNFUNC. The initial value of this field is CFNONE.

CIGWI (10-digit signed integer)

Wait interval for MQGET call issued by bridge task.

This field is applicable only when *CIUOW* has the value CUFRST. It allows the sending application to specify the approximate time in milliseconds that the MQGET calls issued by the bridge should wait for second and subsequent request messages for the unit of work started by this message. This overrides the default wait interval used by the bridge. The following special values may be used:

WIDFLT

Default wait interval.

This causes the CICS bridge to wait for the period specified when the bridge was started.

WIULIM

Unlimited wait interval.

This is a request field. The initial value of this field is WIDFLT.

CIHI (10-digit signed integer)

Reserved.

This is a reserved field. The value must be 0. This field is not present if *CIVER* is less than *CIVER2*.

CILEN (10-digit signed integer)

Length of MQCIH structure.

The value must be one of the following:

CILEN1

Length of version-1 CICS information header structure.

CILEN2

Length of version-2 CICS information header structure.

The following constant specifies the length of the current version:

CILENC

Length of current version of CICS information header structure.

This is a request field. The initial value of this field is *CILEN2*.

CILT (10-digit signed integer)

Link type.

This indicates the type of object that the bridge should try to link. The value must be one of the following:

LTPROG

DPL program.

LTTRAN

3270 transaction.

This is a request field. The initial value of this field is *LTPROG*.

CINTI (4-byte character string)

Next transaction to attach.

This is the name of the next transaction returned by the user transaction (typically by EXEC CICS RETURN TRANSID). If there is no next transaction, this field is set to blanks.

This is a response field used only for 3270 transactions. The length of this field is given by *LNTRID*. The initial value of this field is 4 blanks.

CIODL (10-digit signed integer)

Output COMMAREA data length.

This is the length of the user data to be returned to the client in a reply message. This length includes the 8-byte program name. The length of the COMMAREA passed to the linked program is the maximum of this field and the length of the user data in the request message, minus 8.

Note: The length of the user data in a message is the length of the message *excluding* the MQCIH structure.

If the length of the user data in the request message is smaller than *CIODL*, the *DATALength* option of the LINK command is used; this allows the LINK to be function-shipped efficiently to another CICS region.

The following special value can be used:

OLINPT

Output length is same as input length.

This value might be needed even if no reply is requested, in order to ensure that the COMMAREA passed to the linked program is of sufficient size.

This is a request field used only for DPL programs. The initial value of this field OLINPT.

CIREA (10-digit signed integer)

IBM MQ reason or feedback code, or CICS EIBRESP2.

The value returned in this field is dependent on *CIRET* ; see [Table 581 on page 995](#).

This is a response field. The initial value of this field is RCNONE.

CIRET (10-digit signed integer)

Return code from bridge.

This is the return code from the CICS bridge describing the outcome of the processing performed by the bridge. The *CIFNC*, *CICC*, *CIREA*, and *CIAC* fields may contain additional information (see [Table 581 on page 995](#)). The value is one of the following:

CRC000

(0, X'000') No error.

CRC001

(1, X'001') EXEC CICS statement detected an error.

CRC002

(2, X'002') IBM MQ call detected an error.

CRC003

(3, X'003') CICS bridge detected an error.

CRC004

(4, X'004') CICS bridge ended abnormally.

CRC005

(5, X'005') Application ended abnormally.

CRC006

(6, X'006') Security error occurred.

CRC007

(7, X'007') Program not available.

CRC008

(8, X'008') Second or later message within current unit of work not received within specified time.

CRC009

(9, X'009') Transaction not available.

This is a response field. The initial value of this field is CRC000.

CIRFM (8-byte character string)

IBM MQ format name of reply message.

This is the IBM MQ format name of the reply message that will be sent in response to the current message. The rules for coding this are the same as those for the *MDFMT* field in MQMD.

This is a request field used only for DPL programs. The length of this field is given by LNFMT. The initial value of this field is FMNONE.

CIRSI (4-byte character string)

Reserved.

This is a reserved field. The value must be 4 blanks. The length of this field is given by LNRSID.

CIRS1 (8-byte character string)

Reserved.

This is a reserved field. The value must be 8 blanks.

CIRS2 (8-byte character string)

Reserved.

This is a reserved field. The value must be 8 blanks.

CIRS3 (8-byte character string)

Reserved.

This is a reserved field. The value must be 8 blanks.

CIRS4 (10-digit signed integer)

Reserved.

This is a reserved field. The value must be 0. This field is not present if *CIVER* is less than *CIVER2*.

CIRTI (4-byte character string)

Reserved.

This is a reserved field. The value must be 4 blanks. The length of this field is given by *LNTRID*.

CISC (4-byte character string)

Transaction start code.

This is an indicator specifying whether the bridge emulates a terminal transaction or a START transaction. The value must be one of the following:

SCSTRT

Start.

SCDATA

Start data.

SCTERM

Terminate input.

SCNONE

None.

In the response from the bridge, this field is set to the start code appropriate to the next transaction ID contained in the *CINTI* field. The following start codes are possible in the response:

- SCSTRT
- SCDATA
- SCTERM

For CICS Transaction Server Version 1.2, this field is a request field only; its value in the response is undefined.

For CICS Transaction Server Version 1.3 and subsequent releases, this is both a request and a response field.

This field is used only for 3270 transactions. The length of this field is given by *LNSTCO*. The initial value of this field is *SCNONE*.

CISID (4-byte character string)

Structure identifier.

The value must be:

CISIDV

Identifier for CICS information header structure.

This is a request field. The initial value of this field is CISIDV.

CITES (10-digit signed integer)

Status at end of task.

This field shows the status of the user transaction at end of task. One of the following values is returned:

TENOSY

Not synchronized.

The user transaction has not yet completed and has not syncpointed. The *MDMT* field in MQMD is MTRQST in this case.

TECMIT

Commit unit of work.

The user transaction has not yet completed, but has syncpointed the first unit of work. The *MDMT* field in MQMD is MTDGRM in this case.

TEBACK

Back out unit of work.

The user transaction has not yet completed. The current unit of work will be backed out. The *MDMT* field in MQMD is MTDGRM in this case.

TEENDT

End task.

The user transaction has ended (or abended). The *MDMT* field in MQMD is MTRPLY in this case.

This is a response field used only for 3270 transactions. The initial value of this field is TENOSY.

CITI (4-byte character string)

Transaction to attach.

If *CILT* has the value LTTRAN, *CITI* is the transaction identifier of the user transaction to be run; a nonblank value must be specified in this case.

If *CILT* has the value LTPROG, *CITI* is the transaction code under which all programs within the unit of work are to be run. If the value specified is blank, the CICS DPL bridge default transaction code (CKBP) is used. If the value is nonblank, it must have been defined to CICS as a local TRANSACTION with an initial program of CSQCBP00. This field is applicable only when *CIUOW* has the value CUFRST or CUONLY.

This is a request field. The length of this field is given by LNTRID. The initial value of this field is 4 blanks.

CIUOW (10-digit signed integer)

Unit-of-work control.

This controls the unit-of-work processing performed by the CICS bridge. You can request the bridge to run a single transaction, or one or more programs within a unit of work. The field indicates whether the CICS bridge should start a unit of work, perform the requested function within the current unit of work, or end the unit of work by committing it or backing it out. Various combinations are supported, to optimize the data transmission flows.

The value must be one of the following:

CUONLY

Start unit of work, perform function, then commit the unit of work (DPL and 3270).

CUCONT

Additional data for the current unit of work (3270 only).

CUFRST

Start unit of work and perform function (DPL only).

CUMIDL

Perform function within current unit of work (DPL only).

CULAST

Perform function, then commit the unit of work (DPL only).

CUCMIT

Commit the unit of work (DPL only).

CUBACK

Back out the unit of work (DPL only).

This is a request field. The initial value of this field is CUONLY.

CIVER (10-digit signed integer)

Structure version number.

The value must be one of the following:

CIVER1

Version-1 CICS information header structure.

CIVER2

Version-2 CICS information header structure.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

CIVERC

Current version of CICS information header structure.

This is a request field. The initial value of this field is CIVER2.

Initial values

<i>Table 582. Initial values of fields in MQCIH</i>

MQCMHO - Create message handle options

The **MQCMHO** structure allows applications to specify options that control how message handles are created.

Overview

Purpose

The structure is an input parameter on the **MQCRTMH** call.

Character set and encoding

Data in **MQCMHO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1007](#)
- [“Initial values” on page 1008](#)
- [“RPG declaration” on page 1008](#)

Fields

The MQCMHO structure contains the following fields; the fields are described in alphabetical order:

CMOPT (10 digit signed integer)

One of the following options can be specified:

CMVAL

When **MQSETMP** is called to set a property in this message handle, the property name is validated to ensure that it:

- contains no invalid characters.
- does not begin "JMS" or "usr.JMS" except for the following:
 - JMSCorrelationID
 - JMSReplyTo
 - JMSType
 - JMSXGroupID
 - JMSXGroupSeq

These names are reserved for JMS properties.

- is not one of the following keywords, in any mixture of upper or lowercase:
 - "AND"
 - "BETWEEN"
 - "ESCAPE"
 - "FALSE"
 - "IN"
 - "IS"
 - "LIKE"
 - "NOT"
 - "NULL"
 - "OR"
 - "TRUE"
- does not begin "Body." or "Root." (except for "Root.MQMD").

If the property is MQ-defined ("mq.*") and the name is recognized, the property descriptor fields are set to the correct values for the property. If the property is not recognized, the *Support* field of the property descriptor is set to **PDSUPO** (for more information, see [PDSUP](#)).

CMDEFV

This specifies that the default level of validation of property names occurs.

The default level of validation is equivalent to that specified by **CMVAL**.

In a future release an administrative option might be defined which will change the level of validation that will occur when **CMDEFV** is defined.

This is the default value.

CMNOVA

No validation on the property name occurs. See the description of **CMVAL**.

Default option: If none of the options previously described in this section is required, the following option can be used:

CMNONE

All options assume their default values. Use this value to indicate that no other options have been specified. **CMNONE** aids program documentation; it is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

This is always an input field. The initial value of this field is **CMDEFV**.

CMSID (10 digit signed integer)

This is the structure identifier; the value must be:

CMSIDV

Identifier for create message handle options structure.

This is always an input field. The initial value of this field is **CMSIDV**.

CMVER (10 digit signed integer)

This is the structure version number; the value must be:

CMVER1

Version-1 create message handle options structure.

The following constant specifies the version number of the current version:

CMVERC

Current version of create message handle options structure.

This is always an input field. The initial value of this field is **CMVER1**.

Initial values

Table 583. Initial values of fields in MQCMHO

MQCNO - Connect options

The MQCNO structure allows the application to specify options relating to the connection to the local queue manager.

Overview

Purpose: The structure is an input/output parameter on the MQCONN call.

Version: The current version of MQCNO is CNVER5. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQCNO that is supported by the environment, but with the initial value of the *CNVER* field set to CNVER1. To use fields that are not present in the version-1 structure, the application must set the *CNVER* field to the version number of the version required.

Character set and encoding: Data in MQCNO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1009](#)
- [“Initial values” on page 1013](#)
- [“RPG declaration” on page 1014](#)

Fields

The MQCNO structure contains the following fields; the fields are described in **alphabetical order**:

CNCCO (10-digit signed integer)

This is the offset in bytes of an MQCD channel definition structure from the start of the MQCNO structure.

CNCCP (pointer)

This is a pointer to an MQCD channel definition structure.

CNCONID (24-byte character string)

Unique connection identifier. This field allows the queue manager to reliably identify an application process by assigning it a unique identifier when it first connects to the queue manager.

Applications use the connection identifier for correlation purposes when making PUT and GET calls. All connections are assigned an identifier by the queue manager, no matter how the connection was established.

It is possible to use the connection identifier to force the end of a long running unit of work. To do this, specifying the connection identifier using the PCF command 'Stop Connection', or the MQSC command STOP CONN. For more information about using these commands, see the related links.

The initial value of the field is 24 null bytes.

CNCT (128-byte bit string)

This is a tag that the queue manager associates with the resources that are affected by the application during this connection.

Queue-manager connection tag.

Each application or application instance must use a different value for the tag, so that the queue manager can correctly serialize access to the affected resources. See the descriptions of the CN*CT* options for further details. The tag ceases to be valid when the application terminates, or issues the MQDISC call.

Use the following special value if no tag is required:

CTNONE

No connection tag specified.

The value is binary zero for the length of the field.

This is an input field. The length of this field is given by LNCTAG. The initial value of this field is CTNONE. This field is ignored if CNVER is less than CNVER3.

Use the field ConnTag when connecting to a z/OS queue manager.

CNOPT (10 digit signed integer)

Options that control the action of MQCONN.

Binding options

The binding options control the type of IBM MQ binding that is used; specify only one of these options:

CNSBND

Standard binding.

The standard binding option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs.

Use CNSBND in situations where the application might not have been fully tested, or might be unreliable or untrustworthy. CNSBND is the default.

CNSBND is defined to aid program documentation. Do not use this option with any other option controlling the type of binding used; but because its value is zero, such use cannot be detected.

This option is supported in all environments.

CNFBND

Fast path binding.

The fast path binding option causes the application and the local queue manager agent to be part of the same unit of execution. Fast path is in contrast to the standard binding, where the application and the local-queue manager agent run in separate units of execution.

CNFBND is ignored if the queue manager does not support this type of binding; processing continues as though the option had not been specified.

CNFBND can be of advantage in situations where multiple processes consume more resources than the overall resource used by the application. An application that uses the fast path binding is known as a *trusted application*.

Consider the following important points when deciding whether to use the fast path binding:

- **Using the CNFBND option does not prevent an application altering or corrupting messages and other data areas belonging to the queue manager. Use this option only in situations where you have fully evaluated these issues.**
- The application must not use asynchronous signals or timer interrupts (such as sigkill) with CNFBND. There are also restrictions on the use of shared memory segments.
- The application must not have more than one thread connected to the queue manager at any one time.
- The application must use the MQDISC call to disconnect from the queue manager.
- The application must finish before ending the queue manager with the endmqm command.

The following points apply to the use of CNFBND in the environments indicated:

- On IBM i, the job must run under user profile QMQM that belongs to the QMQMADM group. Also, the program must not terminate abnormally, otherwise unpredictable results might occur.

For more information about the implications of using trusted applications, see [Connecting to a queue manager using the MQCONN call](#) and [Restrictions for trusted applications](#).

CNSHBD

Shared Bindings.

The shared bindings option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs. However some resources are shared between the application and the local queue manager agent. CNSHBD is ignored if the queue manager does not support this type of binding. Processing continues as though the option had not been specified.

CNIBND

Isolated Bindings.

The isolated bindings option causes the application and the local queue manager agent to run in separate units of execution, typically in separate processes. The arrangement maintains the integrity of the queue manager; that is, it protects the queue manager from errant programs. The application process and the local queue manager agent are isolated from each other in that they do not share resources. CNIBND is ignored if the queue manager does not support this type of binding. Processing continues as though the option had not been specified.

Handle-sharing options

The following options control the sharing of handles between different threads (units of parallel processing) within the same process. Only one of these options can be specified.

CNHSN

No handle sharing between threads.

The no handle sharing between threads option indicates that connection and object handles can be used only by the thread that caused the handle to be allocated; that is, the thread that issued the MQCONN, MQCONNX, or MQOPEN call. The handles cannot be used by other threads belonging to the same process.

CNHSB

Serial handle sharing between threads, with call blocking.

The serial handle sharing between threads, with call blocking, option indicates that connection and object handles allocated by one thread of a process can be used by other threads belonging to the same process. However, only one thread at a time can use any particular handle, that is, only serial use of a handle is permitted. If a thread tries to use a handle that is already in use by another thread, the call blocks (waits) until the handle becomes available.

CNHSNB

Serial handle sharing between threads, without call blocking.

The serial handle sharing between threads, *without* call blocking, option is the same as the "*with* blocking" option, except that, if the handle is in use by another thread, the call completes immediately with CCFAIL and RC2219 instead of blocking until the handle becomes available.

A thread can have zero or one nonshared handles, plus zero or more shared handles:

- Each MQCONN or MQCONNX call that specifies CNHSN returns a new nonshared handle on the first call, and the same nonshared handle on subsequent calls (assuming no intervening MQDISC call). The reason code is RC2002 for the second and later calls.
- Each MQCONNX call that specifies CNHSB or CNHSNB returns a new shared handle on each call.

Object handles inherit the same sharing properties as the connection handle specified on the MQOPEN call that created the object handle. Also, units of work inherit the same sharing properties as the connection handle used to start the unit of work; if the unit of work is started

in one thread using a shared handle, the unit of work can be updated in another thread using the same handle.

If you do not specify a handle-sharing option, the default is determined by the environment:

- In the Microsoft Transaction Server (MTS) environment, the default is the same as CNHSB.
- In other environments, the default is the same as CNHSN.

Reconnection options

Reconnection options determine if a connection is reconnectable. Only client connections are reconnectable.

CNRCDF

The reconnection option is resolved to its default value. If no default is set, the value of this option resolves to **DISABLED**. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

CNRC

The application can be reconnected to any queue manager consistent with the value of the MQCONN **QMNAME** parameter. Use the CNRC option only if there is no affinity between the client application and the queue manager with which it initially established a connection. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

CNRCD

The application cannot be reconnected. The value of the option is *not* passed to the server.

CNRCQM

The application can only be reconnected to the queue manager with which it originally connected. Use this value if a client can be reconnected, but there is an affinity between the client application, and the queue manager with which it originally established a connection. Choose this value if you want a client to automatically reconnect to the standby instance of a highly available queue manager. The value of the option is passed to the server, and can be queried by **PCF** and **MQSC**.

Use the options CNRC, CNRCD, and CNRCQM only for client connections. If the options are used for a binding connection, MQCONN fails with completion code, MQCC_FAILED and reason code, MQRC_OPTIONS_ERROR.

Default option: If none of the options described is required, the following option can be used:

CNNONE

No options are specified.

CNNONE is defined to aid program documentation. It is not intended that this option is used with any other CN* option, but because its value is zero, such use cannot be detected.

CNSCO (10-digit signed integer)

This is the offset in bytes of an MQSCO structure from the start of the MQCNO structure.

This field is ignored if *CNVER* is less than CNVER4.

CNSCP (pointer)

This is the address of an MQSCO structure.

This field is ignored if *CNVER* is less than CNVER4.

CNSECPO (10-digit signed integer)

Security parameters offset. The offset of the MQCSP structure used for specifying a user ID and password.

The value may be positive or negative. The initial value of this field is 0.

This field is ignored if *CNVER* is less than CNVER5.

CNSECPP (pointer)

Security parameters pointer. Address of the MQCSP structure used for specifying a user ID and a password.

The initial value of this field is a null pointer or null bytes.

This field is ignored if *CNVER* is less than *CNVER5*.

CNSID (4-byte character string)

The structure identifier for the MQCNO structure.

The value must be:

CNSIDV

Identifier for connect-options structure.

This is always an input field. The initial value of this field is *CNSIDV*.

CNVER (10-digit signed integer)

The structure version number for the MQCNO structure.

The value must be:

CNVER5

Version-5 connect-options structure.

This version is supported in all environments.

The following constant specifies the version number of the current version:

CNVERC

Current version of connect-options structure.

This is always an input field. The initial value of this field is *CNVER5*.

Initial values

<i>Table 584. Initial values of fields in MQCNO</i>		
Field name	Name of constant	Value of constant
<i>CNSID</i>	<i>CNSIDV</i>	'CNO–

[illegible]

Summary of the MQCSP structure for IBM MQ for IBM i.

Purpose: The MQCSP structure enables the authorization service to authenticate a user ID and password. You specify the MQCSP connection security parameters structure on an MQCONN call.

- “Fields” on page 1014
- “Initial values” on page 1016
- “RPG declaration” on page 1016

The MQCSP structure contains the following fields; the fields are described in **alphabetical order**:

This is the type of authentication to perform.

CSAN

1014 IBM MQ Developing Applications Reference

CSAUIAP

Authenticate user ID and password fields.

This is an input field. The initial value of this field is CSAN.

CSCPPL (10-digit signed integer)

This is the length of the password to be used in authentication.

The maximum length of the password is not dependent on the platform. If the length of the password is greater than that allowed, the authentication request fails with an RC2035.

This is an input field. The initial value of this field is 0.

CSCPPO (10-digit signed integer)

This is the offset in bytes of the password to be used in authentication.

The offset can be positive or negative.

This is an input field. The initial value of this field is 0.

CSCPPP (pointer)

This is the address of the password to be used in authentication.

This is an input field. The initial value of this field is the null pointer.

CSCSPUIL (10-digit signed integer)

This is the length of the user ID to be used in authentication.

The maximum length of the user ID is not dependent on the platform. If the length of the user ID is greater than that allowed, the authentication request fails with an RC2035.

This is an input field. The initial value of this field is 0.

CSCSPUIO (10-digit signed integer)

This is the offset in bytes of the user ID to be used in authentication.

The offset can be positive or negative.

This is an input field. The initial value of this field is 0.

CSCSPUIP (pointer)

This is the address of the user ID to be used in authentication.

This is an input field. The initial value of this field is the null pointer. This field is ignored if CSVER is less than CSVER5.

CSRE1 (4-byte character string)

A reserved field, required for pointer alignment on IBM i.

This is an input field. The initial value of this field is all null.

CSRS2 (8-byte character string)

A reserved field, required for pointer alignment on IBM i.

This is an input field. The initial value of this field is all null.

CSSID (4-byte character string)

Structure identifier.

The value must be:

CSSIDV

Identifier for the security parameters structure.

CSVER (10-digit signed integer)

Structure version number.

The value must be:

CSVER1

Version-1 security parameters structure.

The following constant specifies the version number of the current version:

CSVERC

Current version of security parameters structure.

This is always an input field. The initial value of this field is CSVER1.

Initial values

Table 585. Initial values of fields in MQCNO		
Field name	Name of constant	Value of constant
CSSID	CSSIDV	'CSP~'
CSVER	CSVER1	1

MQCTLO - Control callback options structure

Structure specifying the control callback function.

Overview

Purpose

The MQCTLO structure is used to specify options relating to a control callbacks function.

The structure is an input and output parameter on the [MQCTL](#) call.

Version

The current version of MQCTLO is CTLV1.

Character set and encoding

Data in MQCTLO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1017](#)
- [“Initial values” on page 1018](#)
- [“RPG declaration” on page 1018](#)

Fields

The MQCTLO structure contains the following fields; the fields are described in alphabetical order:

COCONNAREA (10 digit signed integer)

Control options structure - ConnectionArea field.

This is a field that is available for the callback function to use.

The queue manager makes no decisions based on the contents of this field and it is passed unchanged from the [CBCCONNAREA](#) field in the MQCBC structure, which is a parameter on the MQCB call.

This field is ignored for all operations other than CTLSR and CTLSW.

This is an input and output field to the callback function. The initial value of this field is a null pointer or null bytes.

COOPT (10 digit signed integer)

Options that control the action of MQCTLO.

CTLFQ

Force the MQCTLO call to fail if the queue manager or connection is in the quiescing state.

Specify GMFIQ, in the MQGMO options passed on the MQCB call, to cause notification to message consumers when they are quiescing.

CTLTHR

This option informs the system that the application requires that all message consumers, for the same connection, are called on the same thread.

Default option: If you do not need any of the options described, use the following option:

CTLNO

Use this value to indicate that no other options have been specified; all options assume their default values. CTLNO is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *COOPT* field is CTLNO.

CORSV (10 digit signed integer)

This is a reserved field. The initial value of this field is a blank character.

COSID (10 digit signed integer)

Control options structure - StrucId field.

This is the structure identifier; the value must be:

CTLSI

Identifier for Control Options structure.

This is always an input field. The initial value of this field is CTLSI.

COVER (10 digit signed integer)

Control options structure - Version field.

This is the structure version number; the value must be:

CTLV1

Version-1 Control options structure.

The following constant specifies the version number of the current version:

CTLCV

Current version of Control options structure.

This is always an input field. The initial value of this field is CTLV1.

Initial values

Table 586. Initial values of fields in MQCTLO		
Field name	Name of constant	Value of constant

MQDH - Distribution header

The MQDH structure describes the additional data that is present in a message when that message is a distribution-list message stored on a transmission queue.

Overview

Purpose: A distribution-list message is a message that is sent to multiple destination queues. The additional data consists of the MQDH structure followed by an array of MQOR records and an array of MQPMR records.

This structure is for use by specialized applications that put messages directly on transmission queues, or which remove messages from transmission queues (for example: message channel agents).

This structure should *not* be used by normal applications which simply want to put messages to distribution lists. Those applications should use the MQOD structure to define the destinations in the distribution list, and the MQPMO structure to specify message properties or receive information about the messages sent to the individual destinations.

Character set and encoding: Data in MQDH must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQDH must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQDH structure is at the start of the message data), or
- The header structure that precedes the MQDH structure (all other cases).

Usage: When an application puts a message to a distribution list, and some or all of the destinations are remote, the queue manager prefixes the application message data with the MQXQH and MQDH structures, and places the message on the relevant transmission queue. The data therefore occurs in the following sequence when the message is on a transmission queue:

- MQXQH structure
- MQDH structure plus arrays of MQOR and MQPMR records
- Application message data

Depending on the destinations, more than one such message might be generated by the queue manager, and placed on different transmission queues. In this case, the MQDH structures in those messages identify different subsets of the destinations defined by the distribution list opened by the application.

An application that puts a distribution-list message directly on a transmission queue must conform to the sequence described previously, and must ensure that the MQDH structure is correct. If the MQDH structure is not valid, the queue manager may choose to fail the MQPUT or MQPUT1 call with reason code RC2135.

Messages can be stored on a queue in distribution-list form only if the queue is defined as being able to support distribution list messages (see the *DistLists* queue attribute described in “Attributes for queues” on page 1324). If an application puts a distribution-list message directly on a queue that does not support distribution lists, the queue manager splits the distribution list message into individual messages, and places those on the queue instead.

- “Fields” on page 1019
- “Initial values” on page 1022
- “RPG declaration” on page 1023

Fields

The MQDH structure contains the following fields; the fields are described in **alphabetical order**:

DHCNT (10-digit signed integer)

Number of MQOR records present.

This defines the number of destinations. A distribution list must always contain at least one destination, so *DHCNT* must always be greater than zero.

The initial value of this field is 0.

DHCSI (10-digit signed integer)

Character set identifier of data that follows the MQOR and MQPMR records.

This specifies the character set identifier of the data that follows the arrays of MQOR and MQPMR records; it does not apply to character data in the MQDH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

DHENC (10-digit signed integer)

Numeric encoding of data that follows the MQOR and MQPMR records.

This specifies the numeric encoding of the data that follows the arrays of MQOR and MQPMR records; it does not apply to numeric data in the MQDH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

DHFLG (10-digit signed integer)

General flags.

The following flag can be specified:

DHFNEW

Generate new message identifiers.

This flag indicates that a new message identifier is to be generated for each destination in the distribution list. This can be set only when there are no put-message records present, or when the records are present but they do not contain the *PRMID* field.

Using this flag defers generation of the message identifiers until the last possible moment, namely the moment when the distribution-list message is finally split into individual messages. This minimizes the amount of control information that must flow with the distribution-list message.

When an application puts a message to a distribution list, the queue manager sets DHFNEW in the MQDH it generates when both of the following are true:

- There are no put-message records provided by the application, or the records provided do not contain the *PRMID* field.
- The *MDMID* field in MQMD is MINONE, or the *PMOPT* field in MQPMO includes PMNMID

If no flags are needed, the following can be specified:

DHFNON

No flags.

This constant indicates that no flags have been specified. DHFNON is defined to aid program documentation. It is not intended that this constant is used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is DHFNON.

DHFMT (8-byte character string)

Format name of data that follows the MQOR and MQPMR records.

This specifies the format name of the data that follows the arrays of MQOD and MQPMR records (whichever occurs last).

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

DHLEN (10-digit signed integer)

Length of MQDH structure plus following MQOR and MQPMR records.

This is the number of bytes from the start of the MQDH structure to the start of the message data following the arrays of MQOR and MQPMR records. The data occurs in the following sequence:

- MQDH structure
- Array of MQOR records
- Array of MQPMR records
- Message data

The arrays of MQOR and MQPMR records are addressed by offsets contained within the MQDH structure. If these offsets result in unused bytes between one or more of the MQDH structure, the arrays of records, and the message data, those unused bytes must be included in the value of *DHLEN*, but the content of those bytes is not preserved by the queue manager. It is valid for the array of MQPMR records to precede the array of MQOR records.

The initial value of this field is 0.

DHORO (10-digit signed integer)

Offset of first MQOR record from start of MQDH.

This field gives the offset in bytes of the first record in the array of MQOR object records containing the names of the destination queues. There are *DHCNT* records in this array. These records (plus any bytes skipped between the first object record and the previous field) are included in the length given by the *DHLEN* field.

A distribution list must always contain at least one destination, so *DHORO* must always be greater than zero.

The initial value of this field is 0.

DHPRF (10-digit signed integer)

Flags indicating which MQPMR fields are present.

Zero or more of the following flags can be specified:

PFMID

Message-identifier field is present.

PFCID

Correlation-identifier field is present.

PFGID

Group-identifier field is present.

PFFB

Feedback field is present.

PFACC

Accounting-token field is present.

If no MQPMR fields are present, the following can be specified:

PFNONE

No put-message record fields are present.

PFNONE is defined to aid program documentation. It is not intended that this constant be used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is PFNONE.

DHPRO (10-digit signed integer)

Offset of first MQPMR record from start of MQDH.

This field gives the offset in bytes of the first record in the array of MQPMR put message records containing the message properties. If present, there are *DHCNT* records in this array. These records (plus any bytes skipped between the first put message record and the previous field) are included in the length given by the *DHLEN* field.

Put message records are optional; if no records are provided, *DHPRO* is zero, and *DHPRF* has the value PFNONE.

The initial value of this field is 0.

DHSID (4-byte character string)

Structure identifier.

The value must be:

DHSIDV

Identifier for distribution header structure.

The initial value of this field is DHSIDV.

DHVER (10-digit signed integer)

Structure version number.

The value must be:

DHVER1

Version number for distribution header structure.

The following constant specifies the version number of the current version:

DHVERC

Current version of distribution header structure.

The initial value of this field is DHVER1.

Initial values

MQDLH - Dead-letter header

Overview

Purpose

The MQDLH structure describes the information that prefixes the application message data of messages on the dead-letter (undelivered-message) queue. A message can arrive on the dead-letter queue because the queue manager or message channel agent redirected it to the queue. An application might put the message directly on the queue.

Format name

FMDLH

Character set and encoding

The MQDLH might be at the start of the application message data. If so, the fields in the MQDLH structure are in the character set and encoding given by the MDCSI and MDENC fields. If not, the character set and encoding are set by the MDCSI and MDENC fields in the header structure that precedes the MQDLH.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

Usage

Applications that put messages directly on the dead-letter queue must prefix the message data with an MQDLH structure, and initialize the fields with appropriate values. However, the queue manager does not require that an MQDLH structure is present, or that valid values are specified for the fields.

If a message is too long to put on the dead-letter queue, the application must consider doing one of the following things:

- Truncate the message data to fit on the dead-letter queue.
- Record the message on auxiliary storage and place an exception report message on the dead-letter queue indicating the message is too long.
- Discard the message and return an error to its originator. If the message is a critical message. Discard the message only if it is known that the originator still has a copy of the message. For example, a message received by a message channel agent from a communication channel.

Which of the choices is appropriate depends on the design of the application.

The queue manager performs special processing when a message which is a segment is put with an MQDLH structure at the front. See the description of the MQMDE structure for further details.

- [“Putting messages on the dead-letter queue” on page 1024](#)
- [“Getting messages from the dead-letter queue” on page 1025](#)
- [“Fields” on page 1025](#)
- [“Initial values” on page 1028](#)
- [“RPG declaration” on page 1029](#)

Putting messages on the dead-letter queue

If a message is put on the dead-letter queue, the MQMD structure used for the MQPUT or MQPUT1 call must be identical to the MQMD associated with the message. The MQMD is typically the one returned by the MQGET call, except for the following cases:

- The MDCSI and MDENC fields must be set to whatever character set and encoding are used for fields in the MQDLH structure.
- The MDFMT field must be set to FMDLH to indicate that the data begins with an MQDLH structure.
- The context fields, MDACC, MDAID, MDAOD, MDPAN, MDPAT, MDPD, MDPT, and MDUID must be set by using a context option appropriate to the circumstances:
 - An application putting on the dead-letter queue a message that is not related to any preceding message must use the PMDEFC option. The PMDEFC option causes the queue manager to set all of the context fields in the message descriptor to their default values.
 - A server application putting on the dead-letter queue a message it received must use the PMPASA option, in order to preserve the original context information.
 - A server application putting on the dead-letter queue a reply to message it received must use the PMPASI option. The PMPASI option preserves the identity information but sets the origin information to be that of the server application.
 - A message channel agent putting on the dead-letter queue a message it received from its communication channel must use the PMSETA option. The PMSETA option preserves the original context information.

In the MQDLH structure itself, the fields must be set as follows:

- The DLCSI, DLENC, and *DLFMT* fields must be set to the values that describe the data that follows the MQDLH structure. These values are typically the values from the original message descriptor.
- The context fields DLPAT, DLPAN, DLPD, and DLPT must be set to values appropriate to the application that is putting the message on the dead-letter queue. These values are not related to the original message.
- Other fields must be set as appropriate.

The application must ensure that all fields have valid values, and that character fields are padded with blanks to the defined length of the field. The character data must not be terminated prematurely by using a null character. The queue manager does not convert the null and subsequent characters to blanks in the MQDLH structure.

Getting messages from the dead-letter queue

Applications that get messages from the dead-letter queue must verify that the messages begin with an MQDLH structure. The application can determine whether an MQDLH structure is present by examining the MDFMT field in the message descriptor MQMD. If the field has the value FMDLH, the message data begins with an MQDLH structure. Messages on the dead-letter queue might be truncated if they were originally too long for the queue they were intended for.

Fields

The MQDLH structure contains the following fields; the fields are described in alphabetical order:

DLCSI (10-digit signed integer)

Character set identifier of data that follows MQDLH.

DLCSI specifies the character set identifier of the data that follows the MQDLH structure. The data is typically from the original message. It does not apply to character data in the MQDLH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data following this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the MDPAT field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

DLDM (48-byte character string)

Name of original destination queue manager.

This is the name of the queue manager that was the original destination for the message.

The length of this field is given by LNQM. The initial value of this field is 48 blank characters.

DLDQ (48-byte character string)

Name of original destination queue.

This is the name of the message queue that was the original destination for the message.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

DLENC (10-digit signed integer)

Numeric encoding of data that follows MQDLH.

DLENC specifies the numeric encoding of the data that follows the MQDLH structure. The data is typically from the original message. It does not apply to numeric data in the MQDLH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

DLFMT (8-byte character string)

Format name of data that follows MQDLH.

This specifies the format name of the data that follows the MQDLH structure (typically the data from the original message).

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as the rules for the MDFMT field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

DLPAN (28-byte character string)

Name of application that put message on dead-letter (undelivered-message) queue.

The format of the name depends on the DLPAT field. See the description of the MDPAN field in [“MQMD - Message descriptor”](#) on page 1068.

If it is the queue manager that redirects the message to the dead-letter queue, DLPAN contains the first 28 characters of the queue manager name. The name is padded with blanks if necessary.

The length of this field is given by LNPAN. The initial value of this field is 28 blank characters.

DLPAT (10-digit signed integer)

Type of application that put message on dead-letter (undelivered-message) queue.

This field has the same meaning as the MDPAT field in the message descriptor MQMD (see [“MQMD - Message descriptor”](#) on page 1068 for details).

If it is the queue manager that redirects the message to the dead-letter queue, DLPAT has the value ATQM.

The initial value of this field is 0.

DLPD (8-byte character string)

Date when message was put on dead-letter (undelivered-message) queue.

The format used for the date when this field is generated by the queue manager is:

- YYYYMMDD

where the characters represent:

YYYY

year (four numeric digits)

MM

month of year (01 through 12)

DD

day of month (01 through 31)

Greenwich Mean Time (GMT) is used for the DLPD and DLPT fields, subject to the system clock being set accurately to GMT.

The length of this field is given by LNPDAT. The initial value of this field is eight blank characters.

DLPT (8-byte character string)

Time when message was put on the dead-letter (undelivered-message) queue.

The format used for the time when this field is generated by the queue manager is:

- HHMMSSTH

where the characters represent (in order):

HH

hours (00 through 23)

MM

minutes (00 through 59)

SS

seconds (00 through 59; see note later in this topic)

T

tenths of a second (0 through 9)

H

hundredths of a second (0 through 9)

Note: If the system clock is synchronized to an accurate time standard, it is possible for 60 or 61 to be returned for the seconds in DLPT. The extra second occurs when leap seconds are inserted into the global time standard.

Greenwich Mean Time (GMT) is used for the DLPD and DLPT fields, subject to the system clock being set accurately to GMT.

The length of this field is given by LNPTIM. The initial value of this field is eight blank characters.

DLREA (10-digit signed integer)

Reason message arrived on dead-letter (undelivered-message) queue.

This identifies the reason why the message was placed on the dead-letter queue instead of on the original destination queue. It must be one of the FB* or RC* values (for example, RC2053). See the description of the *MDFB* field in [“MQMD - Message descriptor” on page 1068](#) for details of the common FB* values that can occur.

If the value is in the range FBIFST through FBILST, the actual IMS error code can be determined by subtracting FBIERR from the value of the *DLREA* field.

Some FB* values occur only in this field. They relate to repository messages, trigger messages, or transmission-queue messages that are transferred to the dead-letter queue. These values are:

FBABEG

Application cannot be started.

An application processing a trigger message was unable to start the application named in the TMAI field of the trigger message; see [“MQTM - Trigger message” on page 1191](#).

FBATYP

Application type error.

An application processing a trigger message was unable to start the application because the TMAI field of the trigger message is not valid; see [“MQTM - Trigger message” on page 1191](#).

FBBOCD

Cluster-receiver channel deleted.

The message was on a cluster transmission queue intended for a cluster queue that was opened with the FBIERR option. The remote cluster-receiver channel to be used to transmit the message to the destination queue was deleted before the message could be sent. Because FBIERR was specified, only the channel selected when the queue was opened can be used to transmit the message. As this channel is not longer available, the message was placed on the dead-letter queue.

FBNARM

Message is not a repository message.

FBSBCX

Message stopped by channel auto-definition exit.

FBSBMX

Message stopped by channel message exit.

FBTM

MQTM structure not valid or missing.

The MDFMT field in MQMD specifies FMTM, but the message does not begin with a valid MQTM structure. For example, the *TMSID* mnemonic eye-catcher might not be valid. The *TMVER* might

not be recognized. The length of the trigger message might be insufficient to contain the MQTM structure.

FBXQME

Message on transmission queue not in correct format.

A message channel agent found that a message on the transmission queue is not in the correct format. The message channel agent puts the message on the dead-letter queue using this feedback code.

The initial value of this field is RCNONE.

DLSID (4-byte character string)

Structure identifier.

The value must be:

DLSIDV

Identifier for dead-letter header structure.

The initial value of this field is DLSIDV.

DLVER (10-digit signed integer)

Structure version number.

The value must be:

DLVER1

Version number for dead-letter header structure.

The following constant specifies the version number of the current version:

DLVERC

Current version of dead-letter header structure.

The initial value of this field is DLVER1.

Initial values

Table 588. Initial values of fields in MQDLH.

MQDMHO - Delete message handle options

The **MQDMHO** structure allows applications to specify options that control how message handles are deleted.

Overview

Purpose: The structure is an input parameter on the **MQDLTMH** call.

Character set and encoding: Data in **MQDMHO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1029](#)
- [“Initial values” on page 1030](#)
- [“RPG declaration” on page 1030](#)

Fields

The **MQDMHO** structure contains the following fields; the fields are described in **alphabetical order**:

DMOPT (10-digit signed integer)

The value must be:

DMNONE

No options specified.

This is always an input field. The initial value of this field is **DMNONE**.

DMSID (10-digit signed integer)

This is the structure identifier; the value must be:

DMSIDV

Identifier for delete message handle options structure.

This is always an input field. The initial value of this field is **DMSIDV**.

DMVER (10-digit signed integer)

This is the structure version number; the value must be:

DMVER1

Version-1 delete message handle options structure.

The following constant specifies the version number of the current version:

DMVERC

Current version of delete message handle options structure.

This is always an input field. The initial value of this field is **DMVER1**.

MQDMPO - Delete message property options

Structure defining the delete message property options.

Overview

Purpose: The MQDMPO structure allows applications to specify options that control how properties of messages are deleted. The structure is an input parameter on the MQDLTMP call.

Character set and encoding: Data in MQDMPO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1031](#)
- [“Initial values” on page 1032](#)
- [“RPG declaration” on page 1032](#)

Fields

The MQDMPO structure contains the following fields; the fields are described in alphabetic order:

DPOPT (10-digit signed integer)

Delete message property options structure - DPOPT field.

Location options: The following options relate to the relative location of the property compared to the property cursor.

DPDELF

Deletes the first property that matches the specified name.

DPDELC

Deletes the property pointed to by the property cursor; that is the property that was last inquired by using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused. It is also reset when the message handle is specified in the *HMSG* field of the MQGMO on an MQGET call, or MQPMO structure on an MQPUT call.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET structure on an MQGET call or MQPMO structure on an MQPUT call.

The call fails with completion code CCFAIL and reason RC2471 if this option is used when the property cursor has not yet been established. It also fails with these codes if the property pointed to by the property cursor has already been deleted..

If neither of these options is required, the following option can be used:

DPNONE

No options specified.

The initial value of this input field is DPDELF.

DPSID (10-digit signed integer)

Delete message property options structure - DPSID field.

This is the structure identifier. The value must be:

DPSIDV

Identifier for delete message property options structure.

This field is always an input field. The initial value of this field is DPSIDV.

DPVER (10-digit signed integer)

Delete message property options structure - DPVER field.

This is the structure version number. The value must be:

DPVER1

Version number for delete message property options structure.

The following constant specifies the version number of the current version:

DPVERC

Current version of delete message property options structure.

This field is always an input field. The initial value of this field is DPVER1.

Initial values

Table 590. Initial values of fields in MQDPMO

MQEPH - Embedded PCF header

Overview

Purpose

The MQEPH structure describes the additional data that is present in a message when that message is a programmable command format (PCF) message. The *EPPFH* field defines the PCF parameters that follow this structure and this allows you to follow the PCF message data with other headers.

Format name

EPFMT

Character set and encoding

Data in MQEPH must be in the character set and encoding of the local queue manager; this is given by the *CCSID* queue-manager attribute.

Set the character set and encoding of the MQEPH into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQEPH structure is at the start of the message data), or
- The header structure that precedes the MQEPH structure (all other cases).

Usage

You cannot use MQEPH structures to send commands to the command server or any other queue manager PCF-accepting server.

Similarly, the command server or any other queue manager PCF-accepting server do not generate responses or events containing MQEPH structures.

- [“Fields” on page 1032](#)
- [“Initial values” on page 1034](#)
- [“RPG declaration” on page 1035](#)

Fields

The MQEPH structure contains the following fields; the fields are described in **alphabetical order**:

EPCSI (10-digit signed integer)

This is the character set identifier of the data that follows the MQEPH structure and the associated PCF parameters; it does not apply to character data in the MQEPH structure itself.

The initial value of this field is EPCUND.

EPENC (10-digit signed integer)

This is the numeric encoding of the data that follows the MQEPH structure and the associated PCF parameters; it does not apply to character data in the MQEPH structure itself.

The initial value of this field is 0.

EPFLG (10-digit signed integer)

The following values are available:

EPNONE

No flags have been specified. *MDCSI* EPNONE is defined to aid program documentation. It is not intended that this constant be used with any other, but as its value is zero, such use cannot be detected.

EPCSEM

The character set of the parameters containing character data is specified individually within the *CCSID* field in each structure. The character set of the *EPSID* and *EPFMT* fields are defined by the *CCSID* in the header structure that precedes the MQEPH structure, or by the *MDCSI* field in the MQMD if the MQEPH is at the start of the message.

The initial value of this field is EPNONE.

EPFMT (8-byte character string)

This is the format name of the data that follows the MQEPH structure and the associated PCF parameters.

The initial value of this field is EPFMNO.

EPLEN (10-digit signed integer)

This is the amount of data preceding the next header structure. It includes:

- The length of the MQEPH header
- The length of all PCF parameters following the header
- Any blank padding following those parameters

EPLEN must be a multiple of 4.

The fixed-length part of the structure is defined by EPSTLF.

The initial value of this field is 68.

EPPCFH (MQCFH)

This is the programmable command format (PCF) header, defining the PCF parameters that follow the MQEPH structure. This enables you to follow the PCF message data with other headers.

The PCF header is initially defined with the following values:

Table 591. Initial values of fields in EPPCFH		
Field name	Name of constant	Value of constant
EP3TYP	CFTNON	0
EP3LEN	FHLENV	36
EP3VER	FHVER3	3
EP3CMD	CMNONE	0

<i>Table 591. Initial values of fields in EPPCFH (continued)</i>		
Field name	Name of constant	Value of constant
EP3SEQ	None	1
EP3CTL	CFCLST	1
EEP3CC	CCOK	0
EP3REA	RCNONE	0
EP3CNT	None	0

The application must change EP3TYP from CFTNON to a valid structure type for the use it is making of the embedded PCF header.

EPSID (4-byte character string)

The value must be:

EPSTID

Identifier for the Embedded PCF header structure.

The initial value of this field is EPSTID.

EPVER (10-digit signed integer)

The value can be:

EPVER1

Version number for embedded PCF header structure.

The following constant specifies the version number of the current version:

EPVER3

Current version of embedded PCF header structure.

The initial value of this field is EPVER3.

Initial values

<i>Table 592. Initial values of fields in MQEPH</i>		
Field name	Name of constant	Value of constant
EPSID	EPSTID	'EP--'
EPVER	EPVER1	1
EPLEN	EPSTLF	68
EPENC	None	0
EPCSI	EPCUND	0
EPFMT	EPFMNO	Blanks
EPFLG	EPNONE	0
EPPCFH	Names and values as defined in Table 591 on page 1033	0

Note:

1. The symbol – represents a single blank character.

MQGMO - Get-message options

The MQGMO structure allows the application to specify options that control how messages are removed from queues.

Overview

Purpose

The structure is an input/output parameter on the MQGET call.

Version

The current version of MQGMO is GMVER4. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQGMO that is supported by the environment, but with the initial value of the *GMVER* field set to GMVER1. To use fields that are not present in the version-1 structure, the application must set the *GMVER* field to the version number of the version required.

Character set and encoding

Data in MQGMO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1035](#)
- [“Initial values” on page 1055](#)
- [“RPG declaration” on page 1055](#)

Fields

The MQGMO structure contains the following fields; the fields are described in alphabetical order:

GMGST (1 byte character string)

Flag indicating whether message retrieved is in a group.

It has one of the following values:

GSNIG

Message is not in a group.

GSMIG

Message is in a group, but is not the last in the group.

GSLMIG

Message is the last in the group.

This value is also the value returned if the group consists of only one message.

This field is an output field. The initial value of this field is GSNIG. This field is ignored if *GMVER* is less than GMVER2.

GMMH (10 digit signed integer)

Message Handle

If the GMPRAQ option is specified and the PRPCTL queue attribute is not set to PRPRFH then this is the handle to a message which is populated with the properties of the message being retrieved from the queue. The handle is created by an MQCRTMH call. Any properties already associated with the handle are cleared before retrieving a message.

The following value can also be specified:

MQHM_NONE

No message handle supplied.

No message descriptor is required on the MQGET call if a valid message handle is supplied and used on output to contain the message properties, the message descriptor associated with the message handle is used for input fields.

If a message descriptor is specified on the MQGET call, it always takes precedence over the message descriptor associated with a message handle.

If GMPRRF is specified, or the GMPRAQ is specified and the PRPCTL queue attribute is PRPRFH then the call fails with reason code RC2026 when no message descriptor parameter is specified.

On return from the MQGET call, the properties and message descriptor associated with this message handle are updated to reflect the state of the message retrieved (as well as the message descriptor if one was supplied on the MQGET call). The properties of the message can then be inquired using the MQINQMP call.

Except for message descriptor extensions, when present, a property that can be inquired with the MQINQMP call is not contained in the message data; if the message on the queue contained properties in the message data these are removed from the message data before the data is returned to the application.

If no message handle is provided or Version is less than GMVER4 then you must supply a valid message descriptor on the MQGET call. Any message properties (except those properties contained in the message descriptor) are returned in the message data subject to the value of the property options in the MQGMO structure and the PRPCTL queue attribute.

This field is an always an input field. The initial value of this field is HMNONE. This field is ignored if *GMVER* is less than GMVER4.

GMMO (10 digit signed integer)

Options controlling selection criteria used for MQGET.

These options allow the application to choose which fields in the *MSGDSC* parameter is used to select the message returned by the MQGET call. The application sets the required options in this field, and then sets the corresponding fields in the *MSGDSC* parameter to the values required for those fields. Only messages that have those values in the MQMD for the message are candidates for retrieval using that *MSGDSC* parameter on the MQGET call. Fields for which the corresponding match option is not specified are ignored when selecting the message to be returned. If no selection criteria are to be used on the MQGET call (that is, any message is acceptable), *GMMO* should be set to MONONE.

If GMLOGO is specified, only certain messages are eligible for return by the next MQGET call:

- If there is no current group or logical message, only messages that have *MDSEQ* equal to 1 and *MDOFF* equal to 0 are eligible for return. In this situation, one or more of the following options can be used to select which of the eligible messages is the one returned:
 - MOMSGI
 - MOCORI
 - MOGRPI
- If there is a current group or logical message, only the next message in the group or next segment in the logical message is eligible for return, and this cannot be altered by specifying MO* options.

In both cases, match options which are not applicable can still be specified, but the value of the relevant field in the *MSGDSC* parameter must match the value of the corresponding field in the message to be returned; the call fails with reason code RC2247 if this condition is not satisfied.

GMMO is ignored if either *GMMUC* or *GMBRWC* is specified.

One or more of the following options can be specified:

MOMSGI

Retrieve message with specified message identifier.

This option specifies that the message to be retrieved must have a message identifier that matches the value of the *MDMID* field in the *MSGDSC* parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the correlation identifier).

If this option is not specified, the *MDMID* field in the *MSGDSC* parameter is ignored, and any message identifier matches.

Note: The message identifier MINONE is a special value that matches any message identifier in the MQMD for the message. Therefore, specifying MOMSGI with MINONE is the same as not specifying MOMSGI.

MOCORI

Retrieve message with specified correlation identifier.

This option specifies that the message to be retrieved must have a correlation identifier that matches the value of the *MDCID* field in the *MSGDSC* parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the message identifier).

If this option is not specified, the *MDCID* field in the *MSGDSC* parameter is ignored, and any correlation identifier matches.

Note: The correlation identifier CINONE is a special value that matches any correlation identifier in the MQMD for the message. Therefore, specifying MOCORI with CINONE is the same as not specifying MOCORI.

MOGRPI

Retrieve message with specified group identifier.

This option specifies that the message to be retrieved must have a group identifier that matches the value of the *MDGID* field in the *MSGDSC* parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the correlation identifier).

If this option is not specified, the *MDGID* field in the *MSGDSC* parameter is ignored, and any group identifier matches.

Note: The group identifier GINONE is a special value that matches any group identifier in the MQMD for the message. Therefore, specifying MOGRPI with GINONE is the same as not specifying MOGRPI.

MOSEQN

Retrieve message with specified message sequence number.

This option specifies that the message to be retrieved must have a message sequence number that matches the value of the *MDSEQ* field in the *MSGDSC* parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the group identifier).

If this option is not specified, the *MDSEQ* field in the *MSGDSC* parameter is ignored, and any message sequence number matches.

MOFFS

Retrieve message with specified offset.

This option specifies that the message to be retrieved must have an offset that matches the value of the *MDOFF* field in the *MSGDSC* parameter of the MQGET call. This match is in addition to any other matches that might apply (for example, the message sequence number).

If this option is not specified, the *MDOFF* field in the *MSGDSC* parameter is ignored, and any offset matches.

If none of the options described is specified, the following option can be used:

MONONE

No matches.

This option specifies that no matches are to be used in selecting the message to be returned; therefore, all messages on the queue are eligible for retrieval (but subject to control by the GMAMSA, GMASGA, and GMCMPM options).

MONONE is defined to aid program documentation. It is not intended that this option is used with any other MO* option, but as its value is zero, such use cannot be detected.

This field is an input field. The initial value of this field is MOMSGI with MOCORI. This field is ignored if *GMVER* is less than *GMVER2*.

Note: The initial value of the *GMMO* field is defined for compatibility with earlier version queue managers. However, when reading a series of messages from a queue without using selection criteria, this initial value requires the application to reset the *MDMID* and *MDCID* fields to MINONE and CINONE before each MQGET call. The need to reset *MDMID* and *MDCID* can be avoided by setting *GMVER* to *GMVER2*, and *GMMO* to MONONE.

GMOPT (10 digit signed integer)

Options that control the action of MQGET.

Zero or more of the following described options can be specified. If more than one is required the values can be added (do not add the same constant more than once). Combinations of options that are not valid are noted; all other combinations are valid.

Wait options: The following options relate to waiting for messages to arrive on the queue:

GMWT

Wait for message to arrive.

The application is to wait until a suitable message arrives. The maximum time the application waits is specified in *GMWT*.

If MQGET requests are inhibited, or MQGET requests become inhibited while waiting, the wait is canceled and the call completes with CCFAIL and reason code RC2016, regardless of whether there are suitable messages on the queue.

This option can be used with the GMBRWF or GMBRWN options.

If several applications are waiting on the same shared queue, the application, or applications, that are activated when a suitable message arrives are described later in this section.

Note: In the following description, a browse MQGET call is one which specifies one of the browse options, but not GMLK; an MQGET call specifying the GMLK option is treated as a nonbrowse call.

- If one or more nonbrowse MQGET calls is waiting, but no browse MQGET calls are waiting, one is activated.

- If one or more browse MQGET calls is waiting, but no nonbrowse MQGET calls are waiting, all are activated.
- If one or more nonbrowse MQGET calls, and one or more browse MQGET calls are waiting, one nonbrowse MQGET call is activated, and none, some, or all the browse MQGET calls. (The number of browse MQGET calls activated cannot be predicted, because it depends on the scheduling considerations of the operating system, and other factors.)

If more than one nonbrowse MQGET call is waiting on the same queue, only one is activated; in this situation the queue manager attempts to give priority to waiting nonbrowse calls in the following order:

1. Specific get-wait requests that can be satisfied only by certain messages, for example, ones with a specific *MDMID* or *MDCID* (or both).
2. General get-wait requests that can be satisfied by any message.

The following points must be noted:

- Within the first category, no additional priority is given to more specific get-wait requests, for example those that specify both *MDMID* and *MDCID*.
- Within either category, it cannot be predicted which application is selected. In particular, the application waiting longest is not necessarily the one selected.
- Path length, and priority-scheduling considerations of the operating system, can mean that a waiting application of lower operating system priority than expected retrieves the message.
- It might also happen that an application that is not waiting retrieves the message in preference to one that is.

GMWT is ignored if specified with GMBRWC or GMMUC; no error is raised.

GMNWT

Return immediately if no suitable message.

The application is not to wait if no suitable message is available. This is the opposite of the GMWT option, and is defined to aid program documentation. It is the default if neither is specified.

GMFIQ

Fail if queue manager is quiescing.

This option forces the MQGET call to fail if the queue manager is in the quiescing state.

If this option is specified together with GMWT, and the wait is outstanding at the time the queue manager enters the quiescing state:

- The wait is canceled and the call returns completion code CCFAIL with reason code RC2161 .

If GMFIQ is not specified and the queue manager enters the quiescing state, the wait is not canceled.

Syncpoint options: The following options relate to the participation of the MQGET call within a unit of work:

GMSYP

Get message with syncpoint control.

The request is to operate within the normal unit-of-work protocols. The message is marked as being unavailable to other applications, but it is deleted from the queue only when the unit of work is committed. The message is made available again if the unit of work is backed out.

If this option or GMNSYP is not specified, the get request is not within a unit of work.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN

- GMLK
- GMNSYP
- GMPSYP
- GMUNLK

GMPSYP

Get message with syncpoint control if message is persistent.

The request is to operate within the normal unit-of-work protocols, but only if the message retrieved is persistent. A persistent message has the value PEPER in the *MDPER* field in MQMD.

- If the message is persistent, the queue manager processes the call as though the application had specified GMSYP.
- If the message is not persistent, the queue manager processes the call as though the application had specified GMNSYP (see the following section for details).

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN
- GMCMPM
- GMNSYP
- GMSYP
- GMUNLK

GMNSYP

Get message without syncpoint control.

The request is to operate outside the normal unit-of-work protocols. The message is deleted from the queue immediately (unless this is a browse request). The message cannot be made available again by backing out the unit of work.

This option is assumed if GMBRWF or GMBRWN is specified.

If this option and GMSYP are not specified, the get request is not within a unit of work.

This option is not valid with any of the following options:

- GMSYP
- GMPSYP

Browse options: The following options relate to browsing messages on the queue:

GMBRWF

Browse from start of queue.

When a queue is opened with the OOBWF option, a browse cursor is established, positioned logically before the first message on the queue. Subsequent MQGET calls specifying the GMBRWF, GMBRWN, or GMBRWC option can be used to retrieve messages from the queue nondestructively. The browse cursor marks the position, within the messages on the queue, from which the next MQGET call with GMBRWN searches for a suitable message.

An MQGET call with GMBRWF causes the previous position of the browse cursor to be ignored. The first message on the queue that satisfies the conditions specified in the message descriptor is retrieved. The message remains on the queue, and the browse cursor is positioned on this message.

After this call, the browse cursor is positioned on the message that has been returned. If the message is removed from the queue before the next MQGET call with GMBRWN is issued, the browse cursor remains at the position in the queue that the message occupied, even though that position is now empty.

The GMMUC option can then be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by a nonbrowse MQGET call using the same *HOB*J handle. Nor is it moved by a browse MQGET call that returns a completion code of CCFAIL, or a reason code of RC2080 .

The GMLK option can be specified together with this option, to cause the message that is browsed to be locked.

GMBRWF can be specified with any valid combination of the GM* and MO* options that control the processing of messages in groups and segments of logical messages.

If GMLOGO is specified, the messages are browsed in logical order. If that option is omitted, the messages are browsed in physical order. When GMBRWF is specified, it is possible to switch between logical order and physical order, but subsequent MQGET calls using GMBRWN must browse the queue in the same order as the most recent call that specified GMBRWF for the queue handle.

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that the queue manager retains for MQGET calls that remove messages from the queue. When GMBRWF is specified, the queue manager ignores the group and segment information for browsing, and scans the queue as though there were no current group and no current logical message. If the MQGET call is successful (completion code CCOK or CCWARN), the group and segment information for browsing is set to that of the message returned; if the call fails, the group and segment information remains the same as it was before the call.

This option is not valid with any of the following options:

- GMBRWC
- GMBRWN
- GMMUC
- GMSYP
- GMPSPY
- GMUNLK

It is also an error if the queue was not opened for browse.

GMBRWN

Browse from current position in queue.

The browse cursor is advanced to the next message on the queue that satisfies the selection criteria specified on the MQGET call. The message is returned to the application, but remains on the queue.

After a queue has been opened for browse, the first browse call using the handle has the same effect whether it specifies the GMBRWF or GMBRWN option.

If the message is removed from the queue before the next MQGET call with GMBRWN is issued, the browse cursor logically remains at the position in the queue that the message occupied, even though that position is now empty.

Messages are stored on the queue in one of two ways:

- FIFO within priority (MSPRIO), or
- FIFO regardless of priority (MSFIFO)

The *MsgDeliverySequence* queue attribute indicates which method applies (see [“Attributes for queues”](#) on page 1324 for details).

If the queue has a *MsgDeliverySequence* of MSPRIO, and a message arrives on the queue that is of a higher priority than the one currently pointed to by the browse cursor, that message is

not found during the current sweep of the queue using GMBRWN. It can only be found after the browse cursor has been reset with GMBRWF (or by reopening the queue).

The GMMUC option can later be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by nonbrowse MQGET calls using the same *HOBJ* handle.

The GMLK option can be specified together with this option, to cause the message that is browsed to be locked.

GMBRWN can be specified with any valid combination of the GM* and MO* options that control the processing of messages in groups and segments of logical messages.

If GMLOGO is specified, the messages are browsed in logical order. If that option is omitted, the messages are browsed in physical order. When GMBRWF is specified, it is possible to switch between logical order and physical order, but subsequent MQGET calls using GMBRWN must browse the queue in the same order as the most recent call that specified GMBRWF for the queue handle. The call fails with reason code RC2259 if this condition is not satisfied.

Note: Special care is needed if an MQGET call is used to browse beyond the end of a message group (or logical message not in a group) when GMLOGO is not specified. For example, if the last message in the group happens to precede the first message in the group on the queue, using GMBRWN to browse beyond the end of the group, specifying MOSEQN with *MDSEQ* set to 1 (to find the first message of the next group) would return again the first message in the group already browsed. This could happen immediately, or a number of MQGET calls later (if there are intervening groups).

The possibility of an infinite loop can be avoided by opening the queue twice for browse:

- Use the first handle to browse only the first message in each group.
- Use the second handle to browse only the messages within a specific group.
- Use the MO* options to move the second browse cursor to the position of the first browse cursor, before browsing the messages in the group.
- Do not use GMBRWN to browse beyond the end of a group.

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that it retains for MQGET calls that remove messages from the queue.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMMUC
- GMSYP
- GMPSYP
- GMUNLK

It is also an error if the queue was not opened for browse.

GMBRWC

Browse message under browse cursor.

This option causes the message pointed to by the browse cursor to be retrieved nondestructively, regardless of the MO* options specified in the *GMMO* field in MQGMO.

The message pointed to by the browse cursor is the one that was last retrieved using either the GMBRWF or the GMBRWN option. The call fails if neither of these calls has been issued for this queue since it was opened, or if the message that was under the browse cursor has since been retrieved destructively.

The position of the browse cursor is not changed by this call.

The GMMUC option can then be used with a nonbrowse MQGET call if required, to remove the message from the queue.

The browse cursor is not moved by a nonbrowse MQGET call using the same *HOBJ* handle. Nor is it moved by a browse MQGET call that returns a completion code of CCFAIL, or a reason code of RC2080.

If GMBRWC is specified with GMLK:

- If there is already a message locked, it must be the one under the cursor, so that is returned without unlocking and relocking it; the message remains locked.
- If there is no locked message, the message under the browse cursor (if there is one) is locked and returned to the application; if there is no message under the browse cursor the call fails.

If GMBRWC is specified without GMLK:

- If there is already a message locked, it must be the one under the cursor. This message is returned to the application and then unlocked. Because the message is now unlocked, there is no guarantee that it can be browsed again, or retrieved destructively (it might be retrieved destructively by another application getting messages from the queue).
- If there is no locked message, the message under the browse cursor (if there is one) is returned to the application; if there is no message under the browse cursor the call fails.

If GMCMPM is specified with GMBRWC, the browse cursor must identify a message with a *MDOFF* field in MQMD that is zero. If this condition is not satisfied, the call fails with reason code RC2246 .

The group and segment information that the queue manager retains for MQGET calls that browse messages on the queue, is separate from the group and segment information that it retains for MQGET calls that remove messages from the queue.

This option is not valid with any of the following options:

- GMBRWF
- GMBRWN
- GMMUC
- GMSYP
- GMPSYP
- GMUNLK

It is also an error if the queue was not opened for browse.

GMMUC

Get message under browse cursor.

This option causes the message pointed to by the browse cursor to be retrieved, regardless of the MO* options specified in the *GMMO* field in MQGMO. The message is removed from the queue.

The message pointed to by the browse cursor is the one that was last retrieved using either the GMBRWF or the GMBRWN option.

If GMCMPM is specified with GMMUC, the browse cursor must identify a message with a *MDOFF* field in MQMD that is zero. If this condition is not satisfied, the call fails with reason code RC2246 .

This option is not valid with any of the following options:

- GMBRWF
- GMBRWC
- GMBRWN
- GMUNLK

It is also an error if the queue was not opened both for browse and for input. If the browse cursor is not currently pointing to a retrievable message, an error is returned by the MQGET call.

Lock options: The following options relate to locking messages on the queue:

GMLK

Lock message.

This option locks the message that is browsed, so that the message becomes invisible to any other handle open for the queue. The option can be specified only if one of the following options is also specified:

- GMBRWF
- GMBRWN
- GMBRWC

Only one message can be locked per queue handle, but this can be a logical message or a physical message:

- If GMCMPM is specified, all the message segments that make up the logical message are locked to the queue handle (if they are all present on the queue and available for retrieval).
- If GMCMPM is not specified, only a single physical message is locked to the queue handle. If this message happens to be a segment of a logical message, the locked segment prevents other applications using GMCMPM to retrieve or browse the logical message.

The locked message is always the one under the browse cursor, and the message can be removed from the queue by a later MQGET call that specifies the GMMUC option. Other MQGET calls using the queue handle can also remove the message (for example, a call that specifies the message identifier of the locked message).

If the call returns completion code CCFAIL, or CCWARN with reason code RC2080, no message is locked.

If the application decides not to remove the message from the queue, the lock is released by:

- Issuing another MQGET call for this handle, with either GMBRWF or GMBRWN specified (with or without GMLK); the message is unlocked if the call completes with CCOK or CCWARN, but remains locked if the call completes with CCFAIL. However, the following exceptions apply:
 - The message is not unlocked if CCWARN is returned with RC2080.
 - The message is unlocked if CCFAIL is returned with RC2033.

If GMLK is also specified, the message returned is locked. If GMLK is not specified, there is no locked message after the call.

If GMWT is specified, and no message is immediately available, the unlock on the original message occurs before the start of the wait (providing the call is otherwise free from error).

- Issuing another MQGET call for this handle, with GMBRWC (without GMLK); the message is unlocked if the call completes with CCOK or CCWARN, but remains locked if the call completes with CCFAIL. However, the following exception applies:
 - The message is not unlocked if CCWARN is returned with RC2080.
- Issuing another MQGET call for this handle with GMUNLK.
- Issuing an MQCLOSE call for this handle (either explicitly, or implicitly by the application ending).

No special open option is required to specify this option, other than OOBROW, which is needed in order to specify the accompanying browse option.

This option is not valid with any of the following options:

- GMSYP
- GMPSYP
- GMUNLK

GMUNLK

Unlock message.

The message to be unlocked must have been previously locked by an MQGET call with the GMLK option. If there is no message locked for this handle, the call completes with CCWARN and RC2209 .

The *MSGDSC*, *BUFLN*, *BUFFER*, and *DATLEN* parameters are not checked or altered if GMUNLK is specified. No message is returned in *BUFFER*.

No special open option is required to specify this option (although OOBROW is needed to issue the lock request in the first place).

This option is not valid with any options except the following:

- GMNWT
- GMNSYP

Both of these options are assumed whether specified or not.

Message-data options: The following options relate to the processing of the message data when the message is read from the queue:

GMATM

Allow truncation of message data.

If the message buffer is too small to hold the complete message, this option allows the MQGET call to fill the buffer with as much of the message as the buffer can hold, issue a warning completion code, and complete its processing. This means:

- When browsing messages, the browse cursor is advanced to the returned message.
- When removing messages, the returned message is removed from the queue.
- Reason code RC2079 is returned if no other error occurs.

Without this option, the buffer is still filled with as much of the message as it can hold, a warning completion code is issued, but processing is not completed. This means:

- When browsing messages, the browse cursor is not advanced.
- When removing messages, the message is not removed from the queue.
- Reason code RC2080 is returned if no other error occurs.

GMCONV

Convert message data.

This option requests that the application data in the message is converted, to conform to the *MDCSI* and *MDENC* values specified in the *MSGDSC* parameter on the MQGET call, before the data is copied to the *BUFFER* parameter.

The *MDFMT* field specified when the message was put is assumed by the conversion process to identify the nature of the data in the message. Conversion of the message data is by the queue manager for built-in formats, and by a user-written exit for other formats.

- If conversion is performed successfully, the *MDCSI* and *MDENC* fields specified in the *MSGDSC* parameter are unchanged on return from the MQGET call.
- If conversion cannot be performed successfully (but the MQGET call otherwise completes without error), the message data is returned unconverted, and the *MDCSI* and *MDENC* fields in *MSGDSC* are set to the values for the unconverted message. The completion code is CCWARN in this case.

In either case, therefore, these fields describe the character-set identifier and encoding of the message data that is returned in the *BUFFER* parameter.

See the *MDFMT* field described in [“MQMD - Message descriptor” on page 1068](#) for a list of format names for which the queue manager performs the conversion.

Group and segment options: The following options relate to the processing of messages in groups and segments of logical messages. These definitions might be of help in understanding the options:

Physical message

This is the smallest unit of information that can be placed on or removed from a queue; it often corresponds to the information specified or retrieved on a single MQPUT, MQPUT1, or MQGET call. Every physical message has its own message descriptor (MQMD). Generally, physical messages are distinguished by differing values for the message identifier (*MDMID* field in MQMD), although this is not enforced by the queue manager.

Logical message

This is a single unit of application information. In the absence of system constraints, a logical message would be the same as a physical message. But where logical messages are large, system constraints might make it advisable or necessary to split a logical message into two or more physical messages, called segments.

A logical message that has been segmented consists of two or more physical messages that have the same nonnull group identifier (*MDGID* field in MQMD), and the same message sequence number (*MDSEQ* field in MQMD). The segments are distinguished by differing values for the segment offset (*MDOFF* field in MQMD), which gives the offset of the data in the physical message from the start of the data in the logical message. Because each segment is a physical message, the segments in a logical message typically have differing message identifiers.

A logical message that has not been segmented, but for which segmentation has been permitted by the sending application, also has a nonnull group identifier, although in this case there is only one physical message with that group identifier if the logical message does not belong to a message group. Logical messages for which segmentation has been inhibited by the sending application have a null group identifier (GINONE), unless the logical message belongs to a message group.

Message group

This is a set of one or more logical messages that have the same nonnull group identifier. The logical messages in the group are distinguished by differing values for the message sequence number, which is an integer in the range 1 through n, where n is the number of logical messages in the group. If one or more of the logical messages is segmented, there are more than n physical messages in the group.

GMLOGO

Messages in groups and segments of logical messages are returned in logical order.

This option controls the order in which messages are returned by successive MQGET calls for the queue handle. The option must be specified on each of those calls in order to have an effect.

If GMLOGO is specified for successive MQGET calls for the queue handle, messages in groups are returned in the order given by their message sequence numbers, and segments of logical messages are returned in the order given by their segment offsets. This order might be different from the order in which those messages and segments occur on the queue.

Note: Specifying GMLOGO has no adverse consequences on messages that do not belong to groups and that are not segments. In effect, such messages are treated as though each belonged to a message group consisting of only one message. Thus it is perfectly safe to specify GMLOGO when retrieving messages from queues that might contain a mixture of messages in groups, message segments, and unsegmented messages not in groups.

To return the messages in the required order, the queue manager retains the group and segment information between successive MQGET calls. This information identifies the current message group and current logical message for the queue handle, the current position within the group and logical message, and whether the messages are being retrieved within a unit of work. Because the queue manager retains this information, the application does not need to set the group and segment information before each MQGET call. Specifically, it means that the application does not need to set the *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD. However, the application does need to set the GMSYP or GMNSYP option correctly on each call.

When the queue is opened, there is no current message group and no current logical message. A message group becomes the current message group when a message that has the MFMIG flag is

returned by the MQGET call. With GMLOGO specified on successive calls, that group remains the current group until a message is returned that has:

- MFLMIG without MFSEG (that is, the last logical message in the group is not segmented), or
- MFLMIG with MFLSEG (that is, the message returned is the last segment of the last logical message in the group).

When such a message is returned, the message group is terminated, and on successful completion of that MQGET call there is no longer a current group. In a similar way, a logical message becomes the current logical message when a message that has the MFSEG flag is returned by the MQGET call, and that logical message is terminated when the message that has the MFLSEG flag is returned.

If no selection criteria are specified, successive MQGET calls return (in the correct order) the messages for the first message group on the queue, then the messages for the second message group, and so on, until there are no more messages available. It is possible to select the particular message groups returned by specifying one or more of the following options in the *GMMO* field:

- MOMSGI
- MOCORI
- MOGRPI

However, these options are effective only when there is no current message group or logical message; see the *GMMO* field described in this topic.

Table 593 on page 1047 shows the values of the *MDMID*, *MDCID*, *MDGID*, *MDSEQ*, and *MDOFF* fields that the queue manager looks for when attempting to find a message to return on the MQGET call. This applies both to removing messages from the queue, and browsing messages on the queue. The columns in the table have the following meanings:

LOG ORD

Indicates whether the GMLOGO option is specified on the call.

Cur grp

Indicates whether a current message group exists before the call.

Cur log msg

Indicates whether a current logical message exists before the call.

Other columns

Show the values that the queue manager looks for. "Previous" denotes the value returned for the field in the previous message for the queue handle.

Table 593. MQGET options relating to messages in groups and segments of logical messages							
Options you specify	Group and log-msg status before call		Values the queue manager looks for				
LOG ORD	Cur grp	Cur log msg	<i>MDMID</i>	<i>MDCID</i>	<i>MDGID</i>	<i>MDSEQ</i>	<i>MDOFF</i>
Yes	No	No	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	Controlled by <i>GMMO</i>	1	0
Yes	No	Yes	Any message identifier	Any correlation identifier	Previous group identifier	1	Previous offset + previous segment length
Yes	Yes	No	Any message identifier	Any correlation identifier	Previous group identifier	Previous sequence number + 1	0

Table 593. MQGET options relating to messages in groups and segments of logical messages (continued)							
Options you specify	Group and log-msg status before call		Values the queue manager looks for				
Yes	Yes	Yes	Any message identifier	Any correlation identifier	Previous group identifier	Previous sequence number	Previous offset + previous segment length
No	Either	Either	Controlled by GMMO	Controlled by GMMO	Controlled by GMMO	Controlled by GMMO	Controlled by GMMO

When multiple message groups are present on the queue and eligible for return, the groups are returned in the order determined by the position on the queue of the first segment of the first logical message in each group (that is, the physical messages that have message sequence numbers of 1, and offsets of 0, determine the order in which eligible groups are returned).

The GMLOGO option affects units of work as follows:

- If the first logical message or segment in a group is retrieved within a unit of work, all the other logical messages and segments in the group must be retrieved within a unit of work, if the same queue handle is used. However, they need not be retrieved within the same unit of work. This allows a message group consisting of many physical messages to be split across two or more consecutive units of work for the queue handle.
- If the first logical message or segment in a group is *not* retrieved within a unit of work, none of the other logical messages and segments in the group can be retrieved within a unit of work, if the same queue handle is used.

If these conditions are not satisfied, the MQGET call fails with reason code RC2245 .

When GMLOGO is specified, the MQGMO supplied on the MQGET call must not be less than GMVER2, and the MQMD must not be less than MDVER2. If this condition is not satisfied, the call fails with reason code RC2256 or RC2257 , as appropriate.

If GMLOGO is not specified for successive MQGET calls for the queue handle, messages are returned without regard for whether they belong to message groups, or whether they are segments of logical messages. This means that messages or segments from a particular group or logical message might be returned out of order, or they might be intermingled with messages or segments from other groups or logical messages, or with messages that are not in groups and are not segments. In this situation, the particular messages that are returned by successive MQGET calls is controlled by the MO* options specified on those calls (see the GMMO field described in [“MQGMO - Get-message options” on page 1035](#) for details of these options).

This is the technique that can be used to restart a message group or logical message in the middle, after a system failure has occurred. When the system restarts, the application can set the MDGID, MDSEQ, MDOFF, and GMMO fields to the appropriate values, and then issue the MQGET call with GMSYP or GMNSYP set as needed, but without specifying GMLOGO. If this call is successful, the queue manager retains the group and segment information, and subsequent MQGET calls using that queue handle can specify GMLOGO as normal.

The group and segment information that the queue manager retains for the MQGET call is separate from the group and segment information that it retains for the MQPUT call. In addition, the queue manager retains separate information for:

- MQGET calls that remove messages from the queue.
- MQGET calls that browse messages on the queue.

For any given queue handle, the application is free to mix MQGET calls that specify GMLOGO with MQGET calls that do not, but the following points must be noted:

- If GMLOGO is not specified, each successful MQGET call causes the queue manager to set the saved group and segment information to the values corresponding to the message returned; this replaces the existing group and segment information retained by the queue manager for the queue handle. Only the information appropriate to the action of the call (browse or remove) is modified.
- If GMLOGO is not specified, the call does not fail if there is a current message group or logical message; the call might however succeed with a CCWARN completion code. [Table 594 on page 1049](#) shows the various cases that can arise. In these cases, if the completion code is not CCOK, the reason code is one of the following:
 - RC2241
 - RC2242
 - RC2245

Note: The queue manager does not check the group and segment information when browsing a queue, or when closing a queue that was opened for browse but not input; in those cases the completion code is always CCOK (assuming no other errors).

<i>Table 594. Outcome when MQGET or MQCLOSE call is not consistent with group and segment information</i>		
Current call is	Previous call was MQGET with GMLOGO	Previous call was MQGET without GMLOGO
MQGET with GMLOGO	CCFAIL	CCFAIL
MQGET without GMLOGO	CCWARN	CCOK
MQCLOSE with an unterminated group or logical message	CCWARN	CCOK

Applications that simply want to retrieve messages and segments in logical order are recommended to specify GMLOGO, as this is the simplest option to use. This option relieves the application of the need to manage the group and segment information, because the queue manager manages that information. However, specialized applications might need more control than provided by the GMLOGO option, and this can be achieved by not specifying that option. If this is done, the application must ensure that the *MDMID*, *MDCID*, *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD, and the MO* options in GMMO in MQGMO, are set correctly, before each MQGET call.

For example, an application that wants to forward physical messages that it receives, without regard for whether those messages are in groups or segments of logical messages, should not specify GMLOGO. This is because in a complex network with multiple paths between sending and receiving queue managers, the physical messages might arrive out of order. By not specifying GMLOGO and the corresponding PMLOGO on the MQPUT call, the forwarding application can retrieve and forward each physical message as soon as it arrives, without having to wait for the next one in logical order to arrive.

GMLOGO can be specified with any of the other GM* options, and with various of the MO* options in appropriate circumstances.

GMCMPM

Only complete logical messages are retrievable.

This option specifies that only a complete logical message can be returned by the MQGET call. If the logical message is segmented, the queue manager reassembles the segments and returns the complete logical message to the application; the fact that the logical message was segmented is not apparent to the application retrieving it.

Note: This is the only option that causes the queue manager to reassemble message segments. If not specified, segments are returned individually to the application if they are present on the

queue (and they satisfy the other selection criteria specified on the MQGET call). Applications that do not want to receive individual segments should therefore always specify GMCMPM.

To use this option, the application must provide a buffer which is large enough to accommodate the complete message, or specify the GMATM option.

If the queue contains segmented messages with some of the segments missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMCMPM prevents the retrieval of segments belonging to incomplete logical messages. However, those message segments still contribute to the value of the *CurrentQDepth* queue attribute; this means that there might be no retrievable logical messages, even though *CurrentQDepth* is greater than zero.

For persistent messages, the queue manager can reassemble the segments only within a unit of work:

- If the MQGET call is operating within a user-defined unit of work, that unit of work is used. If the call fails part way through the reassembly process, the queue manager reinstates on the queue any segments that were removed during reassembly. However, the failure does not prevent the unit of work being committed successfully.
- If the call is operating outside a user-defined unit of work, and there is no user-defined unit of work in existence, the queue manager creates a unit of work just for the duration of the call. If the call is successful, the queue manager commits the unit of work automatically (the application does not need to do this). If the call fails, the queue manager backs out the unit of work.
- If the call is operating outside a user-defined unit of work, but a user-defined unit of work does exist, the queue manager is unable to perform reassembly. If the message does not require reassembly, the call can still succeed. But if the message does require reassembly, the call fails with reason code RC2255 .

For nonpersistent messages, the queue manager does not require a unit of work to be available in order to perform reassembly.

Each physical message that is a segment has its own message descriptor. For the segments constituting a single logical message, most of the fields in the message descriptor is the same for all segments in the logical message - typically it is only the *MDMID*, *MDOFF*, and *MDMFL* fields that differ between segments in the logical message. However, if a segment is placed on a dead-letter queue at an intermediate queue manager, the DLQ handler retrieves the message specifying the GMCONV option, and this might result in the character set or encoding of the segment being changed. If the DLQ handler successfully sends the segment on its way, the segment might have a character set or encoding that differs from the other segments in the logical message when the segment finally arrives at the destination queue manager.

A logical message consisting of segments in which the *MDCSI*, *MDENC*, or both fields differ cannot be reassembled by the queue manager into a single logical message. Instead, the queue manager reassembles and returns the first few consecutive segments at the start of the logical message that have the same character-set identifiers and encodings, and the MQGET call completes with completion code CCWARN and reason code RC2243 or RC2244 , as appropriate. This happens regardless of whether GMCONV is specified. To retrieve the remaining segments, the application must reissue the MQGET call without the GMCMPM option, retrieving the segments one by one. GMLOGO can be used to retrieve the remaining segments in order.

It is also possible for an application which puts segments to set other fields in the message descriptor to values that differ between segments. However, there is no advantage in doing this if the receiving application uses GMCMPM to retrieve the logical message. When the queue manager reassembles a logical message, it returns in the message descriptor the values from the message descriptor for the first segment; the only exception is the *MDMFL* field, which the queue manager sets to indicate that the reassembled message is the only segment.

If GMCMPM is specified for a report message, the queue manager performs special processing. The queue manager checks the queue to see if all the report messages of that report type relating

to the different segments in the logical message are present on the queue. If they are, they can be retrieved as a single message by specifying GMCMPM. For this to be possible, either the report messages must be generated by a queue manager or MCA which supports segmentation, or the originating application must request at least 100 bytes of message data (that is, the appropriate RO*D or RO*F options must be specified). If less than the full amount of application data is present for a segment, the missing bytes are replaced by nulls in the report message returned.

If GMCMPM is specified with GMMUC or GMBRWC, the browse cursor must be positioned on a message with a *MDOFF* field in MQMD that has a value of 0. If this condition is not satisfied, the call fails with reason code RC2246 .

GMCMPM implies GMASGA, which need not therefore be specified.

GMCMPM can be specified with any of the other GM* options apart from GMPSTP, and with any of the MO* options apart from MOOFFS.

GMAMSA

All messages in group must be available.

This option specifies that messages in a group become available for retrieval only when all messages in the group are available. If the queue contains message groups with some of the messages missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMAMSA prevents retrieval of messages belonging to incomplete groups. However, those messages still contribute to the value of the *CurrentQDepth* queue attribute; this means that there might be no retrievable message groups, even though *CurrentQDepth* is greater than zero. If there are no other messages that are retrievable, reason code RC2033 is returned after the specified wait interval (if any) has expired.

The processing of GMAMSA depends on whether GMLOGO is also specified:

- If both options are specified, GMAMSA affects *only* when there is no current group or logical message. If there *is* a current group or logical message, GMAMSA is ignored. This means that GMAMSA can remain on when processing messages in logical order.
- If GMAMSA is specified without GMLOGO, GMAMSA always has an effect. This means that the option must be turned off after the first message in the group has been removed from the queue, in order to be able to remove the remaining messages in the group.

Successful completion of an MQGET call specifying GMAMSA means that at the time that the MQGET call was issued, all the messages in the group were on the queue. However, be aware that other applications are still able to remove messages from the group (the group is not locked to the application that retrieves the first message in the group).

If this option is not specified, messages belonging to groups can be retrieved even when the group is incomplete.

GMAMSA implies GMASGA, which need not therefore be specified.

GMAMSA can be specified with any of the other GM* options, and with any of the MO* options.

GMASGA

All segments in a logical message must be available.

This option specifies that segments in a logical message become available for retrieval only when all segments in the logical message are available. If the queue contains segmented messages with some of the segments missing (perhaps because they have been delayed in the network and have not yet arrived), specifying GMASGA prevents retrieval of segments belonging to incomplete logical messages. However those segments still contribute to the value of the *CurrentQDepth* queue attribute; this means that there might be no retrievable logical messages, even though *CurrentQDepth* is greater than zero. If there are no other messages that are retrievable, reason code RC2033 is returned after the specified wait interval (if any) has expired.

The processing of GMASGA depends on whether GMLOGO is also specified:

- If both options are specified, GMASGA has an effect only when there is no current logical message. If there is a current logical message, GMASGA is ignored. This means that GMASGA can remain on when processing messages in logical order.
- If GMASGA is specified without GMLOGO, GMASGA always has an effect. This means that the option must be turned off after the first segment in the logical message has been removed from the queue, in order to be able to remove the remaining segments in the logical message.

If this option is not specified, message segments can be retrieved even when the logical message is incomplete.

While both GMCMPM and GMASGA require all segments to be available before any of them can be retrieved, the former returns the complete message, whereas the latter allows the segments to be retrieved one by one.

If GMASGA is specified for a report message, the queue manager performs special processing. The queue manager checks the queue to see if there is at least one report message for each of the segments that make up the complete logical message. If there is, the GMASGA condition is satisfied. However, the queue manager does not check the type of the report messages present, and so there might be a mixture of report types in the report messages relating to the segments of the logical message. As a result, the success of GMASGA does not imply that GMCMPM succeeds. If there is a mixture of report types present for the segments of a particular logical message, those report messages must be retrieved one by one.

GMASGA can be specified with any of the other GM* options, and with any of the MO* options.

Default option: If none of the options described are required, the following option can be used:

GMNONE

No options specified.

This value can be used to indicate that no other options have been specified; all options assume their default values. GMNONE is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

The initial value of the *GMOPT* field is GMNWT.

GMRE1 (1 byte character string)

Reserved.

This is a reserved field. The initial value of this field is a blank character. This field is ignored if *GMVER* is less than GMVER2.

GMRL (10 digit signed integer)

Length of message data returned (bytes).

This is an output field that is set by the queue manager to the length in bytes of the message data returned by the MQGET call in the *BUFFER* parameter. If the queue manager does not support this capability, *GMRL* is set to the value RLUNDF.

When messages are converted between encodings or character sets, the message data can sometimes change size. On return from the MQGET call:

- If *GMRL* is not RLUNDF, the number of bytes of message data returned is given by *GMRL*.
- If *GMRL* has the value RLUNDF, the number of bytes of message data returned is typically given by the smaller of *BUFLN* and *DATLEN*, but can be less than this if the MQGET call completes with reason code RC2079. If this happens, the insignificant bytes in the *BUFFER* parameter are set to nulls.

The following special value is defined:

RLUNDF

Length of returned data not defined.

The initial value of this field is RLUNDF. This field is ignored if *GMVER* is less than GMVER3.

GMRQN (48 byte character string)

Resolved name of destination queue.

This is an output field which is set by the queue manager to the local name of the queue from which the message was retrieved, as defined to the local queue manager. This is different from the name used to open the queue if:

- An alias queue was opened (in which case, the name of the local queue to which the alias resolved is returned), or
- A model queue was opened (in which case, the name of the dynamic local queue is returned).

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

GMRS2 (1 byte character string)

Reserved.

This is a reserved field. The initial value of this field is a blank character. This field is ignored if *GMVER* is less than GMVER4.

GMSEG (1 byte character string)

Flag indicating whether further segmentation is allowed for the message retrieved.

It has one of the following values:

SEGIHB

Segmentation not allowed.

SEGALW

Segmentation allowed.

This is an output field. The initial value of this field is SEGIHB. This field is ignored if *GMVER* is less than GMVER2.

GMSG1 (10 digit signed integer)

Signal.

This is a reserved field; its value is not significant. The initial value of this field is 0.

GMSG2 (10 digit signed integer)

Signal identifier.

This is a reserved field; its value is not significant.

GMSID (4 byte character string)

Structure identifier.

The value must be:

GMSIDV

Identifier for get-message options structure.

This field is always an input field. The initial value of this field is GMSIDV.

GMSST (1 byte character string)

Flag indicating whether message retrieved is a segment of a logical message.

It has one of the following values:

SSNSEG

Message is not a segment.

SSSEG

Message is a segment, but is not the last segment of the logical message.

SSLSEG

Message is the last segment of the logical message.

This is also the value returned if the logical message consists of only one segment.

This field is an output field. The initial value of this field is SSNSEG. This field is ignored if *GMVER* is less than GMVER2.

GMTOK (16 byte bit string)

Message token.

This is a reserved field; its value is not significant. The following special value is defined:

MTKNON

No message token.

The value is binary zero for the length of the field.

The length of this field is given by LNMTOk. The initial value of this field is MTKNON. This field is ignored if *GMVER* is less than GMVER3.

GMVER (10 digit signed integer)

Structure version number.

The value must be one of the following:

GMVER1

Version-1 get-message options structure.

GMVER2

Version-2 get-message options structure.

GMVER3

Version-3 get-message options structure.

GMVER4

Version-4 get-message options structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

GMVERC

Current version of get-message options structure.

This field is always an input field. The initial value of this field is GMVER1.

GMVER (10 digit signed integer)

Structure version number.

The value must be one of the following:

GMVER1

Version-1 get-message options structure.

GMVER2

Version-2 get-message options structure.

GMVER3

Version-3 get-message options structure.

GMVER4

Version-4 get-message options structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

GMVERC

Current version of get-message options structure.

This field is always an input field. The initial value of this field is GMVER1.

GMWI (10 digit signed integer)

Wait interval.

This is the approximate time, expressed in milliseconds, that the MQGET call waits for a suitable message to arrive (that is, a message satisfying the selection criteria specified in the *MSGDSC* parameter of the MQGET call; see the *MDMID* field described in “MQMD - Message descriptor” on page 1068 for more details). If no suitable message has arrived after this time has elapsed, the call completes with CCFAIL and reason code RC2033.

GMWI is used with the *GMWT* option. It is ignored if this option is not specified. If it is specified, *GMWI* must be greater than or equal to zero, or the following special value:

WIULIM

Unlimited wait interval.

The initial value of this field is 0.

Initial values

Table 595. Initial values of fields in MQGMO		
Field name	Name of constant	Value of constant
<i>GMSID</i>	GMSIDV	'GMO¬'
<i>GMVER</i>	GMVER1	1
<i>GMOPT</i>	GMNWT	0
<i>GMWI</i>	None	0
<i>GMSG1</i>	None	0
<i>GMSG2</i>	None	0
<i>GMRQN</i>	None	Blanks
<i>GMMO</i>	MOMSGI + MOCORI	3
<i>GMGST</i>	GSNIG	'¬'

MQIIH - IMS information header

The MQIIH structure describes the information that must be present at the start of a message sent to the IMS bridge through IBM MQ for z/OS.

Overview

Format name: FMIMS.

Character set and encoding: Special conditions apply to the character set and encoding used for the MQIIH structure and application message data:

- Applications that connect to the queue manager that owns the IMS bridge queue must provide an MQIIH structure that is in the character set and encoding of the queue manager. This is because data conversion of the MQIIH structure is not performed in this case.
- Applications that connect to other queue managers can provide an MQIIH structure that is in any of the supported character sets and encodings; conversion of the MQIIH is performed by the receiving message channel agent connected to the queue manager that owns the IMS bridge queue.

Note: There is one exception to this. If the queue manager that owns the IMS bridge queue is using CICS for distributed queuing, the MQIIH must be in the character set and encoding of the queue manager that owns the IMS bridge queue.

- The application message data following the MQIIH structure must be in the same character set and encoding as the MQIIH structure. The *IICSI* and *IIENC* fields in the MQIIH structure cannot be used to specify the character set and encoding of the application message data.

A data-conversion exit must be provided by the user to convert the application message data if the data is not one of the built-in formats supported by the queue manager.

- [“Authenticating passtickets for IMS bridge applications” on page 1057](#)
- [“Fields” on page 1057](#)
- [“Initial values” on page 1060](#)
- [“RPG declaration” on page 1060](#)

Authenticating passtickets for IMS bridge applications

It is now possible for IBM MQ administrators to specify the application name to be used for authenticating passtickets, for IMS bridge applications. To do this, the application name is specified as a new attribute PTKTAPPL for the STGCLASS object definition, as a 1 to 8 character alphanumeric string.

A blank value means that authentication occurs as with previous releases of IBM MQ, that is, no application name flows on the authentication request, and the MVSxxxx value is used instead.

A value of 1 - 8 alphanumeric characters must follow the rules for passticket application names as described in the RACF publications.

IBM MQ Administrators and RACF administrators must both agree on the valid application names to be used. The RACF administrator must create a profile in the PTKTDATA class giving READ access to the user IDs of all applications that are to be granted access. The IBM MQ administrator must create or alter the required STGCLASS definitions that specify the application name to be used for passticket authentication.

For related information, see the *Script (MQSC) Command Reference*.

Fields

The MQIIH structure contains the following fields; the fields are described in **alphabetical order**:

IIAUT (8-byte character string)

RACF password or passticket.

This is optional; if specified, it is used with the user ID in the MQMD security context to build a UTOKEN that is sent to IMS to provide a security context. If it is not specified, the user ID is used without verification. This depends on the setting of the RACF switches, which may require an authenticator to be present.

This is ignored if the first byte is blank or null. The following special value may be used:

IAUNON

No authentication.

The length of this field is given by LNAUTH. The initial value of this field is IAUNON.

IICMT (1-byte character string)

Commit mode.

See the *OTMA Reference* for more information about IMS commit modes. The value must be one of the following:

ICMCTS

Commit then send.

This mode implies double queuing of output, but shorter region occupancy times. Fast-path and conversational transactions cannot run with this mode.

ICMSTC

Send then commit.

The initial value of this field is ICMCTS.

IICSI (10-digit signed integer)

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

IIENC (10-digit signed integer)

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is 0.

IIFLG (10-digit signed integer)

Flags.

The value must be:

IINONE

No flags.

The initial value of this field is IINONE.

IIFMT (8-byte character string)

IBM MQ format name of data that follows MQIIH.

This specifies the IBM MQ format name of the data that follows the MQIIH structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

IILEN (10-digit signed integer)

Length of MQIIH structure.

The value must be:

IILEN1

Length of IMS information header structure.

The initial value of this field is IILEN1.

IILTO (8-byte character string)

Logical terminal override.

This is placed in the IO PCB field. It is optional; if it is not specified the TPIPE name is used. It is ignored if the first byte is blank, or null.

The length of this field is given by LNLTOV. The initial value of this field is 8 blank characters.

IIMMN (8-byte character string)

Message format services map name.

This is placed in the IO PCB field. It is optional. On input it represents the MID, on output it represents the MOD. It is ignored if the first byte is blank or null.

The length of this field is given by LNMFMN. The initial value of this field is 8 blank characters.

IIRFM (8-byte character string)

IBM MQ format name of reply message.

This is the IBM MQ format name of the reply message that will be sent in response to the current message. The rules for coding this are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

IIRSV (1-byte character string)

Reserved.

This is a reserved field; it must be blank.

IISEC (1-byte character string)

Security scope.

This indicates the required IMS security processing. The following values are defined:

ISSCHK

Check security scope.

An ACEE is built in the control region, but not in the dependent region.

ISSFUL

Full security scope.

A cached ACEE is built in the control region and a non-cached ACEE is built in the dependent region. If you use ISSFUL, you must ensure that the user ID for which the ACEE is built has access to the resources used in the dependent region.

If ISSCHK and ISSFUL are not specified for this field, ISSCHK is assumed.

The initial value of this field is ISSCHK.

IISID (4-byte character string)

Structure identifier.

The value must be:

IISIDV

Identifier for IMS information header structure.

The initial value of this field is IISIDV.

IITID (16-byte bit string)

Transaction instance identifier.

This field is used by output messages from IMS so is ignored on first input. If *IITST* is set to ITSIC, this must be provided in the next input, and all subsequent inputs, to enable IMS to correlate the messages to the correct conversation. The following special value may be used:

ITINON

No transaction instance id.

The length of this field is given by LNTIID. The initial value of this field is ITINON.

IITST (1-byte character string)

Transaction state.

This indicates the IMS conversation state. This is ignored on first input because no conversation exists. On subsequent inputs it indicates whether a conversation is active or not. On output it is set by IMS. The value must be one of the following:

ITSIC

In conversation.

ITSNIC

Not in conversation.

ITSARC

Return transaction state data in architected form.

This value is used only with the IMS /DISPLAY TRAN command. It causes the transaction state data to be returned in the IMS architected form instead of character form. See [Writing IMS transaction programs through IBM MQ](#) for further details.

The initial value of this field is ITSNIC.

IIVER (10-digit signed integer)

Structure version number.

The value must be:

IIVER1

Version number for IMS information header structure.

The following constant specifies the version number of the current version:

IIVERC

Current version of IMS information header structure.

The initial value of this field is IIVER1.

Initial values

Table 596. Initial values of fields in MQIIH		
Field name	Name of constant	Value of constant
IISID	IISIDV	'IIH¬'
IIVER	IIVER1	1
IILEN	IILEN1	84
IIENC	None	0
IICSI	None	0
IIFMT	FMNONE	Blanks
IIFLG	IINONE	0
IILTO	None	Blanks
IIMMN	None	Blanks

MQIMPO - Inquire message property options

The MQIMPO structure allows applications to specify options that control how properties of messages are inquired.

Overview

Purpose: The structure is an input parameter on the MQINQMP call.

Character set and encoding: Data in MQIMPO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1061](#)
- [“Initial values” on page 1067](#)
- [“RPG declaration” on page 1067](#)

Fields

The MQIMPO structure contains the following fields; the fields are described in **alphabetical order**:

IPOPT (10-digit signed integer)

The following options control the action of MQINQMP. You can specify one or more of these options. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations). Combinations of options that are not valid are noted; all other combinations are valid.

Value data options: The following options relate to the processing of the value data when the property is retrieved from the message.

IPCVAL

This option requests that the value of the property be converted to conform to the *IPREQCSI* and *IPREQENC* values specified before the MQINQMP call returns the property value in the *Value* area.

- If conversion is successful, the *IPRETCSI* and *IPRETENC* fields are set to the same as *IPREQCSI* and *IPREQENC* on return from the MQINQMP call.
- If conversion fails, but the MQINQMP call otherwise completes without error, the property value is returned unconverted.

If the property is a string, the *IPRETCSI* and *IPRETENC* fields are set to the character set and encoding of the unconverted string.

The completion code is CCWARN in this case, with reason code RC2466. The property cursor is advanced to the returned property.

If the property value expands during conversion, and exceeds the size of the *Value* parameter, the value is returned unconverted, with completion code CCFAIL; the reason code is set to RC2469.

The *DataLength* parameter of the MQINQMP call returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

This option also requests that:

- If the property name contains a wildcard, and
- The *IPRETNAMECHRP* field is initialized with an address or offset for the returned name, then the returned name is converted to conform to the *IPREQCSI* and *IPREQENC* values.
- If conversion is successful, the *VSCCSID* field of *IPRETNAMECHRP* and the encoding of the returned name are set to the input value of *IPREQCSI* and *IPREQENC*.
- If conversion fails, but the MQINQMP call otherwise completes without error or warning, the returned name is unconverted. The completion code is CCWARN in this case, with reason code RC2492.

The property cursor is advanced to the returned property. RC2466 is returned if both the value and the name are not converted.

If the returned name expands during conversion, and exceeds the size of the *VSBuFSIZE* field of the *RequestedName*, the returned string is left unconverted, with completion code CCFAIL and the reason code is set to RC2465.

The *VSLength* field of the MQCHARV structure returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

IPCTYP

This option requests that the value of the property be converted from its current data type, into the data type specified on the *Type* parameter of the MQINQMP call.

- If conversion is successful, the *Type* parameter is unchanged on return of the MQINQMP call.
- If conversion fails, but the MQINQMP call otherwise completes without error, the call fails with reason RC2470. The property cursor is unchanged.

If the conversion of the data type causes the value to expand during conversion, and the converted value exceeds the size of the *Value* parameter, the value is returned unconverted, with completion code CCFAIL and the reason code is set to RC2469.

The *DataLength* parameter of the MQINQMP call returns the length that the property value would have converted to, in order to allow the application to determine the size of the buffer required to accommodate the converted property value. The property cursor is unchanged.

If the value of the *Type* parameter of the MQINQMP call is not valid, the call fails with reason RC2473.

If the requested data type conversion is not supported, the call fails with reason RC2470. The following data type conversions are supported:

Property data type	Supported target data types
TYPBOL	TYPSTR, TYPI8, TYPI16, TYPI32, TYPI64
TYPBST	TYPSTR
TYPI8	TYPSTR, TYPI16, TYPI32, TYPI64
TYPI16	TYPSTR, TYPI32, TYPI64
TYPI32	TYPSTR, TYPI64

Property data type	Supported target data types
TYPI64	TYPSTR
TYPF32	TYPSTR, TYPF64
TYPF64	TYPSTR
TYPSTR	TYPBOL, TYPI8, TYPI16, TYPI32, TYPI64, TYPF32, TYPF64
TYPNUL	None

The general rules governing the supported conversions are as follows:

- Numeric property values can be converted from one data type to another, provided that no data is lost during the conversion.

For example, the value of a property with data type TYPI32 can be converted into a value with data type TYPI64, but cannot be converted into a value with data type TYPI16.

- A property value of any data type can be converted into a string.
- A string property value can be converted to any other data type provided the string is formatted correctly for the conversion. If an application attempts to convert a string property value that is not formatted correctly, IBM MQ returns reason code RC2472.
- If an application attempts a conversion that is not supported, IBM MQ returns reason code RC2470.

The specific rules for converting a property value from one data type to another are as follows:

- When converting a TYPBOL property value to a string, the value TRUE is converted to the string "TRUE", and the value false is converted to the string "FALSE".
- When converting a TYPBOL property value to a numeric data type, the value TRUE is converted to one, and the value FALSE is converted to zero.
- When converting a string property value to a TYPBOL value, the string "TRUE" , or "1" , is converted to TRUE, and the string "FALSE", or "0", is converted to FALSE.

Note that the terms "TRUE" and "FALSE" are not case sensitive.

Any other string cannot be converted; IBM MQ returns reason code RC2472.

- When converting a string property value to a value with data type TYPI8, TYPI16, TYPI32 or TYPI64, the string must have the following format:

```
[blanks][sign]digits
```

The meanings of the components of the string are as follows:

blanks

Optional leading blank characters

sign

An optional plus sign (+) or minus sign (-) character.

digits

A contiguous sequence of digit characters (0-9). At least one digit character must be present.

After the sequence of digit characters, the string can contain other characters that are not digit characters, but the conversion stops as soon as the first of these characters is reached. The string is assumed to represent a decimal integer.

IBM MQ returns reason code RC2472 if the string is not formatted correctly.

- When converting a string property value to a value with data type TYPF32 or TYPF64, the string must have the following format:

```
[blanks][sign]digits[.digits][e_char[e_sign]e_digits]
```

The meanings of the components of the string are as follows:

blanks

Optional leading blank characters

sign

An optional plus sign (+) or minus sign (-) character.

digits

A contiguous sequence of digit characters (0-9). At least one digit character must be present.

e_char

An exponent character, which is either "E" or "e".

e_sign

An optional plus sign (+) or minus sign (-) character for the exponent.

e_digits

A contiguous sequence of digit characters (0-9) for the exponent. At least one digit character must be present if the string contains an exponent character.

After the sequence of digit characters, or the optional characters representing an exponent, the string can contain other characters that are not digit characters, but the conversion stops as soon as the first of these characters is reached. The string is assumed to represent a decimal floating point number with an exponent that is a power of 10.

IBM MQ returns reason code RC2472 if the string is not formatted correctly.

- When converting a numeric property value to a string, the value is converted to the string representation of the value as a decimal number, not the string containing the ASCII character for that value. For example, the integer 65 is converted to the string "65", not the string "A".
- When converting a byte string property value to a string, each byte is converted to the two hexadecimal characters that represent the byte. For example, the byte array {0xF1, 0x12, 0x00, 0xFF} is converted to the string "F11200FF".

IPQLEN

Query the type and length of the property value. The length is returned in the *DataLength* parameter of the MQINQMP call. The property value is not returned.

If a *ReturnedName* buffer is specified, the *VSLength* field of the MQCHARV structure is filled in with the length of the property name. The property name is not returned.

Iteration options: The following options relate to iterating over properties, using a name with a wildcard character

IPINQF

Inquire on the first property that matches the specified name. After this call, a cursor is established on the property that is returned.

This is the default value.

The IPINQC option can subsequently be used with an MQINQMP call, if required, to inquire on the same property again.

Note that there is only one property cursor; therefore, if the property name, specified in the MQINQMP call, changes the cursor is reset.

This option is not valid with either of the following options:

IPINQN

IPINQC

IPINQN

Inquires on the next property that matches the specified name, continuing the search from the property cursor. The cursor is advanced to the property that is returned.

If this is the first MQINQMP call for the specified name, then the first property that matches the specified name is returned.

The IPINQC option can subsequently be used with an MQINQMP call if required, to inquire on the same property again.

If the property under the cursor has been deleted, MQINQMP returns the next matching property following the one that has been deleted.

If a property is added that matches the wildcard, while an iteration is in progress, the property might or might not be returned during the completion of the iteration. The property is returned once the iteration restarts using IPINQF.

A property matching the wildcard that was deleted, while the iteration was in progress, is not returned subsequent to its deletion.

This option is not valid with either of the following options:

IPINQF

IPINQC

IPINQC

Retrieve the value of the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired, using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused, when the message handle is specified in the *MsgHandle* field of the MQGMO on an MQGET call, or when the message handle is specified in *OriginalMsgHandle* or *NewMsgHandle* fields of the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established, or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason RC2471.

This option is not valid with either of the following options:

IPINQF

IPINQN

If none of the options previously described is required, the following option can be used:

IPNONE

Use this value to indicate that no other options have been specified; all options assume their default values.

IPNONE aids program documentation; it is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

This is always an input field. The initial value of this field is IPINQF.

IPREQCSI (10-digit signed integer)

The character set that the inquired property value is to be converted into if the value is a character string. This is also the character set into which the *ReturnedName* is to be converted when IPCVAL or IPCTYP is specified.

The initial value of this field is CSAPL.

IPREQENC (10-digit signed integer)

This is the encoding into which the inquired property value is to be converted when IPCVAL or IPCTYP is specified.

The initial value of this field is ENNAT.

IPRE1 (10-digit signed integer)

This is a reserved field. The initial value of this field is a blank character.

IPRETCSI (10-digit signed integer)

On output, this is the character set of the value returned if the *Type* parameter of the MQINQMP call is TYPSTR.

If the IPCVAL option is specified and conversion was successful, the *ReturnedCCSID* field, on return, is the same value as the value passed in.

The initial value of this field is zero.

IPRETENC (10-digit signed integer)

On output, this is the encoding of the value returned.

If the IPCVAL option is specified and conversion was successful, the *ReturnedEncoding* field, on return, is the same value as the value passed in.

The initial value of this field is ENNAT.

IPRETNAMCHRP (10-digit signed integer)

The actual name of the inquired property.

On input a string buffer can be passed in using the *VSPtr* or *VSOffset* field of the MQCHARV structure. The length of the string buffer is specified using the *VSBuFSIZE* field of the MQCHARV structure.

On return from the MQINQMP call, the string buffer is completed with the name of the property that was inquired, provided the string buffer was long enough to fully contain the name. The *VSLength* field of the MQCHARV structure is filled in with the length of the property name. The *VSCCSID* field of the MQCHARV structure is filled in to indicate the character set of the returned name, whether or not conversion of the name failed.

This is an input/output field. The initial value of this field is MQCHARV_DEFAULT.

IPSID (10-digit signed integer)

This is the structure identifier. The value must be:

IPSIDV

Identifier for inquire message property options structure.

This is always an input field. The initial value of this field is IPSIDV.

IPTYP (10-digit signed integer)

A string representation of the data type of the property.

If the property was specified in an MQRFH2 header and the MQRFH2 dt attribute is not recognized, this field can be used to determine the data type of the property. *TypeString* is returned in coded character set 1208 (UTF-8), and is the first eight bytes of the value of the dt attribute of the property that failed to be recognized

This is always an output field. The initial value of this field is the null string in the C programming language, and 8 blank characters in other programming languages.

IPVER (10-digit signed integer)

This is the structure version number. The value must be:

IPVER1

Version number for inquire message property options structure.

The following constant specifies the version number of the current version:

IPVERC

Current version of inquire message property options structure.

This is always an input field. The initial value of this field is IPVER1.

Initial values

Table 597. Initial values of fields in MQIPMO		
Field name	Name of constant	Value of constant
<i>IPSID</i>	IPSIDV	'IMPO'
<i>IPVER</i>	IPVER1	1

MQMD - Message descriptor

Overview

Purpose: The MQMD structure contains the control information that accompanies the application data when a message travels between the sending and receiving applications. The structure is an input/output parameter on the MQGET, MQPUT, and MQPUT1 calls.

Version: The current version of MQMD is MDVER2. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQMD that is supported by the environment, but with the initial value of the *MDVER* field set to MDVER1. To use fields that are not present in the version-1 structure, the application must set the *MDVER* field to the version number of the version required.

A declaration for the version-1 structure is available with the name MQMD1.

Character set and encoding: Data in MQMD must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ MQI client, the structure must be in the character set and encoding of the client.

If the sending and receiving queue managers use different character sets or encodings, the data in MQMD is converted automatically. It is not necessary for the application to convert the MQMD.

- [“Message expiry” on page 1069](#)
- [“Fields” on page 1069](#)
- [“Initial values” on page 1109](#)
- [“RPG declaration” on page 1110](#)

Using different versions of MQMD

A version-2 MQMD is generally equivalent to using a version-1 MQMD and prefixing the message data with an MQMDE structure. However, if all of the fields in the MQMDE structure have their default values, the MQMDE can be omitted. A version-1 MQMD plus MQMDE are used as described later in this section.

- On the MQPUT and MQPUT1 calls, if the application provides a version-1 MQMD, the application can optionally prefix the message data with an MQMDE, setting the *MDFMT* field in MQMD to FMMDE to indicate that an MQMDE is present. If the application does not provide an MQMDE, the queue manager assumes default values for the fields in the MQMDE.

Note: Several of the fields that exist in the version-2 MQMD but not the version-1 MQMD are input/output fields on the MQPUT and MQPUT1 calls. However, the queue manager does *not* return any values in the equivalent fields in the MQMDE on output from the MQPUT and MQPUT1 calls; if the application requires those output values, it must use a version-2 MQMD.

- On the MQGET call, if the application provides a version-1 MQMD, the queue manager prefixes the message returned with an MQMDE, but only if one or more of the fields in the MQMDE has a non-default value. The *MDFMT* field in MQMD will have the value FMMDE to indicate that an MQMDE is present.

The default values that the queue manager used for the fields in the MQMDE are the same as the initial values of those fields, shown in [Table 598 on page 1109](#).

When a message is on a transmission queue, some of the fields in MQMD are set to particular values; see [“MQXQH - Transmission-queue header” on page 1201](#) for details.

Message context

Certain fields in MQMD contain the message context. Typically:

- **Identity** context relates to the application that *originally* put the message
- **Origin** context relates to the application that *most recently* put the message
- **User** context relates to the application that *originally* put the message.

These two applications can be the same application, but they can also be different applications (for example, when a message is forwarded from one application to another).

Although identity and origin context usually have the meanings described previously, the content of both types of context fields in MQMD actually depends on the PM* options that are specified when the message is put. As a result, identity context does not necessarily relate to the application that originally put the message, and origin context does not necessarily relate to the application that most recently put the message - it depends on the design of the application suite.

There is one class of application that never alters message context, namely the message channel agent (MCA). MCAs that receive messages from remote queue managers use the context option PMSETA on the MQPUT or MQPUT1 call. This allows the receiving MCA to preserve exactly the message context that travelled with the message from the sending MCA. However, the result is that the origin context does not relate to the application that most recently put the message (the receiving MCA), but instead relates to an earlier application that put the message (possibly the originating application itself).

For more information see [Message context](#).

Message expiry

Messages that have expired on a loaded queue (a queue that has been opened) are automatically removed from the queue within a reasonable period of time after their expiry. Some other new features of this release of IBM MQ can lead to loaded queues being scanned less frequently than in the previous product version, however expired messages on loaded queues are always removed within a reasonable period of their expiry.

Fields

The MQMD structure contains the following fields; the fields are described in alphabetical order:

MDACC (32-byte bit string)

Accounting token.

This is part of the **identity context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDACC allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content.

When the queue manager generates this information, it is set as follows:

- The first byte of the field is set to the length of the accounting information present in the bytes that follow; this length is in the range zero through 30, and is stored in the first byte as a binary integer.
- The second and subsequent bytes (as specified by the length field) are set to the accounting information appropriate to the environment.
 - On z/OS the accounting information is set to:

- For z/OS batch, the accounting information from the JES JOB card or from a JES ACCT statement in the EXEC card (comma separators are changed to X'FF'). This information is truncated, if necessary, to 31 bytes.
- For TSO, the user's account number.
- For CICS, the LU 6.2 unit of work identifier (UEPUOWDS) (26 bytes).
- For IMS, the 8-character PSB name concatenated with the 16-character IMS recovery token.
- On IBM i, the accounting information is set to the accounting code for the job.
- On HP Integrity NonStop Server, and UNIX systems, the accounting information is set to the numeric user identifier, in ASCII characters.
- On Windows, the accounting information is set to a Windows NT security identifier (SID) in a compressed format. The SID uniquely identifies the user identifier stored in the *MDUID* field. When the SID is stored in the *MDACC* field, the 6-byte Identifier Authority (located in the third and subsequent bytes of the SID) is omitted. For example, if the Windows NT SID is 28 bytes long, 22 bytes of SID information are stored in the *MDACC* field.
- The last byte is set to the accounting-token type, one of the following values:

ATTCIC

CICS LUOW identifier.

ATTDOS

PC DOS default accounting token.

ATTWNT

Windows security identifier.

ATT400

IBM i accounting token.

ATTUNIX

UNIX systems numeric identifier.

ATTUSR

User-defined accounting token.

ATTUNK

Unknown accounting-token type.

The accounting-token type is set to an explicit value only in the following environments: AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ MQI clients connected to these systems. In other environments, the accounting-token type is set to the value ATTUNK. In these environments the *MDPAT* field can be used to deduce the type of accounting token received.

- All other bytes are set to binary zero.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETI or PMSETA is specified in the *PMO* parameter. If neither PMSETI nor PMSETA is specified, this field is ignored on input and is an output-only field. For more information on message context, see [Message context](#) and [Controlling context information](#).

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDACC* that was transmitted with the message if it was put to a queue. This will be the value of *MDACC* that is kept with the message if it is retained (see description of PMRET in [“MQPMO - Put-message options”](#) on page 1131 for more details about retained publications) but is not used as the *MDACC* when the message is sent as a publication to subscribers since they provide a value to override *MDACC* in all publications sent to them. If the message has no context, the field is entirely binary zero.

This is an output field for the MQGET call.

This field is not subject to any translation based on the character set of the queue manager-the field is treated as a string of bits, and not as a string of characters.

The queue manager does nothing with the information in this field. The application must interpret the information if it wants to use the information for accounting purposes.

The following special value may be used for the *MDACC* field:

ACNONE

No accounting token is specified.

The value is binary zero for the length of the field.

The length of this field is given by LNAACC. The initial value of this field is ACNONE.

MDAID (32-byte character string)

Application data relating to identity.

This is part of the **identity context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDAID is information that is defined by the application suite, and can be used to provide additional information about the message or its originator. The queue manager treats this information as character data, but does not define the format of it. When the queue manager generates this information, it is entirely blank.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETI or PMSETA is specified in the *PMO* parameter. If a null character is present, the null and any following characters are converted to blanks by the queue manager. If neither PMSETI nor PMSETA is specified, this field is ignored on input and is an output-only field. For more information on message context, see [Message context](#) and [Controlling context information](#).

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDAID* that was transmitted with the message if it was put to a queue. This will be the value of *MDAID* that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDAID* when the message is sent as a publication to subscribers since they provide a value to override *MDAID* in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNAIDD. The initial value of this field is 32 blank characters.

MDAOD (4-byte character string)

Application data relating to origin.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDAOD is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted.

The queue manager treats this information as character data, but does not define the format of it. When the queue manager generates this information, it is entirely blank.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the *PMO* parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDAOD* that was transmitted with the message if it was put to a queue. This will be the value of *MDAOD* that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDAOD* when the message is sent as a publication to subscribers since they provide a value to override *MDAOD* in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNAORD. The initial value of this field is 4 blank characters.

MDBOC (10-digit signed integer)

Backout counter.

This is a count of the number of times the message has been previously returned by the MQGET call as part of a unit of work, and subsequently backed out. It is provided as an aid to the application in detecting processing errors that are based on message content. The count excludes MQGET calls that specified any of the GMBRW* options.

The accuracy of this count is affected by the *HardenGetBackout* queue attribute; see [“Attributes for queues”](#) on page 1324.

This is an output field for the MQGET call. It is ignored for the MQPUT and MQPUT1 calls. The initial value of this field is 0.

MDCID (24-byte bit string)

Correlation identifier.

This is a byte string that the application can use to relate one message to another, or to relate the message to other work that the application is performing. The correlation identifier is a permanent property of the message, and persists across restarts of the queue manager. Because the correlation identifier is a byte string and not a character string, the correlation identifier is *not* converted between character sets when the message flows from one queue manager to another.

For the MQPUT and MQPUT1 calls, the application can specify any value. The queue manager transmits this value with the message and delivers it to the application that issues the get request for the message.

If the application specifies PMNCID, the queue manager generates a unique correlation identifier which is sent with the message, and also returned to the sending application on output from the MQPUT or MQPUT1 call.

This generated correlation identifier is kept with the message if it is retained and is used as the correlation identifier when the message is sent as a publication to subscribers who specify CINONE in the *SDCID* field in the MQSD passed on the MQSUB call.

See [“MQPMO - Put-message options”](#) on page 1131 for more details about retained publications

When the queue manager or a message channel agent generates a report message, it sets the *MDCID* field in the way specified by the *MDREP* field of the original message, either ROCMTC or ROPCI. Applications which generate report messages should also do this.

For the MQGET call, *MDCID* is one of the five fields that can be used to select a particular message to be retrieved from the queue. See the description of the *MDMID* field for details of how to specify values for this field.

Specifying CINONE as the correlation identifier has the same effect as *not* specifying MOCORI, that is, *any* correlation identifier will match.

If the GMMUC option is specified in the *GMO* parameter on the MQGET call, this field is ignored.

On return from an MQGET call, the *MDCID* field is set to the correlation identifier of the message returned (if any).

The following special values may be used:

CINONE

No correlation identifier is specified.

The value is binary zero for the length of the field.

CINEWS

Message is the start of a new session.

This value is recognized by the CICS bridge as indicating the start of a new session, that is, the start of a new sequence of messages.

For the MQGET call, this is an input/output field. For the MQPUT and MQPUT1 calls, this is an input field if PMNCID is *not* specified, and an output field if PMNCID is specified. The length of this field is given by LNCID. The initial value of this field is CINONE.

MDCSI (10-digit signed integer)

This specifies the character set identifier of character data in the message.

Note: Character data in MQMD and the other IBM MQ data structures that are parameters on calls must be in the character set of the queue manager. This is defined by the queue manager's *CodedCharSetId* attribute; see [“Attributes for the queue manager” on page 1355](#) for details of this attribute.

The following special values can be used:

CSQM

Queue manager's character set identifier.

Character data in the message is in the queue manager's character set.

On the MQPUT and MQPUT1 calls, the queue manager changes this value in the MQMD sent with the message to the true character-set identifier of the queue manager. As a result, the value CSQM is never returned by the MQGET call.

CSINHT

Inherit character-set identifier of this structure.

Character data in the message is in the same character set as this structure; this is the queue manager's character set. (For MQMD only, CSINHT has the same meaning as CSQM).

The queue manager changes this value in the MQMD sent with the message to the actual character-set identifier of MQMD. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

CSEMBD

Embedded character set identifier.

Character data in the message is in a character set with the identifier that is contained within the message data itself. There can be any number of character-set identifiers embedded within the message data, applying to different parts of the data. This value must be used for PCF messages that contain data in a mixture of character sets. PCF messages have a format name of FMPCF.

Specify this value only on the MQPUT and MQPUT1 calls. If it is specified on the MQGET call, it prevents conversion of the message.

On the MQPUT and MQPUT1 calls, the queue manager changes the values CSQM and CSINHT in the MQMD sent with the message as described previously, but does not change the MQMD specified on the MQPUT or MQPUT1 call. No other check is carried out on the value specified.

Applications that retrieve messages should compare this field against the value the application is expecting; if the values differ, the application may need to convert character data in the message.

If the GMCONV option is specified on the MQGET call, this field is an input/output field. The value specified by the application is the coded character-set identifier to which the message data should be converted if necessary. If conversion is successful or unnecessary, the value is unchanged (except that the value CSQM or CSINHT is converted to the actual value). If conversion is unsuccessful, the value after the MQGET call represents the coded character-set identifier of the unconverted message that is returned to the application.

Otherwise, this is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is CSQM.

MDENC (10-digit signed integer)

Numeric encoding of message data.

This specifies the numeric encoding of numeric data in the message; it does not apply to numeric data in the MQMD structure itself. The numeric encoding defines the representation used for binary integers, packed-decimal integers, and floating-point numbers.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that the field is valid. The following special value is defined:

ENNAT

Native machine encoding.

The encoding is the default for the programming language and machine on which the application is running.

Note: The value of this constant depends on the programming language and environment. For this reason, applications must be compiled using the header, macro, COPY, or INCLUDE files appropriate to the environment in which the application will run.

Applications that put messages should normally specify ENNAT. Applications that retrieve messages should compare this field against the value ENNAT; if the values differ, the application may need to convert numeric data in the message. The GMCONV option can be used to request the queue manager to convert the message as part of the processing of the MQGET call.

If the GMCONV option is specified on the MQGET call, this field is an input/output field. The value specified by the application is the encoding to which the message data should be converted if necessary. If conversion is successful or unnecessary, the value is unchanged. If conversion is unsuccessful, the value after the MQGET call represents the encoding of the unconverted message that is returned to the application.

In other cases, this is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is ENNAT.

MDEXP (10-digit signed integer)

Message lifetime.

This is a period of time expressed in tenths of a second, set by the application that puts the message. The message becomes eligible to be discarded if it has not been removed from the destination queue before this period of time elapses.

The value is decremented to reflect the time the message spends on the destination queue, and also on any intermediate transmission queues if the put is to a remote queue. It may also be decremented by message channel agents to reflect transmission times, if these are significant. Likewise, an application forwarding this message to another queue might decrement the value if necessary, if it has retained the message for a significant time. However, the expiration time is treated as approximate, and the value need not be decremented to reflect small time intervals.

When the message is retrieved by an application using the MQGET call, the *MDEXP* field represents the amount of the original expiry time that still remains.

After a message's expiry time has elapsed, it becomes eligible to be discarded by the queue manager. In the current implementations, the message is discarded when a browse or nonbrowse MQGET call occurs that would have returned the message had it not already expired. For example, a nonbrowse MQGET call with the *GMMO* field in MQGMO set to MONONE reading from a FIFO ordered queue will cause all the expired messages to be discarded up to the first unexpired message. With a priority ordered queue, the same call will discard expired messages of higher priority and messages of an equal priority that arrived on the queue before the first unexpired message.

A message that has expired is never returned to an application (either by a browse or a non-browse MQGET call), so the value in the *MDEXP* field of the message descriptor after a successful MQGET call is either greater than zero, or the special value EIULIM.

If a message is put on a remote queue, the message may expire (and be discarded) while it is on an intermediate transmission queue, before the message reaches the destination queue.

A report is generated when an expired message is discarded, if the message specified one of the ROEXP* report options. If none of these options is specified, no such report is generated; the message

is assumed to be no longer relevant after this time period (perhaps because a later message has superseded it).

Any other program that discards messages based on expiry time must also send an appropriate report message if one was requested.

Note:

1. If a message is put with an *MDEXP* time of zero, the MQPUT or MQPUT1 call fails with reason code RC2013; no report message is generated in this case.
2. Since a message with an expiry time that has elapsed may not actually be discarded until later, there may be messages on a queue that have passed their expiry time, and which are not therefore eligible for retrieval. These messages nevertheless count towards the number of messages on the queue for all purposes, including depth triggering.
3. An expiration report is generated, if requested, when the message is actually discarded, not when it becomes eligible for discarding.
4. Discarding of an expired message, and the generation of an expiration report if requested, are never part of the application's unit of work, even if the message was scheduled for discarding as a result of an MQGET call operating within a unit of work.
5. If a nearly-expired message is retrieved by an MQGET call within a unit of work, and the unit of work is subsequently backed out, the message may become eligible to be discarded before it can be retrieved again.
6. If a nearly-expired message is locked by an MQGET call with GMLK, the message may become eligible to be discarded before it can be retrieved by an MQGET call with GMMUC; reason code RC2034 is returned on this subsequent MQGET call if that happens.
7. When a request message with an expiry time greater than zero is retrieved, the application can take one of the following actions when it sends the reply message:
 - Copy the remaining expiry time from the request message to the reply message.
 - Set the expiry time in the reply message to an explicit value greater than zero.
 - Set the expiry time in the reply message to EIULIM.

The action to take depends on the design of the application suite. However, the default action for putting messages to a dead-letter (undelivered-message) queue should be to preserve the remaining expiry time of the message, and to continue to decrement it.

8. Trigger messages are always generated with EIULIM.
9. A message (normally on a transmission queue) which has a *MDFMT* name of FMXQH has a second message descriptor within the MQXQH. It therefore has two *MDEXP* fields associated with it. The following additional points should be noted in this case:
 - When an application puts a message on a remote queue, the queue manager places the message initially on a local transmission queue, and prefixes the application message data with an MQXQH structure. The queue manager sets the values of the two *MDEXP* fields to be the same as that specified by the application.

If an application puts a message directly on a local transmission queue, the message data must already begin with an MQXQH structure, and the format name must be FMXQH (but the queue manager does not enforce this). In this case the application need not set the values of these two *MDEXP* fields to be the same. (The queue manager does not check that the *MDEXP* field within the MQXQH contains a valid value, or even that the message data is long enough to include it.)

 - When a message with a *MDFMT* name of FMXQH is retrieved from a queue (whether this is a normal or a transmission queue), the queue manager decrements *both* these *MDEXP* fields with the time spent waiting on the queue. No error is raised if the message data is not long enough to include the *MDEXP* field in the MQXQH.
 - The queue manager uses the *MDEXP* field in the separate message descriptor (that is, not the one in the message descriptor embedded within the MQXQH structure) to test whether the message is eligible for discarding.

- If the initial values of the two *MDEXP* fields were different, it is therefore possible for the *MDEXP* time in the separate message descriptor when the message is retrieved to be greater than zero (so the message is not eligible for discarding), while the time according to the *MDEXP* field in the MQXQH has elapsed. In this case the *MDEXP* field in the MQXQH is set to zero.

The following special value is recognized:

EIULIM

Unlimited lifetime.

The message has an unlimited expiration time.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is EIULIM.

MDFB (10-digit signed integer)

Feedback or reason code.

This is used with a message of type MTRPRT to indicate the nature of the report, and is only meaningful with that type of message. The field can contain one of the FB* values, or one of the RC* values. Feedback codes are grouped as follows:

FBNONE

No feedback provided.

FBSFST

Lowest value for system-generated feedback.

FBSLST

Highest value for system-generated feedback.

The range of system-generated feedback codes FBSFST through FBSLST includes the general feedback codes listed later in this section (FB*), and also the reason codes (RC*) that can occur when the message cannot be put on the destination queue.

FBAFST

Lowest value for application-generated feedback.

FBALST

Highest value for application-generated feedback.

Applications that generate report messages should not use feedback codes in the system range (other than FBQUIT), unless they want to simulate report messages generated by the queue manager or message channel agent.

On the MQPUT or MQPUT1 calls, the value specified must either be FBNONE, or be within the system range or application range. This is checked whatever the value of *MDMT*.

General feedback codes:

FBCOA

Confirmation of arrival on the destination queue (see ROCOA).

FBCOD

Confirmation of delivery to the receiving application (see ROCOD).

FBEXP

Message expired.

Message was discarded because it had not been removed from the destination queue before its expiry time had elapsed.

FBPAN

Positive action notification (see ROPAN).

FBNAN

Negative action notification (see RONAN).

FBQUIT

Application should end.

This can be used by a workload scheduling program to control the number of instances of an application program that are running. Sending an MTRPRT message with this feedback code to an instance of the application program indicates to that instance that it should stop processing. However, adherence to this convention is a matter for the application; it is not enforced by the queue manager.

IMS-bridge feedback codes: When the IMS bridge receives a nonzero IMS-OTMA sense code, the IMS bridge converts the sense code from hexadecimal to decimal, adds the value FBIERR (300), and places the result in the *MDFB* field of the reply message. This results in the feedback code having a value in the range FBIFST (301) through FBILST (399) when an IMS-OTMA error has occurred.

The following feedback codes can be generated by the IMS bridge:

FBDLZ

Data length zero.

A segment length was zero in the application data of the message.

FBDLN

Data length negative.

A segment length was negative in the application data of the message.

FBDLTB

Data length too big.

A segment length was too big in the application data of the message.

FBBUFO

Buffer overflow.

The value of one of the length fields would cause the data to overflow the message buffer.

FBLOB1

Length in error by one.

The value of one of the length fields was one byte too short.

FBIIH

MQIIH structure not valid or missing.

The *MDFMT* field in MQMD specifies FMIMS, but the message does not begin with a valid MQIIH structure.

FBNAFI

User ID not authorized for use in IMS.

The user ID contained in the message descriptor MQMD, or the password contained in the *IIAUT* field in the MQIIH structure, failed the validation performed by the IMS bridge. As a result the message was not passed to IMS.

FBIERR

Unexpected error returned by IMS.

An unexpected error was returned by IMS. Consult the IBM MQ error log on the system on which the IMS bridge resides for more information about the error.

FBIFST

Lowest value for IMS-generated feedback.

IMS-generated feedback codes occupy the range FBIFST (300) through FBILST (399). The IMS-OTMA sense code itself is *MDFB* minus FBIERR.

FBILST

Highest value for IMS-generated feedback.

CICS-bridge feedback codes: The following feedback codes can be generated by the CICS bridge:

FBCAAB

Application abended.

The application program specified in the message abended. This feedback code occurs only in the *DLREA* field of the MQDLH structure.

FBCANS

Application cannot be started.

The EXEC CICS LINK for the application program specified in the message failed. This feedback code occurs only in the *DLREA* field of the MQDLH structure.

FBCBRF

CICS bridge terminated abnormally without completing normal error processing.

FBCCSSE

Character set identifier not valid.

FBCIHE

CICS information header structure missing or not valid.

FBCCAE

Length of CICS commarea not valid.

FBCIE

Correlation identifier not valid.

FBCDLQ

Dead-letter queue not available.

The CICS bridge task was unable to copy a reply to this request to the dead-letter queue. The request was backed out.

FBCENE

Encoding not valid.

FBCINE

CICS bridge encountered an unexpected error.

This feedback code occurs only in the *DLREA* field of the MQDLH structure.

FBCNTA

User identifier not authorized or password not valid.

This feedback code occurs only in the *DLREA* field of the MQDLH structure.

FBCUBO

Unit of work backed out.

The unit of work was backed out, for one of the following reasons:

- A failure was detected while processing another request within the same unit of work.
- A CICS abend occurred while the unit of work was in progress.

FBCUWE

Unit-of-work control field *CIUOW* not valid.

MQ reason codes: For exception report messages, *MDFB* contains an MQ reason code. Among possible reason codes are:

RC2051

(2051, X'803') Put calls inhibited for the queue.

RC2053

(2053, X'805') Queue already contains maximum number of messages.

RC2035

(2035, X'7F3') Not authorized for access.

RC2056

(2056, X'808') No space available on disk for queue.

RC2048

(2048, X'800') Queue does not support persistent messages.

RC2031

(2031, X'7EF') Message length greater than maximum for queue manager.

RC2030

(2030, X'7EE') Message length greater than maximum for queue.

This is an output field for the MQGET call, and an input field for MQPUT and MQPUT1 calls. The initial value of this field is FBNONE.

MDFMT (8-byte character string)

Format name of message data.

This is a name that the sender of the message may use to indicate to the receiver the nature of the data in the message. Any characters that are in the queue manager's character set may be specified for the name, but it is recommended that the name be restricted to the following:

- Uppercase A through Z
- Numeric digits 0 through 9

If other characters are used, it may not be possible to translate the name between the character sets of the sending and receiving queue managers.

The name should be padded with blanks to the length of the field, or a null character used to terminate the name before the end of the field; the null and any subsequent characters are treated as blanks. Do not specify a name with leading or embedded blanks. For the MQGET call, the queue manager returns the name padded with blanks to the length of the field.

The queue manager does not check that the name complies with the recommendations described previously.

Names beginning "MQ" in upper, lower, and mixed case have meanings that are defined by the queue manager; you should not use names beginning with these letters for your own formats. The queue manager built-in formats are:

FMNONE

No format name.

The nature of the data is undefined. This means that the data cannot be converted when the message is retrieved from a queue using the GMCONV option.

If GMCONV is specified on the MQGET call, and the character set or encoding of data in the message differs from that specified in the *MSGDSC* parameter, the message is returned with the following completion and reason codes (assuming no other errors):

- Completion code CCWARN and reason code RC2110 if the FMNONE data is at the beginning of the message.
- Completion code CCOK and reason code RCNONE if the FMNONE data is at the end of the message (that is, preceded by one or more MQ header structures). The MQ header structures are converted to the requested character set and encoding in this case.

FMADMN

Command server request/reply message.

The message is a command-server request or reply message in programmable command format (PCF). Messages of this format can be converted if the GMCONV option is specified on the MQGET call. For more information about using programmable command format messages, see [Using Programmable Command Formats](#).

FMCICS

CICS information header.

The message data begins with the CICS information header MQCIH, which is followed by the application data. The format name of the application data is given by the *CIFMT* field in the MQCIH structure.

FMCMD1

Type 1 command reply message.

The message is an MQSC command-server reply message containing the object count, completion code, and reason code. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

FMCMD2

Type 2 command reply message.

The message is an MQSC command-server reply message containing information about the object(s) requested. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

FMDLH

Dead-letter header.

The message data begins with the dead-letter header MQDLH. The data from the original message immediately follows the MQDLH structure. The format name of the original message data is given by the *DLFMT* field in the MQDLH structure; see [“MQDLH - Dead-letter header” on page 1023](#) for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

COA and COD reports are not generated for messages which have a *MDFMT* of FMDLH.

FMDH

Distribution-list header.

The message data begins with the distribution-list header MQDH; this includes the arrays of MQOR and MQPMR records. The distribution-list header may be followed by additional data. The format of the additional data (if any) is given by the *DHFMT* field in the MQDH structure; see [“MQDH - Distribution header” on page 1019](#) for details of this structure. Messages with format FMDH can be converted if the GMCONV option is specified on the MQGET call.

FMEVNT

Event message.

The message is an MQ event message that reports an event that occurred. Event messages have the same structure as programmable commands; for more information about this structure, see [Structures for commands and responses](#). For information about events, see [Event monitoring](#).

Version-1 event messages can be converted if the GMCONV option is specified on the MQGET call.

FMIMS

IMS information header.

The message data begins with the IMS information header MQIIH, which is followed by the application data. The format name of the application data is given by the *IIFMT* field in the MQIIH structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

FMIMVS

IMS variable string.

The message is an IMS variable string, which is a string of the form 11zzccc, where:

11

is a 2-byte length field specifying the total length of the IMS variable string item. This length is equal to the length of 11 (2 bytes), plus the length of zz (2 bytes), plus the length of the character string itself. 11 is a 2-byte binary integer in the encoding specified by the *MDENC* field.

zz

is a 2-byte field containing flags that are significant to IMS. *zz* is a byte string consisting of two 1-byte bit string fields, and is transmitted without change from sender to receiver (that is, *zz* is not subject to any conversion).

ccc

is a variable-length character string containing 11-4 characters. *ccc* is in the character set specified by the *MDCSI* field.

Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMMDE

Message-descriptor extension.

The message data begins with the message-descriptor extension *MQMDE*, and is optionally followed by other data (usually the application message data). The format name, character set, and encoding of the data which follows the *MQMDE* is given by the *MEFMT*, *MECSI*, and *MEENC* fields in the *MQMDE*. See [“MQMDE - Message descriptor extension” on page 1111](#) for details of this structure. Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMPCF

User-defined message in programmable command format (PCF).

The message is a user-defined message that conforms to the structure of a programmable command format (PCF) message. Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call. See [Using Programmable Command Formats](#) for more information about using programmable command format messages.

FMRMH

Reference message header.

The message data begins with the reference message header *MQRMH*, and is optionally followed by other data. The format name, character set, and encoding of the data is given by the *RMFMT*, *RMCSI*, and *RMENC* fields in the *MQRMH*. See [“MQRMH - Reference message header” on page 1157](#) for details of this structure. Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMRFH

Rules and formatting header.

The message data begins with the rules and formatting header *MQRFH*, and is optionally followed by other data. The format name, character set, and encoding of the data (if any) is given by the *RFFMT*, *RFCSI*, and *RFENC* fields in the *MQRFH*. Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMRFH2

Rules and formatting header version 2.

The message data begins with the version-2 rules and formatting header *MQRFH2*, and is optionally followed by other data. The format name, character set, and encoding of the optional data (if any) is given by the *RF2FMT*, *RF2CSI*, and *RF2ENC* fields in the *MQRFH2*. Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMSTR

Message consisting entirely of characters.

The application message data can be either an SBCS string (single-byte character set), or a DBCS string (double-byte character set). Messages of this format can be converted if the *GMCONV* option is specified on the *MQGET* call.

FMTM

Trigger message.

The message is a trigger message, described by the MQTM structure; see [“MQTM - Trigger message” on page 1191](#) for details of this structure. Messages of this format can be converted if the GMCONV option is specified on the MQGET call.

FMWIH

Work information header.

The message data begins with the work information header MQWIH, which is followed by the application data. The format name of the application data is given by the *WIFMT* field in the MQWIH structure.

FMXQH

Transmission queue header.

The message data begins with the transmission queue header MQXQH. The data from the original message immediately follows the MQXQH structure. The format name of the original message data is given by the *MDFMT* field in the MQMD structure which is part of the transmission queue header MQXQH. See [“MQXQH - Transmission-queue header” on page 1201](#) for details of this structure.

COA and COD reports are not generated for messages which have a *MDFMT* of FMXQH.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNFMT. The initial value of this field is FMNONE.

MDGID (24-byte bit string)

Group identifier.

This is a byte string that is used to identify the particular message group or logical message to which the physical message belongs. *MDGID* is also used if segmentation is allowed for the message. In all of these cases, *MDGID* has a non-null value, and one or more of the following flags is set in the *MDMFL* field:

- MFMIG
- MFLMIG
- MFSEG
- MFLSEG
- MFSEGA

If none of these flags is set, *MDGID* has the special null value GINONE.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOGRPI is *not* specified.

Consider using these calls for messages that are not report messages. However, if the application requires more control, or the call is MQPUT1, the application must ensure that *MDGID* is set to an appropriate value.

Message groups and segments can be processed correctly only if the group identifier is unique. For this reason, *applications should not generate their own group identifiers* ; instead, applications should do one of the following:

- If PMLOGO is specified, the queue manager automatically generates a unique group identifier for the first message in the group or segment of the logical message, and uses that group identifier for the remaining messages in the group or segments of the logical message, so the application does not need to take any special action. Consider using this procedure.
- If PMLOGO is *not* specified, the application should request the queue manager to generate the group identifier, by setting *MDGID* to GINONE on the first MQPUT or MQPUT1 call for a message in the group or segment of the logical message. The group identifier returned by the queue manager on output from that call should then be used for the remaining messages in the group or segments

of the logical message. If a message group contains segmented messages, the same group identifier must be used for all segments and messages in the group.

When PMLOGO is not specified, messages in groups and segments of logical messages can be put in any order (for example, in reverse order), but the group identifier must be allocated by the *first* MQPUT or MQPUT1 call that is issued for any of those messages.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in [PMOPT](#). On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message if the object opened is a single queue and not a distribution list, but leaves it unchanged if the object opened is a distribution list. In the latter case, if the application needs to know the group identifiers generated, the application must provide MQPMR records containing the *PRGID* field.

On input to the MQGET call, the queue manager uses the value detailed in [Table 1](#). On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The following special value is defined:

GINONE

No group identifier specified.

The value is binary zero for the length of the field. This is the value that is used for messages that are not in groups, not segments of logical messages, and for which segmentation is not allowed.

The length of this field is given by LNGID. The initial value of this field is GINONE. This field is ignored if MDVER is less than MDVER2.

MDMFL (10-digit signed integer)

Message flags.

These are flags that specify attributes of the message, or control its processing. The flags are divided into the following categories:

- Segmentation flag
- Status flags

These are described in turn.

Segmentation flags: When a message is too big for a queue, an attempt to put the message on the queue usually fails. Segmentation is a technique whereby the queue manager or application splits the message into smaller pieces called segments, and places each segment on the queue as a separate physical message. The application which retrieves the message can either retrieve the segments one by one, or request the queue manager to reassemble the segments into a single message which is returned by the MQGET call. The latter is achieved by specifying the GMCMPM option on the MQGET call, and supplying a buffer that is big enough to accommodate the complete message. (See [“MQGMO - Get-message options”](#) on page 1035 for details of the GMCMPM option.) Segmentation of a message can occur at the sending queue manager, at an intermediate queue manager, or at the destination queue manager.

You can specify one of the following to control the segmentation of a message:

MFSEGI

Segmentation inhibited.

This option prevents the message being broken into segments by the queue manager. If specified for a message that is already a segment, this option prevents the segment being broken into smaller segments.

The value of this flag is binary zero. This is the default.

MFSEGA

Segmentation allowed.

This option allows the message to be broken into segments by the queue manager. If specified for a message that is already a segment, this option allows the segment to be broken into smaller segments. MFSEGA can be set without either MFSEG or MFLSEG being set.

When the queue manager segments a message, the queue manager turns on the MFSEG flag in the copy of the MQMD that is sent with each segment, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call. For the last segment in the logical message, the queue manager also turns on the MFLSEG flag in the MQMD that is sent with the segment.

Note: Care is needed when messages are put with MFSEGA but without PMLOGO. If the message is:

- Not a segment, and
- Not in a group, and
- Not being forwarded,

the application must remember to reset the *MDGID* field to GINONE before *each* MQPUT or MQPUT1 call, in order to cause a unique group identifier to be generated by the queue manager for each message. If this is not done, unrelated messages could inadvertently end up with the same group identifier, which might lead to incorrect processing subsequently. See the descriptions of the *MDGID* field and the PMLOGO option for more information about when the *MDGID* field must be reset.

The queue manager splits messages into segments as necessary in order to ensure that the segments (plus any header data that may be required) fit on the queue. However, there is a lower limit for the size of a segment generated by the queue manager, and only the last segment created from a message can be smaller than this limit. (The lower limit for the size of an application-generated segment is one byte.) Segments generated by the queue manager may be of unequal length. The queue manager processes the message as follows:

- User-defined formats are split on boundaries which are multiples of 16 bytes. This means that the queue manager will not generate segments that are smaller than 16 bytes (other than the last segment).
- Built-in formats other than FMSTR are split at points appropriate to the nature of the data present. However, the queue manager never splits a message in the middle of an MQ header structure. This means that a segment containing a single MQ header structure cannot be split further by the queue manager, and as a result the minimum possible segment size for that message is greater than 16 bytes.

The second or later segment generated by the queue manager will begin with one of the following:

- An MQ header structure
- The start of the application message data
- Part-way through the application message data
- FMSTR is split without regard for the nature of the data present (SBCS, DBCS, or mixed SBCS/DBCS). When the string is DBCS or mixed SBCS/DBCS, this may result in segments which cannot be converted from one character set to another. The queue manager never splits FMSTR messages into segments that are smaller than 16 bytes (other than the last segment).
- The *MDFMT*, *MDCSI*, and *MDENC* fields in the MQMD of each segment are set by the queue manager to describe correctly the data present at the *start* of the segment; the format name will be either the name of a built-in format, or the name of a user-defined format.
- The *MDREP* field in the MQMD of segments with *MDOFF* greater than zero are modified as follows:
 - For each report type, if the report option is RO*D, but the segment cannot possibly contain any of the first 100 bytes of user data (that is, the data following any MQ header structures that may be present), the report option is changed to RO*.

The queue manager follows the previously rules, but otherwise splits messages unpredictably; do not make assumptions about where a message is split

For *persistent* messages, the queue manager can perform segmentation only within a unit of work:

- If the MQPUT or MQPUT1 call is operating within a user-defined unit of work, that unit of work is used. If the call fails partway through the segmentation process, the queue manager removes any segments that were placed on the queue as a result of the failing call. However, the failure does not prevent the unit of work being committed successfully.
- If the call is operating outside a user-defined unit of work, and there is no user-defined unit of work in existence, the queue manager creates a unit of work just for the duration of the call. If the call is successful, the queue manager commits the unit of work automatically (the application does not need to do this). If the call fails, the queue manager backs out the unit of work.
- If the call is operating outside a user-defined unit of work, but a user-defined unit of work *does* exist, the queue manager is unable to perform segmentation. If the message does not require segmentation, the call can still succeed. But if the message *does* require segmentation, the call fails with reason code RC2255.

For *nonpersistent* messages, the queue manager does not require a unit of work to be available in order to perform segmentation.

Special consideration must be given to data conversion of messages which may be segmented:

- If data conversion is performed only by the receiving application on the MQGET call, and the application specifies the GMCMPM option, the data-conversion exit will be passed the complete message for the exit to convert, and the fact that the message was segmented will not be apparent to the exit.
- If the receiving application retrieves one segment at a time, the data-conversion exit will be invoked to convert one segment at a time. The exit must therefore be capable of converting the data in a segment independently of the data in any of the other segments.

If the nature of the data in the message is such that arbitrary segmentation of the data on 16-byte boundaries may result in segments which cannot be converted by the exit, or the format is FMSTR and the character set is DBCS or mixed SBCS/DBCS, the sending application should itself create and put the segments, specifying MFSEGI to suppress further segmentation. In this way, the sending application can ensure that each segment contains sufficient information to allow the data-conversion exit to convert the segment successfully.

- If sender conversion is specified for a sending message channel agent (MCA), the MCA converts only messages which are not segments of logical messages; the MCA never attempts to convert messages which are segments.

This flag is an input flag on the MQPUT and MQPUT1 calls, and an output flag on the MQGET call. On the latter call, the queue manager also echoes the value of the flag to the *GMSEG* field in MQGMO.

The initial value of this flag is MFSEGI.

Status flags: These are flags that indicate whether the physical message belongs to a message group, is a segment of a logical message, both, or neither. One or more of the following can be specified on the MQPUT or MQPUT1 call, or returned by the MQGET call:

MFMI

Message is a member of a group.

MFLMI

Message is the last logical message in a group.

If this flag is set, the queue manager turns on MFMI in the copy of MQMD that is sent with the message, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call.

It is valid for a group to consist of only one logical message. If this is the case, MFLMI is set, but the *MDSEQ* field has the value one.

MFSEG

Message is a segment of a logical message.

When MFSEG is specified without MFLSEG, the length of the application message data in the segment (*excluding* the lengths of any MQ header structures that may be present) must be at least one. If the length is zero, the MQPUT or MQPUT1 call fails with reason code RC2253.

MFLSEG

Message is the last segment of a logical message.

If this flag is set, the queue manager turns on MFSEG in the copy of MQMD that is sent with the message, but does not alter the settings of these flags in the MQMD provided by the application on the MQPUT or MQPUT1 call.

It is valid for a logical message to consist of only one segment. If this is the case, MFLSEG is set, but the *MDOFF* field has the value zero.

When MFLSEG is specified, it is permissible for the length of the application message data in the segment (*excluding* the lengths of any header structures that may be present) to be zero.

The application must ensure that these flags are set correctly when putting messages. If PMLOGO is specified, or was specified on the preceding MQPUT call for the queue handle, the settings of the flags must be consistent with the group and segment information retained by the queue manager for the queue handle. The following conditions apply to *successive* MQPUT calls for the queue handle when PMLOGO is specified:

- If there is no current group or logical message, all of these flags (and combinations of them) are valid.
- Once MFMIG has been specified, it must remain on until MFLMIG is specified. The call fails with reason code RC2241 if this condition is not satisfied.
- Once MFSEG has been specified, it must remain on until MFLSEG is specified. The call fails with reason code RC2242 if this condition is not satisfied.
- Once MFSEG has been specified without MFMIG, MFMIG must remain *off* until after MFLSEG has been specified. The call fails with reason code RC2242 if this condition is not satisfied.

Table 1 shows the valid combinations of the flags, and the values used for various fields.

These flags are input flags on the MQPUT and MQPUT1 calls, and output flags on the MQGET call. On the latter call, the queue manager also echoes the values of the flags to the *GMGST* and *GMSST* fields in MQGMO.

Default flags: The following can be specified to indicate that the message has default attributes:

MFNONE

No message flags (default message attributes).

This inhibits segmentation, and indicates that the message is not in a group and is not a segment of a logical message. MFNONE is defined to aid program documentation. It is not intended that this flag be used with any other, but as its value is zero, such use cannot be detected.

The *MDMFL* field is partitioned into subfields; for details see [“Report options and message flags” on page 1388](#).

The initial value of this field is MFNONE. This field is ignored if *MDVER* is less than MDVER2.

MDMID (24-byte bit string)

Message identifier.

This is a byte string that is used to distinguish one message from another. Generally, no two messages should have the same message identifier, although this is not disallowed by the queue manager. The message identifier is a permanent property of the message, and persists across restarts of the queue manager. Because the message identifier is a byte string and not a character string, the message identifier is *not* converted between character sets when the message flows from one queue manager to another.

For the MQPUT and MQPUT1 calls, if MINONE or PMNMID is specified by the application, the queue manager generates a unique message identifier ⁴ when the message is put, and places it in the message descriptor sent with the message. The queue manager also returns this message identifier in the message descriptor belonging to the sending application. The application can use this value to record information about particular messages, and to respond to queries from other parts of the application.

If the message is being put to a topic, the queue manager generates unique message identifiers as necessary for each message published. If PMNMID is specified by the application, the queue manager generates a unique message identifier to return on output. If MINONE is specified by the application, the value of the *MDMID* field in the MQMD is unchanged on return from the call.

See the description of PMRET in [PMOPT](#) for more details about retained publications.

If the message is being put to a distribution list, the queue manager generates unique message identifiers as necessary, but the value of the *MDMID* field in MQMD is unchanged on return from the call, even if MINONE or PMNMID was specified. If the application needs to know the message identifiers generated by the queue manager, the application must provide MQPMR records containing the *PRMID* field.

The sending application can also specify a particular value for the message identifier, other than MINONE; this stops the queue manager generating a unique message identifier. An application that is forwarding a message can use this facility to propagate the message identifier of the original message.

The queue manager does not itself make any use of this field except to:

- Generate a unique value if requested, as described previously
- Deliver the value to the application that issues the get request for the message
- Copy the value to the *MDCID* field of any report message that it generates about this message (depending on the *MDREP* options)

When the queue manager or a message channel agent generates a report message, it sets the *MDMID* field in the way specified by the *MDREP* field of the original message, either RONMI or ROPMI. Applications that generate report messages should also do this.

For the MQGET call, *MDMID* is one of the five fields that can be used to select a particular message to be retrieved from the queue. Normally the MQGET call returns the next message on the queue, but if a particular message is required, this can be obtained by specifying one or more of the five selection criteria, in any combination; these fields are:

- *MDMID*
- *MDCID*
- *MDGID*
- *MDSEQ*
- *MDOFF*

The application sets one or more of these field to the values required, and then sets the corresponding MO* match options in the *GMMO* field in MQGMO to indicate that those fields should be used as selection criteria. Only messages that have the specified values in those fields are candidates

⁴ An *MDMID* generated by the queue manager consists of a 4-byte product identifier (AMQ- or CSQ- in either ASCII or EBCDIC, where - represents a single blank character), followed by a product-specific implementation of a unique string. In IBM MQ this contains the first 12 characters of the queue manager name, and a value derived from the system clock. All queue managers that can intercommunicate must therefore have names that differ in the first 12 characters, to ensure that message identifiers are unique. The ability to generate a unique string also depends upon the system clock not being changed backward. To eliminate the possibility of a message identifier generated by the queue manager duplicating one generated by the application, the application should avoid generating identifiers with initial characters in the range A through I in ASCII or EBCDIC (X'41' through X'49' and X'C1' through X'C9'). However, the application is not prevented from generating identifiers with initial characters in these ranges.

for retrieval. The default for the *GMMO* field (if not altered by the application) is to match both the message identifier and the correlation identifier.

Normally, the message returned is the *first* message on the queue that satisfies the selection criteria. But if *GMBRWN* is specified, the message returned is the *next* message that satisfies the selection criteria; the scan for this message starts with the message *following* the current cursor position.

Note: The queue is scanned sequentially for a message that satisfies the selection criteria, so retrieval times will be slower than if no selection criteria are specified, especially if many messages have to be scanned before a suitable one is found.

See [Table 1](#) for more information about how selection criteria are used in various situations.

Specifying *MINONE* as the message identifier has the same effect as *not* specifying *MOMSGI*, that is, *any* message identifier will match.

This field is ignored if the *GMMUC* option is specified in the *GMO* parameter on the *MQGET* call.

On return from an *MQGET* call, the *MDMID* field is set to the message identifier of the message returned (if any).

The following special value may be used:

MINONE

No message identifier is specified.

The value is binary zero for the length of the field.

This is an input/output field for the *MQGET*, *MQPUT*, and *MQPUT1* calls. The length of this field is given by *LN MID*. The initial value of this field is *MINONE*.

MDMT (10-digit signed integer)

Message type.

This indicates the type of the message. Message types are grouped as follows:

MTSFST

Lowest value for system-defined message types.

MTSLST

Highest value for system-defined message types.

The following values are currently defined within the system range:

MTDGRM

Message not requiring a reply.

The message is one that does not require a reply.

MTRQST

Message requiring a reply.

The message is one that requires a reply.

The name of the queue to which the reply should be sent must be specified in the *MDRQ* field. The *MDREP* field indicates how the *MDMID* and *MDCID* of the reply are to be set.

MTRPLY

Reply to an earlier request message.

The message is the reply to an earlier request message (*MTRQST*). The message should be sent to the queue indicated by the *MDRQ* field of the request message. The *MDREP* field of the request should be used to control how the *MDMID* and *MDCID* of the reply are set.

Note: The queue manager does not enforce the request-reply relationship; this is an application responsibility.

MTRPRT

Report message.

The message is reporting on some expected or unexpected occurrence, usually related to some other message (for example, a request message was received which contained data that was not valid). The message should be sent to the queue indicated by the *MDRQ* field of the message descriptor of the original message. The *MDFB* field should be set to indicate the nature of the report. The *MDREP* field of the original message can be used to control how the *MDMID* and *MDCID* of the report message should be set.

Report messages generated by the queue manager or message channel agent are always sent to the *MDRQ* queue, with the *MDFB* and *MDCID* fields set as described previously.

Other values within the system range may be defined in future versions of the MQI, and are accepted by the MQPUT and MQPUT1 calls without error.

Application-defined values can also be used. They must be within the following range:

MTAFST

Lowest value for application-defined message types.

MTALST

Highest value for application-defined message types.

For the MQPUT and MQPUT1 calls, the *MDMT* value must be within either the system-defined range or the application-defined range; if it is not, the call fails with reason code RC2029.

This is an output field for the MQGET call, and an input field for MQPUT and MQPUT1 calls. The initial value of this field is MTDGRM.

MDOFF (10-digit signed integer)

Offset of data in physical message from start of logical message.

This is the offset in bytes of the data in the physical message from the start of the logical message of which the data forms part. This data is called a *segment*. The offset is in the range 0 through 999 999 999. A physical message which is not a segment of a logical message has an offset of zero.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOOFFS is *not* specified.

These are the recommended ways of using these calls for messages that are not report messages. However, if the application does not comply with these conditions, or the call is MQPUT1, the application must ensure that *MDOFF* is set to an appropriate value.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in Table 1. On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message.

For a report message reporting on a segment of a logical message, the *MDOLN* field (provided it is not OLUNDF) is used to update the offset in the segment information retained by the queue manager.

On input to the MQGET call, the queue manager uses the value detailed in Table 1. On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The initial value of this field is zero. This field is ignored if *MDVER* is less than MDVER2.

MDOLN (10-digit signed integer)

Length of original message.

This field is of relevance only for report messages that are segments. It specifies the length of the message segment to which the report message relates; it does not specify the length of the logical message of which the segment forms part, nor the length of the data in the report message.

Note: When generating a report message for a message that is a segment, the queue manager and message channel agent copy into the MQMD for the report message the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL*, fields from the original message. As a result, the report message is also a segment.

Applications that generate report messages are recommended to do the same, and to ensure that the *MDOLN* field is set correctly.

The following special value is defined:

OLUNDF

Original length of message not defined.

MDOLN is an input field on the MQPUT and MQPUT1 calls, but the value provided by the application is accepted only in particular circumstances:

- If the message being put is a segment and is also a report message, the queue manager accepts the value specified. The value must be:
 - Greater than zero if the segment is not the last segment
 - Not less than zero if the segment is the last segment
 - Not less than the length of data present in the message

If these conditions are not satisfied, the call fails with reason code RC2252.

- If the message being put is a segment but not a report message, the queue manager ignores the field and uses the length of the application message data instead.
- In all other cases, the queue manager ignores the field and uses the value OLUNDF instead.

This is an output field on the MQGET call.

The initial value of this field is OLUNDF. This field is ignored if *MDVER* is less than MDVER2.

MDPAN (28-byte character string)

Name of application that put the message.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format of the *MDPAN* depends on the value of *MDPAT*.

When this field is set by the queue manager (that is, for all options except PMSETA), it is set to value which is determined by the environment:

- On z/OS, the queue manager uses:
 - For z/OS batch, the 8-character job name from the JES JOB card
 - For TSO, the 7-character TSO user identifier
 - For CICS, the 8-character applid, followed by the 4-character tranid
 - For IMS, the 8-character IMS system identifier, followed by the 8-character PSB name
 - For XCF, the 8-character XCF group name, followed by the 16-character XCF member name
 - For a message generated by a queue manager, the first 28 characters of the queue manager name
 - For distributed queuing without CICS, the 8-character jobname of the channel initiator followed by the 8-character name of the module putting to the dead-letter queue followed by an 8-character task identifier.
 - For MQSeries Java language bindings processing with IBM MQ for z/OS the 8-character jobname of the address space created for the UNIX System Services environment. Typically, this will be a TSO user identifier with a single numeric character appended.

The name or names are each padded to the right with blanks, as is any space in the remainder of the field. Where there is more than one name, there is no separator between them.

- On PC DOS, and Windows systems, the queue manager uses:
 - For a CICS application, the CICS transaction name
 - For a non-CICS application, the rightmost 28 characters of the fully-qualified name of the executable

- On IBM i, the queue manager uses the fully-qualified job name.
- On HP Integrity NonStop Server, the queue manager uses: the rightmost 28 characters of the fully-qualified name of the executable, if this is available to the queue manager, and blanks otherwise
- On UNIX systems, the queue manager uses:
 - For a CICS application, the CICS transaction name
 - For a non-CICS application, the rightmost 14 characters of the fully-qualified name of the executable if this is available to the queue manager, and blanks otherwise (for example, on AIX)
- On VSE/ESA, the queue manager uses the 8-character applid, followed by the 4-character tranid.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the *PMO* parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

This is an output field for the MQGET call. The length of this field is given by LNPAN. The initial value of this field is 28 blank characters.

MDPAT (10-digit signed integer)

Type of application that put the message.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDPAT may have one of the following standard types. User-defined types can also be used but should be restricted to values in the range ATUFST through ATULST.

ATAIX

AIX application (same value as ATUNIX).

ATBRKR

Broker.

ATCICS

CICS transaction.

ATCICB

CICS bridge.

ATVSE

CICS/VSE transaction.

ATDOS

IBM MQ MQI client application on PC DOS.

ATDQM

Distributed queue manager agent.

ATGUAR

Tandem Guardian application (same value as ATNSK).

ATIMS

IMS application.

ATIMSB

IMS bridge.

ATJAVA

Java.

ATMVS

MVS or TSO application (same value as ATZOS).

ATNOTE

Lotus Notes Agent application.

ATNSK

Tandem NonStop Kernel application.

AT390

OS/390 application (same value as ATZOS).

AT400

IBM i application.

ATQM

Queue manager.

ATUNIX

UNIX application.

ATVOS

Stratus VOS application.

ATWIN

16-bit Windows application.

ATWINT

32-bit Windows application.

ATXCF

XCF.

ATZOS

z/OS application.

ATDEF

Default application type.

This is the default application type for the platform on which the application is running.

Note: The value of this constant is environment-specific.

ATUNK

Unknown application type.

This value can be used to indicate that the application type is unknown, even though other context information is present.

ATUFST

Lowest value for user-defined application type.

ATULST

Highest value for user-defined application type.

The following special value can also occur:

ATNCON

No context information present in message.

This value is set by the queue manager when a message is put with no context (that is, the PMNOC context option is specified).

When a message is retrieved, *MDPAT* can be tested for this value to decide whether the message has context (it is recommended that *MDPAT* is never set to ATNCON, by an application using PMSETA, if any of the other context fields are nonblank).

ATSIB

Indicates a message originated in another IBM MQ messaging product and arrived via the SIB (Service Integration Bus) bridge.

When the queue manager generates this information as a result of an application put, the field is set to a value that is determined by the environment. Note that on IBM i, it is set to AT400; the queue manager never uses ATCICS on IBM i.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the *PMO* parameter. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDPAT* that was transmitted with the message if it was put to a queue. This will be the value of *MDPAT* that is kept with

the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDPAT* when the message is sent as a publication to subscribers since they provide a value to override *MDPAT* in all publications sent to them. If the message has no context, the field is set to ATNCON.

This is an output field for the MQGET call. The initial value of this field is ATNCON.

MDPD (8-byte character string)

Date when message was put.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format used for the date when this field is generated by the queue manager is:

- YYYYMMDD

where the characters represent:

YYYY

year (four numeric digits)

MM

month of year (01 through 12)

DD

day of month (01 through 31)

Greenwich Mean Time (GMT) is used for the *MDPD* and *MDPT* fields, subject to the system clock being set accurately to GMT.

If the message was put as part of a unit of work, the date is that when the message was put, and not the date when the unit of work was committed.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the *PMO* parameter. The contents of the field are not checked by the queue manager, except that any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDPD* that was transmitted with the message if it was put to a queue. This will be the value of *MDPD* that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDPD* when the message is sent as a publication to subscribers since they provide a value to override *MDPD* in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNPDAT. The initial value of this field is 8 blank characters.

MDPER (10-digit signed integer)

Message persistence.

This indicates whether the message survives system failures and restarts of the queue manager. For the MQPUT and MQPUT1 calls, the value must be one of the following:

PEPER

Message is persistent.

This means that the message survives system failures and restarts of the queue manager. Once the message has been put, and the putter's unit of work committed (if the message is put as part of a unit of work), the message is preserved on auxiliary storage. It remains there until the message is removed from the queue, and the getter's unit of work committed (if the message is retrieved as part of a unit of work).

When a persistent message is sent to a remote queue, a store-and-forward mechanism is used to hold the message at each queue manager along the route to the destination, until the message is known to have arrived at the next queue manager.

Persistent messages cannot be placed on:

- Temporary dynamic queues
- Shared queues where the coupling facility structure level is less than three, or the coupling facility structure is not recoverable.

Persistent messages can be placed on permanent dynamic queues, predefined queues, and shared queues where the coupling facility structure level is 3, and the coupling facility is recoverable.

PENPER

Message is not persistent.

This means that the message does not normally survive system failures or restarts of the queue manager. This applies even if an intact copy of the message is found on auxiliary storage during restart of the queue manager.

In the special case of shared queues, nonpersistent messages *do* survive restarts of queue managers in the queue-sharing group, but do not survive failures of the coupling facility used to store messages on the shared queues.

PEQDEF

Message has default persistence.

- If the queue is a cluster queue, the persistence of the message is taken from the *DefPersistence* attribute defined at the *destination* queue manager that owns the particular instance of the queue on which the message is placed. Usually, all of the instances of a cluster queue have the same value for the *DefPersistence* attribute, although this is not mandated.

The value of *DefPersistence* is copied into the *MDPER* field when the message is placed on the destination queue. If *DefPersistence* is changed subsequently, messages that have already been placed on the queue are not affected.

- If the queue is not a cluster queue, the persistence of the message is taken from the *DefPersistence* attribute defined at the *local* queue manager, even if the destination queue manager is remote.

If there is more than one definition in the queue-name resolution path, the default persistence is taken from the value of this attribute in the *first* definition in the path. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

The value of *DefPersistence* is copied into the *MDPER* field when the message is put. If *DefPersistence* is changed subsequently, messages that have already been put are not affected.

Both persistent and nonpersistent messages can exist on the same queue.

When replying to a message, applications should normally use for the reply message the persistence of the request message.

For an MQGET call, the value returned is either PEPER or PENPER.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is PEQDEF.

MDPRI (10-digit signed integer)

Message priority.

For the MQPUT and MQPUT1 calls, the value must be greater than or equal to zero; zero is the lowest priority. The following special value can also be used:

PRQDEF

Default priority for queue.

- If the queue is a cluster queue, the priority for the message is taken from the *DefPriority* attribute as defined at the *destination* queue manager that owns the particular instance of the queue on which the message is placed. Usually, all of the instances of a cluster queue have the same value for the *DefPriority* attribute, although this is not mandated.

The value of *DefPriority* is copied into the *MDPRI* field when the message is placed on the destination queue. If *DefPriority* is changed subsequently, messages that have already been placed on the queue are not affected.

- If the queue is not a cluster queue, the priority for the message is taken from the *DefPriority* attribute as defined at the *local* queue manager, even if the destination queue manager is remote.

If there is more than one definition in the queue-name resolution path, the default priority is taken from the value of this attribute in the *first* definition in the path. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

The value of *DefPriority* is copied into the *MDPRI* field when the message is put. If *DefPriority* is changed subsequently, messages that have already been put are not affected.

The value returned by the MQGET call is always greater than or equal to zero; the value PRQDEF is never returned.

If a message is put with a priority greater than the maximum supported by the local queue manager (this maximum is given by the *MaxPriority* queue manager attribute), the message is accepted by the queue manager, but placed on the queue at the queue manager's maximum priority; the MQPUT or MQPUT1 call completes with CCWARN and reason code RC2049. However, the *MDPRI* field retains the value specified by the application which put the message.

When replying to a message, applications should normally use for the reply message the priority of the request message. In other situations, specifying PRQDEF allows priority tuning to be carried out without changing the application.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is PRQDEF.

MDPT (8-byte character string)

Time when message was put.

This is part of the **origin context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

The format used for the time when this field is generated by the queue manager is:

- HHMMSSSTH

where the characters represent (in order):

HH

hours (00 through 23)

MM

minutes (00 through 59)

SS

seconds (00 through 59; see [note](#))

T

tenths of a second (0 through 9)

H

hundredths of a second (0 through 9)

Note: If the system clock is synchronized to a very accurate time standard, it is possible on rare occasions for 60 or 61 to be returned for the seconds in *MDPT*. This happens when leap seconds are inserted into the global time standard.

Greenwich Mean Time (GMT) is used for the *MDPD* and *MDPT* fields, subject to the system clock being set accurately to GMT.

If the message was put as part of a unit of work, the time is that when the message was put, and not the time when the unit of work was committed.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETA is specified in the *PMO* parameter. The contents of the field are not checked by the queue manager, except that any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDPT* that was transmitted with the message if it was put to a queue. This will be the value of *MDPT* that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDPT* when the message is sent as a publication to subscribers since they provide a value to override *MDPT* in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNPTIM. The initial value of this field is 8 blank characters.

MDREP (10-digit signed integer)

Options for report messages.

A report message is a message about another message, used to inform an application about expected or unexpected events that relate to the original message. The *MDREP* field enables the application sending the original message to specify which report messages are required, whether the application message data is to be included in them, and also (for both reports and replies) how the message and correlation identifiers in the report or reply message are to be set. Any or all (or none) of the following types of report message can be requested:

- Exception
- Expiration
- Confirm on arrival (COA)
- Confirm on delivery (COD)
- Positive action notification (PAN)
- Negative action notification (NAN)

If more than one type of report message is required, or other report options are needed, the values can be added together (do not add the same constant more than once).

The application that receives the report message can determine the reason the report was generated by examining the *MDFB* field in the MQMD; see the *MDFB* field for more details.

The use of report options when putting a message to a topic can cause zero, one or many report messages to be generated and sent to the application. This is because the publication message may be sent to zero, one or many subscribing applications.

Exception options: You can specify one of the following options to request an exception report message.

ROACTIVITY

Activity reports required

This report option enables an activity report to be generated, whenever a message with this report option set is processed by supporting applications.

Messages with this report option set must be accepted by any queue manager, even if they do not 'understand' the option. This allows the report option to be set on any user message, even if they are processed by previous queue managers. To achieve this, the report option is placed in the ROAUM subfield.

If a process (either a queue manager or a user process) performs an Activity on a message with ROACT set, it can choose to generate and put an activity report.

The activity report option allows the route of any message to be traced throughout a queue manager network. The report option can be specified on any current user message and instantly they can begin to calculate the route of the message through the network. If the application generating the message cannot switch on activity reports, it can be turned on by using an API crossing exit supplied by queue manager administrators.

Several conditions are applicable to activity reports:

1. The route will be less detailed if there are fewer queue managers in the network which are able to generate activity reports.
2. The activity reports may not be easily 'orderable' in order to determine the route taken.
3. The activity reports may not be able to find a route to their requested destination.

ROEXC

Exception reports required.

This type of report can be generated by a message channel agent when a message is sent to another queue manager and the message cannot be delivered to the specified destination queue. For example, the destination queue or an intermediate transmission queue might be full, or the message might be too big for the queue.

Generation of the exception report message depends on the persistence of the original message, and the speed of the message channel (normal or fast) through which the original message travels:

- For all persistent messages, and for nonpersistent messages traveling through normal message channels, the exception report is generated *only* if the action specified by the sending application for the error condition can be completed successfully. The sending application can specify one of the following actions to control the disposition of the original message when the error condition arises:

- RODLQ (this causes the original message to be placed on the dead-letter queue).
- RODISC (this causes the original message to be discarded).

If the action specified by the sending application cannot be completed successfully, the original message is left on the transmission queue, and no exception report message is generated.

- For nonpersistent messages traveling through fast message channels, the original message is removed from the transmission queue and the exception report generated *even if* the specified action for the error condition cannot be completed successfully. For example, if RODLQ is specified, but the original message cannot be placed on the dead-letter queue because (say) that queue is full, the exception report message is generated and the original message discarded.

See [Message persistence](#) for more information about normal and fast message channels.

An exception report is not generated if the application that put the original message can be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call.

Applications can also send exception reports, to indicate that a message that it has received cannot be processed (for example, because it is a debit transaction that would cause the account to exceed its credit limit).

Message data from the original message is not included with the report message.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

ROEXCD

Exception reports with data required.

This is the same as ROEXC, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

ROEXCF

Exception reports with full data required.

This is the same as ROEXC, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROEXC, ROEXCD, and ROEXCF.

Expiration options: You can specify one of the following options to request an expiration report message.

ROEXP

Expiration reports required.

This type of report is generated by the queue manager if the message is discarded before delivery to an application because its expiry time has passed (see the *MDEXP* field). If this option is not set, no report message is generated if a message is discarded for this reason (even if one of the ROEXC* options is specified).

Message data from the original message is not included with the report message.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

ROEXPD

Expiration reports with data required.

This is the same as ROEXP, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

ROEXPF

Expiration reports with full data required.

This is the same as ROEXP, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROEXP, ROEXPD, and ROEXPF.

Confirm-on-arrival options: You can specify one of the following options to request a confirm-on-arrival report message.

ROCOA

Confirm-on-arrival reports required.

This type of report is generated by the queue manager that owns the destination queue, when the message is placed on the destination queue. Message data from the original message is not included with the report message.

If the message is put as part of a unit of work, and the destination queue is a local queue, the COA report message generated by the queue manager becomes available for retrieval only if and when the unit of work is committed.

A COA report is not generated if the *MDFMT* field in the message descriptor is FMXQH or FMDLH. This prevents a COA report being generated if the message is put on a transmission queue, or is undeliverable and put on a dead-letter queue.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

ROCOAD

Confirm-on-arrival reports with data required.

This is the same as ROCOA, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

ROCOAF

Confirm-on-arrival reports with full data required.

This is the same as ROCOA, except that all of the application message data from the original message is included in the report message.

Do not specify more than one of ROCOA, ROCOAD, and ROCOAF.

Discard and expiry options: You can specify the following option to set the expiry time and discard flag for report messages.

ROPDAE

Set report message expiry time and discard flag.

This option ensures that report messages and reply messages inherit the expiry time and discard flag (whether to discard or not), from their original messages. With this option set, report and reply messages:

1. Inherit the RODISC flag (if it was set).
2. Inherit the remaining expiry time of the message, if the message is not an expiry report. If the message is an expiry report, the expiry time is set to 60 seconds.

With this option set, the following applies:

Note:

1. Report and reply messages are generated with a discard flag and an expiry value, and cannot remain within the system.
2. Trace route messages are prevented from reaching destination queues on non-trace route enabled queue managers.
3. Queues are prevented from being filled with reports that cannot be delivered, if communications links are broken.
4. Command server responses inherit the remaining expiry of the request.

Confirm-on-delivery options: You can specify one of the following options to request a confirm-on-delivery report message.

ROCOD

Confirm-on-delivery reports required.

This type of report is generated by the queue manager when an application retrieves the message from the destination queue in a way that causes the message to be deleted from the queue. Message data from the original message is not included with the report message.

If the message is retrieved as part of a unit of work, the report message is generated within the same unit of work, so that the report is not available until the unit of work is committed. If the unit of work is backed out, the report is not sent.

A COD report is not generated if the *MDFMT* field in the message descriptor is *FMDLH*. This prevents a COD report being generated if the message is undeliverable and put on a dead-letter queue.

ROCOD is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

ROCODD

Confirm-on-delivery reports with data required.

This is the same as ROCOD, except that the first 100 bytes of the application message data from the original message are included in the report message. If the original message contains one or more MQ header structures, they are included in the report message, in addition to the 100 bytes of application data.

If GMATM is specified on the MQGET call for the original message, and the message retrieved is truncated, the amount of application message data placed in the report message is the minimum of:

- The length of the original message
- 100 bytes.

ROCODD is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

ROCODF

Confirm-on-delivery reports with full data required.

This is the same as ROCOD, except that all of the application message data from the original message is included in the report message.

ROCODF is not valid if the destination queue is an XCF queue.

Do not specify more than one of ROCOD, ROCODD, and ROCODF.

Action-notification options: You can specify one or both of the following options to request that the receiving application send a positive-action or negative-action report message.

ROPAN

Positive action notification reports required.

This type of report is generated by the application that retrieves the message and acts upon it. It indicates that the action requested in the message has been performed successfully. The application generating the report determines whether any data is to be included with the report.

Other than conveying this request to the application retrieving the message, the queue manager takes no action based upon this option. It is the responsibility of the retrieving application to generate the report if appropriate.

RONAN

Negative action notification reports required.

This type of report is generated by the application that retrieves the message and acts upon it. It indicates that the action requested in the message has *not* been performed successfully. The application generating the report determines whether any data is to be included with the report. For example, it may be desirable to include some data indicating why the request could not be performed.

Other than conveying this request to the application retrieving the message, the queue manager takes no action based upon this option. It is the responsibility of the retrieving application to generate the report if appropriate.

Determination of which conditions correspond to a positive action and which correspond to a negative action is the responsibility of the application. However, it is recommended that if the request has been only partially performed, a NAN report rather than a PAN report should be generated if requested. It is also recommended that every possible condition should correspond to either a positive action, or a negative action, but not both.

Message-identifier options: You can specify one of the following options to control how the *MDMID* of the report message (or of the reply message) is to be set.

RONMI

New message identifier.

This is the default action, and indicates that if a report or reply is generated as a result of this message, a new *MDMID* is to be generated for the report or reply message.

ROPMI

Pass message identifier.

If a report or reply is generated as a result of this message, the *MDMID* of this message is to be copied to the *MDMID* of the report or reply message.

The *MsgId* of a publication message will be different for each subscriber that receives a copy of the publication and therefore the *MsgId* copied into the report or reply message will be different for each one.

If this option is not specified, RONMI is assumed.

Correlation-identifier options: You can specify one of the following options to control how the *MDCID* of the report message (or of the reply message) is to be set.

ROCMTC

Copy message identifier to correlation identifier.

This is the default action, and indicates that if a report or reply is generated as a result of this message, the *MDMID* of this message is to be copied to the *MDCID* of the report or reply message.

The *MsgId* of a publication message will be different for each subscriber that receives a copy of the publication and therefore the *MsgId* copied into the *CorrelId* of the report or reply message will be different for each one.

ROPICI

Pass correlation identifier.

If a report or reply is generated as a result of this message, the *MDCID* of this message is to be copied to the *MDCID* of the report or reply message.

The *MDCID* of a publication message will be specific to a subscriber unless it uses the *SOSCID* option and sets the *SCDIC* field in the MQSD to CINONE. Therefore it is possible that the *MDCID* copied into the *MDCID* of the report or reply message will be different for each one.

If this option is not specified, ROCMTC is assumed.

Servers replying to requests or generating report messages are recommended to check whether the ROPMI or ROPICI options were set in the original message. If they were, the servers should take the action described for those options. If neither is set, the servers should take the corresponding default action.

: You can specify one of the following options to control the disposition of the original message when it cannot be delivered to the destination queue. These options apply only to those situations that would result in an exception report message being generated if one had been requested by the sending application. The application can set the disposition options independently of requesting exception reports.

RODLQ

Place message on dead-letter queue.

This is the default action, and indicates that the message should be placed on the dead-letter queue, if the message cannot be delivered to the destination queue. This happens in the following situations:

- When the application that put the original message cannot be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call. An exception report message is generated, if one was requested by the sender.
- When the application that put the original message was putting to a topic

An exception report message will be generated, if one was requested by the sender.

RODISC

Discard message.

This indicates that the message should be discarded if it cannot be delivered to the destination queue. This happens in the following situations:

- When the application that put the original message cannot be notified synchronously of the problem by means of the reason code returned by the MQPUT or MQPUT1 call. An exception report message is generated, if one was requested by the sender.
- When the application that put the original message was putting to a topic

An exception report message will be generated, if one was requested by the sender.

If it is desired to return the original message to the sender, without the original message being placed on the dead-letter queue, the sender should specify RODISC with ROEXCF.

Default option: You can specify the following if no report options are required:

RONONE

No reports required.

This value can be used to indicate that no other options have been specified. RONONE is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

General information:

1. All report types required must be specifically requested by the application sending the original message. For example, if a COA report is requested but an exception report is not, a COA report is generated when the message is placed on the destination queue, but no exception report is generated if the destination queue is full when the message arrives there. If no *MDREP* options are set, no report messages are generated by the queue manager or message channel agent (MCA).

Some report options can be specified even though the local queue manager does not recognize them; this is useful when the option is to be processed by the *destination* queue manager. See [“Report options and message flags” on page 1388](#) for more details.

If a report message is requested, the name of the queue to which the report should be sent must be specified in the *MDRQ* field. When a report message is received, the nature of the report can be determined by examining the *MDFB* field in the message descriptor.

2. If the queue manager or MCA that generates a report message is unable to put the report message on the reply queue (for example, because the reply queue or transmission queue is full), the report message is placed instead on the dead-letter queue. If that *also* fails, or there is no dead-letter queue, the action taken depends on the type of the report message:
 - If the report message is an exception report, the message which caused the exception report to be generated is left on its transmission queue; this ensures that the message is not lost.
 - For all other report types, the report message is discarded and processing continues normally. This is done because either the original message has already been delivered safely (for COA or COD report messages), or is no longer of any interest (for an expiration report message).

Once a report message has been placed successfully on a queue (either the destination queue or an intermediate transmission queue), the message is no longer subject to special processing; it is treated just like any other message.

3. When the report is generated, the *MDRQ* queue is opened and the report message put using the authority of the *MDUID* in the MQMD of the message causing the report, except in the following cases:
 - Exception reports generated by a receiving MCA are put with whatever authority the MCA used when it tried to put the message causing the report. The *CDPA* channel attribute determines the user identifier used.
 - COA reports generated by the queue manager are put with whatever authority was used when the message causing the report was put on the queue manager generating the report. For example, if the message was put by a receiving MCA using the MCA's user identifier, the queue manager puts the COA report using the MCA's user identifier.

Applications generating reports should normally use the same authority as they would have used to generate a reply; this should normally be the authority of the user identifier in the original message.

If the report has to travel to a remote destination, senders and receivers can decide whether to accept it, in the same way as they do for other messages.

4. If a report message with data is requested:
 - The report message is always generated with the amount of data requested by the sender of the original message. If the report message is too big for the reply queue, the processing described previously occurs; the report message is never truncated in order to fit on the reply queue.
 - If the *MDFMT* of the original message is *FMXQH*, the data included in the report does not include the *MQXQH*. The report data starts with the first byte of the data beyond the *MQXQH* in the original message. This occurs whether the queue is a transmission queue.
5. If a COA, COD, or expiration report message is received at the reply queue, it is guaranteed that the original message arrived, was delivered, or expired, as appropriate. However, if one or more of these report messages is requested and is *not* received, the reverse cannot be assumed, since one of the following may have occurred:
 - a. The report message is held up because a link is down.
 - b. The report message is held up because a blocking condition exists at an intermediate transmission queue or at the reply queue (for example, the queue is full or inhibited for puts).
 - c. The report message is on a dead-letter queue.
 - d. When the queue manager was attempting to generate the report message, it was unable to put it on the appropriate queue, and was also unable to put it on the dead-letter queue, so the report message could not be generated.
 - e. A failure of the queue manager occurred between the action being reported (arrival, delivery or expiry), and generation of the corresponding report message. (This does not happen for COD report messages if the application retrieves the original message within a unit of work, as the COD report message is generated within the same unit of work.)

Exception report messages may be held up in the same way for reasons 1, 2, and 3 previously. However, when an MCA is unable to generate an exception report message (the report message cannot be put either on the reply queue or the dead-letter queue), the original message remains on the transmission queue at the sender, and the channel is closed. This occurs irrespective of whether the report message was to be generated at the sending or the receiving end of the channel.

6. If the original message is temporarily blocked (resulting in an exception report message being generated and the original message being put on a dead-letter queue), but the blockage clears and an application then reads the original message from the dead-letter queue and puts it again to its destination, the following may occur:

- Even though an exception report message has been generated, the original message eventually arrives successfully at its destination.
- More than one exception report message is generated in respect of a single original message, since the original message may encounter another blockage later.

Report messages when putting to a topic:

1. Reports can be generated when putting a message to a topic. This message will be sent to all subscribers to the topic, which could be zero, one or many. This should be taken into account when choosing to use report options as many report messages could be generated as a result.
2. When putting a message to a topic, there may be many destination queues that are to be given a copy of the message. If some of these destination queues have a problem, such as queue full, then the successful completion of the MQPUT depends on the setting of NPMMSGDLV or PMSGDLV (depending on the persistence of the message). If the setting is such that message delivery to the destination queue must be successful (for example, it is a persistent message to a durable subscriber and PMSGDLV is set to ALL or ALLDUR), then success is defined as one of the following criteria being met:
 - Successful put to the subscriber queue
 - Use of RODLQ and a successful put to the Dead-letter queue if the subscriber queue cannot take the message
 - Use of RODISC if the subscriber queue cannot take the message.

Report messages for message segments:

1. Report messages can be requested for messages that have segmentation allowed (see the description of the MFSEGA flag). If the queue manager finds it necessary to segment the message, a report message can be generated for each of the segments that subsequently encounters the relevant condition. Applications should therefore be prepared to receive multiple report messages for each type of report message requested. The *MDGID* field in the report message can be used to correlate the multiple reports with the group identifier of the original message, and the *MDFB* field used to identify the type of each report message.
2. If GMLOGO is used to retrieve report messages for segments, be aware that reports of *different types* may be returned by the successive MQGET calls. For example, if both COA and COD reports are requested for a message that is segmented by the queue manager, the MQGET calls for the report messages may return the COA and COD report messages interleaved in an unpredictable fashion. This can be avoided by using the GMCMPM option (optionally with GMATM). GMCMPM causes the queue manager to reassemble report messages that have the same report type. For example, the first MQGET call might reassemble all of the COA messages relating to the original message, and the second MQGET call might reassemble all of the COD messages. Which is reassembled first depends on which type of report message happens to occur first on the queue.
3. Applications that themselves put segments can specify different report options for each segment. However, the following points should be noted:
 - If the segments are retrieved using the GMCMPM option, only the report options in the *first* segment are honored by the queue manager.
 - If the segments are retrieved one by one, and most of them have one of the ROCOD* options, but at least one segment does not, it will not be possible to use the GMCMPM option to retrieve the report messages with a single MQGET call, or use the GMASGA option to detect when all of the report messages have arrived.
4. In an MQ network, it is possible for the queue managers to have differing capabilities. If a report message for a segment is generated by a queue manager or MCA that does not support segmentation, the queue manager or MCA will not by default include the necessary segment information in the report message, and this may make it difficult to identify the original message that caused the report to be generated. This difficulty can be avoided by requesting data with the report message, that is, by specifying the appropriate RO*D or RO*F options. However, be aware that if RO*D is specified, *less than* 100 bytes of application message data may be returned to the

application which retrieves the report message, if the report message is generated by a queue manager or MCA that does not support segmentation.

Contents of the message descriptor for a report message: When the queue manager or message channel agent (MCA) generates a report message, it sets the fields in the message descriptor to the following values, and then puts the message in the normal way.

Field in MQMD	Value used
<i>MDSID</i>	MDSIDV
<i>MDVER</i>	MDVER2
<i>MDREP</i>	RONONE
<i>MDMT</i>	MTRPRT
<i>MDEXP</i>	EIULIM
<i>MDFB</i>	As appropriate for the nature of the report (FBCOA, FBCOD, FBEXP, or an RC* value)
<i>MDENC</i>	Copied from the original message descriptor
<i>MDCSI</i>	Copied from the original message descriptor
<i>MDFMT</i>	Copied from the original message descriptor
<i>MDPRI</i>	Copied from the original message descriptor
<i>MDPER</i>	Copied from the original message descriptor
<i>MDMID</i>	As specified by the report options in the original message descriptor
<i>MDCID</i>	As specified by the report options in the original message descriptor
<i>MDBOC</i>	0
<i>MDRQ</i>	Blanks
<i>MDRM</i>	Name of queue manager
<i>MDUID</i>	As set by the PMPASI option
<i>MDACC</i>	As set by the PMPASI option
<i>MDAID</i>	As set by the PMPASI option
<i>MDPAT</i>	ATQM, or as appropriate for the message channel agent
<i>MDPAN</i>	First 28 bytes of the queue manager name or message channel agent name. For report messages generated by the IMS bridge, this field contains the XCF group name and XCF member name of the IMS system to which the message relates.
<i>MDPD</i>	Date when report message is sent
<i>MDPT</i>	Time when report message is sent
<i>MDAOD</i>	Blanks
<i>MDGID</i>	Copied from the original message descriptor
<i>MDSEQ</i>	Copied from the original message descriptor
<i>MDOFF</i>	Copied from the original message descriptor
<i>MDMFL</i>	Copied from the original message descriptor
<i>MDOLN</i>	Copied from the original message descriptor if not OLUNDF, and set to the length of the original message data otherwise

An application generating a report is recommended to set similar values, except for the following:

- The *MDRM* field can be set to blanks (the queue manager will change this to the name of the local queue manager when the message is put).
- The context fields should be set using the option that would have been used for a reply, normally PMPASI.

Analyzing the report field: The *MDREP* field contains subfields; because of this, applications that need to check whether the sender of the message requested a particular report should use one of the techniques described in [“Analyzing the report field”](#) on page 1389.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The initial value of this field is RNONE.

MDRM (48-byte character string)

Name of reply queue manager.

This is the name of the queue manager to which the reply message or report message should be sent. *MDRQ* is the local name of a queue that is defined on this queue manager.

If the *MDRM* field is blank, the local queue manager looks up the *MDRQ* name in its queue definitions. If a local definition of a remote queue exists with this name, the *MDRM* value in the transmitted message is replaced by the value of the *RemoteQMGrName* attribute from the definition of the remote queue, and this value will be returned in the message descriptor when the receiving application issues an MQGET call for the message. If a local definition of a remote queue does not exist, the *MDRM* that is transmitted with the message is the name of the local queue manager.

If the name is specified, it may contain trailing blanks; the first null character and characters following it are treated as blanks. Otherwise, however, no check is made that the name satisfies the naming rules for queue managers, or that this name is known to the sending queue manager; this is also true for the name transmitted, if the *MDRM* is replaced in the transmitted message.

If a reply-to queue is not required, it is recommended (although this is not checked) that the *MDRM* field should be set to blanks; the field should not be left uninitialized.

For the MQGET call, the queue manager always returns the name padded with blanks to the length of the field.

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNQMNM. The initial value of this field is 48 blank characters.

MDRQ (48-byte character string)

Name of reply queue.

This is the name of the message queue to which the application that issued the get request for the message should send MTRPLY and MTRPRT messages. The name is the local name of a queue that is defined on the queue manager identified by *MDRM*. This queue should not be a model queue, although the sending queue manager does not verify this when the message is put.

For the MQPUT and MQPUT1 calls, this field must not be blank if the *MDMT* field has the value MTRQST, or if any report messages are requested by the *MDREP* field. However, the value specified (or substituted) is passed on to the application that issues the get request for the message, whatever the message type.

If the *MDRM* field is blank, the local queue manager looks up the *MDRQ* name in its own queue definitions. If a local definition of a remote queue exists with this name, the *MDRQ* value in the transmitted message is replaced by the value of the *RemoteQName* attribute from the definition of the remote queue, and this value will be returned in the message descriptor when the receiving application issues an MQGET call for the message. If a local definition of a remote queue does not exist, *MDRQ* is unchanged.

If the name is specified, it may contain trailing blanks; the first null character and characters following it are treated as blanks. Otherwise, however, no check is made that the name satisfies the naming

rules for queues; this is also true for the name transmitted, if the *MDRQ* is replaced in the transmitted message. The only check made is that a name has been specified, if the circumstances require it.

If a reply-to queue is not required, it is recommended (although this is not checked) that the *MDRQ* field should be set to blanks; the field should not be left uninitialized.

For the MQGET call, the queue manager always returns the name padded with blanks to the length of the field.

If a message that requires a report message cannot be delivered, and the report message also cannot be delivered to the queue specified, both the original message and the report message go to the dead-letter (undelivered-message) queue (see the *DeadLetterQName* attribute described in [“Attributes for the queue manager” on page 1355](#)).

This is an output field for the MQGET call, and an input field for the MQPUT and MQPUT1 calls. The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

MDSEQ (10-digit signed integer)

Sequence number of logical message within group.

Sequence numbers start at 1, and increase by 1 for each new logical message in the group, up to a maximum of 999 999 999. A physical message which is not in a group has a sequence number of 1.

This field need not be set by the application on the MQPUT or MQGET call if:

- On the MQPUT call, PMLOGO is specified.
- On the MQGET call, MOSEQN is *not* specified.

These are the recommended ways of using these calls for messages that are not report messages. However, if the application requires more control, or the call is MQPUT1, the application must ensure that *MDSEQ* is set to an appropriate value.

On input to the MQPUT and MQPUT1 calls, the queue manager uses the value detailed in [Table 1](#). On output from the MQPUT and MQPUT1 calls, the queue manager sets this field to the value that was sent with the message.

On input to the MQGET call, the queue manager uses the value detailed in [Table 1](#). On output from the MQGET call, the queue manager sets this field to the value for the message retrieved.

The initial value of this field is one. This field is ignored if *MDVER* is less than MDVER2.

MDSID (4-byte character string)

Structure identifier.

The value must be:

MDSIDV

Identifier for message descriptor structure.

This is always an input field. The initial value of this field is MDSIDV.

MDUID (12-byte character string)

User identifier.

This is part of the **identity context** of the message. For more information about message context, see [Message context](#) and [Controlling context information](#).

MDUID specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it.

After a message has been received, *MDUID* can be used in the *ODAU* field of the *OBJDSC* parameter of a subsequent MQOPEN or MQPUT1 call, so that the authorization check is performed for the *MDUID* user instead of the application performing the open.

When the queue manager generates this information for an MQPUT or MQPUT1 call, the queue manager uses a user identifier determined from the environment.

When the user identifier is determined from the environment:

- On z/OS, the queue manager uses:
 - For batch, the user identifier from the JES JOB card or started task
 - For TSO, the log on user identifier
 - For CICS, the user identifier associated with the task
 - For IMS, the user identifier depends on the type of application:
 - For:
 - Nonmessage BMP regions
 - Nonmessage IFP regions
 - Message BMP and message IFP regions that have *not* issued a successful GU callthe queue manager uses the user identifier from the region JES JOB card or the TSO user identifier. If these are blank or null, it uses the name of the program specification block (PSB).
 - For:
 - Message BMP and message IFP regions that *have* issued a successful GU call
 - MPP regionsthe queue manager uses one of:
 - The signed-on user identifier associated with the message
 - The logical terminal (LTERM) name
 - The user identifier from the region JES JOB card
 - The TSO user identifier
 - The PSB name
- On IBM i, the queue manager uses the name of the user profile associated with the application job.
- On HP Integrity NonStop Server, the queue manager uses the MQSeries principal that is defined for the Tandem user identifier in the MQSeries principal database.
- On UNIX systems, the queue manager uses:
 - The application's logon name
 - The effective user identifier of the process if no logon is available
 - The user identifier associated with the transaction, if the application is a CICS transaction
- On VSE/ESA, this is a reserved field.
- On Windows, the queue manager uses the first 12 characters of the logged-on user name.

For the MQPUT and MQPUT1 calls, this is an input/output field if PMSETI or PMSETA is specified in the *PMO* parameter. Any information following a null character within the field is discarded. The null character and any following characters are converted to blanks by the queue manager. If PMSETI or PMSETA is not specified, this field is ignored on input and is an output-only field.

After the successful completion of an MQPUT or MQPUT1 call, this field contains the *MDUID* that was transmitted with the message if it was put to a queue. This will be the value of *MDUID* that is kept with the message if it is retained (see description of PMRET for more details about retained publications) but is not used as the *MDUID* when the message is sent as a publication to subscribers since they provide a value to override *MDUID* in all publications sent to them. If the message has no context, the field is entirely blank.

This is an output field for the MQGET call. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

MDVER (10-digit signed integer)

Structure version number.

The value must be one of the following:

MDVER1

Version-1 message descriptor structure.

MDVER2

Version-2 message descriptor structure.

Note: When a version-2 MQMD is used, the queue manager performs additional checks on any MQ header structures that may be present at the beginning of the application message data; for further details see the usage notes for the MQPUT call.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

MDVERC

Current version of message descriptor structure.

This is always an input field. The initial value of this field is MDVER1.

Initial values

Table 598. Initial values of fields in MQMD		
Field name	Name of constant	Value of constant
MDSID	MDSIDV	'MD--'
MDVER	MDVER1	1

MQMDE - Message descriptor extension

Overview

Purpose: The MQMDE structure describes the data that sometimes occurs preceding the application message data. The structure contains those MQMD fields that exist in the version-2 MQMD, but not in the version-1 MQMD.

Format name: FMMDE.

Character set and encoding: Data in MQMDE must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQMDE must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQMDE structure is at the start of the message data), or
- The header structure that precedes the MQMDE structure (all other cases).

If the MQMDE is not in the queue manager's character set and encoding, the MQMDE is accepted but not honored, that is, the MQMDE is treated as message data.

Usage: Normal applications should use a version-2 MQMD, in which case they will not encounter an MQMDE structure. However, specialized applications, and applications that continue to use a version-1 MQMD, may encounter an MQMDE in some situations. The MQMDE structure can occur in the following circumstances:

- Specified on the MQPUT and MQPUT1 calls
- Returned by the MQGET call
- In messages on transmission queues
- [“MQMDE specified on MQPUT and MQPUT1 calls” on page 1111](#)
- [“MQMDE returned by MQGET call” on page 1112](#)
- [“MQMDE in messages on transmission queues” on page 1112](#)
- [“Fields” on page 1113](#)
- [“Initial values” on page 1115](#)
- [“RPG declaration” on page 1115](#)

MQMDE specified on MQPUT and MQPUT1 calls

On the MQPUT and MQPUT1 calls, if the application provides a version-1 MQMD, the application can optionally prefix the message data with an MQMDE, setting the *MDFMT* field in MQMD to FMMDE to indicate that an MQMDE is present. If the application does not provide an MQMDE, the queue manager

assumes default values for the fields in the MQMDE. The default values that the queue manager uses are the same as the initial values for the structure - see [Table 600 on page 1115](#).

If the application provides a version-2 MQMD *and* prefixes the application message data with an MQMDE, the structures are processed as shown in [Table 599 on page 1112](#).

<i>Table 599. Queue-manager action when MQMDE specified on MQPUT or MQPUT1</i>			
MQMD version	Values of version-2 fields	Values of corresponding fields in MQMDE	Action taken by queue manager
1	-	Valid	MQMDE is honored
2	Default	Valid	MQMDE is honored
2	Not default	Valid	MQMDE is treated as message data
1 or 2	Any	Not valid	Call fails with an appropriate reason code
1 or 2	Any	MQMDE is in the wrong character set or encoding, or is an unsupported version	MQMDE is treated as message data

There is one special case. If the application uses a version-2 MQMD to put a message that is a segment (that is, the MFSEG or MFLSEG flag is set), and the format name in the MQMD is FMDLH, the queue manager generates an MQMDE structure and inserts it *between* the MQDLH structure and the data that follows it. In the MQMD that the queue manager retains with the message, the version-2 fields are set to their default values.

Several of the fields that exist in the version-2 MQMD but not the version-1 MQMD are input/output fields on MQPUT and MQPUT1. However, the queue manager does *not* return any values in the equivalent fields in the MQMDE on output from the MQPUT and MQPUT1 calls; if the application requires those output values, it must use a version-2 MQMD.

MQMDE returned by MQGET call

On the MQGET call, if the application provides a version-1 MQMD, the queue manager prefixes the message returned with an MQMDE, but only if one or more of the fields in the MQMDE has a nondefault value. The queue manager sets the *MDFMT* field in MQMD to the value FMMDE to indicate that an MQMDE is present.

If the application provides an MQMDE at the start of the *BUFFER* parameter, the MQMDE is ignored. On return from the MQGET call, it is replaced by the MQMDE for the message (if one is needed), or overwritten by the application message data (if the MQMDE is not needed).

If an MQMDE is returned by the MQGET call, the data in the MQMDE is typically in the queue manager's character set and encoding. However the MQMDE may be in some other character set and encoding if:

- The MQMDE was treated as data on the MQPUT or MQPUT1 call (see [Table 599 on page 1112](#) for the circumstances that can cause this).
- The message was received from a remote queue manager connected by a TCP connection, and the receiving message channel agent (MCA) was not set up correctly (see [Security of IBM MQ for IBM i objects](#) for further information).

MQMDE in messages on transmission queues

Messages on transmission queues are prefixed with the MQXQH structure, which contains within it a version-1 MQMD. An MQMDE may also be present, positioned between the MQXQH structure and

application message data, but it will typically be present only if one or more of the fields in the MQMDE has a nondefault value.

Other IBM MQ header structures can also occur between the MQXQH structure and the application message data. For example, when the dead-letter header MQDLH is present, and the message is not a segment, the order is:

- MQXQH (containing a version-1 MQMD)
- MQMDE
- MQDLH
- Application message data

Fields

The MQMDE structure contains the following fields; the fields are described in **alphabetical order**:

MECSI (10-digit signed integer)

Character-set identifier of data that follows MQMDE.

This specifies the character set identifier of the data that follows the MQMDE structure; it does not apply to character data in the MQMDE structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that this field is valid. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

MEENC (10-digit signed integer)

MEENC (10-digit signed integer)

This specifies the numeric encoding of the data that follows the MQMDE structure; it does not apply to numeric data in the MQMDE structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that the field is valid. See the *MDENC* field described in [“MQMD - Message descriptor” on page 1068](#) for more information about data encodings.

The initial value of this field is ENNAT.

MEFLG (10-digit signed integer)

General flags.

The following flag can be specified:

MEFNON

No flags.

The initial value of this field is MEFNON.

MEFMT (8-byte character string)

Format name of data that follows MQMDE.

This specifies the format name of the data that follows the MQMDE structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The queue manager does not check that this field is valid. See the *MDFMT* field described in [“MQMD - Message descriptor”](#) on page 1068 for more information about format names.

The initial value of this field is FMNONE.

MEGID (24-byte bit string)

Group identifier.

See the *MDGID* field described in [“MQMD - Message descriptor”](#) on page 1068. The initial value of this field is GINONE.

MELEN (10-digit signed integer)

Length of MQMDE structure.

The following value is defined:

MELEN2

Length of version-2 message descriptor extension structure.

The initial value of this field is MELEN2.

MEMFL (10-digit signed integer)

Message flags.

See the *MDMFL* field described in [“MQMD - Message descriptor”](#) on page 1068. The initial value of this field is MFNONE.

MEOFF (10-digit signed integer)

Offset of data in physical message from start of logical message.

See the *MDOFF* field described in [“MQMD - Message descriptor”](#) on page 1068. The initial value of this field is 0.

MEOLN (10-digit signed integer)

Length of original message.

See the *MDOLN* field described in [“MQMD - Message descriptor”](#) on page 1068. The initial value of this field is OLUNDF.

MESEQ (10-digit signed integer)

Sequence number of logical message within group.

See the *MDSEQ* field described in [“MQMD - Message descriptor”](#) on page 1068. The initial value of this field is 1.

MESID (4-byte character string)

Structure identifier.

The value must be:

MESIDV

Identifier for message descriptor extension structure.

The initial value of this field is MESIDV.

MEVER (10-digit signed integer)

Structure version number.

The value must be:

MEVER2

Version-2 message descriptor extension structure.

The following constant specifies the version number of the current version:

MEVERC

Current version of message descriptor extension structure.

The initial value of this field is MEVER2.

Initial values

Table 600. Initial values of fields in MQMDE		
Field name	Name of constant	Value of constant
MESID	MESIDV	'MDE¬'
MEVER	MEVER2	2
MELEN	MELEN2	72
MEENC	ENNAT	Depends on environment
MECSI	CSUNDF	0
MEFMT	FMNONE	Blanks
MEFLG	MEFNON	0
MEGID	GINONE	Nulls
MESEQ	None	1
MEOFF	None	0
MEMFL	MFNONE	0
MEOLN	OLUNDF	-1
Notes:		
1. The symbol ¬ represents a single blank character.

MQMHBO - Message handle to buffer options

Structure defining the message handle to buffer options

Overview

Purpose: The MQMHBO structure allows applications to specify options that control how buffers are produced from message handles. The structure is an input parameter on the MQMHBUF call.

Character set and encoding: Data in MQMHBO must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1116](#)
- [“Initial values” on page 1117](#)
- [“RPG declaration” on page 1117](#)

Fields

The MQMHBO structure contains the following fields; the fields are described in **alphabetical order**:

MBOPT (10-digit signed integer)

Message handle to buffer options structure - MBOPT field.

These options control the action of MQMHBUF.

You must specify the following option:

MBPRRF

When converting properties from a message handle into a buffer, convert them into the MQRFH2 format.

Optionally, you can also specify the following option. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

MBDLPR

Properties that are added to the buffer are deleted from the message handle. If the call fails no properties are deleted.

This is always an input field. The initial value of this field is MBPRRF.

MBSID (10-digit signed integer)

Message handle to buffer options structure - MBSID field.

This is the structure identifier. The value must be:

MBSIDV

Identifier for message handle to buffer options structure.

This is always an input field. The initial value of this field is MBSIDV.

MBVER (10-digit signed integer)

This is the structure version number. The value must be:

MBVER1

Version number for message handle to buffer options structure.

The following constant specifies the version number of the current version:

MBVERC

Current version of message handle to buffer options structure.

This is always an input field. The initial value of this field is MBVER1.

Initial values

Table 601. Initial values of fields in MQMHBO		
Field name	Name of constant	Value of constant
MVSID	MBSIDV	'MHBO'
MBVER	MBVER1	1
MBOPT	MBPRRF	

Notes:

1. The value Null string or blanks denotes a blank character.

MQOD - Object descriptor

The MQOD structure is used to specify an object by name.

Overview

Purpose: The following types of object are valid:

- Queue or distribution list
- Namelist
- Process definition
- Queue manager
- Topic

The structure is an input/output parameter on the MQOPEN and MQPUT1 calls.

Version: The current version of MQOD is ODVER4. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQOD that is supported by the environment, but with the initial value of the *ODVER* field set to ODVER1. To use fields that are not present in the version-1 structure, the application must set the *ODVER* field to the version number of the version required.

To open a distribution list, *ODVER* must be ODVER2 or greater.

Character set and encoding: Data in MQOD must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1118](#)

- [“Initial values” on page 1125](#)
- [“RPG declaration” on page 1125](#)

Fields

The MQOD structure contains the following fields; the fields are described in **alphabetical order**:

ODASI (40-byte bit string)

Alternate security identifier.

This is a security identifier that is passed with the *ODAU* to the authorization service to allow appropriate authorization checks to be performed. *ODASI* is used only if:

- OOALTU is specified on the MQOPEN call, or
- PMALTU is specified on the MQPUT1 call,

and the *ODAU* field is not entirely blank up to the first null character or the end of the field.

The *ODASI* field has the following structure:

- The first byte is a binary integer containing the length of the significant data that follows; the value excludes the length byte itself. If no security identifier is present, the length is zero.
- The second byte indicates the type of security identifier that is present; the following values are possible:

SITWNT

Windows security identifier.

SITNON

No security identifier.

- The third and subsequent bytes up to the length defined by the first byte contain the security identifier itself.
- Remaining bytes in the field are set to binary zero.

The following special value may be used:

SINONE

No security identifier specified.

The value is binary zero for the length of the field.

This is an input field. The length of this field is given by LNSCID. The initial value of this field is SINONE. This field is ignored if *ODVER* is less than ODVER3.

ODAU (12-byte character string)

Alternate user identifier.

If OOALTU is specified for the MQOPEN call, or PMALTU for the MQPUT1 call, this field contains an alternate user identifier that is to be used to check the authorization for the open, in place of the user identifier that the application is currently running under. Some checks, however, are still carried out with the current user identifier (for example, context checks).

If OOALTU and PMALTU are not specified and this field is entirely blank up to the first null character or the end of the field, the open can succeed only if no user authorization is needed to open this object with the options specified.

If neither OOALTU nor PMALTU is specified, this field is ignored.

This is an input field. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

ODDN (48-byte character string)

Dynamic queue name.

This is the name of a dynamic queue that is to be created by the MQOPEN call. This is of relevance only when *ODON* specifies the name of a model queue; in all other cases *ODDN* is ignored.

The characters that are valid in the name are the same as those for *ODON*, except that an asterisk is also valid. A name that is blank (or one in which only blanks are shown before the first null character) is not valid if *ODON* is the name of a model queue.

If the last nonblank character in the name is an asterisk (*), the queue manager replaces the asterisk with a string of characters that guarantees that the name generated for the queue is unique at the local queue manager. To allow a sufficient number of characters for this, the asterisk is valid only in positions 1 through 33. There must be no characters other than blanks or a null character following the asterisk.

It is valid for the asterisk to occur in the first character position, in which case the name consists solely of the characters generated by the queue manager.

This is an input field. The length of this field is given by *LNQN*. The initial value of this field is 'AMQ.*', padded with blanks.

ODIDC (10-digit signed integer)

Number of queues that failed to open.

This is the number of queues in the distribution list that failed to open successfully. If present, this field is also set when opening a single queue which is not in a distribution list.

Note: If present, this field is set *only* if the *CMPCOD* parameter on the MQOPEN or MQPUT1 call is CCOK or CCWARN; it is *not* set if the *CMPCOD* parameter is CCFAIL.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than ODVER2.

ODKDC (10-digit signed integer)

Number of local queues opened successfully.

This is the number of queues in the distribution list that resolve to local queues and that were opened successfully. The count does not include queues that resolve to remote queues (even though a local transmission queue is used initially to store the message). If present, this field is also set when opening a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than ODVER2.

ODMN (48-byte character string)

Object queue manager name.

This is the name of the queue manager on which the *ODON* object is defined. The characters that are valid in the name are the same as those for *ODON* (see previously). A name that is entirely blank up to the first null character or the end of the field denotes the queue manager to which the application is connected (the local queue manager).

The following points apply to the types of object indicated:

- If *ODOT* is OTTOP, OTNLST, OTPRO, or OTQM, *ODMN* must be blank or the name of the local queue manager.
- If *ODON* is the name of a model queue, the queue manager creates a dynamic queue with the attributes of the model queue, and returns in the *ODMN* field the name of the queue manager on which the queue is created; this is the name of the local queue manager. A model queue can be specified only on the MQOPEN call; a model queue is not valid on the MQPUT1 call.
- If *ODON* is the name of a cluster queue, and *ODMN* is blank, the actual destination of messages sent using the queue handle returned by the MQOPEN call is chosen by the queue manager (or cluster workload exit, if one is installed) as follows:

- If OOBND0 is specified, the queue manager selects an instance of the cluster queue during the processing of the MQOPEN call, and all messages put using this queue handle are sent to that instance.
- If OOBNDN is specified, the queue manager may choose a different instance of the destination queue (residing on a different queue manager in the cluster) for each successive MQPUT call that uses this queue handle.

If the application needs to send a message to a *specific* instance of a cluster queue (that is, a queue instance that resides on a particular queue manager in the cluster), the application should specify the name of that queue manager in the *ODMN* field. This forces the local queue manager to send the message to the specified destination queue manager.

- If the object being opened is a distribution list (that is, *ODREC* is greater than zero), *ODMN* must be blank or the null string. If this condition is not satisfied, the call fails with reason code RC2153.

This is an input/output field for the MQOPEN call when *ODON* is the name of a model queue, and an input-only field in all other cases. The length of this field is given by *LNQMN*. The initial value of this field is 48 blank characters.

ODON (48-byte character string)

Object name.

This is the local name of the object as defined on the queue manager identified by *ODMN*. The name can contain the following characters:

- Uppercase alphabetic characters (A - Z)
- Lowercase alphabetic characters (a - z)
- Numeric digits (0 - 9)
- Period (.), forward slash (/), underscore (_), percent (%)

The name must not contain leading or embedded blanks, but may contain trailing blanks. A null character can be used to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply in the environments indicated:

- On systems that use EBCDIC Katakana, lowercase characters cannot be used.
- On IBM i, names containing lowercase characters, forward slash, or percent, must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified for names that occur as fields in structures or as parameters on calls.

The following points apply to the types of object indicated:

- If *ODON* is the name of a model queue, the queue manager creates a dynamic queue with the attributes of the model queue, and returns in the *ODON* field the name of the queue created. A model queue can be specified only on the MQOPEN call; a model queue is not valid on the MQPUT1 call.
- If the object being opened is a distribution list (that is, *ODREC* is present and greater than zero), *ODON* must be blank or the null string. If this condition is not satisfied, the call fails with reason code RC2152.
- If *ODOT* is OTQM, special rules apply; in this case the name must be entirely blank up to the first null character or the end of the field.
- If *ODON* is the name of an alias queue with *TARGETYPE(TOPIC)*, a security check is first made on the named alias queue, as is normal for the use of alias queues. If this security check is successful, this MQOPEN call will continue and behaves like an MQOPEN of an OTTOP, including making a security check against the administrative topic object.

This is an input/output field for the MQOPEN call when *ODON* is the name of a model queue, and an input-only field in all other cases. The length of this field is given by *LNQN*. The initial value of this field is 48 blank characters.

The full topic name can be built from two different fields: *ODON* and *ODOS*. For details of how these two fields are used, see [“Using topic strings” on page 554](#).

ODORO (10-digit signed integer)

Offset of first object record from start of MQOD.

This is the offset in bytes of the first MQOR object record from the start of the MQOD structure. The offset can be positive or negative. *ODORO* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

When a distribution list is being opened, an array of one or more MQOR object records must be provided in order to specify the names of the destination queues in the distribution list. This can be done in one of two ways:

- By using the offset field *ODORO*

In this case, the application should declare its own structure containing an MQOD followed by the array of MQOR records (with as many array elements as are needed), and set *ODORO* to the offset of the first element in the array from the start of the MQOD. Care must be taken to ensure that this offset is correct.

- By using the pointer field *ODORP*

In this case, the application can declare the array of MQOR structures separately from the MQOD structure, and set *ODORP* to the address of the array.

Whichever technique is chosen, one of *ODORO* and *ODORP* must be used; the call fails with reason code RC2155 if both are zero, or both are nonzero.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

ODORP (pointer)

Address of first object record.

This is the address of the first MQOR object record. *ODORP* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

This is an input field. The initial value of this field is the null pointer. Either *ODORP* or *ODORO* can be used to specify the object records, but not both; see the description of the *ODORO* field previously for details. If *ODORP* is not used, it must be set to the null pointer or null bytes. This field is ignored if *ODVER* is less than *ODVER2*.

ODOS (MQCHARV)

ODOS specifies the long object name to be used.

This field is referenced only for certain values of *ODOT*. See the description of *ODOT* for details of which values indicate that this field is used.

If *ODOS* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code RC2441.

This is an input field. The initial values of the fields in this structure are the same as those in the *MQCHARV* structure.

The full topic name can be built from two different fields: *ODON* and *ODOS*. For details of how these two fields are used, see [“Using topic strings” on page 554](#). This field is ignored if *ODVER* is less than *ODVER4*.

ODOT (10-digit signed integer)

Object type.

Type of object being named in *ODON*. Possible values are:

OTQ

Queue. The name of the object is found in *ODON*.

OTNLST

Namelist. The name of the object is found in *ODON*.

OTPRO

Process definition. The name of the object is found in *ODON*.

OTQM

Queue manager. The name of the object is found in *ODON*.

OTTOP

Topic. The full topic name can be built from two different fields: *ODON* and *ODOS*.

For details of how those two fields are used, see [“Using topic strings” on page 554](#).

If the object identified by the *ODON* field cannot be found, the call will fail with reason code RC2425 even if there is a string specified in *ODOS*.

This is always an input field. The initial value of this field is OTQ.

ODREC (10-digit signed integer)

Number of object records present.

This is the number of MQOR object records that have been provided by the application. If this number is greater than zero, it indicates that a distribution list is being opened, with *ODREC* being the number of destination queues in the list. It is valid for a distribution list to contain only one destination.

The value of *ODREC* must not be less than zero, and if it is greater than zero *ODOT* must be OTQ; the call fails with reason code RC2154 if these conditions are not satisfied.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than ODVER2.

ODRMN (48-byte character string)

Resolved queue manager name.

This is the name of the destination queue manager after name resolution has been performed by the local queue manager. The name returned is the name of the queue manager that owns the queue identified by *ODRQN*. *ODRMN* can be the name of the local queue manager.

If *ODRQN* is a shared queue that is owned by the queue-sharing group to which the local queue manager belongs, *ODRMN* is the name of the queue-sharing group. If the queue is owned by some other queue-sharing group, *ODRQN* can be the name of the queue-sharing group or the name of a queue manager that is a member of the queue-sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *ODRMN* is set to blanks:

- Not a queue
- A queue, but not opened for browse, input, or output
- A cluster queue with OOBNDN specified (or with OOBNDQ in effect when the *DefBind* queue attribute has the value BNDNOT)
- A distribution list

This is an output field. The length of this field is given by LNQN. The initial value of this field is the null string in C, and 48 blank characters in other programming languages. This field is ignored if *ODVER* is less than ODVER3.

ODRO (MQCHARV)

ODRO is the long object name after the queue manager resolves the name provided in *ODON*.

This field is returned only for certain types of objects, topics, and queue aliases which reference a topic object.

If the long object name is provided in *ODOS* and nothing is provided in *ODON*, the value returned in this field is the same as provided in *ODOS*.

If this field is omitted (that is *ODRO.VSBufSize* is zero), the *ODRO* is not returned, but the length is returned in *ODRO.VSLength*. If the length is shorter than the full *ODRO* then it is truncated and returns as many of the rightmost characters as can fit in the provided length.

If *ODRO* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code RC2520. This field is ignored if *ODVER* is less than *ODVER4*.

ODRQN (48-byte character string)

Resolved queue name.

This is the name of the destination queue after name resolution has been performed by the local queue manager. The name returned is the name of a queue that exists on the queue manager identified by *ODRMN*.

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *ODRQN* is set to blanks:

- Not a queue
- A queue, but not opened for browse, input, or output
- A distribution list
- An alias queue that references a topic object (refer to “*ODRO (MQCHARV)*” on page 1122 instead)

This is an output field. The length of this field is given by *LNQN*. The initial value of this field is the null string in C, and 48 blank characters in other programming languages. This field is ignored if *ODVER* is less than *ODVER3*.

ODRRO (10-digit signed integer)

Offset of first response record from start of *MQOD*.

This is the offset in bytes of the first *MQRR* response record from the start of the *MQOD* structure. The offset can be positive or negative. *ODRRO* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

When a distribution list is being opened, an array of one or more *MQRR* response records can be provided in order to identify the queues that failed to open (*RRCC* field in *MQRR*), and the reason for each failure (*RRREA* field in *MQRR*). The data is returned in the array of response records in the same order as the queue names occur in the array of object records. The queue manager sets the response records only when the outcome of the call is mixed (that is, some queues were opened successfully while others failed, or all failed but for differing reasons); reason code RC2136 from the call indicates this case. If the same reason code applies to all queues, that reason is returned in the *REASON* parameter of the *MQOPEN* or *MQPUT1* call, and the response records are not set. Response records are optional, but if they are supplied there must be *ODREC* of them.

The response records can be provided in the same way as the object records, either by specifying an offset in *ODRRO*, or by specifying an address in *ODRRP*; see the description of *ODORO* previously for details of how to do this. However, no more than one of *ODRRO* and *ODRRP* can be used; the call fails with reason code RC2156 if both are nonzero.

For the *MQPUT1* call, these response records are used to return information about errors that occur when the message is sent to the queues in the distribution list, as well as errors that occur when the queues are opened. The completion code and reason code from the put operation for a queue replace those from the open operation for that queue only if the completion code from the latter was CCOK or CCWARN.

This is an input field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

ODRRP (pointer)

Address of first response record.

This is the address of the first MQRR response record. *ODRRP* is used only when a distribution list is being opened. The field is ignored if *ODREC* is zero.

Either *ODRRP* or *ODRR0* can be used to specify the response records, but not both; see the previous description of the *ODRR0* field for details. If *ODRRP* is not used, it must be set to the null pointer or null bytes.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *ODVER* is less than *ODVER2*.

ODSID (4-byte character string)

Structure identifier.

The value must be:

ODSIDV

Identifier for object descriptor structure.

This is always an input field. The initial value of this field is *ODSIDV*.

ODSS (MQCHARV)

ODSS contains the string used to provide the selection criteria used when retrieving messages off a queue.

ODSS must not be provided in the following cases:

- If *ODOT* is not OTQ
- If the queue being opened is not being opened using one of the input options, *OOINP**

If *ODSS* is provided in these cases, the call fails with reason code RC2516.

If *ODSS* is specified incorrectly, according to the description of how to use the *MQCHARV* structure, or if it exceeds the maximum length, the call fails with reason code RC2519. This field is ignored if *ODVER* is less than *ODVER4*.

ODUDC (10-digit signed integer)

Number of remote queues opened successfully

This is the number of queues in the distribution list that resolve to remote queues and that were opened successfully. If present, this field is also set when opening a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is ignored if *ODVER* is less than *ODVER2*.

ODVER (10-digit signed integer)

Structure version number.

The value must be one of the following:

ODVER1

Version-1 object descriptor structure.

ODVER2

Version-2 object descriptor structure.

ODVER3

Version-3 object descriptor structure.

ODVER4

Version-4 object descriptor structure.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

ODVERC

Current version of object descriptor structure.

This is always an input field. The initial value of this field is ODVER1.

Initial values

Table 602. Initial values of fields in MQOD		
Field name	Name of constant	Value of constant
ODSID	ODSIDV	'OD¬¬'
ODVER	ODVER1	1

MQOR - Object record

The MQOR structure is used to specify the queue name and queue manager name of a single destination queue.

Overview

Purpose: MQOR is an input structure for the MQOPEN and MQPUT1 calls.

Character set and encoding: Data in MQOR must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

Usage: By providing an array of these structures on the MQOPEN call, it is possible to open a list of queues; this list is called a *distribution list*. Each message put using the queue handle returned by that MQOPEN call is placed on each of the queues in the list, if the queue was opened successfully.

- [“Fields” on page 1127](#)
- [“Initial values” on page 1128](#)
- [“RPG declaration” on page 1128](#)

Fields

The MQOR structure contains the following fields; the fields are described in **alphabetical order**:

ORMN (48-byte character string)

Object queue manager name.

This is the same as the *ODMN* field in the MQOD structure (see MQOD for details).

This is always an input field. The initial value of this field is 48 blank characters.

ORON (48-byte character string)

Object name.

This is the same as the *ODON* field in the MQOD structure (see MQOD for details), except that:

- It must be the name of a queue.
- It must not be the name of a model queue.

This is always an input field. The initial value of this field is 48 blank characters.

Initial values

```

MQPD - Property descriptor

The **MQPD** is used to define the attributes of a property.

Overview

Purpose: The structure is an input/output parameter on the MQSETMP call and an output parameter on the MQINQMP call.

Character set and encoding: Data in MQPD must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1128](#)
- [“Initial values” on page 1131](#)
- [“RPG declaration” on page 1131](#)

Fields

The MQPD structure contains the following fields; the fields are described in **alphabetical order**:

PDCT (10-digit signed integer)

This describes what message context the property belongs to.

When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *PDCT* field.

The following option can be specified:

PDUSC

The property is associated with the user context.

No special authorization is required to be able to set a property associated with the user context using the MQSETMP call.

On a IBM WebSphere MQ 7.0 queue manager, a property associated with the user context is saved as described for OOSAVA. An MQPUT call with PMPASA specified, causes the property to be copied from the saved context into the new message.

If the option previously described is not required, the following option can be used:

PDNOC

The property is not associated with a message context.

An unrecognized value is rejected with a *PDREA* code of RC2482.

This is an input/output field to the MQSETMP call and an output field from the MQINQMP call. The initial value of this field is PDNOC.

PDCPYOPT (10-digit signed integer)

This describes which type of messages the property should be copied into.

This is an output only field for recognized IBM MQ-defined properties; IBM MQ sets the appropriate value.

When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *CopyOptions* field.

You can specify one or more of these options. To specify more than one option, either add the values together (do not add the same constant more than once), or combine the values using the bitwise OR operation (if the programming language supports bit operations).

COPFOR

This property is copied into a message being forwarded.

COPPUB

This property is copied into the message received by a subscriber when a message is being published.

COPREP

This property is copied into a reply message.

COPRP

This property is copied into a report message.

COPALL

This property is copied into all types of subsequent messages.

COPNON

This property is not copied into a message.

Default option: The following option can be specified to supply the default set of copy options:

COPDEF

This property is copied into a message being forwarded, into a report message, or into a message received by a subscriber when a message is being published.

This is equivalent to specifying the combination of options COPFOR, plus COPRP, plus COPPUB.

If none of the options described previously are required, use the following option:

COPNON

Use this value to indicate that no other copy options have been specified; programmatically no relationship exists between this property and subsequent messages. This is always returned for message descriptor properties.

This is an input/output field to the MQSETMP call and an output field from the MQINQMP call. The initial value of this field is COPDEF.

PDOPT (10-digit signed integer)

The value must be:

PDNONE

No options specified

This is always an input field. The initial value of this field is PDNONE.

PDSID (10-digit signed integer)

This is the structure identifier; the value must be:

PSIDV

Identifier for property descriptor structure.

This is always an input field. The initial value of this field is **PSIDV**.

PDSUP (10-digit signed integer)

This field describes what level of support for the message property is required of the queue manager, in order for the message containing this property to be put to a queue. This applies only to IBM MQ-defined properties; support for all other properties is optional.

The field is automatically set to the correct value when the IBM MQ-defined property is known by the queue manager. If the property is not recognized, PDSUPO is assigned. When a queue manager receives a message containing an IBM MQ-defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the *PDSUP* field.

When setting an IBM MQ-defined property using the MQSETMP call on a message handle where the CMNOVA option was set, *PDSUP* becomes an input field. This allows an application to put an IBM MQ-defined property, with the correct value, where the property is unsupported by the connected queue manager, but where the message is intended to be processed on another queue manager.

The value PDSUPO is always assigned to properties that are not IBM MQ-defined properties.

If a IBM WebSphere MQ 7.0 queue manager, that supports message properties, receives a property that contains an unrecognized *PDSUP* value, the property is treated as if:

- PDSUPR was specified if any of the unrecognized values are contained in the PDRUM.
- PDSUPL was specified if any of the unrecognized values are contained in the PDAUXM
- PDSUPO was specified otherwise.

One of the following values is returned by the MQINQMP call, or one of the values can be specified, when using the MQSETMP call on a message handle where the CMNOVA option is set:

PDSUPO

The property is accepted by a queue manager even if it is not supported. The property can be discarded in order for the message to flow to a queue manager that does not support message properties. This value is also assigned to properties that are not IBM MQ-defined.

PDSUPR

Support for the property is required. The message is rejected by a queue manager that does not support the IBM MQ-defined property. The MQPUT or MQPUT1 call fails with completion code CCFAIL and reason code RC2490.

PDSUPL

The message is rejected by a queue manager that does not support the IBM MQ-defined property if the message is destined for a local queue. The MQPUT or MQPUT1 call fails with completion code CCFAIL and reason code RC2490.

The MQPUT or MQPUT1 call succeeds if the message is destined for a remote queue manager.

This is an output field on the MQINQMP call and an input field on the MQSETMP call if the message handle was created with the CMNOVA option set. The initial value of this field is PDSUPO.

PDVER (10-digit signed integer)

This is the structure version number; the value must be:

PDVER1

Version-1 property descriptor structure.

The following constant specifies the version number of the current version:

PDVERC

Current version of property descriptor structure.

This is always an input field. The initial value of this field is **PDVER1**.

Initial values

Table 604. Initial values of fields in MQPD		
Field name	Name of constant	Value of constant
PDSID	PDSIDV	'PD'
PDVER	PDVER1	1
PDOPT	PDNONE	0
PDSUP	PDSUPO	0
PDCT	PDNOC	0

MQPMO - Put-message options

The MQPMO structure allows the application to specify options that control how messages are placed on queues or published to topics.

Overview

Purpose

The structure is an input/output parameter on the MQPUT and MQPUT1 calls.

Version

The current version of MQPMO is PMVER2. Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions that follow.

The COPY file provided contains the most recent version of MQPMO that is supported by the environment, but with the initial value of the *PMVER* field set to PMVER1. To use fields that are not present in the version-1 structure, the application must set the *PMVER* field to the version number of the version required.

Character set and encoding

Data in MQPMO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1131](#)
- [“Initial values” on page 1145](#)
- [“RPG declaration” on page 1145](#)

Fields

The MQPMO structure contains the following fields; the fields are described in alphabetical order:

PMCT (10 digit signed integer)

Object handle of input queue.

If PMPASI or PMPASA is specified, this field must contain the input queue handle from which context information to be associated with the message being put is taken.

If PMPASI and PMPASA are not specified, this field is ignored.

This is an input field. The initial value of this field is 0.

PMIDC (10 digit signed integer)

Number of messages that could not be sent.

This is the number of messages that could not be sent to queues in the distribution list. The count includes queues that failed to open, and queues that were opened successfully but for which the put operation failed. This field is also set when putting a message to a single queue which is not in a distribution list.

Note: This field is set only if the *CMPCOD* parameter on the MQPUT or MQPUT1 call is CCOK or CCWARN; it is not set if the *CMPCOD* parameter is CCFAIL.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

PMKDC (10 digit signed integer)

Number of messages sent successfully to local queues.

This is the number of messages that the current MQPUT or MQPUT1 call has sent successfully to queues in the distribution list that are local queues. The count does not include messages sent to queues that resolve to remote queues (even though a local transmission queue is used initially to store the message). This field is also set when putting a message to a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

PMOPT (10 digit signed integer)

Options that control the action of MQPUT and MQPUT1.

Any or none of the following can be specified. If more than one is required the values can be added (do not add the same constant more than once). Combinations that are not valid are noted; any other combinations are valid.

Publishing options: The following options control the way messages are published to a topic.

PMSRTO

Any information filled into the MDRQ and MDRM fields of the MQMD of this publication is not passed on to subscribers. If this option is used with a report option that requires a ReplyToQ, the call fails with RC2027 .

PMRET

The publication being sent is to be retained by the queue manager. This allows a subscriber to request a copy of this publication after the time it was published, by using the MQSUBRQ call. It also allows a publication to be sent to applications which make their subscription after the time this publication was made, unless they choose not to be sent it by using the option SONEWP. If an application is sent a publication which was retained, it is indicated by the mq.IsRetained message property of that publication.

Only one publication can be retained at each node of the topic tree. That means if there already is a retained publication for this topic, published by any other application, it is replaced with this publication. It is therefore better to avoid having more than one publisher retaining messages on the same topic.

When retained publications are requested by a subscriber, the subscription used may contain a wildcard in the topic, in which case a number of retained publications might match (at various nodes in the topic tree) and several publications may be sent to the requesting application. See the description of the “MQSUBRQ - Subscription request” on page 765 call for more details.

If this option is used and the publication cannot be retained, the message is not published and the call fails with RC2479 .

Syncpoint options: The following options relate to the participation of the MQPUT or MQPUT1 call within a unit of work:

PMSYP

Put message with syncpoint control.

The request is to operate within the normal unit-of-work protocols. The message is not visible outside the unit of work until the unit of work is committed. If the unit of work is backed out, the message is deleted.

If this option and PMNSYP are not specified, the put request is not within a unit of work.

PMSYP must not be specified with PMNSYP.

PMNSYP

Put message without syncpoint control.

The request is to operate outside the normal unit-of-work protocols. The message is available immediately, and it cannot be deleted by backing out a unit of work.

If this option and PMSYP are not specified, the put request is not within a unit of work.

PMNSYP must not be specified with PMSYP.

Message-identifier and correlation-identifier options: The following options request the queue manager to generate a new message identifier or correlation identifier:

PMNMID

Generate a new message identifier.

This option causes the queue manager to replace the contents of the *MDMID* field in MQMD with a new message identifier. This message identifier is sent with the message, and returned to the application on output from the MQPUT or MQPUT1 call.

This option can also be specified when the message is being put to a distribution list; see the description of the *PRMID* field in the MQPMR structure for details.

Using this option relieves the application of the need to reset the *MDMID* field to MINONE before each MQPUT or MQPUT1 call.

PMNCID

Generate a new correlation identifier.

This option causes the queue manager to replace the contents of the *MDCID* field in MQMD with a new correlation identifier. This correlation identifier is sent with the message, and returned to the application on output from the MQPUT or MQPUT1 call.

This option can also be specified when the message is being put to a distribution list; see the description of the *PRCID* field in the MQPMR structure for details.

PMNCID is useful in situations where the application requires a unique correlation identifier.

Group and segment options: The following option relates to the processing of messages in groups and segments of logical messages. These definitions might be of help in understanding the option:

Physical message

This is the smallest unit of information that can be placed on or removed from a queue; it often corresponds to the information specified or retrieved on a single MQPUT, MQPUT1, or MQGET call. Every physical message has its own message descriptor (MQMD). Generally, physical messages

are distinguished by differing values for the message identifier (*MDMID* field in MQMD), although this is not enforced by the queue manager.

Logical message

This is a single unit of application information. In the absence of system constraints, a logical message would be the same as a physical message. But where logical messages are large, system constraints may make it advisable or necessary to split a logical message into two or more physical messages, called *segments*.

A logical message that has been segmented consists of two or more physical messages that have the same nonnull group identifier (*MDGID* field in MQMD), and the same message sequence number (*MDSEQ* field in MQMD). The segments are distinguished by differing values for the segment offset (*MDOFF* field in MQMD), which gives the offset of the data in the physical message from the start of the data in the logical message. Because each segment is a physical message, the segments in a logical message typically have differing message identifiers.

A logical message that has not been segmented, but for which segmentation has been permitted by the sending application, also has a nonnull group identifier, although in this case there is only one physical message with that group identifier if the logical message does not belong to a message group. Logical messages for which segmentation has been inhibited by the sending application have a null group identifier (GINONE), unless the logical message belongs to a message group.

Message group

This is a set of one or more logical messages that have the same nonnull group identifier. The logical messages in the group are distinguished by differing values for the message sequence number, which is an integer in the range 1 through n, where n is the number of logical messages in the group. If one or more of the logical messages is segmented, there are more than n physical messages in the group.

PMLOGO

Messages in groups and segments of logical messages are put in logical order.

This option tells the queue manager how the application puts messages in groups and segments of logical messages. It can be specified only on the MQPUT call; it is not valid on the MQPUT1 call.

If PMLOGO is specified, it indicates that the application uses successive MQPUT calls to:

- Put the segments in each logical message in the order of increasing segment offset, starting from 0, with no gaps.
- Put all of the segments in one logical message before putting the segments in the next logical message.
- Put the logical messages in each message group in the order of increasing message sequence number, starting from 1, with no gaps.
- Put all of the logical messages in one message group before putting logical messages in the next message group.

This order is called "logical order".

Because the application has told the queue manager how it puts messages in groups and segments of logical messages, the application does not have to maintain and update the group and segment information about each MQPUT call, as the queue manager does this. Specifically, it means that the application does not need to set the *MDGID*, *MDSEQ*, and *MDOFF* fields in MQMD, as the queue manager sets these to the appropriate values. The application need set only the *MDMFL* field in MQMD, to indicate when messages belong to groups or are segments of logical messages, and to indicate the last message in a group or last segment of a logical message.

Once a message group or logical message has been started, subsequent MQPUT calls must specify the appropriate MF* flags in *MDMFL* in MQMD. If the application tries to put a message not in a group when there is an unterminated message group, or put a message which is not a segment when there is an unterminated logical message, the call fails with reason code RC2241 or RC2242, as appropriate. However, the queue manager retains the information about the

current message group or current logical message, and the application can terminate them by sending a message (possibly with no application message data) specifying MFLMIG or MFLSEG as appropriate, before reissuing the MQPUT call to put the message that is not in the group or not a segment.

Table 605 on page 1135 shows the combinations of options and flags that are valid, and the values of the *MDGID*, *MDSEQ*, and *MDOFF* fields that the queue manager uses in each case. Combinations of options and flags that are not shown in the table are not valid. The columns in the table have the following meanings:

LOG ORD

Indicates whether the PMLOGO option is specified on the call.

MIG

Indicates whether the MFMIG or MFLMIG option is specified on the call.

SEG

Indicates whether the MFSEG or MFLSEG option is specified on the call.

SEG OK

Indicates whether the MFSEGA option is specified on the call.

Cur grp

Indicates whether a current message group exists before the call.

Cur log msg

Indicates whether a current logical message exists before the call.

Other columns

Show the values that the queue manager uses. "Previous" denotes the value used for the field in the previous message for the queue handle.

PMRLOC

Specifies that the PMRQN in the MQPMO structure must be completed with the name of the local queue which the message actually gets put to. The ResolvedQMGrName is similarly completed with the name of the local queue manager hosting the local queue. See OORLOQ for what this means. If a user is authorized for a put to a queue then they have the required authority to specify this flag on the MQPUT call. No special authority is needed.

Table 605. MQPUT options relating to messages in groups and segments of logical messages								
Options you specify				Group and log-msg status before call		Values the queue manager uses		
LOG ORD	MIG	SEG	SEG OK	Cur grp	Cur log msg	MDGID	MDSEQ	MDOFF
Yes	No	No	No	No	No	GINONE	1	0
Yes	No	No	Yes	No	No	New group id	1	0
Yes	No	Yes	Yes or No	No	No	New group id	1	0
Yes	No	Yes	Yes or No	No	Yes	Previous group id	1	Previous offset + previous segment length
Yes	Yes	Yes or No	Yes or No	No	No	New group id	1	0
Yes	Yes	Yes or No	Yes or No	Yes	No	Previous group id	Previous sequence number + 1	0

Table 605. MQPUT options relating to messages in groups and segments of logical messages (continued)

Options you specify				Group and log-msg status before call		Values the queue manager uses		
Yes	Yes	Yes	Yes or No	Yes	Yes	Previous group id	Previous sequence number	Previous offset + previous segment length
No	No	No	No	Yes or No	Yes or No	GINONE	1	0
No	No	No	Yes	Yes or No	Yes or No	New group id if GINONE, else value in field	1	0
No	No	Yes	Yes or No	Yes or No	Yes or No	New group id if GINONE, else value in field	1	Value in field
No	Yes	No	Yes or No	Yes or No	Yes or No	New group id if GINONE, else value in field	Value in field	0
No	Yes	Yes	Yes or No	Yes or No	Yes or No	New group id if GINONE, else value in field	Value in field	Value in field

Note:

- PMLOGO is not valid on the MQPUT1 call.
- For the *MDMID* field, the queue manager generates a new message identifier if PMNMID or MINONE is specified, and uses the value in the field otherwise.
- For the *MDCID* field, the queue manager generates a new correlation identifier if PMNCID is specified, and uses the value in the field otherwise.

When PMLOGO is specified, the queue manager requires that all messages in a group and segments in a logical message be put with the same value in the *MDPER* field in MQMD, that is, all must be persistent, or all must be nonpersistent. If this condition is not satisfied, the MQPUT call fails with reason code RC2185 .

The PMLOGO option affects units of work as follows:

- If the first physical message in a group or logical message is put within a unit of work, all of the other physical messages in the group or logical message must be put within a unit of work, if the same queue handle is used. However, they need not be put within the same unit of work. This allows a message group or logical message consisting of many physical messages to be split across two or more consecutive units of work for the queue handle.
- If the first physical message in a group or logical message is not put within a unit of work, none of the other physical messages in the group or logical message can be put within a unit of work, if the same queue handle is used.

If these conditions are not satisfied, the MQPUT call fails with reason code RC2245 .

When PMLOGO is specified, the MQMD supplied on the MQPUT call must not be less than MDVER2. If this condition is not satisfied, the call fails with reason code RC2257 .

If PMLOGO is not specified, messages in groups and segments of logical messages can be put in any order, and it is not necessary to put complete message groups or complete logical messages.

It is the responsibility of the application to ensure that the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields have appropriate values.

This is the technique that can be used to restart a message group or logical message in the middle, after a system failure has occurred. When the system restarts, the application can set the *MDGID*, *MDSEQ*, *MDOFF*, *MDMFL*, and *MDPER* fields to the appropriate values, and then issue the MQPUT call with PMSYP or PMNSYP set as *necessary*, but without specifying PMLOGO. If this call is successful, the queue manager retains the group and segment information, and subsequent MQPUT calls using that queue handle can specify PMLOGO as normal.

The group and segment information that the queue manager retains for the MQPUT call is separate from the group and segment information that it retains for the MQGET call.

For any given queue handle, the application is free to mix MQPUT calls that specify PMLOGO with MQPUT calls that do not, but the following points should be noted:

- If PMLOGO is not specified, each successful MQPUT call causes the queue manager to set the group and segment information for the queue handle to the values specified by the application; this replaces the existing group and segment information retained by the queue manager for the queue handle.
- If PMLOGO is not specified, the call does not fail if there is a current message group or logical message; the call might however succeed with a CCWARN completion code. [Table 606 on page 1137](#) shows the various cases that can arise. In these cases, if the completion code is not CCOK, the reason code is one of the following (as appropriate):
 - RC2241
 - RC2242
 - RC2185
 - RC2245

Note: The queue manager does not check the group and segment information for the MQPUT1 call.

Table 606. Outcome when MQPUT or MQCLOSE call is not consistent with group and segment information

Current call is	Previous call was MQPUT with PMLOGO	Previous call was MQPUT without PMLOGO
MQPUT with PMLOGO	CCFAIL	CCFAIL
MQPUT without PMLOGO	CCWARN	CCOK
MQCLOSE with an unterminated group or logical message	CCWARN	CCOK

Applications that simply want to put messages and segments in logical order are recommended to specify PMLOGO, as this is the simplest option to use. This option relieves the application of the need to manage the group and segment information, because the queue manager manages that information. However, specialized applications may need more control than provided by the PMLOGO option, and this can be achieved by not specifying that option. If this is done, the application must ensure that the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD are set correctly, before each MQPUT or MQPUT1 call.

For example, an application that wants to forward physical messages that it receives, without regard for whether those messages are in groups or segments of logical messages, must not specify PMLOGO. There are two reasons for this:

- If the messages are retrieved and put in order, specifying PMLOGO causes a new group identifier to be assigned to the messages, and this might make it difficult or impossible for the originator of the messages to correlate any reply or report messages that result from the message group.

- In a complex network with multiple paths between sending and receiving queue managers, the physical messages might arrive out of order. By not specifying PMLOGO and the corresponding GMLOGO on the MQGET call, the forwarding application can retrieve and forward each physical message as soon as it arrives, without needing to wait for the next one in logical order to arrive.

Applications that generate report messages for messages in groups or segments of logical messages must also not specify PMLOGO when putting the report message.

PMLOGO can be specified with any of the other PM* options.

Context options: The following options control the processing of message context:

PMNOC

No context is to be associated with the message.

Both identity and origin context are set to indicate no context. This means that the context fields in MQMD are set to:

- Blanks for character fields
- Nulls for byte fields
- Zeros for numeric fields

PMDEFC

Use default context.

The message is to have default context information associated with it, for both identity and origin. The queue manager sets the context fields in the message descriptor as follows:

Field in MQMD	Value used
<i>MDUID</i>	Determined from the environment if possible; set to blanks otherwise.
<i>MDACC</i>	Determined from the environment if possible; set to ACNONE otherwise.
<i>MDAID</i>	Set to blanks.
<i>MDPAT</i>	Determined from the environment.
<i>MDPAN</i>	Determined from the environment if possible; set to blanks otherwise.
<i>MDPD</i>	Set to date when message is put.
<i>MDPT</i>	Set to time when message is put.
<i>MDAOD</i>	Set to blanks.

For more information about message context, see [Message context](#) and [Controlling context information](#).

This is the default action if no context options are specified.

PMPASI

Pass identity context from an input queue handle.

The message is to have context information associated with it. Identity context is taken from the queue handle specified in the *PMCT* field. Origin context information is generated by the queue manager in the same way that it is for PMDEFC (see the previous table for values). For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOPASI option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOPASI option.

PMPASA

Pass all context from an input queue handle.

The message is to have context information associated with it. Both identity and origin context are taken from the queue handle specified in the *PMCT* field. For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOPASA option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOPASA option.

PMSETI

Set identity context from the application.

The message is to have context information associated with it. The application specifies the identity context in the MQMD structure. Origin context information is generated by the queue manager in the same way that it is for PMDEFC (see the previous table for values). For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOSETI option (or an option that implies it). For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOSETI option.

PMSETA

Set all context from the application.

The message is to have context information associated with it. The application specifies the identity and origin context in the MQMD structure. For more information about message context, see [Message context](#) and [Controlling context information](#).

For the MQPUT call, the queue must have been opened with the OOSETA option. For the MQPUT1 call, the same authorization check is carried out as for the MQOPEN call with the OOSETA option.

Only one of the PM* context options can be specified. If none of these options is specified, PMDEFC is assumed.

Put response types. The following options control the response returned to an MQPUT or MQPUT1 call. You can only specify one of these options. If PMARES and PMSRES are not specified, PMRASQ or PMRAST is assumed.

PMARES

The PMARES option requests that an MQPUT or MQPUT1 operation is completed without the application waiting for the queue manager to complete the call. Using this option can improve messaging performance, particularly for applications using client bindings. An application can periodically check, using the MQSTAT verb, whether an error has occurred during any previous asynchronous calls.

With this option, only the following fields are guaranteed to be completed in the MQMD;

- MDAID
- MDPAT
- MDPAN
- MDAOD

Additionally, if either or both of PMNMID or PMNCID are specified as options, the MDMID and MDCID returned are also completed. (PMNMID can be implicitly specified by specifying a blank MDMID field).

Only the fields previously specified are completed. Other information that would normally be returned in the MQMD or MQPMO structure is undefined.

When requesting asynchronous put response for MQPUT or MQPUT1, a CMPCOD and REASON of CCOK and RCNONE does not necessarily mean that the message was successfully put to a queue. When developing an MQI application that uses asynchronous put response and require confirmation that messages have been put to a queue you should check both CMPCOD and REASON codes from the put operations and also use MQSTAT to query asynchronous error information.

Although the success or failure of each individual MQPUT/MQPUT1 call might not be returned immediately, the first error that occurred under an asynchronous call can be determined at a later juncture through a call to MQSTAT.

If a persistent message under syncpoint fails to be delivered using asynchronous put response, and you attempt to commit the transaction, the commit fails and the transaction is backed out with a completion code of CCFAIL and a reason of RC2003 . The application can make a call to MQSTAT to determine the cause of a previous MQPUT or MQPUT1 failure

PMSRES

Specifying this value for a put option in the MQPMO structure ensures that the MQPUT or MQPUT1 operation is always issued synchronously. If the operation is successful, all fields in the MQMD and MQPMO are completed. It is provided to ensure a synchronous response irrespective of the default put response value defined on the queue or topic object.

PMRASQ

If this value is specified for an MQPUT call, the put response type used is taken from the DEFPRESP value specified on the queue when it was opened by the application. If a client application is connected to a queue manager at a level earlier than Version 7.0, it behaves as if PMSRES was specified.

If this option is specified for an MQPUT1 call, the DEFPRESP value from the queue definition is not used. If the MQPUT1 call is using PMSYP it behaves as for PMARES, and if it is using PMNSYP it behaves as for PMSRES.

PMRAST

This is a synonym for PMRASQ for use with topic objects.

Other options: The following options control authorization checking, and what happens when the queue manager is quiescing:

PMALTU

Validate with specified user identifier.

This indicates that the *ODAU* field in the *OBJDSC* parameter of the MQPUT1 call contains a user identifier that is to be used to validate authority to put messages on the queue. The call can succeed only if this *ODAU* is authorized to open the queue with the specified options, regardless of whether the user identifier under which the application is running is authorized to do so. (This does not apply to the context options specified, however, which are always checked against the user identifier under which the application is running.)

This option is valid only with the MQPUT1 call.

PMFIQ

Fail if queue manager is quiescing.

This option forces the MQPUT or MQPUT1 call to fail if the queue manager is in the quiescing state.

The call returns completion code CCFAIL with reason code RC2161 .

Default option: If none of the options described previously are required, the following option can be used:

PMNONE

No options specified.

This value can be used to indicate that no other options have been specified; all options assume their default values. PMNONE is defined to aid program documentation; it is not intended that this option is used with any other, but as its value is zero, such use cannot be detected.

This is an input field. The initial value of the *PMOPT* field is PMNONE.

PMPRF (10 digit signed integer)

Flags indicating which MQPMR fields are present.

This field contains flags that must be set to indicate which MQPMR fields are present in the put message records provided by the application. *PMPRF* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero, or both *PMPRO* and *PMPRP* are zero.

For fields that are present, the queue manager uses for each destination the values from the fields in the corresponding put message record. For fields that are absent, the queue manager uses the values from the MQMD structure.

One or more of the following flags can be specified to indicate which fields are present in the put message records:

PFMID

Message-identifier field is present.

PFCID

Correlation-identifier field is present.

PFGID

Group-identifier field is present.

PFFB

Feedback field is present.

PFACC

Accounting-token field is present.

If this flag is specified, either *PMSETI* or *PMSETA* must be specified in the *PMOPT* field; if this condition is not satisfied, the call fails with reason code RC2158 .

If no MQPMR fields are present, the following can be specified:

PFNONE

No put-message record fields are present.

If this value is specified, either *PMREC* must be zero, or both *PMPRO* and *PMPRP* must be zero.

PFNONE is defined to aid program documentation. It is not intended that this constant is used with any other, but as its value is zero, such use cannot be detected.

If *PMPRF* contains flags which are not valid, or put message records are provided but *PMPRF* has the value PFNONE, the call fails with reason code RC2158 .

This is an input field. The initial value of this field is PFNONE. This field is ignored if *PMVER* is less than *PMVER2*.

MMPRO (10 digit signed integer)

Offset of first put message record from start of MQPMO.

This is the offset in bytes of the first MQPMR put message record from the start of the MQPMO structure. The offset can be positive or negative. *PMPRO* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

When the message is being put to a distribution list, an array of one or more MQPMR put message records can be provided in order to specify certain properties of the message for each destination individually; these properties are:

- message identifier
- correlation identifier
- group identifier
- feedback value
- accounting token

It is not necessary to specify all of these properties, but whatever subset is chosen, the fields must be specified in the correct order. See the description of the MQPMR structure for further details.

Usually, there should be as many put message records as there are object records specified by MQOD when the distribution list is opened; each put message record supplies the message properties for

the queue identified by the corresponding object record. Queues in the distribution list which fail to open must still have put message records allocated for them at the appropriate positions in the array, although the message properties are ignored in this case.

It is possible for the number of put message records to differ from the number of object records. If there are fewer put message records than object records, the message properties for the destinations which do not have put message records are taken from the corresponding fields in the message descriptor MQMD. If there are more put message records than object records, the excess are not used (although it must still be possible to access them). Put message records are optional, but if they are supplied there must be *PMREC* of them.

The put message records can be provided in a similar way to the object records in MQOD, either by specifying an offset in *PMPRO*, or by specifying an address in *PMPRP* ; for details of how to do this, see the *ODORO* field described in [“MQOD - Object descriptor” on page 1117](#).

No more than one of *PMPRO* and *PMPRP* can be used; the call fails with reason code RC2159 if both are nonzero.

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

PMPRP (pointer)

Address of first put message record.

This is the address of the first MQPMR put message record. *PMPRP* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

Either *PMPRP* or *PMPRO* can be used to specify the put message records, but not both; see the description of the [PMRRO](#) field for details. If *PMPRP* is not used, it must be set to the null pointer or null bytes.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *PMVER* is less than *PMVER2*.

PMREC (10 digit signed integer)

Number of put message records or response records present.

This is the number of MQPMR put message records or MQRR response records that have been provided by the application. This number can be greater than zero only if the message is being put to a distribution list. Put message records and response records are optional - the application need not provide any records, or it can choose to provide records of only one type. However, if the application provides records of both types, it must provide *PMREC* records of each type.

The value of *PMREC* need not be the same as the number of destinations in the distribution list. If too many records are provided, the excess are not used; if too few records are provided, default values are used for the message properties for those destinations that do not have put message records (see *PMPRO* later in this topic).

If *PMREC* is less than zero, or is greater than zero but the message is not being put to a distribution list, the call fails with reason code RC2154 .

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

PMRMN (48 byte character string)

Resolved name of destination queue manager.

This is the name of the destination queue manager after name resolution has been performed by the local queue manager. The name returned is the name of the queue manager that owns the queue identified by *PMRQN*, and can be the name of the local queue manager.

If *PMRQN* is a shared queue that is owned by the queue-sharing group to which the local queue manager belongs, *PMRMN* is the name of the queue-sharing group. If the queue is owned by some other queue-sharing group, *PMRQN* can be the name of the queue-sharing group or the name of a

queue manager that is a member of the queue-sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue; if the object is a distribution list or topic, the value returned is undefined.

This is an output field. The length of this field is given by LNQMNM. The initial value of this field is 48 blank characters.

PMRQN (48 byte character string)

Resolved name of destination queue.

This is the name of the destination queue after name resolution has been performed by the local queue manager. The name returned is the name of a queue that exists on the queue manager identified by *PMRMN*.

A nonblank value is returned only if the object is a single queue; if the object is a distribution list or topic, the value returned is undefined.

This is an output field. The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

PMRRO (10 digit signed integer)

Offset of first response record from start of MQPMO.

This is the offset in bytes of the first MQRR response record from the start of the MQPMO structure. The offset can be positive or negative. *PMRRO* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

When the message is being put to a distribution list, an array of one or more MQRR response records can be provided in order to identify the queues to which the message was not sent successfully (*RRCC* field in MQRR), and the reason for each failure (*RRREA* field in MQRR). The message might not have been sent either because the queue failed to open, or because the put operation failed. The queue manager sets the response records only when the outcome of the call is mixed (that is, some messages were sent successfully while others failed, or all failed but for differing reasons); reason code RC2136 from the call indicates this case. If the same reason code applies to all queues, that reason is returned in the *REASON* parameter of the MQPUT or MQPUT1 call, and the response records are not set.

Usually, there should be as many response records as there are object records specified by MQOD when the distribution list is opened; when necessary, each response record is set to the completion code and reason code for the put to the queue identified by the corresponding object record. Queues in the distribution list which fail to open must still have response records allocated for them at the appropriate positions in the array, although they are set to the completion code and reason code resulting from the open operation, rather than the put operation.

It is possible for the number of response records to differ from the number of object records. If there are fewer response records than object records, it may not be possible for the application to identify all of the destinations for which the put operation failed, or the reasons for the failures. If there are more response records than object records, the excess are not used (although it must still be possible to access them). Response records are optional, but if they are supplied there must be *PMREC* of them.

The response records can be provided in a similar way to the object records in MQOD, either by specifying an offset in *PMRRO*, or by specifying an address in *PMRRP*; for details of how to do this, see the *ODORO* field described in “MQOD - Object descriptor” on page 1117. However, no more than one of *PMRRO* and *PMRRP* can be used; the call fails with reason code RC2156 if both are nonzero.

For the MQPUT1 call, this field must be zero. This is because the response information (if requested) is returned in the response records specified by the object descriptor MQOD.

This is an input field. The initial value of this field is 0. This field is ignored if *PMVER* is less than *PMVER2*.

PMRRP (pointer)

Address of first response record.

This is the address of the first MQRR response record. *PMRRP* is used only when the message is being put to a distribution list. The field is ignored if *PMREC* is zero.

Either *PMRRP* or *PMRRO* can be used to specify the response records, but not both; see the description of the *PMRRO* field for details. If *PMRRP* is not used, it must be set to the null pointer or null bytes.

For the MQPUT1 call, this field must be the null pointer or null bytes. This is because the response information (if requested) is returned in the response records specified by the object descriptor MQOD.

This is an input field. The initial value of this field is the null pointer. This field is ignored if *PMVER* is less than *PMVER2*.

PMSID (4 byte character string)

Structure identifier.

The value must be:

PMSIDV

Identifier for put-message options structure.

This is always an input field. The initial value of this field is PMSIDV.

PMSL (MQLONG)

The level of subscription targeted by this publication.

Only those subscriptions with the highest *PMSL* less than or equal to this value receives this publication. This value must be in the range zero to 9; zero is the lowest level.

The initial value of this field is 9.

PMTO (10 digit signed integer)

Reserved.

This is a reserved field; its value is not significant. The initial value of this field is -1.

PMUDC (10 digit signed integer)

Number of messages sent successfully to remote queues.

This is the number of messages that the current MQPUT or MQPUT1 call has sent successfully to queues in the distribution list that resolve to remote queues. Messages that the queue manager retains temporarily in distribution-list form count as the number of individual destinations that those distribution lists contain. This field is also set when putting a message to a single queue which is not in a distribution list.

This is an output field. The initial value of this field is 0. This field is not set if *PMVER* is less than *PMVER2*.

PMVER (10 digit signed integer)

Structure version number.

The value must be one of the following:

PMVER1

Version-1 put-message options structure.

PMVER2

Version-2 put-message options structure.

Fields that exist only in the more-recent version of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

PMVERC

Current version of put-message options structure.

This is always an input field. The initial value of this field is PMVER1.

Initial values

Table 607. Initial values of fields in MQPMO		
Field name	Name of constant	Value of constant
PMSID	PMSIDV	'PMO '
PMVER	PMVER1	1
PMOPT	PMNONE	0
PMT0	None	-1
PMCT	None	0
PMKDC	None	0
PMUDC	None	0
PMIDC	None	0
PMRQN	None	Blanks
PMRMN	None	Blanks
PMREC	None	0
PMPRF	PFNONE	0
PMPRO	None	0
PMRRO	None	0
PMPRP	None	Null pointer or null bytes
PMRRP	None	Null pointer or null bytes
Note:		
1. The symbol <code> </code> represents a single blank character.

MQPMR - Put-message record

The MQPMR structure is used to specify various message properties for a single destination when a message is being put to a distribution list.

Overview

Purpose: MQPMR is an input/output structure for the MQPUT and MQPUT1 calls.

Character set and encoding: Data in MQPMR must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

Usage: By providing an array of these structures on the MQPUT or MQPUT1 call, it is possible to specify different values for each destination queue in a distribution list. Some of the fields are input only, others are input/output.

Note: This structure is unusual in that it does not have a fixed layout. The fields in this structure are optional, and the presence or absence of each field is indicated by the flags in the *PMPRF* field in MQPMO. Fields that are present **must occur in the following order** :

- *PRMID*
- *PRCID*
- *PRGID*
- *PRFB*
- *PRACC*

Fields that are absent occupy no space in the record.

Because MQPMR does not have a fixed layout, no definition of it is provided in the COPY file. The application programmer should create a declaration containing the fields that are required by the application, and set the flags in *PMPRF* to indicate the fields that are present.

- [“Fields” on page 1146](#)
- [“Initial values” on page 1148](#)
- [“RPG declaration” on page 1148](#)

Fields

The MQPMR structure contains the following fields; the fields are described in **alphabetical order**:

PRACC (32-byte bit string)

Accounting token.

This is the accounting token to be used for the message sent to the queue with a name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDACC* field in MQMD for a put to a single queue. See the description of *MDACC* in [“MQMD - Message descriptor” on page 1068](#) for information about the content of this field.

If this field is not present, the value in MQMD is used.

This is an input field.

PRCID (24-byte bit string)

Correlation identifier.

This is the correlation identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDCID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRCID* field.

If PMNCID is specified, a *single* new correlation identifier is generated and used for all of the destinations in the distribution list, regardless of whether they have MQPMR records. This is different from the way that PMNMID is processed (see *PRMID* field).

This is an input/output field.

PRFB (10-digit signed integer)

Feedback or reason code.

This is the feedback code to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDFB* field in MQMD for a put to a single queue.

If this field is not present, the value in MQMD is used.

This is an input field.

PRGID (24-byte bit string)

Group identifier.

This is the group identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDGID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRGID* field. The value is processed as documented in [Table 605 on page 1135](#), but with the following differences:

- In those cases where a new group identifier would be used, the queue manager generates a different group identifier for each destination (that is, no two destinations have the same group identifier).
- In those cases where the value in the field would be used, the call fails with reason code RC2258.

This is an input/output field.

PRMID (24-byte bit string)

Message identifier.

This is the message identifier to be used for the message sent to the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call. It is processed in the same way as the *MDMID* field in MQMD for a put to a single queue.

If this field is not present in the MQPMR record, or there are fewer MQPMR records than destinations, the value in MQMD is used for those destinations that do not have an MQPMR record containing a *PRMID* field. If that value is MINONE, a new message identifier is generated for *each* of those destinations (that is, no two of those destinations have the same message identifier).

If PMNMID is specified, new message identifiers are generated for all of the destinations in the distribution list, regardless of whether they have MQPMR records. This is different from the way that PMNCID is processed (see *PRCID* field).

This is an input/output field.

Initial values

There are no initial values defined for this structure, as no structure declaration is provided. The following sample declaration shows how the structure should be declared by the application programmer if all of the fields are required.

RPG declaration

```
D*..1....:....2....:....3....:....4....:....5....:....6....:....7..

```

MQRFH - Rules and formatting header

The MQRFH structure defines the layout of the rules and formatting header.

Overview

Purpose: This header can be used to send string data in the form of name/value pairs.

Format name: FMRFH.

Character set and encoding: The fields in the MQRFH structure (including *RFNVS*) are in the character set and encoding given by the *MDCSI* and *MDENC* fields in the header structure that precedes the MQRFH, or by those fields in the MQMD structure if the MQRFH is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

- [“Fields” on page 1148](#)
- [“Initial values” on page 1150](#)
- [“RPG declaration” on page 1151](#)

Fields

The MQRFH structure contains the following fields; the fields are described in **alphabetical order**:

RFCSI (10-digit signed integer)

Character set identifier of data that follows *RFNVS*.

This specifies the character set identifier of the data that follows *RFNVS* ; it does not apply to character data in the MQRFH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

Numeric encoding of data that follows *RFNVS*.

This specifies the numeric encoding of the data that follows *RFNVS* ; it does not apply to numeric data in the MQRFH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is ENNAT.

RFFLG (10-digit signed integer)

Flags.

The following can be specified:

RFNONE

No flags.

The initial value of this field is RFNONE.

RFFMT (8-byte character string)

Format name of data that follows *RFNVS*.

This specifies the format name of the data that follows *RFNVS*.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

RFLEN (10-digit signed integer)

Total length of MQRFH including *RFNVS*.

This is the length in bytes of the MQRFH structure, including the *RFNVS* field at the end of the structure. The length does *not* include any user data that follows the *RFNVS* field.

To avoid problems with data conversion of the user data in some environments, consider using *RFLEN* as a multiple of four.

The following constant gives the length of the *fixed* part of the structure, that is, the length excluding the *RFNVS* field:

RFLENV

Length of fixed part of MQRFH structure.

The initial value of this field is RFLENV.

RFNVS (n-byte character string)

String containing name/value pairs.

This is a variable-length character string containing name/value pairs in the form:

```
name1 value1 name2 value2 name3 value3 ...
```

Each name or value must be separated from the adjacent name or value by one or more blank characters; these blanks are not significant. A name or value can contain significant blanks by prefixing and suffixing the name or value with the quotation mark character; all characters between the opening quotation mark and the matching closing quotation mark are treated as significant. In the following example, the name is FAMOUS_WORDS, and the value is Hello World:

```
FAMOUS_WORDS "Hello World"
```

A name or value can contain any characters other than the null character (which acts as a delimiter for *RFNVS*). However, to assist interoperability an application might prefer to restrict names to the following characters:

- First character: uppercase or lowercase alphabetic (A through Z, or a through z), or underscore.
- Subsequent characters: upper or lowercase alphabetic, decimal digit (0 through 9), underscore, hyphen, or dot.

If a name or value contains one or more quotation marks, the name or value must be enclosed in quotation marks, and each quotation mark within the string must be doubled:

```
Famous_Words "The program displayed ""Hello World"""
```

Names and values are case sensitive, that is, lowercase letters are not considered to be the same as uppercase letters. For example, FAMOUS_WORDS and Famous_Words are two different names.

The length in bytes of *RFNVS* is equal to *RFLEN* minus *RFLENV*. To avoid problems with data conversion of the user data in some environments, it is recommended that this length should be a multiple of four. *RFNVS* must be padded with blanks to this length, or terminated earlier by placing a null character following the last significant character in the string. The null character and the bytes following it, up to the specified length of *RFNVS*, are ignored.

Note: Because the length of this field is not fixed, the field is omitted from the declarations of the structure that are provided for the supported programming languages.

RFSID (4-byte character string)

Structure identifier.

The value must be:

RFSIDV

Identifier for rules and formatting header structure.

The initial value of this field is RFSIDV.

RFVER (10-digit signed integer)

Structure version number.

The value must be:

RFVER1

Version-1 rules and formatting header structure.

The initial value of this field is RFVER1.

Initial values

MQRFH2 - Rules and formatting header 2

The MQRFH2 structure defines the format of the version-2 rules and formatting header.

Overview

Purpose: This header can be used to send data that has been encoded using an XML-like syntax. A message can contain two or more MQRFH2 structures in series, with user data optionally following the last MQRFH2 structure in the series.

Format name: FMRFH2.

Character set and encoding: Special rules apply to the character set and encoding used for the MQRFH2 structure:

- Fields other than *RF2NVD* are in the character set and encoding given by the *MDCSI* and *MDENC* fields in the header structure that precedes MQRFH2, or by those fields in the MQMD structure if the MQRFH2 is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

When GMCONV is specified on the MQGET call, the queue manager converts these fields to the requested character set and encoding.

- RF2NVD* is in the character set given by the *RF2NVC* field. Only certain Unicode character sets are valid for *RF2NVC* (see the description of *RF2NVC* for details).

Some character sets have a representation that is dependent on the encoding. If *RF2NVC* is one of these character sets, *RF2NVD* must be in the same encoding as the other fields in the *MQRFH2*.

When *GMCONV* is specified on the *MQGET* call, the queue manager converts *RF2NVD* to the requested encoding, but does not change its character set.

- [“Fields” on page 1152](#)
- [“Initial values” on page 1156](#)
- [“RPG declaration” on page 1156](#)

Fields

The *MQRFH2* structure contains the following fields; the fields are described in **alphabetical order**:

RF2CSI (10-digit signed integer)

Character set identifier of data that follows last *RF2NVD* field.

This specifies the character set identifier of the data that follows the last *RF2NVD* field; it does not apply to character data in the *MQRFH2* structure itself.

On the *MQPUT* or *MQPUT1* call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value *CSINHT* is not returned by the *MQGET* call.

CSINHT cannot be used if the value of the *MDPAT* field in *MQMD* is *ATBRKR*.

The initial value of this field is *CSINHT*.

RF2ENC (10-digit signed integer)

Numeric encoding of data that follows last *RF2NVD* field.

This specifies the numeric encoding of the data that follows the last *RF2NVD* field; it does not apply to numeric data in the *MQRFH2* structure itself.

On the *MQPUT* or *MQPUT1* call, the application must set this field to the value appropriate to the data.

The initial value of this field is *ENNAT*.

RF2FLG (10-digit signed integer)

Flags.

The following value must be specified:

RFNONE

No flags.

The initial value of this field is *RFNONE*.

RF2FMT (8-byte character string)

Format name of data that follows last *RF2NVD* field.

This specifies the format name of the data that follows the last *RF2NVD* field.

On the *MQPUT* or *MQPUT1* call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in *MQMD*.

The initial value of this field is *FMNONE*.

RF2LEN (10-digit signed integer)

Total length of MQRFH2 including all *RF2NVL* and *RF2NVD* fields.

This is the length in bytes of the MQRFH2 structure, including the *RF2NVL* and *RF2NVD* fields at the end of the structure. It is valid for there to be multiple pairs of *RF2NVL* and *RF2NVD* fields at the end of the structure, in the sequence:

```
length1, data1, length2, data2, ...
```

RF2LEN does *not* include any user data that may follow the last *RF2NVD* field at the end of the structure.

To avoid problems with data conversion of the user data in some environments, consider using *RF2LEN* as a multiple of four.

The following constant gives the length of the *fixed* part of the structure, that is, the length excluding the *RF2NVL* and *RF2NVD* fields:

RFLEN2

Length of fixed part of MQRFH2 structure.

The initial value of this field is RFLEN2.

RF2NVC (10-digit signed integer)

Character set identifier of *RF2NVD*.

This specifies the coded character set identifier of the data in the *RF2NVD* field. This is different from the character set of the other strings in the MQRFH2 structure, and can be different from the character set of the data (if any) that follows the last *RF2NVD* field at the end of the structure.

RF2NVC must have one of the following CCSID values:

1200

UCS-2 open-ended

13488

UCS-2 2.0 subset

17584

UCS-2 2.1 subset (includes the Euro symbol)

1208

UTF-8

For the UCS-2 character sets, the encoding (byte order) of the *RF2NVD* must be the same as the encoding of the other fields in the MQRFH2 structure. Surrogate characters (X'D800' through X'DFFF') are not supported.

Note: If *RF2NVC* does not have one of the values listed previously, and the MQRFH2 structure requires conversion on the MQGET call, the call completes with reason code RC2111 and the message is returned unconverted.

The initial value of this field is 1208.

RF2NVD (n-byte character string)

Name/value data.

This is a variable-length character string containing data encoded using an XML-like syntax. The length in bytes of this string is provided by the *RF2NVL* field that precedes the *RF2NVD* field; this length should be a multiple of four.

The *RF2NVL* and *RF2NVD* fields are optional, but if present they must occur as a pair and be adjacent. The pair of fields can be repeated as many times as required, for example:

```
length1 data1 length2 data2 length3 data3
```

Because these fields are optional, they are omitted from the declarations of the structure that are provided for the various programming languages supported.

RF2NVD is unusual because it is *not* converted to the character set specified on the MQGET call when the message is retrieved with the GMCONV option in effect; *RF2NVD* remains in its original character set. However, *RF2NVD* is converted to the encoding specified on the MQGET call.

Syntax of name/value data: The string consists of a single "folder" that contains zero or more properties. The folder is delimited by XML start and end tags with the same name as the folder:

```
<folder> property1 property2 ... </folder>
```

Characters following the folder end tag, up to the length defined by *RF2NVL*, must be blank. Within the folder, each property is composed of a name and a value, and optionally a data type:

```
<name dt="datatype">value</name>
```

In these examples:

- The delimiter characters (<, =, ", /, and >) must be specified exactly as shown.
- name is the user-specified name of the property; see the following example for more information about names.
- datatype is an optional user-specified data type of the property; see the following example for valid data types.
- value is the user-specified value of the property; see the following paragraphs for more information about values.
- Blanks are significant between the > character which precedes a value, and the < character which follows the value, and at least one blank must precede dt=. Elsewhere blanks can be coded freely between tags, or preceding or following tags (for example, in order to improve readability); these blanks are not significant.

If properties are related to each other, they can be grouped together by enclosing them within XML start and end tags with the same name as the group:

```
<folder> <group> property1 property2 ... </group> </folder>
```

Groups can be nested within other groups, without limit, and a group can occur more than once within a folder. It is also valid for a folder to contain some properties in groups and other properties not in groups.

Names of properties, groups, and folders: Names of properties, groups, and folders must be valid XML tag names, with the exception of the colon character, which is not permitted in a property, group, or folder name. In particular:

- Names must start with a letter or an underscore. Valid letters are defined in the W3C XML specification, and consist essentially of Unicode categories Ll, Lu, Lo, Lt, and Nl.
- The remaining characters in a name can be letters, decimal digits, underscores, hyphens, or dots. These correspond to Unicode categories Ll, Lu, Lo, Lt, Nl, Mc, Mn, Lm, and Nd.
- The Unicode compatibility characters (X'F900' and above) are not permitted in any part of a name.
- Names must not start with the string XML in any mixture of upper or lowercase.

In addition:

- Names are case-sensitive. For example, ABC, abc, and Abc are three different names.
- Each folder has a separate namespace. As a result, a group or property in one folder does not conflict with a group or property of the same name in another folder.
- Groups and properties occupy the same namespace within a folder. As a result, a property cannot have the same name as a group within the folder containing that property.

Generally, programs that analyze the *RF2NVD* field should ignore properties or groups that have names that the program does not recognize, provided that those properties or groups are correctly formed.

Data types of properties: Each property can have an optional data type. If specified, the data type must be one of the following values, in upper, lower, or mixed case:

Data type	Used for
string	Any sequence of characters. Certain characters must be specified using escape sequences.
boolean	The character 0 or 1 (1 denotes TRUE).
bin.hex	Hexadecimal digits representing octets.
i1	Integer number in the range -128 through +127, expressed using only decimal digits and optional sign.
i2	Integer number in the range -32 768 through +32 767, expressed using only decimal digits and optional sign.
i4	Integer number in the range -2 147 483 648 through +2 147 483 647, expressed using only decimal digits and optional sign.
i8	Integer number in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, expressed using only decimal digits and optional sign.
int	Integer number in the range -9 223 372 036 854 775 808 through +9 223 372 036 854 775 807, expressed using only decimal digits and optional sign. This can be used in place of i1, i2, i4, or i8 if the sender does not want to imply a particular precision.
r4	Floating-point number with magnitude in the range 1.175E-37 through 3.402 823 47E+38, expressed using decimal digits, optional sign, optional fractional digits, and optional exponent.
r8	Floating-point number with magnitude in the range 2.225E-307 through 1.797 693 134 862 3E+308 expressed using decimal digits, optional sign, optional fractional digits, and optional exponent.

Values of properties: The value of a property can consist of any characters, except as detailed in the following figure. Each occurrence in the value of a character marked as "mandatory" must be replaced by the corresponding escape sequence. Each occurrence in the value of a character marked as "optional" can be replaced by the corresponding escape sequence, but this is not required.

Character	Escape sequence	Usage
&	&	Mandatory
<	<	Mandatory
>	>	Optional
"	"	Optional
'	'	Optional

Note: The & character at the start of an escape sequence must *not* be replaced by &;.

In the following example, the blanks in the value are significant; however, no escape sequences are needed:

```
<Famous_Words>The program displayed "Hello World"</Famous_Words>
```

RF2NVL (10-digit signed integer)

Length of *RF2NVD*.

This specifies the length in bytes of the data in the *RF2NVD* field. To avoid problems with data conversion of the data (if any) that *follows* the *RF2NVD* field, *RF2NVL* should be a multiple of four.

Note: The *RF2NVL* and *RF2NVD* fields are optional, but if present they must occur as a pair and be adjacent. The pair of fields can be repeated as many times as required, for example:

```
length1 data1 length2 data2 length3 data3
```

Because these fields are optional, they are omitted from the declarations of the structure that are provided for the various programming languages supported.

RF2SID (4-byte character string)

Structure identifier.

The value must be:

RFSIDV

Identifier for rules and formatting header structure.

The initial value of this field is RFSIDV.

RF2VER (10-digit signed integer)

Structure version number.

The value must be:

RFVER2

Version-2 rules and formatting header structure.

The initial value of this field is RFVER2.

Initial values

Table 609. Initial values of fields in MQRFH2		
Field name	Name of constant	Value of constant
<i>RF2SID</i>	RFSIDV	'RFH¬'

```

MQRMH - Reference message header

The MQRMH structure defines the format of a reference message header.

Overview

Purpose: This header is used with user-written message channel exits to send large amounts of data (called "bulk data") from one queue manager to another. The difference compared to normal messaging is that the bulk data is not stored on a queue; instead, only a *reference* to the bulk data is stored on the queue. This reduces the possibility of IBM MQ resources being exhausted by a few large messages.

Format name: FMRMH.

Character set and encoding: Character data in MQRMH, and the strings addressed by the offset fields, must be in the character set of the local queue manager; this is given by the *CodedCharSetId* queue manager attribute. Numeric data in MQRMH must be in the native machine encoding; this is given by the value of ENNAT for the C programming language.

The character set and encoding of the MQRMH must be set into the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQRMH structure is at the start of the message data), or
- The header structure that precedes the MQRMH structure (all other cases).

Usage: An application puts a message consisting of an MQRMH, but omitting the bulk data. When the message is read from the transmission queue by a message channel agent (MCA), a user-supplied message exit is invoked to process the reference message header. The exit can append to the reference message the bulk data identified by the MQRMH structure, before the MCA sends the message through the channel to the next queue manager.

At the receiving end, a message exit that waits for reference messages should exist. When a reference message is received, the exit should create the object from the bulk data that follows the MQRMH in the message, and then pass on the reference message without the bulk data. The reference message can later be retrieved by an application reading the reference message (without the bulk data) from a queue.

Normally, the MQRMH structure is all that is in the message. However, if the message is on a transmission queue, one or more additional headers will precede the MQRMH structure.

A reference message can also be sent to a distribution list. In this case, the MQDH structure and its related records precede the MQRMH structure when the message is on a transmission queue.

Note: A reference message should not be sent as a segmented message, because the message exit cannot process it correctly.

- [“Data conversion” on page 1158](#)
- [“Fields” on page 1158](#)
- [“Initial values” on page 1162](#)
- [“RPG declaration” on page 1163](#)

Data conversion

For data conversion purposes, conversion of the MQRMH structure includes conversion of the source environment data, source object name, destination environment data, and destination object name. Any other bytes within *RMLLEN* bytes of the start of the structure are either discarded or have undefined values after data conversion. The bulk data will be converted provided that all of the following are true:

- The bulk data is present in the message when the data conversion is performed.
- The *RMFMT* field in MQRMH has a value other than FMNONE.
- A user-written data-conversion exit exists with the format name specified.

Be aware, however, that typically the bulk data is *not* present in the message when the message is on a queue, and that as a result the bulk data will not be converted by the GMCONV option.

Fields

The MQRMH structure contains the following fields; the fields are described in **alphabetical order**:

RMCSI (10-digit signed integer)

Character set identifier of bulk data.

This specifies the character set identifier of the bulk data; it does not apply to character data in the MQRMH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

RMDEL (10-digit signed integer)

Length of destination environment data.

If this field is zero, there is no destination environment data, and *RMDEO* is ignored.

RMDEO (10-digit signed integer)

Offset of destination environment data.

This field specifies the offset of the destination environment data from the start of the MQRMH structure. Destination environment data can be specified by the creator of the reference message, if that data is known to the creator. For example, the destination environment data might be the directory path of the object where the bulk data is to be stored. However, if the creator does not know the destination environment data, it is the responsibility of the user-supplied message exit to determine any environment information needed.

The length of the destination environment data is given by *RMDEL* ; if this length is zero, there is no destination environment data, and *RMDEO* is ignored. If present, the destination environment data must reside completely within *RMLLEN* bytes from the start of the structure.

Applications should not assume that the destination environment data is contiguous with any of the data addressed by the *RMSEO*, *RMSNO*, and *RMDNO* fields.

The initial value of this field is 0.

RMDL (10-digit signed integer)

Length of bulk data.

The *RMDL* field specifies the length of the bulk data referenced by the MQRMH structure.

If the bulk data is present in the message, the data begins at an offset of *RMLen* bytes from the start of the MQRMH structure. The length of the entire message minus *RMLen* gives the length of the bulk data present.

If data is present in the message, *RMDL* specifies the amount of that data that is relevant. The normal case is for *RMDL* to have the same value as the length of data present in the message.

If the MQRMH structure represents the remaining data in the object (starting from the specified logical offset), the value zero can be used for *RMDL*, if the bulk data is not present in the message.

If no data is present, the end of MQRMH coincides with the end of the message.

The initial value of this field is 0.

RMDNL (10-digit signed integer)

Length of destination object name.

If this field is zero, there is no destination object name, and *RMDNO* is ignored.

RMDNO (10-digit signed integer)

Offset of destination object name.

This field specifies the offset of the destination object name from the start of the MQRMH structure. The destination object name can be specified by the creator of the reference message, if that data is known to the creator. However, if the creator does not know the destination object name, it is the responsibility of the user-supplied message exit to identify the object to be created or modified.

The length of the destination object name is given by *RMDNL* ; if this length is zero, there is no destination object name, and *RMDNO* is ignored. If present, the destination object name must reside completely within *RMLen* bytes from the start of the structure.

Applications should not assume that the destination object name is contiguous with any of the data addressed by the *RMSEO*, *RMSNO*, and *RMDEO* fields.

The initial value of this field is 0.

RMDO (10-digit signed integer)

Low offset of bulk data.

This field specifies the low offset of the bulk data from the start of the object of which the bulk data forms part. The offset of the bulk data from the start of the object is called the *logical offset*. This is *not* the physical offset of the bulk data from the start of the MQRMH structure - that offset is given by *RMLen*.

To allow large objects to be sent using reference messages, the logical offset is divided into two fields, and the actual logical offset is given by the sum of these two fields:

- *RMDO* represents the remainder obtained when the logical offset is divided by 1 000 000 000. It is thus a value in the range 0 through 999 999 999.
- *RMDO2* represents the result obtained when the logical offset is divided by 1 000 000 000. It is thus the number of complete multiples of 1 000 000 000 that exist in the logical offset. The number of multiples is in the range 0 through 999 999 999.

The initial value of this field is 0.

RMDO2 (10-digit signed integer)

High offset of bulk data.

This field specifies the high offset of the bulk data from the start of the object of which the bulk data forms part. It is a value in the range 0 through 999 999 999. See *RMDO* for details.

The initial value of this field is 0.

RMENC (10-digit signed integer)

Numeric encoding of bulk data.

This specifies the numeric encoding of the bulk data; it does not apply to numeric data in the MQRMH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is ENNAT.

RMFLG (10-digit signed integer)

Reference message flags.

The following flags are defined:

RMLAST

Reference message contains or represents last part of object.

This flag indicates that the reference message represents or contains the last part of the referenced object.

RMNLST

Reference message does not contain or represent last part of object.

RMNLST is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

The initial value of this field is RMNLST.

RMFMT (8-byte character string)

Format name of bulk data.

This specifies the format name of the bulk data.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The initial value of this field is FMNONE.

RMLEN (10-digit signed integer)

Total length of MQRMH, including strings at end of fixed fields, but not the bulk data.

The initial value of this field is zero.

RMOII (24-byte bit string)

Object instance identifier.

This field can be used to identify a specific instance of an object. If it is not needed, it should be set to the following value:

OIINON

No object instance identifier specified.

The value is binary zero for the length of the field.

The length of this field is given by LNOIID. The initial value of this field is OIINON.

RMOT (8-byte character string)

Object type.

This is a name that can be used by the message exit to recognize types of reference message that it supports. Consider making the name conform to the same rules as the *RMFMT* field.

The initial value of this field is 8 blanks.

RMSEL (10-digit signed integer)

Length of source environment data.

If this field is zero, there is no source environment data, and *RMSEO* is ignored.

The initial value of this field is 0.

RMSEO (10-digit signed integer)

Offset of source environment data.

This field specifies the offset of the source environment data from the start of the MQRMH structure. Source environment data can be specified by the creator of the reference message, if that data is known to the creator. For example, the source environment data might be the directory path of the object containing the bulk data. However, if the creator does not know the source environment data, it is the responsibility of the user-supplied message exit to determine any environment information needed.

The length of the source environment data is given by *RMSEL* ; if this length is zero, there is no source environment data, and *RMSEO* is ignored. If present, the source environment data must reside completely within *RMLLEN* bytes from the start of the structure.

Applications should not assume that the environment data starts immediately after the last fixed field in the structure or that it is contiguous with any of the data addressed by the *RMSNO*, *RMDEO*, and *RMDNO* fields.

The initial value of this field is 0.

RMSID (4-byte character string)

Structure identifier.

The value must be:

RMSIDV

Identifier for reference message header structure.

The initial value of this field is RMSIDV.

RMSNL (10-digit signed integer)

Length of source object name.

If this field is zero, there is no source object name, and *RMSNO* is ignored.

The initial value of this field is 0.

RMSNO (10-digit signed integer)

Offset of source object name.

This field specifies the offset of the source object name from the start of the MQRMH structure. The source object name can be specified by the creator of the reference message, if that data is known to the creator. However, if the creator does not know the source object name, it is the responsibility of the user-supplied message exit to identify the object to be accessed.

The length of the source object name is given by *RMSNL* ; if this length is zero, there is no source object name, and *RMSNO* is ignored. If present, the source object name must reside completely within *RMLLEN* bytes from the start of the structure.

Applications should not assume that the source object name is contiguous with any of the data addressed by the *RMSEO*, *RMDEO*, and *RMDNO* fields.

The initial value of this field is 0.

RMVER (10-digit signed integer)

Structure version number.

The value must be:

RMVER1

Version-1 reference message header structure.

The following constant specifies the version number of the current version:

RMVERC

Current version of reference message header structure.

The initial value of this field is RMVER1.

Initial values

RPG declaration

MQRR - Response record

The MQRR structure is used to receive the completion code and reason code resulting from the open or put operation for a single destination queue, when the destination is a distribution list.

Overview

Purpose: MQRR is an output structure for the MQOPEN, MQPUT, and MQPUT1 calls.

Character set and encoding: Data in MQRR must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

Usage: By providing an array of these structures on the MQOPEN and MQPUT calls, or on the MQPUT1 call, it is possible to determine the completion codes and reason codes for all of the queues in a distribution list when the outcome of the call is mixed, that is, when the call succeeds for some queues in the list but fails for others. Reason code RC2136 from the call indicates that the response records (if provided by the application) have been set by the queue manager.

- [“Fields” on page 1163](#)
- [“Initial values” on page 1164](#)
- [“RPG declaration” on page 1164](#)

Fields

The MQRR structure contains the following fields; the fields are described in **alphabetical order**:

RRCC (10-digit signed integer)

Completion code for queue.

This is the completion code resulting from the open or put operation for the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call.

This is always an output field. The initial value of this field is CCOK.

RRREA (10-digit signed integer)

Reason code for queue.

This is the reason code resulting from the open or put operation for the queue with the name that was specified by the corresponding element in the array of MQOR structures provided on the MQOPEN or MQPUT1 call.

This is always an output field. The initial value of this field is RCNONE.

Initial values

MQSCO - SSL configuration options

The MQSCO structure (with the SSL fields in the MQCD structure) allows an application running as an IBM MQ MQI client to specify configuration options that control the use of SSL for the client connection when the channel protocol is TCP/IP.

Overview

Purpose: The structure is an input parameter on the MQCONN call.

If the channel protocol for the client channel is not TCP/IP, the MQSCO structure is ignored.

Character set and encoding: Data in MQSCO must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT.

- [“Fields” on page 1164](#)
- [“Initial values” on page 1168](#)
- [“RPG declaration” on page 1168](#)

Fields

The MQSCO structure contains the following fields; the fields are described in **alphabetical order**:

SCAIC (10-digit signed integer)

This is the number of authentication information (MQAIR) records addressed by the *SCAIP* or *SCAIO* fields. For more information, see “MQAIR - Authentication information record” on page 976. The value must be zero or greater. If the value is not valid, the call fails with reason code RC2383.

This is an input field. The initial value of this field is 0.

SCAIO (10-digit signed integer)

This is the offset in bytes of the first authentication information record from the start of the MQSCO structure. The offset can be positive or negative. The field is ignored if *SCAIC* is zero.

You can use either *SCAIO* or *SCAIP* to specify the MQAIR records, but not both; see the description of the *SCAIP* field for details.

This is an input field. The initial value of this field is 0.

SCAIP (10-digit signed integer)

This is the address of the first authentication information record. The field is ignored if *SCAIC* is zero.

You can provide the array of MQAIR records in one of two ways:

- By using the pointer field *SCAIP*

In this case, the application can declare an array of MQAIR records that is separate from the MQSCO structure, and set *SCAIP* to the address of the array.

Consider using *SCAIP* for programming languages that support the pointer data type in a fashion that is portable to different environments (for example, the C programming language).

- By using the offset field *SCAIO*

In this case, the application must declare a compound structure containing an MQSCO followed by the array of MQAIR records, and set *SCAIO* to the offset of the first record in the array from the start of the MQSCO structure. Ensure that this value is correct, and has a value that can be accommodated within an MQLONG (the most restrictive programming language is COBOL, for which the valid range is -999 999 999 through +999 999 999).

Consider using *SCAIO* for programming languages that do not support the pointer data type, or that implement the pointer data type in a fashion that is not portable to different environments (for example, the COBOL programming language).

Whatever technique you choose, only one of *SCAIP* and *SCAIO* can be used; the call fails with reason code RC2384 if both are nonzero.

This is an input field. The initial value of this field is the null pointer in those programming languages that support pointers, and an all-null byte string otherwise.

Note: On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

SCCERLBL (10-digit signed integer)

This field gives details of the certificate label being used.

IBM MQ initializes the value for the SCCERLBL field as blanks. Either enter the required value, or accept the default value.

`ibmwebsphermq<user_id>` is a valid value for this field for all versions of the product, and for MQSCO versions less than 5.0 it is the only valid value. Therefore the value of this field is interpreted at run time, and changed if necessary. If you specify an MQSCO version less than 5.0, or accept the default value of blanks for the SCCERLBL field, the system uses the value `ibmwebsphermq<user_id>`.

This is an input field.

SCCERTVPOL (10-digit signed integer)

This field specifies what type of certificate validation policy is used. The field can be set to one of the following values:

MQ_CERT_VAL_POLICY_ANY

Apply each of the certificate validation policies supported by the secure sockets library. Accept the certificate chain if any of the policies considers the certificate chain valid.

MQ_CERT_VAL_POLICY_RFC5280

Apply only the RFC5280 compliant certificate validation policy. This setting provides stricter validation than the ANY setting, but rejects some older digital certificates.

The initial value of this field is MQ_CERT_VAL_POLICY_ANY

SCCH (10-digit signed integer)

This field gives configuration details for cryptographic hardware connected to the client system.

Set the field to a string in the following format, or leave it blank or null:

```
GSK_PKCS11=<the PKCS #11 driver path and file name>;<the PKCS #11 token label>;<the PKCS #11 token password>;<symmetric cipher setting>;
```

To use cryptographic hardware which conforms to the PKCS11 interface, for example, the IBM 4960 or IBM 4963, specify the PKCS11 driver path, PKCS11 token label, and PKCS11 token password strings, each terminated by a semi-colon.

The PKCS #11 driver path is an absolute path to the shared library providing support for the PKCS #11 card. The PKCS #11 driver file name is the name of the shared library. An example of the value required for the PKCS #11 path and file name is:

```
/usr/lib/pkcs11/PKCS11_API.so
```

The PKCS #11 token label must be entirely in lowercase. If you have configured your hardware with a mixed case or uppercase token label, reconfigure it with this lowercase label.

If no cryptographic hardware configuration is required, set the field to blank or null.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. If the value is not valid, or leads to a failure when used to configure the cryptographic hardware, the call fails with reason code RC2382.

This is an input field. The length of this field is given by LNSSCH. The initial value of this field is blank characters.

SCEPSUITEB (10-digit signed integer)

This field Specifies whether Suite B compliant cryptography is used and what level of strength is employed. The value can be one or more of:

- SCEPSUITEB0

Suite B compliant cryptography is not used.

- SCEPSUITEB1

Suite B 128-bit strength security is used.

- SCEPSUITEB2

Suite B 192-bit strength security is used.

Note: Using SCEPSUITEB0 with any other value in this field is invalid.

SCFR (10-digit signed integer)

IBM MQ can be configured with cryptographic hardware so that the cryptography modules used are those provided by the hardware product; these can be FIPS-certified to a particular level depending on the cryptographic hardware product in use.

Use this field to specify that only FIPS-certified algorithms are used if the cryptography is provided in IBM MQ-provided software.

When IBM MQ is installed an implementation of SSL cryptography is also installed which provides some FIPS-certified modules.

The values can be:

MQSSL_FIPS_NO

This is the default value. When set to this value:

- Any CipherSpec supported on a particular platform can be used.
- If run without use of cryptographic hardware, the following CipherSpecs run using FIPS 140-2 certified cryptography on the IBM MQ platforms:
 - TLS_RSA_WITH_3DES_EDE_CBC_SHA
 - TLS_RSA_WITH_AES_128_CBC_SHA
 - TLS_RSA_WITH_AES_256_CBC_SHA

MQSSL_FIPS_YES

When set to this value, unless you are using cryptographic hardware to perform the cryptography, you can be sure that

- Only FIPS-certified cryptographic algorithms can be used in the CipherSpec applying to this client connection.
- Inbound and outbound SSL channel connections only succeed if one of the following Cipher Specs are used:
 - TLS_RSA_WITH_3DES_EDE_CBC_SHA
 - TLS_RSA_WITH_AES_128_CBC_SHA
 - TLS_RSA_WITH_AES_256_CBC_SHA

Notes:

1. CipherSpec TLS_RSA_WITH_3DES_EDE_CBC_SHA is deprecated.
2. Where possible, if FIPS-only CipherSpecs is configured then the MQI client rejects connections which specify a non-FIPS CipherSpec with RC2393. IBM MQ does not guarantee to reject all such connections and it is your responsibility to determine whether your IBM MQ configuration is FIPS-compliant.

SCKR (10-digit signed integer)

This field is relevant only for IBM MQ MQI clients running on UNIX systems and Windows systems. It specifies the location of the key database file in which keys and certificates are stored. The key database file must have a file name of the form `zzz.kdb`, where `zzz` is user-selectable. The *SCKR* field contains the path to this file, along with the file name stem (all characters in the file name up to but not including the final `.kdb`). The `.kdb` file suffix is added automatically.

Each key database file has an associated *password stash file*. This holds encrypted passwords that are used to allow programmatic access to the key database. The password stash file must reside in the same directory and have the same file stem as the key database, and must end with the suffix `.sth`.

For example, if the *SCKR* field has the value `/xxx/yyy/key`, the key database file must be `/xxx/yyy/key.kdb`, and the password stash file must be `/xxx/yyy/key.sth`, where `xxx` and `yyy` represent directory names.

If the value is shorter than the length of the field, terminate the value with a null character, or pad it with blanks to the length of the field. The value is not checked; if there is an error in accessing the key repository, the call fails with reason code RC2381.

To run an SSL connection from an IBM MQ MQI client, set *SCKR* to a valid key database file name.

This is an input field. The length of this field is given by LNSSKR. The initial value of this field is a blank character.

SCSID (10-digit signed integer)

This is the structure identifier; the value must be:

SCSIDV

Identifier for SSL configuration options structure.

This is always an input field. The initial value of this field is SCSIDV.

SCVER (10-digit signed integer)

This is the structure version number; the value must be:

SCVER1

Version-1 SSL configuration options structure.

SCVER2

Version-2 SSL configuration options structure.

The following constant specifies the version number of the current version:

SCVERC

Current version of SSL configuration options structure.

This is always an input field. The initial value of this field is SCVER2

Initial values

Table 612. Initial values of fields in MQSCO		
Field name	Name of constant	Value of constant
SCSID	SCSIDV	'SCO~'
SCVER	SCVER5	1
SCKR	None	Null string or blanks
SCCH	None	Null string or blanks
SCAIC	None	0
SCAIO	None	0
SCAIP	None	Null pointer or null bytes
SCKRC	None	Null pointer or null bytes
SCFR	None	Null pointer or null bytes
SCEPSUITEB	None	Null pointer or null bytes
SCCERTVPOL	None	Null pointer or null bytes
SCCERLBL	None	Null pointer or null bytes
Notes:		
1. The symbol ~ represents a single blank character.		
2. See “RPG declaration” on page 1168 for the SCEPSUITEB options.

MQSD - Subscription descriptor

The MQSD structure is used to specify details about the subscription being made.

Overview

Purpose

The structure is an input/output parameter on the MQSUB call.

Managed subscriptions

If an application has no specific need to use a particular queue as the destination for those publications that match its subscription, it can use the managed subscription feature. If an application elects to use a managed subscription, the queue manager informs the subscriber about the destination where published messages are sent, by providing an object handle as an output from the MQSUB call. For more information, see [HOBJ \(10-digit signed integer\) - input/output](#).

When the subscription is removed, the queue manager also undertakes to clean up messages that have not been retrieved from the managed destination, in the following situations:

- When the subscription is removed - by use of MQCLOSE with CORMSB - and the managed Hobj is closed.
- By implicit means when the connection is lost to an application using a non-durable subscription (SONDUR)
- By expiration when a subscription is removed because it has expired and the managed Hobj is closed.

You must use managed subscriptions with non-durable subscriptions, so that the clean up can occur, and so that messages for closed non-durable subscriptions do not take up space in your queue manager. Durable subscriptions can also use managed destinations.

Character set and encoding

Data in MQSD must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT. However, if the application is running as an IBM MQ client, the structure must be in the character set and encoding of the client.

- [“Fields” on page 1170](#)
- [“Initial values” on page 1181](#)
- [“RPG declaration” on page 1182](#)

Fields

The MQSD structure contains the following fields; the fields are described in alphabetical order:

SDAID (32 byte character string)

This value is in the *MDAID* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. *SDAID* is part of the identity context of the message. For more information about message context, see [Message context](#).

For more information about *MDAID* see [MDAID](#).

If the *S0SETI* option is not specified, the *MDAID* which is set in each message published for this subscription is blanks, as default context information.

If the *S0SETI* option is specified, the *SDAID* is being generated by the user and this field is an input field which contains the *MDAID* to be set in each publication for this subscription.

The length of this field is given by *LNAIDD*. The initial value of this field is 32 blank characters.

If altering an existing subscription using the *SOALT* option, the *SDAID* of any future publication messages can be changed.

On return from an *MQSUB* call using *SORES*, this field is set to the current *MDAID* being used for the subscription.

SDACC (32 byte character string)

This value is in the *MDACC* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. *MDACC* is part of the identity context of the message. For more information about message context, see [Message context](#).

For more information about *MDACC* see [MDACC](#).

You can use the following special value for the *SDACC* field:

ACNONE

No accounting token is specified.

The value is binary zero for the length of the field.

If the *S0SETI* option is not specified, the accounting token is generated by the queue manager as default context information and this field is an output field which contains the *MDACC* which is set in each message published for this subscription.

If the *S0SETI* option is specified, the accounting token is being generated by the user and this field is an input field which contains the *MDACC* to be set in each publication for this subscription.

The length of this field is given by *LNACCT*. The initial value of this field is *ACNONE*.

If altering an existing subscription using the *SOALT* option, the value of *MDACC* in any future publication messages can be changed.

On return from an *MQSUB* call using *SORES*, this field is set to the current *MDACC* being used for the subscription.

SDASI (40 byte bit string)

This is a security identifier that is passed with the *SDAU* to the authorization service to allow appropriate authorization checks to be performed.

SDASI is used only if *SOALTU* is specified, and the *SDAU* field is not entirely blank up to the first null character or the end of the field.

On return from an *MQSUB* call using *SORES*, this field is unchanged.

See the description of [ODASI](#) in the MQOD data type for more information.

SDAU (12 byte character string)

If you specify SOALTU, this field contains an alternate user identifier that is used to check the authorization for the subscription and for output to the destination queue (specified in the *Hobj* parameter of the MQSUB call), in place of the user identifier that the application is currently running under.

If successful, the user identifier specified in this field is recorded as the subscription owning user identifier in place of the user identifier that the application is currently running under.

If SOALTU is specified and this field is entirely blank up to the first null character or the end of the field, the subscription can succeed only if no user authorization is needed to subscribe to this topic with the options specified or the destination queue for output.

If SOALTU is not specified, this field is ignored.

On return from an MQSUB call using SORES, this field is unchanged.

This is an input field. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

SDCID (24 byte bit string)

All publications sent to match this subscription contain this correlation identifier in the message descriptor. If multiple subscriptions use the same queue to get their publications from, using MQGET by correlation ID allows only publications for a specific subscription to be obtained. This correlation identifier can either be generated by the queue manager or by the user.

If the S0SCID option is not specified, the correlation identifier is generated by the queue manager and this field is an output field which contains the correlation identifier which is set in each message published for this subscription.

If the S0SCID option is specified, the correlation identifier is being generated by the user and this field is an input field which contains the correlation identifier to be set in each publication for this subscription. In this case, if the field contains CINONE, the correlation identifier which is set in each message published for this subscription is the correlation identifier that was created by the original put of the message.

If the S0GRP option is specified and the correlation identifier specified is the same as an existing grouped subscription using the same queue and an overlapping topic string, only the most significant subscription in the group is provided with a copy of the publication.

The length of this field is given by LNCID. The initial value of this field is CINONE.

If altering an existing subscription using the SOALT option, and this field is an input field, then the subscription correlation ID can be changed, unless the subscription has been created using the S0GRP option.

On return from an MQSUB call using SORES, this field is set to the current correlation ID for the subscription.

SDEXP (10 digit signed integer)

This is the time expressed in tenths of a second after which the subscription expires. No more publications will match this subscription after this interval has passed. This is also used as the value in the *MDEXP* field in the MQMD of the publications sent to this subscriber.

The following special value is recognized:

EIULIM

The subscription has an unlimited expiration time.

If altering an existing subscription using the SOALT option, the expiry of the subscription can be changed.

On return from an MQSUB call using the SORES option this field is set to the original expiry of the subscription and not the remaining expiry time.

SDON (48 byte character string)

This is the name of the topic object as defined on the local queue manager.

The name can contain the following characters:

- Uppercase alphabetic characters (A through Z)
- Lowercase alphabetic characters (a through z)
- Numeric digits (0 through 9)
- Period (.), forward slash (/), underscore (_), percent (%)

The name must not contain leading or embedded blanks, but can contain trailing blanks. Use a null character to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply:

- On systems that use EBCDIC Katakana, lowercase characters cannot be used.
- Names containing lowercase characters, forward slash, or percent, must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified for names that occur as fields in structures or as parameters on calls.

The *SDON* is used to form the Full topic name.

The full topic name can be built from two different fields: *SDON* and *SDOS*. For details of how these two fields are used, see [“Using topic strings” on page 554](#).

On return from an MQSUB call using the SORES option this field is unchanged.

The length of this field is given by LNTOPN. The initial value of this field is 48 blank characters.

If altering an existing subscription using the SDALT option, the name of the topic object subscribed to cannot be changed. This field and *SDOS* can be omitted. If they are provided they must resolve to the same full topic name or the call fails with RC2510 .

SDOPT (10 digit signed integer)

You must specify at least one of the following options:

- SOALT
- SORES
- SOCRT

The values can be added. Do not add the same constant more than once. The table shows how you can combine these options: Combinations that are not valid are noted; any other combinations are valid.

Access or creation options

Access and creation options control whether a subscription is created, or whether an existing subscription is returned or altered. You must specify at least one of these options. The table displays valid combinations of access or creation options.

Combination of options	Notes
SOCRT	Creates a subscription if one does not exist; fails if the subscription exists.
SORES	Resumes an existing subscription, fails if no subscription exists.
SOCRT + SORES	Creates a subscription if one does not exist and resumes a matching one, if it does exist. Useful combination if used in an application that might be run a number of times.

Combination of options	Notes
SORES + SOALT (see note)	Resumes an existing subscription, altering any fields to match those specified in the MQSD, fails if no subscription exists.
SOCRT + SOALT (see note)	Creates a subscription if one does not exist and resumes a matching one, if it does exist, altering any fields to match those specified in the MQSD. Useful combination if used in an application that wants to ensure that its subscription is in a certain state before proceeding.

Note:

Options specifying SOALT can also specify SORES, but this combination has no additional effect to specifying SOALT alone. SOALT implies SORES, because calling MQSUB to alter a subscription implies that the subscriptions are also resumed. The opposite is not true, however: resuming a subscription does not imply it is to be altered.

SOCRT

Create a subscription for the topic specified. If a subscription using the same *SDSN* exists, the call fails with RC2432 . This failure can be avoided by combining the SOCRT option with SORES. The *SDSN* is not always necessary. For more details, see the description of that field.

Combining SOCRT with SORES first checks whether there is an existing subscription for the specified *SDSN*, and if there is returns a handle to that preexisting subscription; but if there is no existing subscription, a new one is created using all the fields provided in the MQSD.

SOCRT can also be combined with SOALT to similar effect (see details about SOALT later in this topic).

SORES

Return a handle to a preexisting subscription which matches those specified by *SDSN*. No changes are made to the matching subscription attributes, and they are returned on output in the MQSD structure. Most of the contents of the MQSD are not used: The fields used are *SDSID*, *SDVER*, *SDOPT*, *SDAID* and *SDASI*, and *SDSN*.

The call fails with reason code RC2428 if a subscription does not exist matching the full subscription name. This failure can be avoided by combining the SOCRT option with SORES. For details about SOCRT, see [SOCRT](#).

The user ID of the subscription is the user ID that created the subscription, or if it has been later altered by a different user ID, it is the user ID of the most recent, successful alteration. If an *SDAID* is used, and use of alternate user IDs is allowed for that user, *SDAID* is recorded as the user ID that created the subscription instead of the user ID under which the subscription was made.

The user ID that created the subscription is recorded as *SDAU* if that field is used, and the use of alternate user IDs is allowed for that user.

If a matching subscription exists which was created without the SOAUID option and the user ID of the subscription is different from that of the application requesting a handle to the subscription, the call fails with reason code RC2434 .

If a matching subscription exists and is currently in use by another application, the call fails with reason code RC2429 . If it is currently in use by the same connection, the call does not fail and a handle to the subscription is returned.

If the subscription named in SubName is not a valid subscription to resume or alter from an application, the call fails with RC2523 .

SORES is implied by SOALT and so is not required to be combined with that option, however, it is not an error if those two options are combined.

SOALT

Return a handle to a preexisting subscription with the full subscription name matching those specified in *SDSN*. Any attributes of the subscription that are different from those specified in the MQSD is altered in the subscription unless alteration is disallowed for that attribute. Details are noted in the description of each attribute and are summarized in the following table. If you try to alter an attribute that cannot be changed, the call fails with the reason code shown in the following table.

The call fails with reason code RC2428 if a subscription does not exist matching the full subscription name. This failure can be avoided by combining the SOCRT option with SOALT.

Combining SOCRT with SOALT first checks whether there is an existing subscription for the specified full subscription name, and if there is returns a handle to that preexisting subscription with alterations made as previously detailed; but if there is no existing subscription, a new one is created using all the fields provided in the MQSD.

The user ID of the subscription is the user ID that created the subscription, or if it has been later altered by a different user ID, it is the user ID of the most recent successful alteration. If *SDAU* is used (and use of alternate user IDs is allowed for that user), then the alternate user ID is recorded as the user ID that created the subscription instead of the user ID under which the subscription was made.

If a matching subscription exists that was created without the option SOAUID and the user ID of the subscription is different from that of the application requesting a handle to the subscription, the call fails with reason code RC2434 .

If a matching subscription exists and is currently in use by another application, the call fails with RC2429 . If it is currently in use by the same connection the call does not fail and a handle to the subscription is returned.

If the subscription named in SubName is not a valid subscription to resume or alter from an application, the call fails with RC2523 .

The following tables show the subscription attributes that can be altered by SOALT.

Data type descriptor or function call	Field name	Can this attribute be altered using SOALT?	Reason Code
MQSD	Durability options	No	RC2509
MQSD	Destination Options	Yes	None
MQSD	Registration options	Yes (see note 1)	RC2515 if you try to alter SOGRP
MQSD	Publication options	Yes (see note 2)	None
MQSD	Wildcard options	No	RC2510
MQSD	Other options	No (see note 3)	None
MQSD	ObjectName	No	RC2510
MQSD	SDAU	No (see note 4)	None
MQSD	SDASI	No (see note 4)	None
MQSD	SDEXP	Yes	None
MQSD	SDOS	No	RC2510
MQSD	SDSN	No (see note 5)	None

Data type descriptor or function call	Field name	Can this attribute be altered using SOALT?	Reason Code
MQSD	SDSUD	Yes	None
MQSD	SDCID	Yes (see note 6)	RC2515 when in a grouped subscription
MQSD	SDPRI	Yes	None
MQSD	SDACC	Yes	None
MQSD	SDAID	Yes	None
MQSD	SDSL	No	RC2512
MQSUB	Hobj	Yes (see note 6)	RC2515 when in a grouped subscription

Notes:

1. SOGRP cannot be altered.
2. SONEWP cannot be altered because it is not part of the subscription
3. These options are not part of the subscription
4. This attribute is not part of the subscription
5. This attribute is the identity of the subscription being altered
6. Alterable except when part of a grouped sub (SOGRP)

Durability options: The following options control how durable the subscription is. You can specify only one of these options. If you are altering an existing subscription using the SOALT option, you cannot change the durability of the subscription. On return from an MQSUB call using SORES, the appropriate durability option is set.

SODUR

Request that the subscription to this topic remains until it is explicitly removed using MQCLOSE with the CORMSB option. If this subscription is not explicitly removed it will remain even after this application connects to the queue manager is closed.

If a durable subscription is requested to a topic that is defined as not allowing durable subscriptions, the call fails with RC2436 .

SONDUR

Request that the subscription to this topic is removed when the application connection to the queue manager is closed, if it has not already been explicitly removed. SONDUR is the opposite of the SODUR option, and is defined to aid program documentation. It is the default if neither is specified.

Destination options: The following options control the destination that publications for a topic that has been subscribed to are sent to. If altering an existing subscription using the SOALT option, the destination used for publications for the subscription can be changed. On return from an MQSUB call using SORES, this option is set if appropriate.

SOMAN

Request that the destination that the publications are sent to is managed by the queue manager.

The object handle returned in *HOBj* represents a queue manager managed queue, and is for use with subsequent MQGET, MQCB, MQINQ, or MQCLOSE calls.

An object handle returned from a previous MQSUB call cannot be provided in the *Hobj* parameter when SOMAN is not specified.

Registration options: The following options control the details of the registration that is made to the queue manager for this subscription. If altering an existing subscription using the SOALT option, these

registration options can be changed. On return from an MQSUB call using SORES the appropriate registration options is set.

SOGRP

This subscription is grouped with other subscriptions of the same *SDSL* using the same queue and specifying the same correlation ID so that any publications to topics that would cause more than one publication message to be provided to the group of subscriptions, due to an overlapping set of topic strings being used, only causes one message to be delivered to the queue. If this option is not used, then each unique subscription (identified by *SDSN*) that matches is provided with a copy of the publication which might mean that more than one copy of the publication might be placed on the queue shared by a number of subscriptions.

Only the most significant subscription in the group is provided with a copy of the publication. The most significant subscription is based on the Full topic name up to the point where a wildcard is found. If a mixture of wildcard schemes is used within the group, only the position of the wildcard is important. You are advised not to combine different wildcard schemes within a group of subscriptions that share the same queue.

When creating a new grouped subscription it must still have a unique *SDSN*, but if it matches the full topic name of an existing subscription in the group, the call fails with RC2514 .

If the most significant subscription in group also specifies SONOLC and this is a publication from the same application, then no publication is delivered to the queue.

When altering a subscription made with this option, the fields which imply the grouping, *Hobj* on the MQSUB call (representing the queue and queue manager name), and the *SDCID* cannot be changed. Attempting to alter them causes the call to fail with RC2515 .

This option must be combined with SOSCID with a *SDCID* that is not set to CINONE, and cannot be combined with SOMAN.

SOAUID

When SOAUID is specified, the identity of the subscriber is not restricted to a single user ID. This allows any user to alter or resume the subscription when they have suitable authority. Only a single user can have the subscription at any one time. An attempt to resume use of a subscription currently in use by another application causes the call to fail with RC2429 .

To add this option to an existing subscription, the MQSUB call, using SOALT, must come from the same user ID as the original subscription itself.

If an MQSUB call references an existing subscription with SOAUID set, and the user ID differs from the original subscription, the call succeeds only if the new user ID has authority to subscribe to the topic. On successful completion, future publications to this subscriber are put to the subscriber's queue with the new user ID set in the publication message.

Do not specify both SOAUID and SOFUID. If neither is specified, the default is SOFUID.

SOFUID

When SOFUID is specified, the subscription can be altered or resumed by only the last user ID to alter the subscription. If the subscription has not been altered, it is the user ID that created the subscription.

If an MQSUB verb references an existing subscription with SOAUID set and alters the subscription using SOALT to use the SOFUID, the user ID of the subscription is now fixed at this new user ID. The call succeeds only if the new user ID has authority to subscribe to the topic.

If a user ID other than the one recorded as owning a subscription tries to resume or alter an SOFUID subscription, the call fails with RC2434 . The owning user ID of a subscription can be viewed using the **DISPLAY SBSTATUS** command.

Do not specify both SOAUID and SOFUID. If neither is specified, the default is SOFUID.

Publication options: The following options control the way publications are sent to this subscriber. If altering an existing subscription using the SOALT option, these publication options can be changed.

SONOLC

Tells the broker that the application does not want to see any of its own publications. Publications are considered to have originated from the same application if the connection handles are the same. On return from an MQSUB call using SORES this option is set if appropriate.

SONEWP

No currently retained publications are to be sent, when this subscription is created, only new publications. This option only applies when SOCRE is specified. Any subsequent changes to a subscription do not alter the flow of publications and so any publications that have been retained on a topic, has already been sent to the subscriber as new publications.

If this option is specified without SOCRE it causes the call to fail with RC2046 . On return from an MQSUB call using SORES this option is not set even if the subscription was created using this option.

If this option is not used, previously retained messages are sent to the destination queue provided. If this action fails due to an error, either RC2525 or RC2526 , the creation of the subscription fails.

This option is not valid in combination with SOPUBR.

SOPUBR

Setting this option indicates that the subscriber requests information specifically when required. The queue manager does not send unsolicited messages to the subscriber. The retained publication (or possibly multiple publications if a wildcard is specified in the topic) is sent to the subscriber each time an MQSUBRQ call is made using the Hsub handle from a previous MQSUB call. No publications are sent as a result of the MQSUB call using this option. On return from an MQSUB call using SORES this option is set if appropriate.

This option is not valid in combination with SONEWP.

Wildcard options: The following options control how wildcards are interpreted in the string provided in the *SDOS* field of the MQSD. You can specify only one of these options. If altering an existing subscription using the SOALT option, these wildcard options cannot be changed. On return from an MQSUB call using SORES the appropriate wildcard option is set.

SOWCHR

Wildcards only operate on characters within the topic string. The SOWCHR field treats forward slash (/) as just another character with no special significance.

The behavior defined by SOWCHR is shown in the following table:

Special Character	Behavior
*	Wildcard, zero or more characters
?	Wildcard, one character
%	Escape character to allow the characters '*', '?', or '%' to be used in a string and not be interpreted as a special character, for example, '%*', '%?' or '%%'.

For example, publishing on the following topic:

```
/level0/level1/level2/level3/level4
```

matches subscribers using the following topics:

```
*  
/*  
/ level0/level1/level2/level3/*  
/ level0/level1/*/*level3/level4  
/ level0/level1/le?e12/level3/level4
```

Note: This use of wildcards supplies exactly the meaning provided in IBM MQ V6 and WebSphere MB V6 when using MQRFH1 formatted messages for Publish/Subscribe. It is recommended

that this is not used for newly written applications and is only used for applications that were previously running against that version and have not been changed to use the default wildcard behavior as described in SOWTOP.

SOWTOP

Wildcards only operate on topic elements within the topic string. This is the default behavior if none is chosen.

The behavior required by SOWTOP is shown in the following table:

Special Character	Behavior
/	Topic level separator
#	Wildcard: multiple topic level
+	Wildcard: single topic level

Note:

The '+' and '#' are not treated as wildcards if they are mixed in with other characters (including themselves) within a topic level. In the following string, the '#' and '+' characters are treated as ordinary characters.

```
level0/level1/#+/level3/level#
```

For example, publishing on the following topic:

```
/level0/level1/level2/level3/level4
```

matches subscribers using the following topics:

```
#  
/#  
/ level0/level1/level2/level3/#  
/ level0/level1/+level3/level4
```

Note: This use of wildcards supplies the meaning provided in WebSphere Message Broker Version 6 when using MQRFH2 formatted messages for Publish/Subscribe.

Other options: The following options control the way the API call is issued rather than the subscription. On return from an MQSUB call using SORES these options are unchanged.

SOALTU

The SDAU field contains a user identifier to use to validate this MQSUB call. The call can succeed only if this SDAU is authorized to open the object with the specified access options, regardless of whether the user identifier under which the application is running is authorized to do so.

SOSCID

The subscription is to use the correlation identifier supplied in the *SDCID* field. If this option is not specified, a correlation identifier is automatically created by the queue manager at subscription time and is returned to the application in the *SDCID* field. See [SDCID \(24-byte bit string\)SDCID](#) for more information.

SOSETI

The subscription is to use the accounting token and application identity data supplied in the *SDACC* and *SDAID* fields.

If this option is specified, the same authorization check is carried out as if the destination queue was accessed using an MQOPEN call with 00SETI, except in the case where the SOMAN option is also used in which case there is no authorization check on the destination queue.

If this option is not specified, the publications sent to this subscriber has default context information associated with them as follows:

Field in MQMD	Value used
<i>MDUID</i>	The user ID associated with the subscription at the time the subscription was made.
<i>MDACC</i>	Determined from the environment if possible; Set to ACNONE if not.
<i>MDAID</i>	Set to blanks

This option is only valid with SOCRE and SOALT. If used with SORES, the *SDACC* and *SDAID* fields are ignored, so this option has no effect.

If a subscription is altered without using this option where previously the subscription had supplied identity context information, default context information is generated for the altered subscription.

If a subscription allowing different user IDs to use it with option SOAUID, is resumed by a different user ID, default identity context is generated for the new user ID now owning the subscription and any subsequent publications are delivered containing the new identity context.

SOFIQ

The MQSUB call fails if the queue manager is in quiescing state. On z/OS, for a CICS or IMS application, this option also forces the MQSUB call to fail if the connection is in quiescing state.

SDAU (12 byte character string)

If you specify SOALTU, this field contains an alternate user identifier that is used to check the authorization for the subscription and for output to the destination queue (specified in the *Hobj* parameter of the MQSUB call), in place of the user identifier that the application is currently running under.

If successful, the user identifier specified in this field is recorded as the subscription owning user identifier in place of the user identifier that the application is currently running under.

If SOALTU is specified and this field is entirely blank up to the first null character or the end of the field, the subscription can succeed only if no user authorization is must subscribe to this topic with the options specified or the destination queue for output.

If SOALTU is not specified, this field is ignored.

On return from an MQSUB call using SORES, this field is unchanged.

This is an input field. The length of this field is given by LNUID. The initial value of this field is 12 blank characters.

SDPRI (10 digit signed integer)

This is the value that is in the *MQPRI* field of the Message Descriptor (MQMD) of all publication messages matching this subscription. For more information about the *MQPRI* field in the MQMD, see [MDPRI](#).

The value must be greater than or equal to zero; zero is the lowest priority. The following special values can also be used:

PRQDEF

When a subscription queue is provided in the *Hobj* field in the MQSUB call, and is not a managed handle, then the priority for the message is taken from the *DefPriority* attribute of this queue. If the queue so identified is a cluster queue or there is more than one definition in the queue-name resolution path then the priority is determined when the publication message is put to the queue as described for [MDPRI](#).

If the MQSUB call uses a managed handle, the priority for the message is taken from the *DefPriority* attribute of the model queue associated with the topic subscribed to.

PRPUB

The priority for the message is the priority of the original publication. This is the initial value of the field.

If altering an existing subscription using the SOALT option, the *MQPRI* of any future publication messages can be changed.

On return from an MQSUB call using SORES, this field is set to the current priority being used for the subscription.

SDRO (MQCHARV)

SDRO is the long object name after the queue manager resolves the name provided in *SDON*.

If the long object name is provided in *SDOS* and nothing is provided in *SDON*, the value returned in this field is the same as provided in *SDOS*.

If this field is omitted (that is *SDRO.VSBufSize* is zero), the *SDRO* is not returned, but the length is returned in *SDRO.VSLength*. If the length is shorter than the full *SDRO*, it is truncated and returns as many of the rightmost characters as can fit in the provided length.

If *SDRO* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, the call fails with reason code RC2520 .

SDSID (4 byte character string)

This is the structure identifier; the value must be:

SDSIDV

Identifier for Subscription Descriptor structure.

This is always an input field. The initial value of this field is SDSIDV

SDSL (10 digit signed integer)

This is the level associated with the subscription. Publications are only delivered to this subscription if it is in the set of subscriptions with the highest *SDSL* value less than or equal to the *PubLevel* used at publication time.

The value must be in the range zero to 9. Zero is the lowest level.

The initial value of this field is 1.

If altering an existing subscription using the SOALT option, then *SDSL* cannot be changed.

SDSN (MQCHARV)

SDSN specifies the subscription name.

This field is required only if *SDOPT* specifies the SODUR option, but if it is provided it is used by the queue manager for SONDUR as well. If specified, *SDSN* must be unique within the queue manager, because it is the field used to identify subscriptions.

The maximum length of *SDSN* is 10240.

This field serves two purposes. For a SODUR subscription, it is the means by which you identify a subscription to resume it after it has been created, if you have either closed the handle to the subscription (using the COKPSB option) or have been disconnected from the queue manager. Identifying a subscription to remove it after it has been created is done using the MQSUB call with the SORES option. The *SDSN* field is also displayed in the administration view of subscriptions in the *SDSN* field in DISPLAY SBSTATUS.

If *SDSN* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, or if it is omitted when it is required (that is *SDSN.VCHRL* is zero), or if it exceeds the maximum length, the call fails with reason code RC2440 .

This is an input field. The initial values of the fields in this structure are the same as those in the MQCHARV structure.

If altering an existing subscription using the SOALT option, the subscription name cannot be changed, because it is the field used to identify the subscription. It is not changed on output from an MQSUB call with the SORES option.

SDSS (MQCHARV)

SDSS is the string that provides the selection criteria used when subscribing for messages from a topic.

This variable length field is returned on output from an MQSUB call using the SORES option, if a buffer is provided, and if there is also a positive buffer length in VSBufSize. If no buffer is provided on the call, only the length of the selection string is returned in the VSLength field of the MQCHARV. If the buffer provided is smaller than the space required to return the field, only VSBufSize bytes are returned in the provided buffer.

If *SDSS* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, the call fails with reason code RC2519.

SDSUD (MQCHARV)

The data provided on the subscription in this field is included as the mq.SubUserData message property of every publication sent to this subscription.

The maximum length of *SDSUD* is 10240.

If *SDSUD* is specified incorrectly, according to the description of how to use the [MQCHARV](#) structure, or if it exceeds the maximum length, the call fails with reason code RC2431.

This is an input field. The initial values of the fields in this structure are the same as those in the MQCHARV structure.

If altering an existing subscription using the SOALT option, the subscription user data can be changed.

This variable length field is returned on output from an MQSUB call using the SORES option, if a buffer is provided and there is a positive buffer length in *VSBufLen*. If no buffer is provided on the call, only the length of the subscription user data is returned in the *VCHRL* field of the MQCHARV. If the buffer provided is smaller than the space required to return the field, only *VSBufLen* bytes are returned in the provided buffer.

SDVER (10 digit signed integer)

This is the structure version number; the value must be:

SDVER1

Version-1 Subscription Descriptor structure.

The following constant specifies the version number of the current version:

SDVERC

Current version of Subscription Descriptor structure.

This is always an input field. The initial value of the field is SDVER1.

Initial values

Field name	Name of constant	Value of constant
<i>SDSID</i>	SDSIDV	'SD- - -'
<i>SDVER</i>	SDVER1	1
<i>SDOPT</i>	SONDUR	0
<i>SDON</i>	None	Blanks

Field name	Name of constant	Value of constant
<i>SDAU</i>	None	Blanks
<i>SDASI</i>	SINONE	Nulls
<i>SDEXP</i>	EIULIM	-1
<i>SDOS</i>	Names and values as defined for MQCHARV	
<i>SDSN</i>	Names and values as defined for MQCHARV	
<i>SDSUD</i>	Names and values as defined for MQCHARV	
<i>SDCID</i>	CINONE	Nulls
<i>SDPRI</i>	PRQDEF	-3
<i>SDACC</i>	ACNONE	Nulls
<i>SDAID</i>	None	Blanks
<i>SDSL</i>	None	1
<i>SDRO</i>	Names and values as defined in MQCHARV	
Note: 1. The symbol ~ represents a single blank character.

MQSMPO - Set message property options

The **MQSMPO** structure allows applications to specify options that control how properties of messages are set.

Overview

Purpose: The structure is an input parameter on the **MQSETMP** call.

Character set and encoding: Data in **MQSMPO** must be in the character set of the application and encoding of the application (ENNAT).

- [“Fields” on page 1183](#)
- [“Initial values” on page 1184](#)
- [“RPG declaration” on page 1185](#)

Fields

The MQSMPO structure contains the following fields; the fields are described in **alphabetical order**:

SPOPT (10-digit signed integer)

Location options: The following options relate to the relative location of the property compared to the property cursor:

SPSETF

Sets the value of the first property that matches the specified name, or if it does not exist, adds a new property after all other properties with a matching hierarchy.

SPSETC

Sets the value of the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired using either the IPINQF or the IPINQN option.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET call or the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason code RC2471.

SPSETA

Sets a new property after the property pointed to by the property cursor. The property pointed to by the property cursor is the one that was last inquired using either the IPINQF or the IPINQO option.

The property cursor is reset when the message handle is reused, or when the message handle is specified in the *HMSG* field of the MQGMO structure on an MQGET call or the MQPMO structure on an MQPUT call.

If this option is used when the property cursor has not yet been established or if the property pointed to by the property cursor has been deleted, the call fails with completion code CCFAIL and reason code RC2471.

If you need none of the options described, use the following option:

SPNONE

No options specified.

This is always an input field. The initial value of this field is SPSETF.

SPSID (10-digit signed integer)

This is the structure identifier; the value must be:

SPSIDV

Identifier for set message property options structure.

This is always an input field. The initial value of this field is **SPSIDV**.

SPVAKCSI (10-digit signed integer)

The character set of the property value to be set if the value is a character string.

This is always an input field. The initial value of this field is **CSAPL**.

SPVALENC (10-digit signed integer)

The encoding of the property value to be set if the value is numeric.

This is always an input field. The initial value of this field is **ENNAT**.

SPVER (10-digit signed integer)

This is the structure version number; the value must be:

SPVER1

Version-1 set message property options structure.

The following constant specifies the version number of the current version:

SPVERC

Current version of set message property options structure.

This is always an input field. The initial value of this field is **SPVER1**.

Initial values

<i>Table 613. Initial values of fields in MQSMPO</i>		
Field name	Name of constant	Value of constant
<i>SPSID</i>	SPSIDV	'SMPO'
<i>SPVER</i>	SPVER1	1
<i>SPOPT</i>	SPNONE	0
<i>SPVALENC</i>	ENNAT	Depends on environment
<i>SPVALCSI</i>	CSAPL	-3

MQSRO - Subscription Request Options

The MQSRO structure allows the application to specify options that control how a subscription request is made.

Overview

Purpose: The structure is an input/output parameter on the MQSUBRQ call.

Version: The current version of MQSRO is SRVER1.

- [“Fields” on page 1185](#)
- [“Initial values” on page 1186](#)
- [“RPG declaration” on page 1186](#)

Fields

The MQSRO structure contains the following fields; the fields are described in **alphabetical order**:

SRNMP (10-digit signed integer)

This is an output field, returned to the application to indicate the number of publications sent to the subscription queue as a result of this call. Although this number of publications have been sent as a result of this call, there is no guarantee that this many messages will be available for the application to get, especially if they are non-persistent messages.

There may be more than one publication if the topic subscribed to, contained a wildcard. If no wildcards were present in the topic string when the subscription represented by *HSUB* was created, then at most one publication is sent as a result of this call.

SROPT (10-digit signed integer)

One of the following options must be specified. Only one option can be specified.

Other options: The following option controls what happens when the queue manager is quiescing:

SRFIQ

The MQSUBRQ call fails if the queue manager is in the quiescing state.

Default option: If the option described previously is not required, the following option must be used:

SRNONE

Use this value to indicate that no other options have been specified; all options assume their default values.

SRNONE helps program documentation. Although it is not intended that this option be used with any other, because its value is zero, this use cannot be detected.

SRSID (4-byte character string)

This is the structure identifier; the value must be:

SRSIDV

Identifier for Subscription Request SROPT structure.

This is always an input field. The initial value of this field is SRSIDV.

SERVER (10-digit signed integer)

This is the structure version number; the value must be:

SERVER1

Version-1 Subscription Request Options structure.

The following constant specifies the version number of the current version:

SERVERC

Current version of Subscription Request Options structure.

This is always an input field. The initial value of this field is SERVER1.

Initial values

Field name	Name of constant	Value of constant
<i>SRSID</i>	SRSIDV	'SR0¬'
<i>SERVER</i>	SERVER1	1
<i>SROPT</i>	SRNONE	0
<i>SRNMP</i>	None	0
Notes: 1. The symbol ¬ represents a single blank character. 2. The value Null string or blanks denotes the null string in C, and blank characters in other programming languages.		

RPG declaration

```

MQSTS - Status reporting structure

The MQSTS structure describes the data in the status structure returned by the MQSTAT command.

Overview

Character set and encoding: Character data in MQSTS is in the character set of the local queue manager; this is given by the *CodedCharSetId* queue-manager attribute. Numeric data in MQSTS is in the native machine encoding; this is given by *ENNAT*.

Usage: The MQSTAT command is used to retrieve status information. This information is returned in an MQSTS structure. For information about MQSTAT, see [“MQSTAT - Retrieve status information”](#) on page 1314.

- [“Fields”](#) on page 1187
- [“Initial values”](#) on page 1190
- [“RPG declaration”](#) on page 1190

Fields

The MQSTS structure contains the following fields; the fields are described in **alphabetical order**:

STSCC (10-digit signed integer)

This is the completion code resulting from the first error reported in the MQSTS structure.

This is always an output field. The initial value of this field is CCOK.

STSFC (10-digit signed integer)

This is the number of asynchronous put calls that failed.

This is an output field. The initial value of this field is 0.

STSOBJN (48-byte character string)

This is the local name of the object involved in the first failure.

This is an output field. The initial value of this field is 48 blank characters.

STSOQMGR (48-byte character string)

This is the name of the queue manager on which the *STSOBJN* object is defined. A name that is entirely blank up to the first null character or the end of the field denotes the queue manager to which the application is connected (the local queue manager).

This is an output field. The initial value of this field is 48 blank characters.

STS00 (10-digit signed integer)

The STS00 used to open the object being reported upon. Present only in Version 2 of MQSTS or higher.

The value of STS00 depends on the value of the MQSTAT STYPE parameter.

STATAPT

Zero.

STATREC

Zero.

STATRER

The STS00 used when the failure occurred. The reason for the failure is reported in the *STSCC* and *STSRC* fields in the MQSTS structure.

STS00 is an output field. Its initial value is zero.

STSOS (MQCHARV)

Long object name of failing object being reported on. Present only in Version 2 of MQSTS or higher.

STSOS is a MQCHARV field with a maximum length of 10240. See [MQCHARV](#) for a description of how to use the MQCHARV structure.

The interpretation of STSOS depends on the value of the MQSTAT STYPE parameter.

STATAPT

This is the long object name of the queue or topic used in the MQPUT operation, which failed.

STATREC

Zero length string

STATRER

This is the long object name of the object that caused the reconnection to fail.

STSOS is an output field. Its initial value is a zero length string.

STSOT (10-digit signed integer)

The type of object being named in *ObjectName*. Possible values are:

OTALSQ

Alias queue.

OTLOCQ

Local queue.

OTMODQ

Model queue.

OTQ

Queue.

OTREMQ

Remote queue.

OTTOP

Topic.

This is always an output field. The initial value of this field is OTQ.

STSRC (10-digit signed integer)

This is the reason code resulting from the first error reported in the MQSTS structure

This is always an output field. The initial value of this field is RCNONE.

STSR OBJN (48-byte character string)

This is the name of the destination queue named in *STSOBJN* after the local queue manager resolves the name. The name returned is the name of a queue that exists on the queue manager identified by *STSRQMGR*.

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *STSR OBJN* is set to blanks:

- A topic
- A queue, but not opened for browse, input, or output

This is an output field. The initial value of this field is 48 blank characters.

STSRQMGR (48-byte character string)

This is the name of the destination queue manager after the local queue manager resolves the name. The name returned is the name of the queue manager that owns the queue identified by *STSR OBJN*. *STSRQMGR* can be the name of the local queue manager.

If *STSR OBJN* is a shared queue that is owned by the queue-sharing group to which the local queue manager belongs, *STSRQMGR* is the name of the queue-sharing group. If the queue is owned by some other queue-sharing group, *STSR OBJN* can be the name of the queue-sharing group or the name of a queue manager that is a member of the queue-sharing group (the nature of the value returned is determined by the queue definitions that exist at the local queue manager).

A nonblank value is returned only if the object is a single queue opened for browse, input, or output (or any combination). If the object opened is any of the following, *STSRQMGR* is set to blanks:

- A topic
- A queue, but not opened for browse, input, or output

- A cluster queue with OOBNDN specified (or with OOBNDQ in effect when the *DefBind* queue attribute has the value OOBNDN)

This is an output field. The initial value of this field is 48 blank characters.

STSSC (10-digit signed integer)

This is the number of asynchronous put calls that succeeded.

This is an output field. The initial value of this field is 0.

STSSID (4-byte character string)

This is the structure identifier. The value must be:

STSSID

Identifier for status reporting structure.

The initial value of this field is STSSID.

STSSO (10 digit signed integer)

The STSSO used to open the failing subscription. Present only in Version 2 of MQSTS or higher.

The interpretation of STSSO depends on the value of the MQSTAT STYPE parameter.

STATAPT

Zero.

STATREC

Zero.

STATRER

The STSSO used when the failure occurred. The reason for the failure is reported in the *STSCC* and *STSRC* fields in the MQSTS structure. If the failure is not related to subscribing to a topic, the value returned is zero.

STSSO is an output field. Its initial value is zero.

STSSUN (MQCHARV)

The name of the failing subscription. Present only in Version 2 of MQSTS or higher.

STSSUN is a MQCHARV field with a maximum length of 10240. See [MQCHARV](#) for a description of how to use the MQCHARV structure.

The interpretation of STSSUN depends on the value of the MQSTAT STYPE parameter.

STATAPT

Zero length string.

STATREC

Zero length string.

STATRER

The name of the subscription that caused reconnection to fail. If no subscription name is available, or the failure is not related to a subscription, this is a zero-length string.

STSSUN is an output field. Its initial value is a zero length string.

STSVER (10-digit signed integer)

This is the structure version number. The value must be:

STSVER1

Version number for status reporting structure.

The following constant specifies the version number of the current version:

STSVRC

Current version of status reporting structure.

The initial value of this field is STSVR1.

STSWC (10-digit signed integer)

This is the number of asynchronous put calls that completed with a warning.

This is an output field. The initial value of this field is 0.

Initial values

MQTM - Trigger message

The MQTM structure describes the data in the trigger message that is sent by the queue manager to a trigger-monitor application when a trigger event occurs for a queue.

Overview

Purpose: This structure is part of the IBM MQ Trigger Monitor Interface (TMI), which is one of the IBM MQ framework interfaces.

Format name: FMTM.

Character set and encoding: Character data in MQTM is in the character set of the queue manager that generates the MQTM. Numeric data in MQTM is in the machine encoding of the queue manager that generates the MQTM.

The character set and encoding of the MQTM are given by the *MDCSI* and *MDENC* fields in:

- The MQMD (if the MQTM structure is at the start of the message data), or
- The header structure that precedes the MQTM structure (all other cases).

Usage: A trigger-monitor application may need to pass some or all of the information in the trigger message to the application which is started by the trigger-monitor application. Information which may be needed by the started application includes *TMQN*, *TMTD*, and *TMUD*. The trigger-monitor application can pass the MQTM structure directly to the started application, or pass an MQTMC2 structure instead, depending on what is permitted by the environment and convenient for the started application. For information about MQTMC2, see [“MQTMC2 - Trigger message 2 \(character format\)” on page 1195](#).

- On IBM i, the trigger-monitor application provided with IBM MQ passes an MQTMC2 structure to the started application.

For information about triggers, see [Prerequisites for triggering](#).

- [“MQMD for a trigger message” on page 1192](#)
- [“Fields” on page 1193](#)

- [“Initial values” on page 1195](#)
- [“RPG declaration” on page 1195](#)

MQMD for a trigger message

MQMD for a trigger message: The fields in the MQMD of a trigger message generated by the queue manager are set as follows:

Field in MQMD	Value used
<i>MDSID</i>	MDSIDV
<i>MDVER</i>	MDVER1
<i>MDREP</i>	RONONE
<i>MDMT</i>	MTDGRM
<i>MDEXP</i>	EIULIM
<i>MDFB</i>	FBNONE
<i>MDENC</i>	ENNAT
<i>MDCSI</i>	Queue manager's <i>CodedCharSetId</i> attribute
<i>MDFMT</i>	FMTM
<i>MDPRI</i>	Initiation queue's <i>DefPriority</i> attribute
<i>MDPER</i>	PENPER
<i>MDMID</i>	A unique value
<i>MDCID</i>	CINONE
<i>MDBOC</i>	0
<i>MDRQ</i>	Blanks
<i>MDRM</i>	Name of queue manager
<i>MDUID</i>	Blanks
<i>MDACC</i>	ACNONE
<i>MDAID</i>	Blanks
<i>MDPAT</i>	ATQM, or as appropriate for the message channel agent
<i>MDPAN</i>	First 28 bytes of the queue manager name
<i>MDPD</i>	Date when trigger message is sent
<i>MDPT</i>	Time when trigger message is sent
<i>MDAOD</i>	Blanks

An application that generates a trigger message is recommended to set similar values, except for the following:

- The *MDPRI* field can be set to PRQDEF (the queue manager will change this to the default priority for the initiation queue when the message is put).
- The *MDRM* field can be set to blanks (the queue manager will change this to the name of the local queue manager when the message is put).
- The context fields should be set as appropriate for the application.

Fields

The MQTM structure contains the following fields; the fields are described in **alphabetical order**:

TMAI (256-byte character string)

Application identifier.

This is a character string that identifies the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the *AppLId* attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions” on page 1353](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The meaning of *TMAI* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ requires *TMAI* to be the name of an executable program.

The length of this field is given by LNPROA. The initial value of this field is 256 blank characters.

TMAT (10-digit signed integer)

Application type.

This identifies the nature of the program to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the *AppLType* attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions” on page 1353](#) for details of this attribute. The content of this data is of no significance to the queue manager.

TMAT can have one of the following standard values. User-defined types can also be used, but should be restricted to values in the range ATUFST through ATULST:

ATCICS

CICS transaction.

ATVSE

CICS/VSE transaction.

AT400

IBM i application.

ATUFST

Lowest value for user-defined application type.

ATULST

Highest value for user-defined application type.

The initial value of this field is 0.

TMED (128-byte character string)

Environment data.

This is a character string that contains environment-related information pertaining to the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the *EnvData* attribute of the process object identified by the *TMPN* field; see [“Attributes for process definitions” on page 1353](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNPROE. The initial value of this field is 128 blank characters.

TMPN (48-byte character string)

Name of process object.

This is the name of the queue manager process object specified for the triggered queue, and can be used by the trigger-monitor application that receives the trigger message. The queue manager

initializes this field with the value of the *ProcessName* attribute of the queue identified by the *TMQN* field; see [“Attributes for queues” on page 1324](#) for details of this attribute.

Names that are shorter than the defined length of the field are always padded to the right with blanks; they are not ended prematurely by a null character.

The length of this field is given by LNPRON. The initial value of this field is 48 blank characters.

TMQN (48-byte character string)

Name of triggered queue.

This is the name of the queue for which a trigger event occurred, and is used by the application started by the trigger-monitor application. The queue manager initializes this field with the value of the *QName* attribute of the triggered queue; see [“Attributes for queues” on page 1324](#) for details of this attribute.

Names that are shorter than the defined length of the field are padded to the right with blanks; they are not ended prematurely by a null character.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

TMSID (4-byte character string)

Structure identifier.

The value must be:

TMSIDV

Identifier for trigger message structure.

The initial value of this field is TMSIDV.

TMTD (64-byte character string)

Trigger data.

This is free-format data for use by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the *TriggerData* attribute of the queue identified by the *TMQN* field; see [“Attributes for queues” on page 1324](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNTRGD. The initial value of this field is 64 blank characters.

TMUD (128-byte character string)

User data.

This is a character string that contains user information relevant to the application to be started, and is used by the trigger-monitor application that receives the trigger message. The queue manager initializes this field with the value of the *UserData* attribute of the process object identified by the *TPPN* field; see [“Attributes for process definitions” on page 1353](#) for details of this attribute. The content of this data is of no significance to the queue manager.

The length of this field is given by LNPROU. The initial value of this field is 128 blank characters.

TMVER (10-digit signed integer)

Structure version number.

The value must be:

TMVER1

Version number for trigger message structure.

The following constant specifies the version number of the current version:

TMVERC

Current version of trigger message structure.

The initial value of this field is TMVER1.

MQTMC2 - Trigger message 2 (character format)

When a trigger-monitor application retrieves a trigger message (MQTM) from an initiation queue, the trigger monitor might need to pass some or all of the information in the trigger message to the application that is started by the trigger monitor.

Overview

Purpose: Information that may be needed by the started application includes *TC2QN*, *TC2TD*, and *TC2UD*. The trigger monitor application can pass the MQTM structure directly to the started application, or pass an MQTMC2 structure instead, depending on what is permitted by the environment and convenient for the started application.

This structure is part of the IBM MQ Trigger Monitor Interface (TMI), which is one of the IBM MQ framework interfaces.

Character set and encoding: Character data in MQTMC2 is in the character set of the local queue manager; this is given by the *CodedCharSetId* queue manager attribute.

Usage: The MQTMC2 structure is like the format of the MQTM structure. The difference is that the non-character fields in MQTM are changed in MQTMC2 to character fields of the same length, and the queue manager name is added at the end of the structure.

- On IBM i, the trigger monitor application provided with IBM MQ passes an MQTMC2 structure to the started application.
- [“Fields” on page 1196](#)
- [“Initial values” on page 1197](#)
- [“RPG declaration” on page 1197](#)

Fields

The MQTMC2 structure contains the following fields; the fields are described in **alphabetical order**:

TC2AI (256-byte character string)

Application identifier.

See the *TMAI* field in the MQTM structure.

TC2AT (4-byte character string)

Application type.

This field always contains blanks, whatever the value in the *TMAT* field in the MQTM structure of the original trigger message.

TC2ED (128-byte character string)

Environment data.

See the *TMED* field in the MQTM structure.

TC2PN (48-byte character string)

Name of process object.

See the *TPPN* field in the MQTM structure.

TC2QMN (48-byte character string)

Queue manager name.

This is the name of the queue manager at which the trigger event occurred.

TC2QN (48-byte character string)

Name of triggered queue.

See the *TMQN* field in the MQTM structure.

TC2SID (4-byte character string)

Structure identifier.

The value must be:

TCSIDV

Identifier for trigger message (character format) structure.

TC2TD (64-byte character string)

Trigger data.

See the *TMTD* field in the MQTM structure.

TC2UD (128-byte character string)

User data.

See the *TMUD* field in the MQTM structure.

TC2VER (4-byte character string)

Structure version number.

The value must be:

TCVER2

Version 2 trigger message (character format) structure.

The following constant specifies the version number of the current version:

TCVERC

Current version of trigger message (character format) structure.

Initial values

MQWIH - Work information header

The MQWIH structure describes the information that must be present at the start of a message that is to be handled by the z/OS workload manager.

Overview

Format name: FMWIH.

Character set and encoding: The fields in the MQWIH structure are in the character set and encoding given by the *MDCSI* and *MDENC* fields in the header structure that precedes MQWIH, or by those fields in the MQMD structure if the MQWIH is at the start of the application message data.

The character set must be one that has single-byte characters for the characters that are valid in queue names.

Usage: If a message is to be processed by the z/OS workload manager, the message must begin with an MQWIH structure.

- [“Fields” on page 1198](#)
- [“Initial values” on page 1200](#)
- [“RPG declaration” on page 1200](#)

Fields

The MQWIH structure contains the following fields; the fields are described in **alphabetical order**:

WICSI (10-digit signed integer)

Character-set identifier of data that follows MQWIH.

This specifies the character set identifier of the data that follows the MQWIH structure; it does not apply to character data in the MQWIH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The following special value can be used:

CSINHT

Inherit character-set identifier of this structure.

Character data in the data *following* this structure is in the same character set as this structure.

The queue manager changes this value in the structure sent in the message to the actual character-set identifier of the structure. Provided no error occurs, the value CSINHT is not returned by the MQGET call.

CSINHT cannot be used if the value of the *MDPAT* field in MQMD is ATBRKR.

The initial value of this field is CSUNDF.

WIENC (10-digit signed integer)

Numeric encoding of data that follows MQWIH.

This specifies the numeric encoding of the data that follows the MQWIH structure; it does not apply to numeric data in the MQWIH structure itself.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data.

The initial value of this field is 0.

WIFLG (10-digit signed integer)

Flags

The value must be:

WINONE

No flags.

The initial value of this field is WINONE.

WIFMT (8-byte character string)

Format name of data that follows MQWIH.

This specifies the format name of the data that follows the MQWIH structure.

On the MQPUT or MQPUT1 call, the application must set this field to the value appropriate to the data. The rules for coding this field are the same as those for the *MDFMT* field in MQMD.

The length of this field is given by LNFMT. The initial value of this field is FMNONE.

WILEN (10-digit signed integer)

Length of MQWIH structure.

The value must be:

WILEN1

Length of version-1 work information header structure.

The following constant specifies the length of the current version:

WILENC

Length of current version of work information header structure.

The initial value of this field is WILEN1.

WIRSV (32-byte character string)

Reserved.

This is a reserved field; it must be blank.

WISID (4-byte character string)

Structure identifier.

The value must be:

WISIDV

Identifier for work information header structure.

The initial value of this field is WISIDV.

WISNM (32-byte character string)

Service name.

This is the name of the service that is to process the message.

The length of this field is given by LNSVNM. The initial value of this field is 32 blank characters.

WISST (8-byte character string)

Service step name.

This is the name of the step of *WISNM* to which the message relates.

The length of this field is given by LNSVST. The initial value of this field is 8 blank characters.

WITOK (16-byte bit string)

Message token.

This is a message token that uniquely identifies the message.

For the MQPUT and MQPUT1 calls, this field is ignored. The length of this field is given by LNMTOK. The initial value of this field is MTKNON.

WIVER (10-digit signed integer)

Structure version number.

The value must be:

WIVER1

Version-1 work information header structure.

The following constant specifies the version number of the current version:

WIVERC

Current version of work information header structure.

The initial value of this field is WIVER1.

Initial values

Table 617. Initial values of fields in MQWIH		
Field name	Name of constant	Value of constant
WISID	WISIDV	'WIH~'
WIVER	WIVER1	1

MQXQH - Transmission-queue header

The MQXQH structure describes the information that is prefixed to the application message data of messages when they are on transmission queues.

Overview

Purpose: A transmission queue is a special type of local queue that temporarily holds messages destined for remote queues (that is, destined for queues that do not belong to the local queue manager). A transmission queue is denoted by the *Usage* queue attribute having the value USTRAN.

Format name: FMXQH.

Character set and encoding: Data in MQXQH must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT for the C programming language.

The character set and encoding of the MQXQH must be set into the *MDCSI* and *MDENC* fields in:

- The separate MQMD (if the MQXQH structure is at the start of the message data), or
- The header structure that precedes the MQXQH structure (all other cases).

Usage: A message that is on a transmission queue has *two* message descriptors:

- One message descriptor is stored separately from the message data; this is called the *separate message descriptor*, and is generated by the queue manager when the message is placed on the transmission queue. Some of the fields in the separate message descriptor are copied from the message descriptor provided by the application on the MQPUT or MQPUT1 call.

The separate message descriptor is the one that is returned to the application in the *MSGDSC* parameter of the MQGET call when the message is removed from the transmission queue.

- A second message descriptor is stored within the MQXQH structure as part of the message data; this is called the *embedded message descriptor*, and is a copy of the message descriptor that was provided by the application on the MQPUT or MQPUT1 call (with minor variations).

The embedded message descriptor is always a version-1 MQMD. If the message put by the application has nondefault values for one or more of the version-2 fields in the MQMD, an MQMDE structure follows the MQXQH, and is in turn followed by the application message data (if any). The MQMDE is either:

- Generated by the queue manager (if the application uses a version-2 MQMD to put the message), or
- Already present at the start of the application message data (if the application uses a version-1 MQMD to put the message).

The embedded message descriptor is the one that is returned to the application in the *MSGDSC* parameter of the MQGET call when the message is removed from the final destination queue.

- [“Fields in the separate message descriptor” on page 1202](#)
- [“Fields in the embedded message descriptor” on page 1203](#)
- [“Putting messages on remote queues” on page 1203](#)
- [“Putting messages directly on transmission queues” on page 1203](#)
- [“Getting messages from transmission queues” on page 1204](#)
- [“Fields” on page 1204](#)
- [“Initial values” on page 1205](#)
- [“RPG declaration” on page 1205](#)

Fields in the separate message descriptor

The fields in the separate message descriptor are set by the queue manager as shown in the following list. If the queue manager does not support the version-2 MQMD, a version-1 MQMD is used without loss of function.

Field in separate MQMD	Value used
<i>MDSID</i>	MDSIDV
<i>MDVER</i>	MDVER2
<i>MDREP</i>	Copied from the embedded message descriptor, but with the bits identified by ROAUXM set to zero. (This prevents a COA or COD report message being generated when a message is placed on or removed from a transmission queue.)
<i>MDMT</i>	Copied from the embedded message descriptor.
<i>MDEXP</i>	Copied from the embedded message descriptor.
<i>MDFB</i>	Copied from the embedded message descriptor.
<i>MDENC</i>	ENNAT
<i>MDCSI</i>	Queue manager's <i>CodedCharSetId</i> attribute.
<i>MDFMT</i>	FMXQH
<i>MDPRI</i>	Copied from the embedded message descriptor.
<i>MDPER</i>	Copied from the embedded message descriptor.
<i>MDMID</i>	A new value is generated by the queue manager. This message identifier is different from the <i>MDMID</i> that the queue manager may have generated for the embedded message descriptor (see described previously).
<i>MDCID</i>	The <i>MDMID</i> from the embedded message descriptor.
<i>MDBOC</i>	0
<i>MDRQ</i>	Copied from the embedded message descriptor.
<i>MDRM</i>	Copied from the embedded message descriptor.
<i>MDUID</i>	Copied from the embedded message descriptor.
<i>MDACC</i>	Copied from the embedded message descriptor.
<i>MDAID</i>	Copied from the embedded message descriptor.
<i>MDPAT</i>	ATQM
<i>MDPAN</i>	First 28 bytes of the queue manager name.
<i>MDPD</i>	Date when message was put on transmission queue.
<i>MDPT</i>	Time when message was put on transmission queue.
<i>MDAOD</i>	Blanks
<i>MDGID</i>	GINONE
<i>MDSEQ</i>	1
<i>MDOFF</i>	0
<i>MDMFL</i>	MFNONE
<i>MDOLN</i>	OLUNDF

Fields in the embedded message descriptor

The fields in the embedded message descriptor have the same values as those in the *MSGDSC* parameter of the *MQPUT* or *MQPUT1* call, except for the following:

- The *MDVER* field always has the value *MDVER1*.
- If the *MDPRI* field has the value *PRQDEF*, it is replaced by the value of the queue's *DefPriority* attribute.
- If the *MDPER* field has the value *PEQDEF*, it is replaced by the value of the queue's *DefPersistence* attribute.
- If the *MDMID* field has the value *MINONE*, or the *PMNMID* option was specified, or the message is a distribution-list message, *MDMID* is replaced by a new message identifier generated by the queue manager.

When a distribution-list message is split into smaller distribution-list messages placed on different transmission queues, the *MDMID* field in each of the new embedded message descriptors is the same as that in the original distribution-list message.

- If the *PMNCID* option was specified, *MDCID* is replaced by a new correlation identifier generated by the queue manager.
- The context fields are set as indicated by the *PM** options specified in the *PMO* parameter; the context fields are:
 - *MDACC*
 - *MDAID*
 - *MDAOD*
 - *MDPAN*
 - *MDPAT*
 - *MDPD*
 - *MDPT*
 - *MDUID*
- The version-2 fields (if they were present) are removed from the *MQMD*, and moved into an *MQMDE* structure, if one or more of the version-2 fields has a nondefault value.

Putting messages on remote queues

: When an application puts a message on a remote queue (either by specifying the name of the remote queue directly, or by using a local definition of the remote queue), the local queue manager:

- Creates an *MQXQH* structure containing the embedded message descriptor
- Appends an *MQMDE* if one is needed and is not already present
- Appends the application message data
- Places the message on an appropriate transmission queue

Putting messages directly on transmission queues

It is also possible for an application to put a message directly on a transmission queue. In this case the application must prefix the application message data with an *MQXQH* structure, and initialize the fields with appropriate values. In addition, the *MDFMT* field in the *MSGDSC* parameter of the *MQPUT* or *MQPUT1* call must have the value *FMXQH*.

Character data in the *MQXQH* structure created by the application must be in the character set of the local queue manager (defined by the *CodedCharSetId* queue manager attribute), and integer data must be in the native machine encoding. In addition, character data in the *MQXQH* structure must be padded with blanks to the defined length of the field; the data must not be ended prematurely by using a null

character, because the queue manager does not convert the null and subsequent characters to blanks in the MQXQH structure.

Note however that the queue manager does not check that an MQXQH structure is present, or that valid values have been specified for the fields.

Getting messages from transmission queues

Applications that get messages from a transmission queue must process the information in the MQXQH structure in an appropriate fashion. The presence of the MQXQH structure at the beginning of the application message data is indicated by the value FMXQH being returned in the *MDFMT* field in the *MSGDSC* parameter of the MQGET call. The values returned in the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter, indicates the character set and encoding of the character and integer data in the MQXQH structure. The character set and encoding of the application message data are defined by the *MDCSI* and *MDENC* fields in the embedded message descriptor.

Fields

The MQXQH structure contains the following fields; the fields are described in **alphabetical order**:

XQMD (MQMD1)

Original message descriptor.

This is the embedded message descriptor, and is a close copy of the message descriptor MQMD that was specified as the *MSGDSC* parameter on the MQPUT or MQPUT1 call when the message was originally put to the remote queue.

Note: This is a version-1 MQMD.

The initial values of the fields in this structure are the same as those in the MQMD structure.

XQRQ (48-byte character string)

Name of destination queue.

This is the name of the message queue that is the apparent eventual destination for the message (this may prove not to be the actual eventual destination if, for example, this queue is defined at *XQRQM* to be a local definition of another remote queue).

If the message is a distribution-list message (that is, the *MDFMT* field in the embedded message descriptor is FMDH), *XQRQ* is blank.

The length of this field is given by LNQN. The initial value of this field is 48 blank characters.

XQRQM (48-byte character string)

Name of destination queue manager.

This is the name of the queue manager or queue-sharing group that owns the queue that is the apparent eventual destination for the message.

If the message is a distribution-list message, *XQRQM* is blank.

The length of this field is given by LNQM. The initial value of this field is 48 blank characters.

XQSID (4-byte character string)

Structure identifier.

The value must be:

XQSIDV

Identifier for transmission-queue header structure.

The initial value of this field is XQSIDV.

XQVER (10-digit signed integer)

Structure version number.

The value must be:

XQVER1

Version number for transmission-queue header structure.

The following constant specifies the version number of the current version:

XQVERC

Current version of transmission-queue header structure.

The initial value of this field is XQVER1.

Initial values

Table 618. Initial values of fields in MQXQH		
Field name	Name of constant	Value of constant
XQSID	XQSIDV	'XQH¬'
XQVER	XQVER1	1
XQRQ	None	Blanks
XQRQM	None	Blanks
XQMD	Same names and values as MQMD; see Table 598 on page 1109	-
Notes:		
1. The symbol ¬ represents a single blank character.

Function calls

Use this information to learn about the function calls available in IBM i programming.

Conventions used in the call descriptions on IBM i

For each call, this collection of topics gives a description of the parameters and usage of the call. This is followed by typical invocations of the call, and typical declarations of its parameters, in the RPG programming language.

Important: When coding IBM MQ API calls you must ensure that all relevant parameters (as described in the following sections) are provided. Failure to do so can produce unpredictable results.

The description of each call contains the following sections:

Call name

The call name, followed by a brief description of the purpose of the call.

Parameters

For each parameter, the name is followed by its data type in parentheses () and its direction; for example:

CMPCOD (9-digit decimal integer) - output

There is more information about the structure data types in [“Elementary data types” on page 959](#).

The direction of the parameter can be:

Input

You (the programmer) must provide this parameter.

Output

The call returns this parameter.

Input/output

You must provide this parameter, but it is modified by the call.

There is also a brief description of the purpose of the parameter, together with a list of any values that the parameter can take.

The last two parameters in each call are a completion code and a reason code. The completion code indicates whether the call completed successfully, partially, or not at all. Further information about the partial success or the failure of the call is given in the reason code.

Usage notes

Additional information about the call, describing how to use it and any restrictions on its use.

RPG invocation

Typical invocation of the call, and declaration of its parameters, in RPG.

Other notational conventions are:

Constants

Names of constants are shown in uppercase; for example, OOOUT.

Arrays

In some calls, parameters are arrays of character strings with a size that is not fixed. In the descriptions of these parameters, a lowercase *n* represents a numeric constant. When you code the declaration for that parameter, replace the *n* with the numeric value you require.

MQBACK - Back out changes

The MQBACK call indicates to the queue manager that all of the message gets and puts that have occurred since the last syncpoint are to be backed out. Messages put as part of a unit of work are deleted; messages retrieved as part of a unit of work are reinstated on the queue.

- On IBM i, this call is not supported for applications running in compatibility mode.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

- [“Syntax” on page 1207](#)
- [“Usage notes” on page 1207](#)
- [“Parameters” on page 1208](#)
- [“RPG Declaration” on page 1209](#)

Syntax

MQBACK (*Hconn*, *CompCode*, *Reason*)

Usage notes

Consider these usage notes when using MQBACK.

1. This call can be used only when the queue manager itself coordinates the unit of work. This is a local unit of work, where the changes affect only IBM MQ resources.
2. In environments where the queue manager does not coordinate the unit of work, the appropriate back-out call must be used instead of MQBACK. The environment may also support an implicit back out caused by the application terminating abnormally.
 - On IBM i, this call can be used for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC - Disconnect queue manager” on page 1246](#) for further details.
4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
 - The values of the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD.
 - Whether the message is part of a unit of work.
 - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps *three* sets of group and segment information, one set for each of the following:

- The last successful MQPUT call (this can be part of a unit of work).
- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).

- The last successful MQGET call that browsed a message on the queue (this *cannot* be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then decides to back out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.
- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues which were updated by the application after the unit of work had started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs. For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [“MQPMO - Put-message options” on page 1131](#), and the GMLOGO option described in [“MQGMO - Get-message options” on page 1035](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

1. A unit of work has the same scope as a connection handle. This means that all IBM MQ calls which affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See the *HCONN* parameter described in [“MQCONN - Connect queue manager” on page 1232](#) for information about the scope of connection handles.
2. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
3. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but which never issues a commit or backout call, can cause queues to fill up with messages that are not available to other applications. To guard against this possibility, the administrator should set the *MaxUncommittedMsgs* queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

Parameters

The MQBACK call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *COMCOD*.

If *COMCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *COMCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2101

(2101, X'835') Object damaged.

RC2123

(2123, X'84B') Result of commit or back-out operation is mixed.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

```

IBM i

AIX, HP-UX, IBM i, Solaris, Windows S/390

MQBEGIN - Begin unit of work

The MQBEGIN call begins a unit of work that is coordinated by the queue manager, and that may involve external resource managers.

- This call is supported in the following environments: AIX, HP-UX, IBM i, Solaris, Windows.
- [“Syntax” on page 1210](#)
- [“Usage notes” on page 1210](#)
- [“Parameters” on page 1211](#)

- [“RPG Declaration” on page 1212](#)

Syntax

MQBEGIN (*HCONN*, *BEGOP*, *CMPCOD*, *REASON*)

Usage notes

1. The MQBEGIN call can be used to start a unit of work that is coordinated by the queue manager and that might involve changes to resources owned by other resource managers. The queue manager supports three types of unit-of-work:

Queue-manager-coordinated local unit of work

This is a unit of work in which the queue manager is the only resource manager participating, and so the queue manager acts as the unit-of-work coordinator.

- To start this type of unit of work, the PMSYP or GMSYP option should be specified on the first MQPUT, MQPUT1, or MQGET call in the unit of work.

It is not necessary for the application to issue the MQBEGIN call to start the unit of work, but if MQBEGIN is used, the call completes with CCWARN and reason code RC2121.

- To commit or back out this type of unit of work, the MQCMIT or MQBACK call must be used.

Queue-manager-coordinated global unit of work

This is a unit of work in which the queue manager acts as the unit-of-work coordinator, both for IBM MQ resources *and* for resources belonging to other resource managers. Those resource managers cooperate with the queue manager to ensure that all changes to resources in the unit of work are committed or backed out together.

- To start this type of unit of work, the MQBEGIN call must be used.
- To commit or back out this type of unit of work, the MQCMIT and MQBACK calls must be used.

Externally-coordinated global unit of work

This is a unit of work in which the queue manager is a participant, but the queue manager does not act as the unit-of-work coordinator. Instead, there is an external unit-of-work coordinator with whom the queue manager cooperates.

- To start this type of unit of work, the relevant call provided by the external unit-of-work coordinator must be used.

If the MQBEGIN call is used to try to start the unit of work, the call fails with reason code RC2012.

- To commit or back out this type of unit of work, the commit and back-out calls provided by the external unit-of-work coordinator must be used.

If the MQCMIT or MQBACK call is used to try to commit or back out the unit of work, the call fails with reason code RC2012.

2. If the application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC - Disconnect queue manager” on page 1246](#) for further details.
3. An application can participate in only one unit of work at a time. The MQBEGIN call fails with reason code RC2128 if there is already a unit of work in existence for the application, regardless of which type of unit of work it is.
4. The MQBEGIN call is not valid in an IBM MQ client environment. An attempt to use the call fails with reason code RC2012.
5. When the queue manager is acting as the unit-of-work coordinator for global units of work, the resource managers that can participate in the unit of work are defined in the queue manager's configuration file.
6. On IBM i, the three types of unit of work are supported as follows:

- **Queue-manager-coordinated local units of work** can be used only when a commitment definition does not exist at the job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must not have been issued for the job.
- **Queue-manager-coordinated global units of work** are not supported.
- **Externally-coordinated global units of work** can be used only when a commitment definition exists at job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must have been issued for the job. If this has been done, the IBM i COMMIT and ROLLBACK operations apply to IBM MQ resources as well as to resources belonging to other participating resource managers.

Parameters

The MQBEGIN call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

BEGOP (MQBO) - input/output

Options that control the action of MQBEGIN.

See [“MQBO - Begin options” on page 980](#) for details.

If no options are required, programs written in C or S/390 assembler can specify a null parameter address, instead of specifying the address of an MQBO structure.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2121

(2121, X'849') No participating resource managers registered.

RC2122

(2122, X'84A') Participating resource manager not available.

If *CMPCOD* is CCFAIL:

RC2134

(2134, X'856') Begin-options structure not valid.

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2012

(2012, X'7DC') Call not valid in environment.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2046

(2046, X'7FE') Options not valid or not consistent.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

RC2128

(2128, X'850') Unit of work already started.

MQBUFMH - Convert buffer into message handle

The MQBUFMH function call converts a buffer into a message handle and is the inverse of the MQMHBUF call.

This call takes a message descriptor and MQRFH2 properties in the buffer and makes them available through a message handle. The MQRFH2 properties in the message data are, optionally, removed. The *Encoding*, *CodedCharSetId*, and *Format* fields of the message descriptor are updated, if necessary, to correctly describe the contents of the buffer after the properties have been removed.

- [“Syntax” on page 1212](#)
- [“Usage notes” on page 1213](#)
- [“Parameters” on page 1213](#)
- [“RPG Declaration” on page 1214](#)

Syntax

MQBUFMH (*Hconn*, *Hmsg*, *BufMsgHOpts*, *MsgDesc*, *Buffer*, *BufferLength*, *DataLength*, *CompCode*, *Reason*)

Usage notes

MQBUFMH calls cannot be intercepted by API exits - a buffer is converted into a message handle in the application space; the call does not reach the queue manager.

Parameters

The MQBUFMH call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* must match the connection handle that was used to create the message handle specified in the *Hmsg* parameter.

If the message handle was created by using HCUNAS, a valid connection must be established on the thread converting a buffer into a message handle. If a valid connection is not established, the call fails with RC2009.

HMSG (20-digit signed integer) - input

This handle is the message handle for which a buffer is required. The value was returned by a previous MQCRTMH call.

BMHOPT (MQBMHO) - input

The MQBMHO structure allows applications to specify options that control how message handles are produced from buffers.

See [“MQBMHO - Buffer to message handle options” on page 979](#) for details.

MSGDSC (MQMD) - input/output

The *MSGDSC* structure contains the message descriptor properties and describes the contents of the buffer area.

On output from the call, the properties are optionally removed from the buffer area and, in this case, the message descriptor is updated to correctly describe the buffer area.

Data in this structure must be in the character set and encoding of the application.

BUFLEN (10-digit signed integer) - input

BUFLEN is the length of the Buffer area, in bytes.

A *BUFLEN* of zero bytes is valid, and indicates that the buffer area contains no data.

BUFFER (1-byte bit string x BUFLEN) - input/output

BUFFER defines the area containing the message buffer. For most data, you must align the buffer on a 4-byte boundary.

If *BUFFER* contains character or numeric data, set the *CodedCharSetId* and *Encoding* fields in the *MSGDSC* parameter to the values appropriate to the data; this enables the data to be converted, if necessary.

If properties are found in the message buffer they are optionally removed; they later become available from the message handle on return from the call.

In the C programming language, the parameter is declared as a pointer-to-void, which means the address of any type of data can be specified as the parameter.

If the *BUFLEN* parameter is zero, *BUFFER* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

DATLEN (10-digit signed integer) - output

DATLEN is the length, in bytes, of the buffer which might have the properties removed.

CMPCOD (10-digit signed integer) - output

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2489

(2489, X'09B9') Buffer to message handle options structure not valid.

RC2004

(2004, X'07D4') Buffer parameter not valid.

RC2005

(2005, X'07D5') Buffer length parameter not valid.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2009

(2009, X'07D9') Connection to queue manager lost.

RC2460

(2460, X'099C') Message handle not valid.

RC2026

(2026, X'07EA') Message descriptor not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2334

(2334, X'091E') MQRFH2 structure not valid.

RC2421

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

RC2195

(2195, X'893') Unexpected error occurred.

RPG Declaration

```
C*.1.....2.....3.....4.....5.....6.....7..

```

MQCB - Manage callback

The MQCB call reregisters a callback for the specified object handle and controls activation and changes to the callback.

A callback is a piece of code (specified as either the name of a function that can be dynamically linked or as a function pointer) that is called by IBM MQ when certain events occur.

To use MQCB and MQCTL on a V7 client you must be connected to a V7 server and the **SHARECNV** parameter of the channel must have a non-zero value.

For information about Global units of work see: [Global units of work](#).

The types of callback that can be defined are:

Message consumer

A message consumer callback function is called when a message, meeting the selection criteria specified, is available on an object handle.

Only one callback function can be registered against each object handle. If a single queue is to be read with multiple selection criteria then the queue must be opened multiple times and a consumer function registered on each handle.

Event handler

The event handler is called for conditions that affect the whole callback environment.

The function is called when an event condition occurs, for example, a queue manager or connection stopping or quiescing.

The function is not called for conditions that are specific to a single message consumer, for example RC2016; it is called however if a callback function does not end normally.

- [“Syntax” on page 1215](#)
- [“Usage notes for MQCB” on page 1215](#)
- [“Parameters for MQCB” on page 1217](#)
- [“RPG Declaration” on page 1223](#)

Syntax

MQCB (*HCONN*, *OPERATN*, *HOBJ*, *CBDS*, *MSGDSC*, *GMO*, *CMPCOD*, *REASON*)

Usage notes for MQCB

1. MQCB is used to define the action to be invoked for each message, matching the specified criteria, available on the queue. When the action is processed, either the message is removed from the queue

and passed to the defined message consumer, or a message token is provided, which is used to retrieve the message.

2. MQCB can be used to define callback routines before starting consumption with MQCTL or it can be used from within a callback routine.
3. To use MQCB from outside of a callback routine, you must first suspend message consumption by using MQCTL and resume consumption afterward.

Message consumer callback sequence

You can configure a consumer to invoke callback at key points during the lifecycle of the consumer. For example:

- when the consumer is first registered,
- when the connection is started,
- when the connection is stopped and
- when the consumer is deregistered, either explicitly, or implicitly by an MQCLOSE.

Table 619. MQCTL verb definitions	
Verb	Meaning
MQCTL(START)	MQCTL call by using the CTLSR Operation
MQCTL(STOP)	MQCTL call by using the CTLSP Operation
MQCTL(WAIT)	MQCTL call by using the CTLSW Operation

Allows the consumer to maintain state associated with the consumer. When a callback is requested by an application, the rules for consumer invocation are as follows:

REGISTER

Is always the first type of invocation of the callback.

Is always called on the same thread as the MQCB(CBREG) call.

START

Is always called synchronously with the MQCTL(START) verb.

- All START callbacks are completed before the MQCTL(START) verb returns.

Is on the same thread as the message delivery if CTLTHR is requested.

The call with start is not guaranteed if, for example, a previous callback issues MQCTL(STOP) during the MQCTL(START).

STOP

No further messages or events are delivered after this call until the connection is restarted.

A STOP is guaranteed if the application was previously called for START, or a message, or an event.

DEREGISTER

Is always the last type of invocation of the callback.

Ensure that your application performs thread-based initialization and cleanup in the START and STOP callbacks. You can do non thread-based initialization and cleanup with REGISTER and DEREGISTER callbacks.

Do not make any assumptions about the life and availability of the thread other than what is stated. For example, do not rely on a thread staying alive beyond the last call to DEREGISTER. Similarly, when you have chosen not to use CTLTHR, do not assume that the thread exists whenever the connection is started.

If your application has particular requirements for thread characteristics, it can always create a thread accordingly, then use MQCTL(WAIT). This step *donates* the thread to IBM MQ for asynchronous message delivery.

Message consumer connection usage

Normally, when an application issues another MQI call while one is outstanding, the call fails with reason code RC2219.

There are special cases, however, when the application must issue a further MQI call before the previous call has completed. For example, the consumer can be invoked during an MQCB call with CBRE.

In such an instance, when as a result of the application issuing either an MQCB or MQCTL verb, the application is called back, the application is allowed to issue a further MQI call. This instance means you can issue, for example, an MQOPEN call, in the consumer function when called with a CBCCALLT type of CBCTRC. Any MQI call, except for MQDISC, is allowed.

Parameters for MQCB

The MQCB call has the following parameters:

HCONN (10-digit signed integer) - input

Manage callback function - HCONN parameter.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and you can specify the following special value for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

OPERATN (10-digit signed integer) - input

Manage callback function - OPERATN parameter.

The operation being processed on the callback defined for the specified object handle. You must specify one of the following options; if more than one option is required, the values can be added (do not add the same constant more than once) or combined by using the bitwise OR operation (if the programming language supports bit operations).

Combinations that are not valid are noted; all other combinations are valid.

CBREG

Define the callback function for the specified object handle. This operation defines the function to be called and the selection criteria to be used.

If a callback function is already defined for the object handle the definition is replaced. If an error is detected while replacing the callback, the function is deregistered.

If a callback is registered in the same callback function in which it was previously deregistered, this is treated as a replace operation; any initial or final calls are not invoked.

You can use CBREG with CTLSU or CTLRE.

CBUNR

Stop the consuming of messages for the object handle and removes the handle from those eligible for a callback.

A callback is automatically deregistered if the associated handle is closed.

If CBUNR is called from within a consumer, and the callback has a stop call defined, it is invoked upon return from the consumer.

If this operation is issued against an *Hobj* with no registered consumer, the call returns with RC2448.

CTLSU

Suspends the consuming of messages for the object handle.

If this operation is applied to an event handler, the event handler does not get events while suspended, and any events missed while in the suspended state are not provided to the operation when it is resumed.

While suspended, the consumer function continues to get the control type callbacks.

CTLRE

Resume the consuming of messages for the object handle.

If this operation is applied to an event handler, the event handler does not get events while suspended, and any events missed while in the suspended state are not provided to the operation when it is resumed.

CBDSC (MQCBD) - input

Manage callback function - CBDSC parameter.

This is a structure that identifies the callback function that is being registered by the application and the options used when registering it.

See “MQCBD - Callback descriptor” on page 278 for details of the structure.

Callback descriptor is required only for the CBREG option; if the descriptor is not required, the parameter address passed can be null.

HOBJ (10-digit signed integer) - input

Manage callback function - HOBJ parameter.

This handle represents the access that has been established to the object from which a message is to be consumed. This is a handle that has been returned from a previous [MQOPEN](#) or [MQSUB](#) call (in the *HOBJ* parameter).

HOBJ is not required when defining an event handler routine (CBTEH) and must be specified as HONONE.

If this *Hobj* has been returned from an [MQOPEN](#) call, the queue must have been opened with one or more of the following options:

- OOINPS
- OOINPX
- OOINPQ
- OOBWR

MSGDSC (MQMD) - input

Manage callback function -MSGDSC parameter.

This structure describes the attributes of the message required, and the attributes of the message retrieved.

The *MsgDesc* parameter defines the attributes of the messages required by the consumer, and the version of the MQMD to be passed to the message consumer.

The *MsgId*, *CorrelId*, *GroupId*, *MsgSeqNumber*, and *Offset* in the MQMD are used for message selection, depending on the options specified in the *GetMsgOpts* parameter.

The *Encoding* and *CodedCharSetId* are used for message conversion if you specify the GMCONV option.

See [MQMD](#) for details.

MsgDesc is used only for CBREG and, if you require values other than the default for any fields. *MsgDesc* is not used for an event handler.

If the descriptor is not required the parameter address passed can be null.

Note, that if multiple consumers are registered against the same queue with overlapping selectors, the chosen consumer for each message is undefined.

GMO (MQGMO) - input

Manage callback function - GMO parameter.

Options that control how the message consumer gets messages.

All options have the meaning as described in [“MQGMO - Get-message options”](#) on page 1035, when used on an MQGET call, except:

GMSSIG

This option is not permitted.

GMBRWF, GMBRWN, GMMBH, GMMBC

The order of messages delivered to a browsing consumer is dictated by the combinations of these options. Significant combinations are:

GMBRWF

The first message on the queue is delivered repeatedly to the consumer. This is useful when the consumer destructively consumes the message in the callback. Use this option with care.

GMBRWN

The consumer is given each message on the queue, from the current cursor position until the end of the queue is reached.

GMBRWF + GMBRWN

The cursor is reset to the start of the queue. The consumer is then given each message until the cursor reaches the end of the queue.

GMBRWF + GMMBH or GMMBC

Starting at the beginning of the queue, the consumer is given the first nonmarked message on the queue, which is then marked for this consumer. This combination ensures that the consumer can receive new messages added behind the current cursor point.

GMBRWN + GMMBH or GMMBC

Starting at the cursor position the consumer is given the next nonmarked message on the queue, which is then marked for this consumer. Use this combination with care because messages can be added to the queue behind the current cursor position.

GMBRWF + GMBRWN + GMMBH or GMMBC

This combination is not permitted, if used the call returns RC2046.

GMNWT, GMWT and GMWI

These options control how the consumer is invoked.

GMNWT

The consumer is never called with RC2033. The consumer is only invoked for messages and events

GMWT with a zero GMWI

The RC2033 code is only passed to the consumer when there are no messages and

- the consumer has been started
- the consumer has been delivered at least one message since the last no messages reason code.

This prevents the consumer from polling in a busy loop when a zero wait interval is specified.

GMWT and a positive GMWI

The user is invoked after the specified wait interval with reason code RC2033. This call is made regardless of whether any messages have been delivered to the consumer. This allows the user to perform heartbeat or batch type processing.

GMWT and GMWI of WIULIM

This specifies an infinite wait before returning RC2033. The consumer is never called with RC2033.

GMO is used only for CBREG and, if you require values other than the default for any fields. *GMO* is not used for an event handler.

If the options are not required the parameter address passed can be null.

If a message properties handle is provided in the MQGMO structure, a copy is provided in the MQGMO structure that is passed into the consumer callback. On return from the MQCB call, the application can delete the message properties handle.

CMPCOD (10-digit signed integer) - output

Manage callback function - CMPCOD parameter.

The completion code; it is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Manage callback function - REASON parameter.

The following reason codes are the codes that the queue manager can return for the *REASON* parameter.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CompCode* is CCFAIL:

RC2204

(2204, X'89C') Adapter not available.

RC2133

(2133, X'855') Unable to load data conversion services modules.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2374

(2374, X'946') API exit failed.

RC2183

(2183, X'887') Unable to load API exit.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2005

(2005, X'7D5') Buffer length parameter not valid.

RC2219

(2219, X'8AB') MQI call entered before previous call complete.

RC2487

(2487, X'9B7') Incorrect callback type field.

RC2448

(2448, X'990') Unable to deregister, suspend, or resume because there is no registered callback.

RC2486
(2486, X'9B6') Either *CallbackFunction* or *CallbackName* must be specified but not both.

RC2483
(2483, X'9B3') Incorrect callback type field.

RC2484
(2484, X'9B4') Incorrect MQCBD options field.

RC2140
(2140, X'85C') Wait request rejected by CICS.

RC2009
(2009, X'7D9') Connection to queue manager lost.

RC2217
(2217, X'8A9') Not authorized for connection.

RC2202
(2202, X'89A') Connection quiescing.

RC2203
(2203, X'89B') Connection shutting down.

RC2207
(2207, X'89F') Correlation-identifier error.

RC2010
(2010, X'7DA') Data length parameter not valid.

RC2016
(2016, X'7E0') Gets inhibited for the queue.

RC2351
(2351, X'92F') Global units of work conflict.

RC2186
(2186, X'88A') Get-message options structure not valid.

RC2353
(2353, X'931') Handle in use for global unit of work.

RC2018
(2018, X'7E2') Connection handle not valid.

RC2019
(2019, X'7E3') Object handle not valid.

RC2259
(2259, X'8D3') Inconsistent browse specification.

RC2245
(2245, X'8C5') Inconsistent unit-of-work specification.

RC2246
(2246, X'8C6') Message under cursor not valid for retrieval.

RC2352
(2352, X'930') Global unit of work conflicts with local unit of work.

RC2247
(2247, X'8C7') Match options not valid.

RC2485
(2485, X'9B4') Incorrect *MaxMsgLength* field.

RC2026
(2026, X'7EA') Message descriptor not valid.

RC2497
(2497, X'9C1') The specified function entry point could not be found in the module.

RC2496

(2496, X'9C0') Module found, however it is of the wrong type; not 32 bit, 64 bit, or a valid dynamic link library.

RC2495

(2495, X'9BF') Module not found in the search path or not authorized to load.

RC2250

(2250, X'8CA') Message sequence number not valid.

RC2331

(2331, X'91B') Use of message token not valid.

RC2033

(2033, X'7F1') No message available.

RC2034

(2034, X'7F2') Browse cursor not positioned on message.

RC2036

(2036, X'7F4') Queue not open for browse.

RC2037

(2037, X'7F5') Queue not open for input.

RC2041

(2041, X'7F9') Object definition changed since opened.

RC2101

(2101, X'835') Object damaged.

RC2206

(2206, X'89E') Incorrect operation code on API Call.

RC2046

(2046, X'7FE') Options not valid or not consistent.

RC2193

(2193, X'891') Error accessing page-set data set.

RC2052

(2052, X'804') Queue has been deleted.

RC2394

(2394, X'95A') Queue has wrong index type.

RC2058

(2058, X'80A') Queue manager name not valid or not known.

RC2059

(2059, X'80B') Queue manager not available for connection.

RC2161

(2161, X'871') Queue manager quiescing.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2069

(2069, X'815') Signal outstanding for this handle.

RC2071

(2071, X'817') Insufficient storage available.

RC2109

(2109, X'83D') Call suppressed by exit program.

RC2024

(2024, X'7E8') No more messages can be handled within current unit of work.

RC2072

(2072, X'818') Syncpoint support not available.

RC2195

(2195, X'893') Unexpected error occurred.

RC2354

(2354, X'932') Enlistment in global unit of work failed.

RC2355

(2355, X'933') Mixture of unit-of-work calls not supported.

RC2255

(2255, X'8CF') Unit of work not available for the queue manager to use.

RC2090

(2090, X'82A') Wait interval in MQGMO not valid.

RC2256

(2256, X'8D0') Wrong version of MQGMO supplied.

RC2257

(2257, X'8D1') Wrong version of MQMD supplied.

RC2298

(2298, X'8FA') The function requested is not available in the current environment.

MQCLOSE - Close object

The MQCLOSE call relinquishes access to an object, and is the inverse of the MQOPEN call.

- [“Syntax” on page 1223](#)
- [“Usage notes” on page 1224](#)
- [“Parameters” on page 1225](#)
- [“RPG Declaration” on page 1229](#)

Syntax

MQCLOSE (*HCONN*, *HOBJ*, *OPTS*, *CMPCOD*, *REASON*)

Usage notes

1. When an application issues the MQDISC call, or ends either normally or abnormally, any objects that were opened by the application and are still open are closed automatically with the CONONE option.
2. The following points apply if the object being closed is a *queue*:
 - If operations on the queue are performed as part of a unit of work, the queue can be closed before or after the syncpoint occurs without affecting the outcome of the syncpoint.
 - If the queue was opened with the OOBROW option, the browse cursor is destroyed. If the queue is later reopened with the OOBROW option, a new browse cursor is created (see the OOBROW option described in MQOPEN).
 - If a message is currently locked for this handle at the time of the MQCLOSE call, the lock is released (see the GMLK option described in [“MQGMO - Get-message options” on page 1035](#)).
3. The following points apply if the object being closed is a *dynamic queue* (either permanent or temporary):

- For a dynamic queue, the options CODEL or COPURG can be specified regardless of the options specified on the corresponding MQOPEN call.
- When a dynamic queue is deleted, all MQGET calls with the GMWT option that are outstanding against the queue are canceled and reason code RC2052 is returned. See the GMWT option described in [“MQGMO - Get-message options” on page 1035](#).

After a dynamic queue has been deleted, any call (other than MQCLOSE) that attempts to reference the queue using a previously acquired *HOBJ* handle fails with reason code RC2052.

Be aware that although a deleted queue cannot be accessed by applications, the queue is not removed from the system, and associated resources are not freed, until all handles that reference the queue have been closed, and all units of work that affect the queue have been either committed or backed out.

- When a permanent dynamic queue is deleted, if the *HOBJ* handle specified on the MQCLOSE call is *not* the one that was returned by the MQOPEN call that created the queue, a check is made that the user identifier which was used to validate the MQOPEN call is authorized to delete the queue. If the OOALTU option was specified on the MQOPEN call, the user identifier checked is the *ODAU*.

This check is not performed if:

- The handle specified is the one returned by the MQOPEN call that created the queue.
- The queue being deleted is a temporary dynamic queue.
- When a temporary dynamic queue is closed, if the *HOBJ* handle specified on the MQCLOSE call is the one that was returned by the MQOPEN call that created the queue, the queue is deleted. This occurs regardless of the close options specified on the MQCLOSE call. If there are messages on the queue, they are discarded; no report messages are generated.

If there are uncommitted units of work that affect the queue, the queue and its messages are still deleted, but this does not cause the units of work to fail. However, as described previously, the resources associated with the units of work are not freed until each of the units of work has been either committed or backed out.

4. The following points apply if the object being closed is a *distribution list*:

- The only valid close option for a distribution list is CONONE; the call fails with reason code RC2046 or RC2045 if any other options are specified.
- When a distribution list is closed, individual completion codes and reason codes are not returned for the queues in the list - only the *CMPCOD* and *REASON* parameters of the call are available for diagnostic purposes.

If a failure occurs closing one of the queues, the queue manager continues processing and attempts to close the remaining queues in the distribution list. The *CMPCOD* and *REASON* parameters of the call are then set to return information describing the failure. Thus it is possible for the completion

code to be CCFAIL, even though most of the queues were closed successfully. The queue that encountered the error is not identified.

If there is a failure on more than one queue, it is not defined which failure is reported in the *CMPCOD* and *REASON* parameters.

5. On IBM i, if the application was connected implicitly when the first MQOPEN call was issued, an implicit MQDISC occurs when the last MQCLOSE is issued.

Only applications running in compatibility mode can be connected implicitly; other applications must issue the MQCONN or MQCONNX call to connect to the queue manager explicitly.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

Parameters

The MQCLOSE call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HOBJ (10-digit signed integer) - input/output

Object handle.

This handle represents the object that is being closed. The object can be of any type. The value of *HOBJ* was returned by a previous MQOPEN call.

On successful completion of the call, the queue manager sets this parameter to a value that is not a valid handle for the environment. This value is:

HOUNUH

Unusable object handle.

OPTS (10-digit signed integer) - input

Options that control the action of MQCLOSE.

The *OPTS* parameter controls how the object is closed. Only permanent dynamic queues and subscriptions can be closed in more than one way. Permanent dynamic queues can either be retained or deleted; these are queues with a *DefinitionType* attribute that has the value QDPERM (see the *DefinitionType* attribute described in [“Attributes for queues” on page 1324](#)). The close options are summarized in a table later in this topic.

Durable subscriptions can either be kept or removed; these are created using the MQSUB call with the SODUR option.

When closing the handle to a managed destination (that is the *Hobj* parameter returned on an MQSUB call which used the SOMAN option) the queue manager will clean up any unretrieved publications when the associated subscription has also been removed. That is done using the CORMSB option on the *Hsub* parameter returned on an MQSUB call. Note that CORMSB is the default behavior on MQCLOSE for a non-durable subscription.

When closing a handle to a non-managed destination you are responsible for cleaning up the queue where publications are sent. You are recommended to close the subscription using CORMSB first and then process messages off the queue until there are none remaining.

One (and only one) of the following must be specified:

Dynamic queue closure options

These options control how permanent dynamic queues are closed:

CODEL

Delete the queue.

The queue is deleted if either of the following is true:

- It is a permanent dynamic queue, created by a previous MQOPEN call, and there are no messages on the queue and no uncommitted get or put requests outstanding for the queue (either for the current task or any other task).
- It is the temporary dynamic queue that was created by the MQOPEN call that returned *HOBj*. In this case, all the messages on the queue are purged.

In all other cases, including the case where the *Hobj* was returned on an MQSUB call, the call fails with reason code RC2045, and the object is not deleted.

COPURG

Delete the queue, purging any messages on it.

The queue is deleted if either of the following is true:

- It is a permanent dynamic queue, created by a previous MQOPEN call, and there are no uncommitted get or put requests outstanding for the queue (either for the current task or any other task).
- It is the temporary dynamic queue that was created by the MQOPEN call that returned *HOBj*.

In all other cases, including the case where the *Hobj* was returned on an MQSUB call, the call fails with reason code RC2045, and the object is not deleted.

The next table shows which close options are valid, and whether the object is retained or deleted.

Table 620. Valid close options for use with retained or deleted objects			
Type of object or queue	CONONE	CODEL	COPURG
Object other than a queue	Retained	Not valid	Not valid
Predefined queue	Retained	Not valid	Not valid
Permanent dynamic queue	Retained	Deleted if empty and no pending updates	Messages deleted; queue deleted if no pending updates
Temporary dynamic queue (call issued by creator of queue)	Deleted	Deleted	Deleted
Temporary dynamic queue (call not issued by creator of queue)	Retained	Not valid	Not valid
Distribution list	Retained	Not valid	Not valid
Managed subscription destination	Retained	Not valid	Not valid
Distribution list (subscription has been removed)	Messages deleted; queue deleted	Not valid	Not valid

Subscription closure options

These options control whether durable subscriptions are removed when the handle is closed, and whether publications still waiting to be read by the application are cleaned up. These options are only valid for use with an object handle returned in the *HSUB* parameter of an MQSUB call.

COKPSB

The handle to the subscription is closed but the subscription made is kept. Publications will continue to be sent to the destination specified in the subscription. This option is only valid if the subscription was made with the option SODUR. COKPSB is the default if the subscription is durable

CORMSB

The subscription is removed and the handle to the subscription is closed.

The *Hobj* parameter of the MQSUB call is not invalidated by closure of the *Hsub* parameter and may continue to be used for MQGET or MQCB to receive the remaining publications. When the *Hobj* parameter of the MQSUB call is also closed, if it was a managed destination any unretrieved publications will be removed.

CORMSB is the default if the subscription is non-durable.

These subscription closure options are summarized in the following tables:

To close a durable subscription handle but leave the subscription around, use the following subscription closure options:

Task	Subscription closure option
Keep publications on an MQOPENed handle	COKPSB
Remove publications on an MQOPENed handle	Action not allowed
Keep publications on a handle with SOMAN	COKPSB
Remove publications on a handle with SOMAN	Action not allowed

To unsubscribe, either by closing a durable subscription handle and unsubscribing it or closing a non-durable subscription handle, use the following subscription closure options:

Task	Subscription closure option
Keep publications on an MQOPENed handle	CORMSB
Remove publications on an MQOPENed handle	Action not allowed
Keep publications on a handle with SOMAN	CORMSB
Remove publications on a handle with SOMAN	COPGSB

Read ahead options

The following options control what happens to non-persistent messages which have been sent to the client before an application requested them and have not yet been consumed by the application. These messages are stored in the client read ahead buffer waiting to be requested by the application and can either be discarded or consumed from the queue before the MQCLOSE is completed.

COIMM

The object is closed immediately and any messages which have been sent to the client before an application requested them are discarded and are not available to be consumed by any application. This is the default value.

COQSC

A request to close the object is made, but if any messages which have been sent to the client before an application requested them, still reside in the client read ahead buffer, the MQCLOSE call will return with a warning code of RC2458, and the object handle will remain valid.

The application can then continue to use the object handle to retrieve messages until no more are available, and then close the object again. No more messages will be sent to the client ahead of an application requesting then, read ahead is now turned off.

Applications are advised to use COQSC rather than trying to reach a point where there are no more messages in the client read ahead buffer, since a message could arrive between the last MQGET call and the following MQCLOSE which would be discarded if COIMM was used.

If an MQCLOSE with COQSC is issued from within an asynchronous callback function, the same behavior of reading ahead messages applies. If the warning code RC2458 is returned, then the callback function will be called at least one more time. When the last remaining message that was read ahead has been passed to the callback function the CBCFLG field is set to CBCFBE.

Default option

If you require none of the options described previously, you can use the following option:

CONONE

No optional close processing required.

This *must* be specified for:

- Objects other than queues
- Predefined queues
- Temporary dynamic queues (but only in those cases where *HOBJ* is *not* the handle returned by the MQOPEN call that created the queue).
- Distribution lists

In all of the previous cases, the object is retained and not deleted.

If this option is specified for a temporary dynamic queue:

- The queue is deleted, if it was created by the MQOPEN call that returned *HOBJ* ; any messages that are on the queue are purged.
- In all other cases the queue (and any messages on it) are retained.

If this option is specified for a permanent dynamic queue, the queue is retained and not deleted.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2241

(2241, X'8C1') Message group not complete.

RC2242

(2242, X'8C2') Logical message not complete.

If *CMPCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2019

(2019, X'7E3') Object handle not valid.

MQCMIT - Commit changes

The MQCMIT call indicates to the queue manager that the application has reached a syncpoint, and that all of the message gets and puts that have occurred since the last syncpoint are to be made permanent. Messages put as part of a unit of work are made available to other applications; messages retrieved as part of a unit of work are deleted.

- On IBM i, this call is not supported for applications running in compatibility mode.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

- [“Syntax” on page 1230](#)
- [“Usage notes” on page 1230](#)
- [“Parameters” on page 1231](#)
- [“RPG Declaration” on page 1232](#)

Syntax

MQCMIT (*HCONN*, *COMCOD*, *REASON*)

Usage notes

Consider these usage notes when using MQCMIT.

1. This call can be used only when the queue manager itself coordinates the unit of work. This is a local unit of work, where the changes affect only IBM MQ resources.
2. In environments where the queue manager does not coordinate the unit of work, the appropriate commit call must be used instead of MQCMIT. The environment may also support an implicit commit caused by the application terminating normally.
 - On IBM i, this call can be used for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC - Disconnect queue manager” on page 1246](#) for further details.
4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
 - The values of the *MDGID*, *MDSEQ*, *MDOFF*, and *MDMFL* fields in MQMD.
 - Whether the message is part of a unit of work.
 - For the MQPUT call: whether the message is persistent or nonpersistent.

When a unit of work is committed, the queue manager retains the group and segment information, and the application can continue putting or getting messages in the current message group or logical message.

Retaining the group and segment information when a unit of work is committed allows the application to spread a large message group or large logical message consisting of many segments across several units of work. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs. For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [“MQPMO -](#)

Put-message options” on page 1131, and the GMLOGO option described in “MQGMO - Get-message options” on page 1035.

The remaining usage notes apply only when the queue manager coordinates the units of work:

1. A unit of work has the same scope as a connection handle. This means that all IBM MQ calls which affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See the *HCONN* parameter described in MQCONN for information about the scope of connection handles.
2. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
3. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but which never issues a commit or back-out call, can cause queues to fill up with messages that are not available to other applications. To guard against this possibility, the administrator should set the *MaxUncommittedMsgs* queue manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

Parameters

The MQCMIT call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

COMCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *COMCOD*.

If *COMCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *COMCOD* is CCWARN:

RC2003

(2003, X'7D3') Unit of work backed out.

RC2124

(2124, X'84C') Result of commit operation is pending.

If *COMCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2101

(2101, X'835') Object damaged.

RC2123

(2123, X'84B') Result of commit or back-out operation is mixed.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

```

MQCONN - Connect queue manager

The MQCONN call connects an application program to a queue manager. It provides a queue manager connection handle, which is used by the application on subsequent message queuing calls.

- On IBM i, applications running in compatibility mode do not have to issue this call. These applications are connected automatically to the queue manager when they issue the first MQOPEN call. However, the MQCONN and MQDISC calls are still accepted from IBM i applications.

Other applications (that is, applications not running in compatibility mode) must use the MQCONN or MQCONNEX call to connect to the queue manager, and the MQDISC call to disconnect from the queue manager. Consider using this style of programming.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

On IBM MQ for Windows, UNIX, and IBM i, each thread in an application can connect to different queue managers. On other systems, all concurrent connections within a process must be to the same queue manager.

- [“Syntax” on page 1233](#)
- [“Usage notes” on page 1233](#)
- [“Parameters” on page 1234](#)
- [“RPG Declaration” on page 1236](#)

Syntax

MQCONN (QMNAME, HCONN, CMPCOD, REASON)

Usage notes

1. The queue manager to which connection is made using the MQCONN call is called the *local queue manager*.
2. Queues that are owned by the local queue manager appear to the application as local queues. It is possible to put messages on and get messages from these queues.

Shared queues that are owned by the queue-sharing group to which the local queue manager belongs appear to the application as local queues. It is possible to put messages on and get messages from these queues.

Queues that are owned by remote queue managers appear as remote queues. It is possible to put messages on these queues, but not possible to get messages from these queues.
3. If the queue manager fails while an application is running, the application must issue the MQCONN call again in order to obtain a new connection handle to use on subsequent IBM MQ calls. The application can issue the MQCONN call periodically until the call succeeds.

If an application is not sure whether it is connected to the queue manager, the application can safely issue an MQCONN call in order to obtain a connection handle. If the application is already connected, the handle returned is the same as that returned by the previous MQCONN call, but with completion code CCWARN and reason code RC2002.

4. When the application has finished using IBM MQ calls, the application should use the MQDISC call to disconnect from the queue manager.
5. On IBM i, applications written for releases earlier than MQSeries V5.1 of the queue manager can run without the need for recompilation.
6. This is a *compatibility mode*. This mode of operation provides a compatible runtime environment for applications written using the dynamic linkage. It comprises the following:

- The service program AMQZSTUB residing in the library QMQM.

AMQZSTUB provides the same public interface as previous releases, and has the same signature. This service program can be used to access the MQI through bound procedure calls.

- The program QMQM residing in the library QMQM.

QMQM provides a means of accessing the MQI through dynamic program calls.

- Programs MQCLOSE, MQCONN, MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQPUT1, and MQSET residing in the library QMQM.

These programs also provide a means of accessing the MQI through dynamic program calls, but with a parameter list that corresponds to the standard descriptions of the IBM MQ calls.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

These three interfaces do not include capabilities that were introduced in version 5.1. For example, the MQBACK, MQCMIT, and MQCONNX calls are not supported. The support provided by these interfaces is for single-threaded applications only.

Support for the static bound IBM MQ calls in single-threaded applications, and for all IBM MQ calls in multi-threaded applications, is provided through the service programs LIBMQM and LIBMQM_R.

7. On IBM i, programs that end abnormally are not automatically disconnected from the queue manager. Therefore applications should be written to allow for the possibility of the MQCONN or MQCONNX call returning completion code CCWARN and reason code RC2002. The connection handle returned in this situation can be used as normal.

Parameters

The MQCONN call has the following parameters:

QMNAME (48-byte character string) - input

Name of queue manager.

This is the name of the queue manager to which the application wants to connect. The name can contain the following characters:

- Uppercase alphabetic characters (A through Z)
- Lowercase alphabetic characters (a through z)
- Numeric digits (0 through 9)
- Period (.), forward slash (/), underscore (_), percent (%)

The name must not contain leading or embedded blanks, but might contain trailing blanks. A null character can be used to indicate the end of significant data in the name; the null and any characters following it are treated as blanks. The following restrictions apply in the environments indicated:

- On IBM i, names containing lowercase characters, forward slash, or percent must be enclosed in quotation marks when specified on commands. These quotation marks must not be specified in the *QMNAME* parameter.

If the name consists entirely of blanks, the name of the *default* queue manager is used.

The name specified for *QMNAME* must be the name of a *connectable* queue manager.

Queue-sharing groups: On systems where several queue managers exist and are configured to form a queue-sharing group, the name of the queue-sharing group can be specified for *QMNAME* in place of the name of a queue manager. This allows the application to connect to *any* queue manager that is available in the queue-sharing group. The system can also be configured so that a blank *QMNAME* causes connection to the queue-sharing group instead of to the default queue manager.

If *QMNAME* specifies the name of the queue-sharing group, but there is also a queue manager with that name on the system, connection is made to the latter in preference to the former. Only if that connection fails is connection to one of the queue managers in the queue-sharing group attempted.

If the connection is successful, the handle returned by the MQCONN or MQCONNX call can be used to access *all* of the resources (both shared and nonshared) that belong to the particular queue manager to which connection has been made. Access to these resources is subject to the typical authorization controls.

If the application issues two MQCONN or MQCONNX calls in order to establish concurrent connections, and one or both calls specifies the name of the queue-sharing group, the second call may return completion code CCWARN and reason code RC2002. This occurs when the second call connects to the same queue manager as the first call.

Queue-sharing groups are supported only on z/OS. Connection to a queue-sharing group is supported only in the batch, RRS batch, and TSO environments.

IBM MQ client applications: For IBM MQ MQI client applications, a connection is attempted for each client-connection channel definition with the specified queue manager name, until one is successful. The queue manager, however, must have the same name as the specified name. If an all-blank name is specified, each client-connection channel with an all-blank queue manager name is tried until one is successful; in this case there is no check against the actual name of the queue manager.

IBM MQ client queue manager groups: If the specified name starts with an asterisk (*), the actual queue manager to which connection is made may have a name that is different from that specified by the application. The specified name (without the asterisk) defines a *group* of queue managers that are eligible for connection. The implementation selects one from the group by trying each one in turn, in alphabetic order, until one is found to which a connection can be made. If none of the queue managers in the group is available for connection, the call fails. Each queue manager is tried once

only. If an asterisk alone is specified for the name, an implementation-defined default queue manager group is used.

Queue-manager groups are supported only for applications running in an MQ-client environment; the call fails if a non-client application specifies a queue manager name beginning with an asterisk. A group is defined by providing several client connection channel definitions with the same queue manager name (the specified name without the asterisk), to communicate with each of the queue managers in the group. The default group is defined by providing one or more client connection channel definitions, each with a blank queue manager name (specifying an all-blank name therefore has the same effect as specifying a single asterisk for the name for a client application).

After connecting to one queue manager of a group, an application can specify blanks in the typical way in the queue manager name fields in the message and object descriptors to mean the name of the queue manager to which the application has actually connected (the *local queue manager*). If the application needs to know this name, the MQINQ call can be issued to inquire the *QMGrName* queue manager attribute.

Prefixing an asterisk to the connection name implies that the application is not dependent on connecting to a particular queue manager in the group. Suitable applications would be:

- Applications that put messages but do not get messages.
- Applications that put request messages and then get the reply messages from a *temporary dynamic* queue.

Unsuitable applications would be those that need to get messages from a particular queue at a particular queue manager; such applications should not prefix the name with an asterisk.

Note that if an asterisk is specified, the maximum length of the remainder of the name is 47 characters.

The length of this parameter is given by LNQMNL.

HCONN (10-digit signed integer) - output

Connection handle.

This handle represents the connection to the queue manager. It must be specified on all subsequent message queuing calls issued by the application. It ceases to be valid when the MQDISC call is issued, or when the unit of processing that defines the scope of the handle terminates.

The scope of the handle is restricted to the smallest unit of parallel processing supported by the platform on which the application is running; the handle is not valid outside the unit of parallel processing from which the MQCONN call was issued.

- On IBM i, the scope of the handle is the job issuing the call.

On IBM i for applications running in compatibility mode, the value returned is:

HCDEFH

Default connection handle.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2002

(2002, X'7D2') Application already connected.

If *CMPCOD* is CCFAIL:

MQCONN - Connect queue manager (extended)

The MQCONN call connects an application program to a queue manager. It provides a queue manager connection handle, which is used by the application on subsequent IBM MQ calls.

The MQCONN call is like the MQCONN call, except that MQCONN allows options to be specified to control the way that the call works.

- On IBM i, this call is not supported for applications running in compatibility mode.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

On IBM MQ for Windows, UNIX, and IBM i, each thread in an application can connect to different queue managers. On other systems, all concurrent connections within a process must be to the same queue manager.

- [“Syntax” on page 1237](#)
- [“Parameters” on page 1237](#)
- [“RPG Declaration” on page 1238](#)

Syntax

MQCONN (*QMNAME*, *CNOPT*, *HCONN*, *CMPCOD*, *REASON*)

Parameters

The MQCONN call has the following parameters:

QMNAME (48-byte character string) - input

Name of queue manager.

See the *QMNAME* parameter described in [“MQCONN - Connect queue manager” on page 1232](#) for details.

CNOPT (MQCNO) - input/output

Options that control the action of MQCONN.

See [“MQCNO - Connect options” on page 1009](#) for details.

HCONN (10-digit signed integer) - output

Connection handle.

See the *HCONN* parameter described in [“MQCONN - Connect queue manager” on page 1232](#) for details.

CMPCOD (10-digit signed integer) - output

Completion code.

See the *CMPCOD* parameter described in [“MQCONN - Connect queue manager” on page 1232](#) for details.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

See the *REASON* parameter described in [“MQCONN - Connect queue manager” on page 1232](#) for details of possible reason codes.

The following additional reason codes can be returned by the MQCONN call:

If *CMPCOD* is CCFAIL:

RC2278

(2278, X'8E6') Client connection fields not valid.

RC2139

(2139, X'85B') Connect-options structure not valid.

RC2046

(2046, X'7FE') Options not valid or not consistent.

RPG Declaration

```

C*.1.....2.....3.....4.....5.....6.....7..

```

MQCRTMH - Create message handle

The MQCRTMH call returns a message handle.

An application can use it on subsequent message queuing calls:

- Use the [MQSETMP](#) call to set a property of the message handle.
- Use the [MQINQMP](#) call to inquire on the value of a property of the message handle.
- Use the [MQDLTMP](#) call to delete a property of the message handle.

The message handle can be used on the MQPUT and MQPUT1 calls to associate the properties of the message handle with the properties of the message being put. Similarly, by specifying a message handle on the MQGET call, the properties of the message being retrieved can be accessed by using the message handle when the MQGET call completes.

Use [MQDLTMH](#) to delete the message handle.

- [“Syntax” on page 1238](#)
- [“Parameters” on page 1238](#)
- [“RPG Declaration” on page 1240](#)

Syntax

MQCRTMH (*Hconn*, *CrtMsgHOpts*, *Hmsg*, *CompCode*, *Reason*)

Parameters

The MQCRTMH call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNX call. If the connection to the queue manager ceases to be valid and no IBM MQ call is operating on the message handle, [MQDLTMH](#) is implicitly called to delete the message.

Alternatively, you can specify the following value:

HCUNAS

The connection handle does not represent a connection to any particular queue manager.

When this value is used, the message handle must be deleted with an explicit call to [MQDLTMH](#) in order to release any storage allocated to it; IBM MQ never implicitly deletes the message handle.

There must be at least one valid connection to a queue manager established on the thread creating the message handle, otherwise the call fails with RC2018.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and you can specify the following value for *HCONN* :

HCDEFH

Default connection handle

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

CRTOPT (MQCMHO) - input

The options that control the action of MQCRTMH. See [MQCMHO](#) for details.

HMSG (20-digit signed integer) - output

On output a message handle is returned that can be used to set, inquire, and delete properties of the message handle. Initially the message handle contains no properties.

A message handle also has an associated message descriptor. Initially this message descriptor contains the default values. The values of the associated message descriptor fields can be set and inquired by using the MQSETMP and MQINQMP calls. The MQDLTMP call resets a field of the message descriptor back to its default value.

If the *HCONN* parameter is specified as the value HCUNAS then the returned message handle can be used on MQGET, MQPUT, or MQPUT1 calls with any connection within the unit of processing, but can be in use by only one IBM MQ call at a time. If the handle is in use when a second IBM MQ call attempts to use the same message handle, the second IBM MQ call fails with reason code RC2499.

If the *HCONN* parameter is not HCUNAS then the returned message handle can be used only on the specified connection.

The same *HCONN* parameter value must be used on the subsequent MQI calls where this message handle is used:

- MQDLTMH
- MQSETMP
- MQINQMP
- MQDLTMP
- MQMHBUFF
- MQBUFMH

The returned message handle ceases to be valid when the MQDLTMH call is issued for the message handle, or when the unit of processing that defines the scope of the handle terminates. MQDLTMH is called implicitly if a specific connection is supplied when the message handle is created and the connection to the queue manager ceases to be valid, for example, if MQDBC is called.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2461

(2461, X'099D') Create message handle options structure not valid.

RC2273

(2273, X'7D9') Connection to queue manager lost.

RC2017

(2017, X'07E1') No more handles available.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2460

(2460, X'099C') Message handle pointer not valid.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)” on page 1381](#) for more details.

MQCTL - Control callback

The MQCTL call performs controlling actions on the object handles opened for a connection.

- [“Syntax” on page 1241](#)
- [“Usage notes” on page 1241](#)
- [“Parameters” on page 1241](#)
- [“RPG Declaration” on page 1246](#)

Syntax

MQCTL (*Hconn*, *Operation*, *ControlOpts*, *CompCode*, *Reason*)

Usage notes

1. Callback routines must check the responses from all services they invoke, and if the routine detects a condition that cannot be resolved, it must issue an MQCB(CBREG) command to prevent repeated calls to the callback routine.

Parameters

The MQCTL call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and you can specify the following special value for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

OPERATN (10-digit signed integer) - input

The operation being processed on the callback defined for the specified object handle. You must specify one, and one only, of the following options:

CTLSR

Start the consuming of messages for all defined message consumer functions for the specified connection handle.

Callbacks run on a thread started by the system, which is different from any of the application threads.

This operation gives control of the provided connection handle to system. The only MQI calls which can be issued by a thread other than the consumer thread are:

- MQCTL with Operation CTLSP
- MQCTL with Operation CTLSU
- MQDISC - This performs MQCTL with Operation CTLSP before disconnection the HConn.

RC2500 is returned if an IBM MQ API call is issued while the connection handle is started, and the call does not originate from a message consumer function.

If a connection fails, this stops the conversation as soon as possible. It is possible, therefore, for an IBM MQ API call being issued on the main thread to receive the return code RC2500 for a while, followed by the return code RC2009 when the connection reverts to the stopped state.

This can be issued in a consumer function. For the same connection as the callback routine, its only purpose is to cancel a previously issued CTLSP operation.

This option is not supported if the application is bound with a nonthreaded IBM MQ library.

CTLSW

Start the consuming of messages for all defined message consumer functions for the specified connection handle.

Message consumers run on the same thread and control is not returned to the caller of MQCTL until:

- Released by the use of the MQCTL CTLSP or CTLSU operations, or
- All consumer routines have been deregistered or suspended.

If all consumers are deregistered or suspended, an implicit CTLSP operation is issued.

This option cannot be used from within a callback routine, either for the current connection handle or any other connection handle. If the call is attempted it returns with RC2012.

If, at any time during a CTLSW operation there are no registered, non-suspended consumers the call fails with a reason code of RC2446.

If, during a CTLSW operation, the connection is suspended, the MQCTL call returns a warning reason code of RC2521; the connection remains 'started'.

The application can choose to issue CTLSP or CTLRE. In this instance, the CTLRE operation blocks.

This option is not supported in a single threaded client.

CTLSP

Stop the consuming of messages, and wait for all consumers to complete their operations before this option completes. This operation releases the connection handle.

If issued from within a callback routine, this option does not take effect until the routine exits. No more message consumer routines are called after the consumer routines for messages already read have completed, and after stop calls (if requested) to callback routines have been made.

If issued outside a callback routine, control does not return to the caller until the consumer routines for messages already read have completed, and after stop calls (if requested) to callbacks have been made. The callbacks themselves, however, remain registered.

This function has no effect on read ahead messages. You must ensure that consumers run MQCLOSE(COQSC), from within the callback function, to determine whether there are any further messages available to be delivered.

CTLSU

Pause the consuming of messages. This operation releases the connection handle.

This does not affect the reading ahead of messages for the application. If you intend to stop consuming messages for a long period, consider closing the queue and reopening it when consumption must continue.

If issued from within a callback routine, it does not take effect until the routine exits. No more message consumer routines will be called after the current routine exits.

If issued outside a callback, control does not return to the caller until the current consumer routine has completed and no more are called.

CTLRE

Resume the consuming of messages.

This option is normally issued from the main application thread, but it can also be used from within a callback routine to cancel an earlier suspension request issued in the same routine.

If CTLRE is used to resume a CTLSW, then the operation blocks.

PCTLOP (MQCTLO) - input

Options that control the action of MQCTL

See [MQCTLO](#) for details of the structure.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The following reason codes are the ones that the queue manager can return for the *Reason* parameter.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2133

(2133, X'855') Unable to load data conversion services modules.

RC2204

(2204, X'89C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2374

(2374, X'946') API exit failed.

RC2183

(2183, X'887') Unable to load API exit.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2005

(2005, X'7D5') Buffer length parameter not valid.

RC2487

(2487, X'9B7') Unable to call the callback routine

RC2448

(2448, X'990') Unable to Deregister, Suspend, or Resume because there is no registered callback

RC2486

(2486, X'9B6') Either, both CallbackFunction and CallbackName have been specified on a CBREG call, or either one of CallbackFunction or CallbackName has been specified but does not match the currently registered callback function.

RC2483

(2483, X'9B3') Incorrect CallBackType field.

RC2219

(2219, X'8AB') MQI call entered before previous call complete.

RC2444

(2444, X'98C') Option block is incorrect.

RC2484
(2484, X'9B4') Incorrect MQCBD options field.

RC2140
(2140, X'85C') Wait request rejected by CICS.

RC2009
(2009, X'7D9') Connection to queue manager lost.

RC2217
(2217, X'8A9') Not authorized for connection.

RC2202
(2202, X'89A') Connection quiescing.

RC2203
(2203, X'89B') Connection shutting down.

RC2207
(2207, X'89F') Correlation-identifier error.

RC2016
(2016, X'7E0') Gets inhibited for the queue.

RC2351
(2351, X'92F') Global units of work conflict.

RC2186
(2186, X'88A') Get-message options structure not valid.

RC2353
(2353, X'931') Handle in use for global unit of work.

RC2018
(2018, X'7E2') Connection handle not valid.

RC2019
(2019, X'7E3') Object handle not valid.

RC2259
(2259, X'8D3') Inconsistent browse specification.

RC2245
(2245, X'8C5') Inconsistent unit-of-work specification.

RC2246
(2246, X'8C6') Message under cursor not valid for retrieval.

RC2352
(2352, X'930') Global unit of work conflicts with local unit of work.

RC2247
(2247, X'8C7') Match options not valid.

RC2485
(2485, X'9B5') Incorrect MaxMsgLength field

RC2026
(2026, X'7EA') Message descriptor not valid.

RC2497
(2497, X'9C1')The specified function entry point was not be found in the module.

RC2496
(2496, X'9C0') Module is found but is of the wrong type (32-bit or 64-bit) or is not a valid dll.

RC2495
(2495, X'9BF') Module not found in the search path or not authorized to load.

RC2206
(2206, X'89E') Message-identifier error.

RC2250
(2250, X'8CA') Message sequence number not valid.

RC2331
(2331, X'91B') Use of message token not valid.

RC2036
(2036, X'7F4') Queue not open for browse.

RC2037
(2037, X'7F5') Queue not open for input.

RC2041
(2041, X'7F9') Object definition changed since opened.

RC2101
(2101, X'835') Object damaged.

RC2488
(2488, X'9B8') Incorrect Operation code on API Call

RC2046
(2046, X'7FE') Options not valid or not consistent.

RC2193
(2193, X'891') Error accessing page-set data set.

RC2052
(2052, X'804') Queue has been deleted.

RC2394
(2394, X'95A') Queue has wrong index type.

RC2058
(2058, X'80A') Queue manager name not valid or not known.

RC2059
(2059, X'80B') Queue manager not available for connection.

RC2161
(2161, X'871') Queue manager quiescing.

RC2162
(2162, X'872') Queue manager shutting down.

RC2102
(2102, X'836') Insufficient system resources available.

RC2069
(2069, X'815') Signal outstanding for this handle.

RC2071
(2071, X'817') Insufficient storage available.

RC2109
(2109, X'83D') Call suppressed by exit program.

RC2072
(2072, X'818') Syncpoint support not available.

RC2195
(2195, X'893') Unexpected error occurred.

RC2354
(2354, X'932') Enlistment in global unit of work failed.

RC2355
(2355, X'933') Mixture of unit-of-work calls not supported.

RC2255
(2255, X'8CF') Unit of work not available for the queue manager to use.

RC2090
(2090, X'82A') Wait interval in MQGMO not valid.

RC2256
(2256, X'8D0') Wrong version of MQGMO supplied.

RC2257

(2257, X'8D1') Wrong version of MQMD supplied.

RC2298

(2298, X'8FA') The function requested is not available in the current environment.

MQDISC - Disconnect queue manager

The MQDISC call breaks the connection between the queue manager and the application program, and is the inverse of the MQCONN or MQCONNX call.

- On IBM i, applications running in compatibility mode do not need to issue this call. See [“MQCONN - Connect queue manager” on page 1232](#) for more information.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

- [“Syntax” on page 1246](#)
- [“Usage notes” on page 1246](#)
- [“Parameters” on page 1247](#)
- [“RPG Declaration” on page 1248](#)

Syntax

MQDISC (*HCONN*, *CMPCOD*, *REASON*)

Usage notes

1. If an MQDISC call is issued when the application still has objects open, those objects are closed by the queue manager, with the close options set to CONONE.
2. If the application ends with uncommitted changes in a unit of work, the disposition of those changes depends on how the application ends:
 - a. If the application issues the MQDISC call before ending:
 - For a queue manager coordinated unit of work, the queue manager issues the MQCMIT call on behalf of the application. The unit of work is committed if possible, and backed out if not.
 - For an externally coordinated unit of work, there is no change in the status of the unit of work; however, the queue manager will indicate that the unit of work should be committed, when asked by the unit-of-work coordinator.

- b. If the application ends normally but without issuing the MQDISC call, the unit of work is backed out.
 - c. If the application ends *abnormally* without issuing the MQDISC call, the unit of work is backed out.
3. On IBM i, applications running in compatibility mode do not have to issue this call; see the MQCONN call for more details.

Parameters

The MQDISC call has the following parameters:

HCONN (10-digit signed integer) - input/output

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN*:

HCDEFH

Default connection handle.

On successful completion of the call, the queue manager sets *HCONN* to a value that is not a valid handle for the environment. This value is:

HCUNUH

Unusable connection handle.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2058

(2058, X'80A') Queue manager name not valid or not known.

RC2059

(2059, X'80B') Queue manager not available for connection.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

RPG Declaration

```

C*.1.....2.....3.....4.....5.....6.....7..
C                                CALLP      MQDISC(HCONN : CMPCOD : REASON)

```

The prototype definition for the call is:

```

D*.1.....2.....3.....4.....5.....6.....7..
DMQDISC      PR      EXTPROC('MQDISC')
D* Connection handle
D HCONN      10I 0

D CMPCOD      10I 0
D* Reason code qualifying CMPCOD
D REASON      10I 0

```

MQDLTMH - Delete message handle

The MQDLTMH call deletes a message handle and is the inverse of the MQCRTMH call.

- [“Syntax” on page 1248](#)
- [“Usage notes” on page 1248](#)
- [“Parameters” on page 1250](#)
- [“RPG Declaration” on page 1251](#)

Syntax

MQDLTMH ((*Hconn*, *Hmsg*, *DltMsgHOpts*, *CompCode*, *Reason*))

Usage notes

1. You can use this call only when the queue manager itself coordinates the unit of work. This can be:
 - A local unit of work, where the changes affect only IBM MQ resources.
 - A global unit of work, where the changes can affect resources belonging to other resource managers, as well as affecting IBM MQ resources.

For further details about local and global units of work, see [“MQBEGIN - Begin unit of work” on page 1209](#).

2. In environments where the queue manager does not coordinate the unit of work, use the appropriate back-out call instead of MQBACK. The environment might also support an implicit back out caused by the application terminating abnormally.
 - On z/OS, use the following calls:
 - Batch programs (including IMS batch DL/I programs) can use the MQBACK call if the unit of work affects only IBM MQ resources. However, if the unit of work affects both IBM MQ resources and resources belonging to other resource managers (for example, Db2), use the SRRBACK call provided by the z/OS Recoverable Resource Service (RRS). The SRRBACK call backs out changes to resources belonging to the resource managers that have been enabled for RRS coordination.

- CICS applications must use the EXEC CICS SYNCPOINT ROLLBACK command to back out the unit of work. Do not use the MQBACK call for CICS applications.
 - IMS applications (other than batch DL/I programs) must use IMS calls such as ROLB to back out the unit of work. Do not use the MQBACK call for IMS applications (other than batch DL/I programs).
 - On IBM i, use this call for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must not have been issued for the job.
3. If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC - Disconnect queue manager”](#) on page 1246 for further details.
 4. When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
 - The values of the *GroupId*, *MsgSeqNumber*, *Offset*, and *MsgFlags* fields in MQMD.
 - Whether the message is part of a unit of work.
 - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps three sets of group and segment information, one set for each of the following:

- The last successful MQPUT call (this can be part of a unit of work).
- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).
- The last successful MQGET call that browsed a message on the queue (this cannot be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then backs out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.
- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues that were updated by the application after the unit of work started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails. Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if that a system failure occurs.

For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [PMOPT \(10 digit signed integer\)](#), and the GMLOGO option described in [GMOPT \(10 digit signed integer\)](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

5. A unit of work has the same scope as a connection handle. All IBM MQ calls that affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See [HCONN \(10 digit signed integer\) - output](#) for information about the scope of connection handles.

6. Only messages that were put or retrieved as part of the current unit of work are affected by this call.
7. A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but that never issues a commit or backout call, can fill queues with messages that are not available to other applications. To guard against this possibility, the administrator must set the *MaxUncommittedMsgs* queue-manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

Parameters

The MQDLTMH call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager.

The value must match the connection handle that was used to create the message handle specified in the *HMSG* parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread deleting the message handle, otherwise the call fails with RC2009 .

HMSG (20-digit signed integer) - input/output

This is the message handle to be deleted. The value was returned by a previous MQCRTMH call.

On successful completion of the call, the handle is set to an invalid value for the environment. This value is:

HMUNUH

Unusable message handle.

The message handle cannot be deleted if another IBM MQ call is in progress that was passed the same message handle.

DLTOPT (MQDMHO) - input

See [MQDMHO](#) for details.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2009

(2009, X'07D9') Connection to queue manager lost.

RC2462

(2462, X'099E') Delete message handle options structure not valid.

RC2460

(2460, X'099C') Message handle pointer not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)”](#) on page 1381 for more details.

RPG Declaration

MQDLTMP - Delete message property

The MQDLTMP call deletes a property from a message handle and is the inverse of the MQSETMP call.

- [“Syntax”](#) on page 1251
- [“Parameters”](#) on page 1251
- [“RPG Declaration”](#) on page 1253

Syntax

MQDLTMP (*Hconn*, *Hmsg*, *DltPropOpts*, *Name*, *CompCode*, *Reason*)

Parameters

The MQDLTMP call has the following parameters:

HCONN (10-digit signed integer) - Input

This handle represents the connection to the queue manager. The value must match the connection handle that was used to create the message handle specified in the *HMSG* parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread deleting the message handle otherwise the call fails with RC2009.

HMSG (20-digit signed integer) - input

This is the message handle containing the property to be deleted. The value was returned by a previous MQCRTMH call.

DLTOPT (MQDMPO) - Input

See the [MQDMPO](#) data type for details.

PRNAME (MQCHARV) - input

The name of the property to delete. See [Property names](#) for further information about property names.

Wildcards are not allowed in the property name.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2471

(2471, X'09A7') Property not available.

RC2421

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'0852') Unable to load adapter service module.

RC2157

(2157, X'086D') Primary and home ASIDs differ.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2009

(2009, X'07D9') Connection to queue manager lost.

RC2481

(2481, X'09B1') Delete message property options structure not valid.

RC2460

(2460, X'099C') Message handle not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2442

(2442, X'098A') Invalid property name.

RC2111

(2111, X'083F') Property name coded character set identifier not valid.

RC2195

(2195, X'0893') Unexpected error occurred.

For more information about these codes, see [API completion and reason codes](#).

RPG Declaration

```

```

MQGET - Get message

The MQGET call retrieves a message from a local queue that has been opened by using the MQOPEN call.

- [“Syntax” on page 1253](#)
- [“Usage notes” on page 1253](#)
- [“Parameters” on page 1256](#)
- [“RPG Declaration” on page 1261](#)

Syntax

MQGET (*HCONN*, *HOBJ*, *MSGDSC*, *GMO*, *BUFLEN*, *BUFFER*, *DATLEN*, *CMPCOD*, *REASON*)

Usage notes

1. The message retrieved is normally deleted from the queue. This deletion can occur as part of the MQGET call itself, or as part of a syncpoint. Message deletion does not occur if a GMBRWF or GMBRWN option is specified on the *GMO* parameter (see the *GMOPT* field described in [“MQGMO - Get-message options” on page 1035](#)).
2. If the GMLK option is specified with one of the browse options, the browsed message is locked so that it is visible only to this handle.

If the GMUNLK option is specified, a previously locked message is unlocked. No message is retrieved in this case, and the *MSGDSC*, *BUFLEN*, *BUFFER* and *DATLEN* parameters are not checked or altered.
3. If the application issuing the MQGET call is running as an IBM MQ MQI client, it is possible for the message retrieved to be lost if during the processing of the MQGET call the IBM MQ MQI client terminates abnormally or the client connection is severed. This arises because the surrogate that is running on the platform of the queue manager and which issues the MQGET call on the behalf of the

client cannot detect the loss of the client until the surrogate is about to return the message to the client; this is after the message has been removed from the queue. This can occur for both persistent messages and nonpersistent messages.

The risk of losing messages in this way can be eliminated by always retrieving messages within units of work (that is, by specifying the GMSYP option on the MQGET call, and using the MQCMIT or MQBACK calls to commit or back out the unit of work when processing of the message is complete). If GMSYP is specified, and the client terminates abnormally or the connection is severed, the surrogate backs out the unit of work on the queue manager and the message is reinstated on the queue.

In principle, the same situation can arise with applications that are running on the platform of the queue manager, but in this case the window during which a message can be lost is small. However, as with IBM MQ MQI clients the risk can be eliminated by retrieving the message within a unit of work.

4. If an application puts a sequence of messages on a particular queue within a single unit of work, and then commits that unit of work successfully, the messages become available for retrieval as follows:
 - If the queue is a *nonshared* queue (that is, a local queue), all messages within the unit of work become available at the same time.
 - If the queue is a *shared* queue, messages within the unit of work become available in the order in which they were put, but not all at the same time. When the system is heavily laden, it is possible for the first message in the unit of work to be retrieved successfully, but for the MQGET call for the second or subsequent message in the unit of work to fail with RC2033. If this occurs, the application must wait a short while and then try the operation again.
5. If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if certain conditions are satisfied. See the usage notes in the description of the MQPUT call for details. If the conditions are satisfied, the messages are presented to the receiving application in the order in which they were sent, if:

- Only one receiver is getting messages from the queue.

If there are two or more applications getting messages from the queue, they must agree with the sender the mechanism to be used to identify messages that belong to a sequence. For example, the sender might set all of the *MDCID* fields in the messages in a sequence to a value that was unique to that sequence of messages.

- The receiver does not deliberately change the order of retrieval, for example by specifying a particular *MDMID* or *MDCID*.

If the sending application put the messages as a message group, the messages are presented to the receiving application in the correct order if the receiving application specifies the GMLOGO option on the MQGET call. For more information about message groups, see:

- *MDMFL* field in MQMD
- PMLOGO option in MQPMO
- GMLOGO option in MQGMO

6. Applications test for the feedback code FBQUIT in the *MDFB* field of the *MSGDSC* parameter. If this value is found, the application ends. See the *MDFB* field described in [“MQMD - Message descriptor” on page 1068](#) for more information.
7. If the queue identified by *HOBJ* was opened with the OOSAVA option, and the completion code from the MQGET call is CCOK or CCWARN, the context associated with the queue handle *HOBJ* is set to the context of the message that has been retrieved (unless the GMBRWF or GMBRWN option is set, in which case the context is marked as not available). This context can be used on a subsequent MQPUT or MQPUT1 call by specifying the PMPASI or PMPASA options. This enables the context of the message received to be transferred in whole or in part to another message (for example, when the message is forwarded to another queue). For more information about message context, see [Message context](#) and [Controlling context information](#).

8. If the *GMCONV* option is included in the *GMO* parameter, the application message data is converted to the representation requested by the receiving application, before the data is placed in the *BUFFER* parameter:
 - The *MDFMT* field in the control information in the message identifies the structure of the application data, and the *MDCSI* and *MDENC* fields in the control information in the message specify its character-set identifier and encoding.
 - The application issuing the *MQGET* call specifies in the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter the character-set identifier and encoding to which the application message data must be converted.

When conversion of the message data is necessary, the conversion is performed either by the queue manager itself or by a user-written exit, depending on the value of the *MDFMT* field in the control information in the message:

- The following formats are converted automatically by the queue manager; these formats are called "built-in" formats:

FMADMN	FMMDE
FMCICS	FMPCF
FMCMND1	FMRMH
FMCMND2	FMRFH
FMDLH	FMRFH2
FMDH	FMSTR
FMEVNT	FMTM
FMIMS	FMXQH
FMIMVS	

- The format name *FMNONE* is a special value that indicates that the nature of the data in the message is undefined. As a consequence, the queue manager does not attempt conversion when the message is retrieved from the queue.

Note: If *GMCONV* is specified on the *MQGET* call for a message that has a format name of *FMNONE*, and the character set or encoding of the message differs from that specified in the *MSGDSC* parameter, the message is still returned in the *BUFFER* parameter (assuming no other errors), but the call completes with completion code *CCWARN* and reason code *RC2110*.

FMNONE can be used either when the nature of the message data means that it does not require conversion, or when the sending and receiving applications have agreed between themselves the form in which the message data should be sent.

- All other format names cause the message to be passed to a user-written exit for conversion. The exit has the same name as the format, apart from environment-specific additions. User-specified format names must not begin with the letters "MQ", as such names might conflict with format names supported in the future.

User data in the message can be converted between any supported character sets and encodings. However, be aware that if the message contains one or more IBM MQ header structures, the message cannot be converted from or to a character set that has double-byte or multi-byte characters for any of the characters that are valid in queue names. Reason code *RC2111* or *RC2115* results if this is attempted, and the message is returned unconverted. Unicode character set *UCS-2* is an example of such a character set.

On return from *MQGET*, the following reason code indicates that the message was converted successfully:

- *RCNONE*

The following reason code indicates that the message might have been converted successfully; the application must check the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter to find out:

- RC2079

All other reason codes indicate that the message was not converted.

Note: The interpretation of the reason code described in this example is true for conversions performed by user-written exits *only* if the exit conforms to the processing guidelines.

9. For the built-in formats listed previously, the queue manager might perform *default conversion* of character strings in the message when the GMCONV option is specified. Default conversion allows the queue manager to use an installation-specified default character set that approximates the actual character set, when converting string data. As a result, the MQGET call can succeed with completion code CCOK, instead of completing with CCWARN and reason code RC2111 or RC2115.

Note: The result of using an approximate character set to convert string data is that some characters might be converted incorrectly. This can be avoided by using in the string only characters which are common to both the actual character set and the default character set.

Default conversion applies both to the application message data and to character fields in the MQMD and MQMDE structures:

- Default conversion of the application message data occurs only when *all* of the following are true:
 - The application specifies GMCONV.
 - The message contains data that must be converted either from or to a character set which is not supported.
 - Default conversion was enabled when the queue manager was installed or restarted.
 - Default conversion of the character fields in the MQMD and MQMDE structures occurs as necessary, if default conversion is enabled for the queue manager. The conversion is performed even if the GMCONV option is not specified by the application on the MQGET call.
10. The *BUFFER* parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter must be declared instead as a structure, or as a field in a physical file.

Declaring the parameter as a structure increases the maximum length possible to 9999 bytes, while declaring the parameter as a field in a physical file increases the maximum length possible to approximately 32 KB.

Parameters

The MQGET call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HOBJ (10-digit signed integer) - input

Object handle.

This handle represents the queue from which a message is to be retrieved. The value of *HOBJ* was returned by a previous *MQOPEN* call. The queue must have been opened with one or more of the following options (see [“MQOPEN - Open object”](#) on page 1278 for details):

- *OOINPS*
- *OOINPX*
- *OOINPQ*
- *OOBRW*

MSGDSC (MQMD) - input/output

Message descriptor.

This structure describes the attributes of the message required, and the attributes of the message retrieved. See [“MQMD - Message descriptor”](#) on page 1068 for details.

If *BUFLen* is less than the message length, *MSGDSC* is still entered by the queue manager, whether *GMATM* is specified on the *GMO* parameter (see the *GMOPT* field described in [“MQGMO - Get-message options”](#) on page 1035).

If the application provides a version-1 *MQMD*, the message returned has an *MQMDE* prefixed to the application message data, but *only* if one or more of the fields in the *MQMDE* has a nondefault value. If all of the fields in the *MQMDE* have default values, the *MQMDE* is omitted. A format name of *FMMDE* in the *MDFMT* field in *MQMD* indicates that an *MQMDE* is present.

GMO (MQGMO) - input/output

Options that control the action of *MQGET*.

See [“MQGMO - Get-message options”](#) on page 1035 for details.

BUFLen (10-digit signed integer) - input

Length in bytes of the *BUFFER* area.

Zero can be specified for messages that have no data, or if the message is to be removed from the queue and the data discarded (*GMATM* must be specified in this case).

Note: The length of the longest message that it is possible to read from the queue is given by the *MaxMsgLength* queue attribute; see [“Attributes for queues”](#) on page 1324.

BUFFER (1-byte bit string x BUFLen) - output

Area to contain the message data.

The buffer must be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment must be suitable for most messages (including messages containing IBM MQ header structures), but some messages might require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If *BUFLen* is less than the message length, as much of the message as possible is moved into *BUFFER* ; this happens whether *GMATM* is specified on the *GMO* parameter (see the *GMOPT* field described in [“MQGMO - Get-message options”](#) on page 1035 for more information).

The character set and encoding of the data in *BUFFER* are given by the *MDCSI* and *MDENC* fields returned in the *MSGDSC* parameter. If these values are different from the values required by the receiver, the receiver must convert the application message data to the character set and encoding required. The *GMCONV* option can be used with a user-written exit to perform the conversion of the message data (see [“MQGMO - Get-message options”](#) on page 1035 for details of this option).

Note: All of the other parameters on the *MQGET* call are in the character set and encoding of the local queue manager (given by the *CodedCharSetId* queue manager attribute and *ENNAT*).

If the call fails, the contents of the buffer might still have changed.

DATLEN (10-digit signed integer) - output

Length of the message.

This is the length in bytes of the application data *in the message*. If this message length is greater than *BUFLen*, only *BUFLen* bytes are returned in the *BUFFER* parameter (that is, the message is truncated). If the value is zero, it means that the message contains no application data.

If *BUFLen* is less than the message length, *DATLEN* is still entered by the queue manager, whether *GMATM* is specified on the *GMO* parameter (see the *GMOPT* field described in “[MQGMO - Get-message options](#)” on page 1035 for more information). This allows the application to determine the size of the buffer required to accommodate the message data, and then reissue the call with a buffer of the appropriate size.

However, if the *GMCONV* option is specified, and the converted message data is too long to fit in *BUFFER*, the value returned for *DATLEN* is:

- The length of the *unconverted* data, for queue manager defined formats.

In this case, if the nature of the data causes it to expand during conversion, the application must allocate a buffer bigger than the value returned by the queue manager for *DATLEN*.

- The value returned by the data-conversion exit, for application-defined formats.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

The following reason codes are the ones that the queue manager can return for the *REASON* parameter. If the application specifies the *GMCONV* option, and a user-written exit is invoked to convert some or all of the message data, it is the exit that decides what value is returned for the *REASON* parameter. As a result, values other than the values documented later in this section are possible.

If *CMPCOD* is *CCOK*:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is *CCWARN*:

RC2120

(2120, X'848') Converted data too large for buffer.

RC2190

(2190, X'88E') Converted string too large for field.

RC2150

(2150, X'866') DBCS string not valid.

RC2110

(2110, X'83E') Message format not valid.

RC2243

(2243, X'8C3') Message segments have differing CCSIDs.

RC2244

(2244, X'8C4') Message segments have differing encodings.

RC2209

(2209, X'8A1') No message locked.

RC2119

(2119, X'847') Message data not converted.

RC2272

(2272, X'8E0') Message data partially converted.

RC2145

(2145, X'861') Source buffer parameter not valid.

RC2111

(2111, X'83F') Source coded character set identifier not valid.

RC2113

(2113, X'841') Packed-decimal encoding in message not recognized.

RC2114

(2114, X'842') Floating-point encoding in message not recognized.

RC2112

(2112, X'840') Source integer encoding not recognized.

RC2143

(2143, X'85F') Source length parameter not valid.

RC2146

(2146, X'862') Target buffer parameter not valid.

RC2115

(2115, X'843') Target coded character set identifier not valid.

RC2117

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

RC2118

(2118, X'846') Floating-point encoding specified by receiver not recognized.

RC2116

(2116, X'844') Target integer encoding not recognized.

RC2079

(2079, X'81F') Truncated message returned (processing completed).

RC2080

(2080, X'820') Truncated message returned (processing not completed).

If *CMPCOD* is CCFAIL:

RC2004

(2004, X'7D4') Buffer parameter not valid.

RC2005

(2005, X'7D5') Buffer length parameter not valid.

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2010

(2010, X'7DA') Data length parameter not valid.

RC2016

(2016, X'7E0') Gets inhibited for the queue.

RC2186

(2186, X'88A') Get-message options structure not valid.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2019
(2019, X'7E3') Object handle not valid.

RC2241
(2241, X'8C1') Message group not complete.

RC2242
(2242, X'8C2') Logical message not complete.

RC2259
(2259, X'8D3') Inconsistent browse specification.

RC2245
(2245, X'8C5') Inconsistent unit-of-work specification.

RC2246
(2246, X'8C6') Message under cursor not valid for retrieval.

RC2247
(2247, X'8C7') Match options not valid.

RC2026
(2026, X'7EA') Message descriptor not valid.

RC2250
(2250, X'8CA') Message sequence number not valid.

RC2033
(2033, X'7F1') No message available.

RC2034
(2034, X'7F2') Browse cursor not positioned on message.

RC2036
(2036, X'7F4') Queue not open for browse.

RC2037
(2037, X'7F5') Queue not open for input.

RC2041
(2041, X'7F9') Object definition changed since opened.

RC2101
(2101, X'835') Object damaged.

RC2046
(2046, X'7FE') Options not valid or not consistent.

RC2052
(2052, X'804') Queue has been deleted.

RC2058
(2058, X'80A') Queue manager name not valid or not known.

RC2059
(2059, X'80B') Queue manager not available for connection.

RC2161
(2161, X'871') Queue manager quiescing.

RC2162
(2162, X'872') Queue manager shutting down.

RC2102
(2102, X'836') Insufficient system resources available.

RC2071
(2071, X'817') Insufficient storage available.

RC2024
(2024, X'7E8') No more messages can be handled within current unit of work.

RC2072
(2072, X'818') Syncpoint support not available.

RC2195

(2195, X'893') Unexpected error occurred.

RC2255

(2255, X'8CF') Unit of work not available for the queue manager to use.

RC2090

(2090, X'82A') Wait interval in MQGMO not valid.

RC2256

(2256, X'8D0') Wrong version of MQGMO supplied.

RC2257

(2257, X'8D1') Wrong version of MQMD supplied.

RPG Declaration

```

C*..1.....2.....3.....4.....5.....6.....7..

MQINQ - Inquire about object attributes

The MQINQ call returns an array of integers and a set of character strings containing the attributes of an object.

The following types of object are valid:

- Queue
- Namelist
- Process definition
- Queue manager
- [“Syntax” on page 1261](#)
- [“Usage notes” on page 1262](#)
- [“Parameters” on page 1263](#)
- [“RPG Declaration” on page 1270](#)

Syntax

MQINQ (*HCONN*, *HOBJ*, *SELCNT*, *SELS*, *IACNT*, *INTATR*, *CALEN*, *CHRATR*, *CMPCOD*, *REASON*)

Usage notes

1. The values returned are a snapshot of the selected attributes. There is no guarantee that the attributes are not changed before the application can act upon the returned values.
2. When you open a model queue, a dynamic local queue is created. This is true even if you open the model queue to inquire about its attributes.

The attributes of the dynamic queue (with certain exceptions) are the same as those of the model queue at the time the dynamic queue is created. If you then use the MQINQ call on this queue, the queue manager returns the attributes of the dynamic queue, and not those of the model queue. See [Table 1](#) for details of which attributes of the model queue are inherited by the dynamic queue.

3. If the object being inquired is an alias queue, the attribute values returned by the MQINQ call are those of the alias queue, and not those of the base queue to which the alias resolves.
4. If the object being inquired is a cluster queue, the attributes that can be inquired depend on how the queue is opened:
 - If the cluster queue is opened for inquire plus one or more of input, browse, or set, there must be a local instance of the cluster queue in order for the open to succeed. In this case the attributes that can be inquired are those valid for local queues.
 - If the cluster queue is opened for inquire alone, or inquire and output, only the following attributes can be inquired; the *QType* attribute has the value QTCLUS in this case:
 - CAQD
 - CAQN
 - IADBND
 - IADPER
 - IADPRI
 - IAIPUT
 - IAQTYP

If the cluster queue is opened with no fixed binding (that is, OOBNDN specified on the MQOPEN call, or OOBNDQ specified when the *DefBind* attribute has the value BNDNOT), successive MQINQ calls for the queue might inquire different instances of the cluster queue, although typically all of the instances have the same attribute values.

For more information about cluster queues, see [Configuring a queue manager cluster](#).

5. If a number of attributes are to be inquired, and then some of them are to be set using the MQSET call, it might be convenient to position at the beginning of the selector arrays the attributes that are to be set, so that the same arrays (with reduced counts) can be used for MQSET.
6. If more than one of the warning situations arise (see the *CMPCOD* parameter), the reason code returned is the *first* one in the following list that applies:
 - a. RC2068
 - b. RC2022
 - c. RC2008
7. For more information about object attributes, see:
 - [“Attributes for queues” on page 1324](#)
 - [“Attributes for namelists” on page 1352](#)
 - [“Attributes for process definitions” on page 1353](#)
 - [“Attributes for the queue manager” on page 1355](#)
8. A new local queue SYSTEM.ADMIN.COMMAND.EVENT is used for queuing messages that are generated whenever commands are issued. Messages are put onto this queue for most commands, depending on how the CMDEV queue manager attribute is set:

- **ENABLED** - command event messages are generated and put onto the queue for all successful commands.
- **NODISPLAY** - command event messages are generated and put onto the queue for all successful commands other than the **DISPLAY (MQSC)** command, and the **Inquire (PCF)** command.
- **DISABLED** - command event messages are not generated (this is the queue manager's initial default value).

Parameters

The **MQINQ** call has the following parameters:

HCONN (10 digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous **MQCONN** or **MQCONNEX** call.

On IBM i for applications running in compatibility mode, the **MQCONN** call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HOBJ (10 digit signed integer) - input

Object handle.

This handle represents the object (of any type) with attributes that are required. The handle must have been returned by a previous **MQOPEN** call that specified the **OOINQ** option.

SELCNT (10 digit signed integer) - input

Count of selectors.

This is the count of selectors that are supplied in the *SELS* array. It is the number of attributes that are to be returned. Zero is a valid value. The maximum number allowed is 256.

SELS (10 digit signed integer x SELCNT) - input

Array of attribute selectors.

This is an array of *SELCNT* attribute selectors; each selector identifies an attribute (integer or character) with a value that is required.

Each selector must be valid for the type of object that *HOBJ* represents, otherwise the call fails with completion code **CCFAIL** and reason code **RC2067**.

In the special case of queues:

- If the selector is not valid for queues of *any* type, the call fails with completion code **CCFAIL** and reason code **RC2067**.
- If the selector is applicable *only* to queues of type or types other than that of the object, the call succeeds with completion code **CCWARN** and reason code **RC2068**.
- If the queue being inquired is a cluster queue, the selectors that are valid depend on how the queue was resolved; see usage note 4 for further details.

Selectors can be specified in any order. Attribute values that correspond to integer attribute selectors (**IA*** selectors) are returned in *INTATR* in the same order in which these selectors occur in *SELS*. Attribute values that correspond to character attribute selectors (**CA*** selectors) are returned in

CHRATR in the same order in which those selectors occur. IA* selectors can be interleaved with the CA* selectors; only the relative order within each type is important.

Note:

1. The integer and character attribute selectors are allocated within two different ranges; the IA* selectors reside within the range IAFRST through IALAST, and the CA* selectors within the range CAFRST through CALAST.

For each range, the constants IALSTU and CALSTU define the highest value that the queue manager accepts.

2. If all the IA* selectors occur first, the same element numbers can be used to address corresponding elements in the *SELS* and *INTATR* arrays.

The attributes that can be inquired are listed in the following tables. For the CA* selectors, the constant that defines the length in bytes of the resulting string in *CHRATR* is given in parentheses.

Table 621. MQINQ attribute selectors for queues.		
See the bottom of the table for an explanation of the notes.		
Selector	Description	Note
CAALTD	Date of most recent alteration (LNDATE).	1
CAALTT	Time of most recent alteration (LNTIME).	1
CABRQN	Excessive backout-requeue name (LNQN).	5
CABASQ	Name of queue that alias resolves to (LNQN).	
CACFSN	Coupling-facility structure name (LNCFSN).	3
CACLN	Cluster name (LNCLUN).	1
CACLNL	Cluster namelist (LNNLN).	1
CACRTD	Queue creation date (LNCRTD).	
CACRTT	Queue creation time (LNCRTT).	
CAINIQ	Initiation queue name (LNQN).	
CAPRON	Name of process definition (LNPRON).	
CAQD	Queue description (LNQD).	
CAQN	Queue name (LNQN).	
CARQMN	Name of remote queue manager (LNQMN).	
CARQN	Name of remote queue as known on remote queue manager (LNQN).	
CATRGD	Trigger data (LNTRGD).	5
CAXQN	Transmission queue name (LNQN).	
IABTHR	Backout threshold.	5
IACDEP	Number of messages on queue.	
IADBND	Default binding.	1
IADINP	Default open-for-input option.	5
IADPER	Default message persistence.	
IADPRI	Default message priority.	5
IADEFT	Queue definition type.	

Table 621. MQINQ attribute selectors for queues.

See the bottom of the table for an explanation of the notes.

(continued)

Selector	Description	Note
IADIST	Distribution list support.	2
IAHGB	Whether to harden backout count.	5
IAIGET	Whether get operations are allowed.	
IAIPUT	Whether put operations are allowed.	
IAMLEN	Maximum message length.	
IAMDEP	Maximum number of messages allowed on queue.	
IAMDS	Whether message priority is relevant.	5
IAOIC	Number of MQOPEN calls that have the queue open for input.	
IAOOC	Number of MQOPEN calls that have the queue open for output.	
IAQDHE	Control attribute for queue depth high events.	4, 5
IAQDHL	High limit for queue depth.	4, 5
IAQDLE	Control attribute for queue depth low events.	4, 5
IAQDLL	Low limit for queue depth.	4, 5
IAQDME	Control attribute for queue depth max events.	4, 5
IAQSI	Limit for queue service interval.	4, 5
IAQSIE	Control attribute for queue service interval events.	4, 5
IAQTYP	Queue type.	
IAQSGD	Queue-sharing group disposition.	3
IARINT	Queue retention interval.	5
IASCOP	Queue definition scope.	4, 5
IASHAR	Whether queue can be shared for input.	
IATRGC	Trigger control.	
IATRGD	Trigger depth.	5
IATRGP	Threshold message priority for triggers.	5
IATRGT	Trigger type.	
IAUSAG	Usage.	
CLWLUSEQ	Use remote queues.	

Note:

1. Supported on AIX, HP-UX, z/OS, IBM i, Solaris, Windows, plus IBM MQ MQI clients connected to these systems.
2. Supported on AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.
3. Supported on z/OS.

4. Not supported on z/OS.

5. Not supported on VSE/ESA.

IAMPRI	Maximum priority	5
IAMUNC	Maximum number of uncommitted messages within a unit of work	5
IAPFME	Control attribute for performance events	4, 5
IAPLAT	Platform on which the queue manager resides	5
IARMTE	Control attribute for remote events	4, 5
IASSE	Control attribute for start stop events	4, 5
IASYNC	Sync point availability	5
IATRLFT	Lifetime of unused non-administrative topics	
IATRGI	Trigger interval	5

IACNT (10 digit signed integer) - input

Count of integer attributes.

This is the number of elements in the *INTATR* array. Zero is a valid value.

If this is at least the number of IA* selectors in the *SELS* parameter, all integer attributes requested are returned.

INTATR (10 digit signed integer x IACNT) - output

Array of integer attributes.

This is an array of *IACNT* integer attribute values.

Integer attribute values are returned in the same order as the IA* selectors in the *SELS* parameter. If the array contains more elements than the number of IA* selectors, the excess elements are unchanged.

If *HOBj* represents a queue, but an attribute selector is not applicable to that type of queue, the specific value *IAVNA* is returned for the corresponding element in the *INTATR* array.

CALEN (10 digit signed integer) - input

Length of character attributes buffer.

This is the length in bytes of the *CHRATR* parameter.

This must be at least the sum of the lengths of the requested character attributes (see *SELS*). Zero is a valid value.

CHRATR (1 byte character string x CALEN) - output

Character attributes.

This is the buffer in which the character attributes are returned, concatenated together. The length of the buffer is given by the *CALEN* parameter.

Character attributes are returned in the same order as the CA* selectors in the *SELS* parameter. The length of each attribute string is fixed for each attribute (see *SELS*), and the value in it is padded to the right with blanks if necessary. If the buffer is larger than that needed to contain all of the requested character attributes (including padding), the bytes beyond the last attribute value returned are unchanged.

If *HOBj* represents a queue, but an attribute selector is not applicable to that type of queue, a character string consisting entirely of asterisks (*) is returned as the value of that attribute in *CHRATR*.

CMPCOD (10 digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10 digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2008

(2008, X'7D8') Not enough space allowed for character attributes.

RC2022

(2022, X'7E6') Not enough space allowed for integer attributes.

RC2068

(2068, X'814') Selector not applicable to queue type.

If *CMPCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2006

(2006, X'7D6') Length of character attributes not valid.

RC2007

(2007, X'7D7') Character attributes string not valid.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2019

(2019, X'7E3') Object handle not valid.

RC2021

(2021, X'7E5') Count of integer attributes not valid.

RC2023

(2023, X'7E7') Integer attributes array not valid.

RC2038

(2038, X'7F6') Queue not open for inquire.

RC2041

(2041, X'7F9') Object definition changed since opened.

RC2101

(2101, X'835') Object damaged.

RC2052

(2052, X'804') Queue has been deleted.

RC2058

(2058, X'80A') Queue manager name not valid or not known.

RC2059

(2059, X'80B') Queue manager not available for connection.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2065

(2065, X'811') Count of selectors not valid.

RC2067

(2067, X'813') Attribute selector not valid.

RC2066

(2066, X'812') Count of selectors too large.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

RPG Declaration

```
D*.1.....2.....3.....4.....5.....6.....7..

MQINQMP - Inquire message property

The MQINQMP call returns the value of a property of a message.

- [“Syntax” on page 1270](#)
- [“Parameters” on page 1270](#)
- [“RPG Declaration” on page 1274](#)

Syntax

MQINQMP (*Hconn*, *Hmsg*, *InqPropOpts*, *Name*, *PropDesc*, *Type*, *ValueLength*, *Value*, *DataLength*, *CompCode*, *Reason*)

Parameters

The MQINQMP call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *Hconn* must match the connection handle that was used to create the message handle specified in the *Hmsg* parameter.

If the message handle was created using HCUNAS then a valid connection must be established on the thread inquiring a property of the message handle, otherwise the call fails with RC2009.

HMSG (20-digit signed integer) - input

This is the message handle to be inquired. The value was returned by a previous **MQCRTMH** call.

INQOPT (MQIMPO) - input

See the [MQIMPO](#) data type for details.

PRNAME (MQCHARV) - input

This describes the name of the property to inquire.

If no property with this name can be found, the call fails with reason RC2471.

You can use the percent sign (%) character at the end of the property name. The wildcard matches zero or more characters, including the period (.) character. This allows an application to inquire the value of many properties. Call MQINQMP with option IPINQF to get the first matching property and again with the option IPINQN to get the next matching property. When no more matching properties are available, the call fails with RC2471. If the *ReturnedName* field of the InqPropOpts structure is initialized with an address or offset for the returned name of the property, this is completed on return from MQINQMP with the name of the property that has been matched. If the *VSBuFSIZE* field of the *ReturnedName* in the InqPropOpts structure is less than the length of the returned property name the completion code is set CCFAIL with reason RC2465.

Properties that have known synonyms are returned as follows:

1. Properties with the prefix "mqps." are returned with the IBM MQ property name. For example, "MQTopicString" is the returned name rather than "mqps.Top".
2. Properties with the prefix "jms." or "mcd." are returned as the JMS header field name. For example, "JMSExpiration" is the returned name rather than "jms.Exp".
3. Properties with the prefix "usr." are returned without that prefix. For example, "Color" is returned rather than "usr.Color".

Properties with synonyms are only returned once.

In the RPG programming language, the following macro variables are defined for inquiring on all properties and all properties that begin "usr.":

INQALL

Inquire on all properties of the message.

INQUSR

Inquire on all properties of the message that start "usr.". The returned name is returned without the "usr." prefix.

If IPINQN is specified but Name has changed since the previous call or this is the first call, then IPINQF is implied.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

PRPDSC (MQPD) - output

This structure is used to define the attributes of a property, including what happens if the property is not supported, what message context the property belongs to, and what messages the property should be copied into. See [MQPD](#) for details of this structure.

TYPE (10-digit signed integer) - input/output

On return from the MQINQMP call this parameter is set to the data type of *Value*. The data type can be any of the following:

TYPBOL

A boolean.

TYPBST

a byte string.

TYPI8

An 8-bit signed integer.

TYPI16

A 16-bit signed integer.

TYPI32

A 32-bit signed integer.

TYPI64

A 64-bit signed integer.

TYPF32

A 32-bit floating-point number.

TYPF64

A 64-bit floating-point number.

TYPSTR

A character string.

TYPNUL

The property exists but has a null value.

If the data type of the property value is not recognized then TYPSTR is returned and a string representation of the value is placed into the *Value* area. A string representation of the data type can be found in the *IPCTYP* field of the *IPOPT* parameter. A warning completion code is returned with reason RC2467.

Additionally, if the option IPCTYP is specified, conversion of the property value is requested. Use *Type* as an input to specify the data type that you want the property to be returned as. See the description of the IPCTYP option of the [“MQIMPO - Inquire message property options”](#) on page 1061 for details of data type conversion.

If you do not request type conversion, you can use the following value on input:

TYPAST

The value of the property is returned without converting its data type.

VALLEN (10-digit signed integer) - input

The length in bytes of the Value area.

Specify zero for properties that you do not require the value returned for. These could be properties which are designed by an application to have a null value or an empty string. Also specify zero if the IPQLEN option has been specified; in this case no value is returned.

VALUE (1-byte bit string x VALLEN) - output

This is the area to contain the inquired property value. The buffer should be aligned on a boundary appropriate for the value being returned. Failure to do so might result in an error when the value is later accessed.

If *VALLEN* is less than the length of the property value, as much of the property value as possible is moved into *VALUE* and the call fails with completion code CCFAIL and reason RC2469.

The character set of the data in *VALUE* is given by the IPRETCSI field in the INQOPT parameter. The encoding of the data in *VALUE* is given by the IPRETENC field in the INQOPT parameter.

If the *VALLEN* parameter is zero, *VALUE* is not referred to.

DATLEN (10-digit signed integer) - output

This is the length in bytes of the actual property value as returned in the *Value* area.

If *DataLength* is less than the property value length, *DataLength* is still entered on return from the MQINQMP call. This allows the application to determine the size of the buffer required to accommodate the property value, and then reissue the call with a buffer of the appropriate size.

The following values may also be returned.

If the *Type* parameter is set to TYPSTR or TYPBST:

VLEMP

The property exists but contains no characters or bytes.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CompCode*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CompCode* is CCWARN:

RC2492

(2492, X'09BC') Returned property name not converted.

RC2466

(2466, X'09A2') Property value not converted.

RC2467

(2467, X'09A3') Property data type is not supported.

RC2421

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'0852') Unable to load adapter service module.

RC2157

(2157, X'086D') Primary and home ASIDs differ.

RC2004

(2004, X'07D4') Value parameter not valid.

RC2005

(2005, X'07D5') Value length parameter not valid.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2009

(2009, X'07D9') Connection to queue manager lost.

RC2010

(2010, X'07DA') Data length parameter not valid.

RC2464

(2464, X'09A0') Inquire message property options structure not valid.

RC2460

(2460, X'099C') Message handle not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2064

(2046, X'07F8') Options not valid or not consistent.

RC2482

(2482, X'09B2') Property descriptor structure not valid.

RC2470

(2470, X'09A6') Conversion from the actual to requested data type not supported.

RC2442

(2442, X'098A') Invalid property name.

RC2465

(2465, X'09A1') Property name too large for returned name buffer.

RC2471

(2471, X'09A7') Property not available.

RC2469

(2469, X'09A5') Property value too large for the Value area.

RC2472

(2472, X'09A8') Number format error encountered in value data.

RC2473

(2473, X'09A9') Invalid requested property type.

RC2111

(2111, X'083F') Property name coded character set identifier not valid.

RC2071

(2071, X'0871') Insufficient storage available.

RC2195

MQMHBUF - Convert message handle into buffer

The MQMHBUF converts a message handle into a buffer and is the inverse of the MQBUFMH call.

- [“Syntax” on page 1275](#)

- [“Usage notes” on page 1275](#)
- [“Parameters” on page 1275](#)
- [“RPG Declaration” on page 1277](#)

Syntax

MQMHBUF (*Hconn, Hmsg, MsgHBufOpts, Name, MsgDesc, BufferLength, Buffer, DataLength, CompCode, Reason*)

Usage notes

MQMHBUF converts a message handle into a buffer.

You can use it with an MQGET API exit to access certain properties, by using the message property APIs, and then pass these properties in a buffer back to an application designed to use MQRFH2 headers rather than message handles.

This call is the inverse of the MQBUFMH call, which you can use to parse message properties from a buffer into a message handle.

Parameters

The MQMHBUF call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager.

The value of *HCONN* must match the connection handle that was used to create the message handle specified in the *HMSG* parameter.

If the message handle was created by using HCUNAS, a valid connection must be established on the thread deleting the message handle. If a valid connection is not established, the call fails with RC2009.

HMSG (20-digit signed integer) - input

This handle is the message handle for which a buffer is required.

The value was returned by a previous MQCRTMH call.

MHBOPT (MQMHBO) - input

The MQMHBO structure allows applications to specify options that control how buffers are produced from message handles.

See [“MQBMHO - Buffer to message handle options” on page 979](#) for details.

PRNAME (MQCHARV) - input

The name of the property or properties to put into the buffer.

If no property matching the name can be found, the call fails with RC2471.

Wildcards

You can use a wildcard to put more than one property into the buffer. To do so, use the percent sign (%) at the end of the property name. This wildcard matches zero or more characters, including the period (.) character.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

MSGDSC (MQMD) - input/output

The *MSGDSC* structure describes the contents of the buffer area.

On output, the *Encoding*, *CodedCharSetId* and *Format* fields are set to correctly describe the encoding, character set identifier, and format of the data in the buffer area as written by the call.

Data in this structure is in the character set and encoding of the application.

BUFLEN (10-digit signed integer) - input

BUFLEN is the length of the Buffer area, in bytes.

BUFFER (1-byte bit string x BUFLEN) - input/output

BUFFER defines the area containing the message buffer. For most data, you must align the buffer on a 4-byte boundary.

If *BUFFER* contains character or numeric data, set the *CodedCharSetId* and *Encoding* fields in the *MSGDSC* parameter to the values appropriate to the data; this enables the data to be converted, if necessary.

If properties are found in the message buffer they are optionally removed; they later become available from the message handle on return from the call.

In the C programming language, the parameter is declared as a pointer-to-void, which means the address of any type of data can be specified as the parameter.

If the *BUFLEN* parameter is zero, *BUFFER* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

DATLEN (10-digit signed integer) - output

DATLEN is the length, in bytes, of the returned properties in the buffer. If the value is zero, no properties matched the value given in *PRNAME* and the call fails with reason code RC2471.

If *BUFLEN* is less than the length required to store the properties in the buffer, the MQMHBUF call fails with RC2469, but a value is still entered into *DATLEN*. This allows the application to determine the size of the buffer required to accommodate the properties, and then reissue the call with the required *BUFLEN*.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2501

(2501, X'095C') Message handle to buffer options structure not valid.

RC2004

(2004, X'07D4') Buffer parameter not valid.

RC2005

(2005, X'07D5') Buffer length parameter not valid.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2009

(2009, X'07D9') Connection to queue manager lost.

RC2010

(2010, X'07DA') Data length parameter not valid.

RC2460

(2460, X'099C') Message handle not valid.

RC2026

(2026, X'07EA') Message descriptor not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2442

(2442, X'098A') Property name is not valid.

RC2471

(2471, X'09A7') Property not available.

RC2469

(2469, X'09A5') BufferLength value is too small to contain specified properties.

RC2195

(2195, X'893') Unexpected error occurred.

MQOPEN - Open object

The MQOPEN call establishes access to an object.

The following types of object are valid:

- Queue (including distribution lists)
- Namelist
- Process definition
- Queue manager
- Topic
- [“Syntax” on page 1278](#)
- [“Usage notes” on page 1278](#)
- [“Parameters” on page 1282](#)
- [“RPG Declaration” on page 1288](#)

Syntax

MQOPEN (*HCONN*, *OBJDSC*, *OPTS*, *HOBJ*, *CMPCOD*, *REASON*)

Usage notes

1. The object opened is one of the following:

- A queue, in order to:
 - Get or browse messages (using the MQGET call)
 - Put messages (using the MQPUT call)
 - Inquire about the attributes of the queue (using the MQINQ call)
 - Set the attributes of the queue (using the MQSET call)

If the queue named is a model queue, a dynamic local queue is created.

A distribution list is a special type of queue object that contains a list of queues. It can be opened to put messages, but not to get or browse messages, or to inquire or set attributes. See usage note 8 for further details.

A queue that has QSGDISP(GROUP) is a special type of queue definition that cannot be used with the MQOPEN or MQPUT1 calls.

- A namelist, in order to:
 - Inquire about the names of the queues in the list (using the MQINQ call).
- A process definition, in order to:
 - Inquire about the process attributes (using the MQINQ call).
- The queue manager, in order to:
 - Inquire about the attributes of the local queue manager (using the MQINQ call).

2. It is valid for an application to open the same object more than once. A different object handle is returned for each open. Each handle that is returned can be used for the functions for which the corresponding open was performed.

3. If the object being opened is a queue but not a cluster queue, all name resolution within the local queue manager takes place at the time of the MQOPEN call. This might include one or more of the following for a particular MQOPEN call:

- Alias resolution to the name of a base queue
- Resolution of the name of a local definition of a remote queue to the name of the remote queue manager, and the name by which the queue is known at the remote queue manager

- Resolution of the remote queue manager name to the name of a local transmission queue

However, be aware that subsequent MQINQ or MQSET calls for the handle relate solely to the name that has been opened, and not to the object resulting after name resolution has occurred. For example, if the object opened is an alias, the attributes returned by the MQINQ call are the attributes of the alias, not the attributes of the base queue to which the alias resolves. Name resolution checking is still carried out, however, regardless of what is specified for the *OPTS* parameter on the corresponding MQOPEN.

If the object being opened is a cluster queue, name resolution can occur at the time of the MQOPEN call, or be deferred until later. The point at which resolution occurs is controlled by the OOBND* options specified on the MQOPEN call:

- OOBND0
- OOBNDN
- OOBNDQ

See [Name resolution](#) for more information about name resolution for cluster queues.

4. The attributes of an object can change while an application has the object open. In many cases, the application does not notice this, but for certain attributes the queue manager marks the handle as no longer valid. These are:

- Any attribute that affects the name resolution of the object. This applies regardless of the open options used, and includes the following:
 - A change to the *BaseQName* attribute of an alias queue that is open.
 - A change to the *RemoteQName* or *RemoteQMGrName* queue attributes, for any handle that is open for this queue, or for a queue which resolves through this definition as a queue manager alias.
 - Any change that causes a currently open handle for a remote queue to resolve to a different *transmission* queue, or to fail to resolve to one at all. For example, this can include:
 - A change to the *XmitQName* attribute of the local definition of a remote queue, whether the definition is being used for a queue, or for a queue manager alias.

There is one exception to this, namely the creation of a new transmission queue. A handle that would have resolved to this queue had it been present when the handle was opened, but instead resolved to the default transmission queue, is not made invalid.

- A change to the *DefXmitQName* queue manager attribute. In this case all open handles that resolved to the previously named queue (that resolved to it only because it was the default transmission queue) are marked as invalid. Handles that resolved to this queue for other reasons are not affected.
- The *Shareability* queue attribute, if there are two or more handles that are currently providing OOINPS access for this queue, or for a queue that resolves to this queue. If so, *all* handles that are open for this queue, or for a queue that resolves to this queue, are marked as invalid, regardless of the open options.
- The *Usage* queue attribute, for all handles that are open for this queue, or for a queue that resolves to this queue, regardless of the open options.

When a handle is marked as invalid, all subsequent calls (other than MQCLOSE) using this handle fail with reason code RC2041; the application should issue an MQCLOSE call (using the original handle) and then reopen the queue. Any uncommitted updates against the old handle from previous successful calls can still be committed or backed out, as required by the application logic.

If changing an attribute will cause this to happen, a special "force" version of the command must be used.

5. The queue manager performs security checks when an MQOPEN call is issued, to verify that the user identifier under which the application is running has the appropriate level of authority before access is permitted. The authority check is made on the name of the object being opened, and not on the name, or names, resulting after a name has been resolved.

If the object being opened is a model queue, the queue manager performs a full security check against both the name of the model queue and the name of the dynamic queue that is created. If the resulting dynamic queue is then opened explicitly, a further resource security check is performed against the name of the dynamic queue.

6. A remote queue can be specified in one of two ways in the *OBJDSC* parameter of this call (see the *ODON* and *ODMN* fields described in “MQOD - Object descriptor” on page 1117):

- By specifying for *ODON* the name of a local definition of the remote queue. In this case, *ODMN* refers to the local queue manager, and can be specified as blanks.

The security validation performed by the local queue manager verifies that the user is authorized to open the local definition of the remote queue.

- By specifying for *ODON* the name of the remote queue as known to the remote queue manager. In this case, *ODMN* is the name of the remote queue manager.

The security validation performed by the local queue manager verifies that the user is authorized to send messages to the transmission queue resulting from the name resolution process.

In either case:

- No messages are sent by the local queue manager to the remote queue manager in order to check that the user is authorized to put messages on the queue.
- When a message arrives at the remote queue manager, the remote queue manager might reject it because the user originating the message is not authorized.

7. An MQOPEN call with the OOBROW option establishes a browse cursor, for use with MQGET calls that specify the object handle and one of the browse options. This allows the queue to be scanned without altering its contents. A message that has been found by browsing can later be removed from the queue by using the GMMUC option.

Multiple browse cursors can be active for a single application by issuing several MQOPEN requests for the same queue.

8. The following notes apply to the use of distribution lists.

- Fields in the MQOD structure must be set as follows when opening a distribution list:
 - *ODVER* must be *ODVER2* or greater.
 - *ODOT* must be *OTQ*.
 - *ODON* must be blank or the null string.
 - *ODMN* must be blank or the null string.
 - *ODREC* must be greater than zero.
 - One of *ODORO* and *ODORP* must be zero and the other nonzero.
 - No more than one of *ODRRO* and *ODRRP* can be nonzero.
 - There must be *ODREC* object records, addressed by either *ODORO* or *ODORP*. The object records must be set to the names of the destination queues to be opened.
 - If one of *ODRRO* and *ODRRP* is nonzero, there must be *ODREC* response records present. They are set by the queue manager if the call completes with reason code RC2136.

A version-2 MQOD can also be used to open a single queue that is not in a distribution list, by ensuring that *ODREC* is zero.

- Only the following open options are valid in the *OPTS* parameter:
 - *OOOUT*
 - *OOPAS**
 - *OOSSET**
 - *OOALTU*
 - *OOFIQ*

- The destination queues in the distribution list can be local, alias, or remote queues, but they cannot be model queues. If a model queue is specified, that queue fails to open, with reason code RC2057. However, this does not prevent other queues in the list being opened successfully.
- The completion code and reason code parameters are set as follows:
 - If the open operations for the queues in the distribution list all succeed or fail in the same way, the completion code and reason code parameters are set to describe the common result. The MQRR response records (if provided by the application) are not set in this case.

For example, if every open succeeds, the completion code is set to CCOK and the reason code is RCNONE; if every open fails because none of the queues exists, the parameters are set to CCFAIL and RC2085.
 - If the open operations for the queues in the distribution list do not all succeed or fail in the same way:
 - The completion code parameter is set to CCWARN if at least one open succeeded, and to CCFAIL if all failed.
 - The reason code parameter is set to RC2136.
 - The response records (if provided by the application) are set to the individual completion codes and reason codes for the queues in the distribution list.
- When a distribution list has been opened successfully, the handle *HOBj* returned by the call can be used on subsequent MQPUT calls to put messages to queues in the distribution list, and on an MQCLOSE call to relinquish access to the distribution list. The only valid close option for a distribution list is CONONE.

The MQPUT1 call can also be used to put a message to a distribution list; the MQOD structure defining the queues in the list is specified as a parameter on that call.

- Each successfully opened destination in the distribution list counts as a *separate* handle when checking whether the application has exceeded the permitted maximum number of handles (see the *MaxHandles* queue manager attribute). This is true even when two or more of the destinations in the distribution list actually resolve to the same physical queue. If the MQOPEN or MQPUT1 call for a distribution list would cause the number of handles in use by the application to exceed *MaxHandles*, the call fails with reason code RC2017.
- Each destination that is opened successfully has the value of its *OpenOutputCount* attribute incremented by one. If two or more of the destinations in the distribution list actually resolve to the same physical queue, that queue has its *OpenOutputCount* attribute incremented by the number of destinations in the distribution list that resolve to that queue.
- Any change to the queue definitions that would have caused a handle to become invalid had the queues been opened individually (for example, a change in the resolution path), does not cause the distribution-list handle to become invalid. However, it does result in a failure for that particular queue when the distribution-list handle is used on a subsequent MQPUT call.
- It is valid for a distribution list to contain only one destination.

9. The following notes apply to the use of cluster queues.

- When a cluster queue is opened for the first time, and the local queue manager is not a full repository queue manager, the local queue manager obtains information about the cluster queue from a full repository queue manager. When the network is busy, it may take several seconds for the local queue manager to receive the needed information from the repository queue manager. As a result, the application issuing the MQOPEN call might have to wait for up to 10 seconds before control returns from the MQOPEN call. If the local queue manager does not receive the needed information about the cluster queue within this time, the call fails with reason code RC2189.
- When a cluster queue is opened and there are multiple instances of the queue in the cluster, the instance actually opened depends on the options specified on the MQOPEN call:
 - If the options specified include any of the following:
 - OOBROW

- OOINPQ
- OOINPX
- OOINPS
- OOSSET

the instance of the cluster queue opened is required to be the local instance. If there is no local instance of the queue, the MQOPEN call fails.

- If the options specified include none of the above, but do include one or both of the following:
 - OOINQ
 - OOOOUT

the instance opened is the local instance if there is one, and a remote instance otherwise. The instance chosen by the queue manager can, however, be altered by a cluster workload exit (if there is one).

For more information about cluster queues, see [Cluster queues](#).

10. Applications started by a trigger monitor are passed the name of the queue that is associated with the application when the application is started. This queue name can be specified in the *OBJDSC* parameter to open the queue. See the description of the MQTMC structure for further details.
11. On IBM i, applications running in compatibility mode are connected automatically to the queue manager by the first MQOPEN call issued by the application (if the application has not already connected to the queue manager by using the MQCONN call).

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

Applications not running in compatibility mode must issue the MQCONN or MQCONNEX call to connect to the queue manager explicitly, before using the MQOPEN call to open an object.

12. When using the OORLOQ option, the local queue is already returned when either a local, alias, or model queue is opened, but this is not the case when, for example, a remote queue or a non-local cluster queue is opened; the ResolvedQName and ResolvedQMGrName are entered with the RemoteQName and RemoteQMGrName found in the remote queue definition, or similarly with the chosen remote cluster queue. If OORLOQ is specified when opening, for example, a remote queue, ResolvedQName will now be the transmission queue which messages will be put to. The ResolvedQMGrName will be entered with the name of the local queue manager hosting the transmission queue. If a user is authorized for browse, input or output on a queue, they have the required authority to specify this flag on the MQOPEN call. No special authority is needed.

Parameters

The MQOPEN call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

OBJDSC (MQOD) - input/output

Object descriptor.

This is a structure that identifies the object to be opened; see [“MQOD - Object descriptor”](#) on page 1117 for details.

If the *ODON* field in the *OBJDSC* parameter is the name of a model queue, a dynamic local queue is created with the attributes of the model queue; this happens irrespective of the open options specified by the *OPTS* parameter. Subsequent operations using the *HOBJ* returned by the *MQOPEN* call are performed on the new dynamic queue, and not on the model queue. This is true even for the *MQINQ* and *MQSET* calls. The name of the model queue in the *OBJDSC* parameter is replaced with the name of the dynamic queue created. The type of the dynamic queue is determined by the value of the *DefinitionType* attribute of the model queue (see [“Attributes for queues”](#) on page 1324). For information about the close options applicable to dynamic queues, see the description of the *MQCLOSE* call.

OPTS (10-digit signed integer) - input

Options that control the action of *MQOPEN*.

At least one of the following options must be specified:

- *OOBRW*
- *OOINP** (only one of these)
- *OOINQ*
- *OOOUT*
- *OOSET*
- *OORLQ*

Other options can be specified as required. If more than one option is required, the values can be added (do not add the same constant more than once). Combinations that are not valid are noted; all other combinations are valid. Only options that are applicable to the type of object specified by *OBJDSC* are allowed (see [Valid MQOPEN options for each queue type](#)).

Access options: The following options control the type of operations that can be performed on the object:

OOINPQ

Open queue to get messages using queue-defined default.

The queue is opened for use with subsequent *MQGET* calls. The type of access is either shared or exclusive, depending on the value of the *DefInputOpenOption* queue attribute; see [“Attributes for queues”](#) on page 1324 for details.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

OOINPS

Open queue to get messages with shared access.

The queue is opened for use with subsequent *MQGET* calls. The call can succeed if the queue is currently open by this or another application with *OOINPS*, but fails with reason code RC2042 if the queue is currently open with *OOINPX*.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

OOINPX

Open queue to get messages with exclusive access.

The queue is opened for use with subsequent *MQGET* calls. The call fails with reason code RC2042 if the queue is currently open by this or another application for input of any type (*OOINPS* or *OOINPX*).

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects that are not queues.

The following notes apply to these options:

- Only one of these options can be specified.
- An MQOPEN call with one of these options can succeed even if the *InhibitGet* queue attribute is set to QAGETI (although subsequent MQGET calls will fail while the attribute is set to this value).
- If the queue is defined as not being shareable (that is, the *Shareability* queue attribute has the value QANSHR), attempts to open the queue for shared access are treated as attempts to open the queue with exclusive access.
- If an alias queue is opened with one of these options, the test for exclusive use (or for whether another application has exclusive use) is against the base queue to which the alias resolves.
- These options are not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the *RemoteQMGrName* attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

OOBRW

Open queue to browse messages.

The queue is opened for use with subsequent MQGET calls with one of the following options:

- GMBRWF
- GMBRWN
- GMBRWC

This is allowed even if the queue is currently open for OOINPX. An MQOPEN call with the OOBRW option establishes a browse cursor, and positions it logically before the first message on the queue; see the *GMOPT* field described in [“MQGMO - Get-message options” on page 1035](#) for further information.

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects which are not queues. It is also not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the *RemoteQMGrName* attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

OOOUT

Open queue to put messages, or a topic or topic string to publish messages.

The queue is opened for use with subsequent MQPUT calls.

An MQOPEN call with this option can succeed even if the *InhibitPut* queue attribute is set to QAPUTI (although subsequent MQPUT calls will fail while the attribute is set to this value).

This option is valid for all types of queue, including distribution lists and topics.

OOINQ

Open object to inquire attributes.

The queue, namelist, process definition, or queue manager is opened for use with subsequent MQINQ calls.

This option is valid for all types of object other than distribution lists. It is not valid if *ODMN* is the name of a queue manager alias; this is true even if the value of the *RemoteQMGrName* attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

OOSSET

Open queue to set attributes.

The queue is opened for use with subsequent MQSET calls.

This option is valid for all types of queue other than distribution lists. It is not valid if *ODMN* is the name of a local definition of a remote queue; this is true even if the value of the *RemoteQMGrName* attribute in the local definition of a remote queue used for queue manager aliasing is the name of the local queue manager.

Binding options: The following options apply when the object being opened is a cluster queue; these options control the binding of the queue handle to an instance of the cluster queue:

OOBNDQ

Bind handle to destination when queue is opened.

This causes the local queue manager to bind the queue handle to an instance of the destination queue when the queue is opened. As a result, all messages put using this handle are sent to the same instance of the destination queue, and by the same route.

This option is valid only for queues, and affects only cluster queues. If specified for a queue that is not a cluster queue, the option is ignored.

OOBNDN

Do not bind to a specific destination.

This stops the local queue manager binding the queue handle to an instance of the destination queue. As a result, successive MQPUT calls using this handle may result in the messages being sent to *different* instances of the destination queue, or being sent to the same instance but by different routes. It also allows the instance selected to be changed later by the local queue manager, by a remote queue manager, or by a message channel agent (MCA), according to network conditions.

Note: Client and server applications which need to exchange a *series* of messages in order to complete a transaction should not use OOBNDN (or OOBNDQ when *DefBind* has the value BNDNOT), because successive messages in the series may be sent to different instances of the server application.

If OOBROW or one of the OOINP* options is specified for a cluster queue, the queue manager is forced to select the local instance of the cluster queue. As a result, the binding of the queue handle is fixed, even if OOBNDN is specified.

If OOINQ is specified with OOBNDN, successive MQINQ calls using that handle may inquire different instances of the cluster queue, although typically all of the instances have the same attribute values.

OOBNDN is valid only for queues, and affects only cluster queues. If specified for a queue that is not a cluster queue, the option is ignored.

OOBNDQ

Use default binding for queue.

This causes the local queue manager to bind the queue handle in the way defined by the *DefBind* queue attribute. The value of this attribute is either BNDOPN or BNDNOT.

OOBNDQ is the default if OOBNDQ and OOBNDN are not specified.

OOBNDQ is defined to aid program documentation. It is not intended that this option is used with either of the other two bind options, but because its value is zero such use cannot be detected.

Context options: The following options control the processing of message context:

OOSAVA

Save context when message retrieved.

Context information is associated with this queue handle. This information is set from the context of any message retrieved using this handle. For more information about message context, see [Message context](#) and [Controlling context information](#).

This context information can be passed to a message that is later put on a queue using the MQPUT or MQPUT1 calls. See the PMPASI and PMPASA options described in [“MQPMO - Put-message options” on page 1131](#).

Until a message has been successfully retrieved, context cannot be passed to a message being put on a queue.

A message retrieved using one of the GMBRW* browse options does not have its context information saved (although the context fields in the *MSGDSC* parameter are set after a browse).

This option is valid only for local, alias, and model queues; it is not valid for remote queues, distribution lists, and objects which are not queues. One of the OOINP* options must be specified.

OOPASI

Allow identity context to be passed.

This allows the PMPASI option to be specified in the *PMO* parameter when a message is put on a queue; this gives the message the identity context information from an input queue that was opened with the OOSAVA option. For more information about message context, see [Message context](#) and [Controlling context information](#).

The OOOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

OOPASA

Allow all context to be passed.

This allows the PMPASA option to be specified in the *PMO* parameter when a message is put on a queue; this gives the message the identity and origin context information from an input queue that was opened with the OOSAVA option. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies OOPASI, which need not therefore be specified. The OOOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

OOSETI

Allow identity context to be set.

This allows the PMSETI option to be specified in the *PMO* parameter when a message is put on a queue; this gives the message the identity context information contained in the *MSGDSC* parameter specified on the MQPUT or MQPUT1 call. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies OOPASI, which need not therefore be specified. The OOOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

OOSETA

Allow all context to be set.

This allows the PMSETA option to be specified in the *PMO* parameter when a message is put on a queue; this gives the message the identity and origin context information contained in the *MSGDSC* parameter specified on the MQPUT or MQPUT1 call. For more information about message context, see [Message context](#) and [Controlling context information](#).

This option implies the following options, which need not therefore be specified:

- OOPASI
- OOPASA
- OOSETI

The OOOOUT option must be specified.

This option is valid for all types of queue, including distribution lists.

Other options: The following options control authorization checking, and what happens when the queue manager is quiescing:

OOALTU

Validate with specified user identifier.

This indicates that the *ODAU* field in the *OBJDSC* parameter contains a user identifier that is to be used to validate this MQOPEN call. The call can succeed only if this *ODAU* is authorized to open the object with the specified access options, regardless of whether the user identifier under which the application is running is authorized to do so. This does not apply to any context options specified, however, which are always checked against the user identifier under which the application is running.

This option is valid for all types of object.

OOFIQ

Fail if queue manager is quiescing.

This option forces the MQOPEN call to fail if the queue manager is in quiescing state.

This option is valid for all types of object.

OO RLQ

Enter the name of local queue that was opened.

This option specifies that the ResolvedQName in the MQOD structure (if available) should be entered with the name of the local queue which was opened. The ResolvedQMGrName will similarly be entered with the name of the local queue manager hosting the local queue.

Valid MQOPEN options for each queue type

Option	Alias (“1” on page 1288)	Local and Model	Remote	Nonlocal Cluster	Distribution list	Topic
OOINPQ	✓	✓	-	-	-	-
OOINPS	✓	✓	-	-	-	-

Notes:

1. The validity of options for aliases depends on the validity of the option for the queue to which the alias resolves.
2. This option is valid only for the local definition of a remote queue.
3. This option can be specified for any queue type, but is ignored if the queue is not a cluster queue.
4. This attribute is ignored for a topic.
5. These attributes can be used with a topic, but only affect the context set for the retained message, not the context fields sent to any subscriber.

HOBj (10-digit signed integer) - output

Object handle.

This handle represents the access that has been established to the object. It must be specified on subsequent message queuing calls that operate on the object. It ceases to be valid when the MQCLOSE call is issued, or when the unit of processing that defines the scope of the handle terminates.

The scope of the handle is restricted to the smallest unit of parallel processing supported by the platform on which the application is running; the handle is not valid outside the unit of parallel processing from which the MQOPEN call was issued:

- On IBM i, the scope of the handle is the job issuing the call.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

RPG Declaration

```

C*.1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQOPEN(HCONN : OBJDSC : OPTS :
C                      HOBj : CMPCOD : REASON)

```

The prototype definition for the call is:

```

```

MQPUT - Put message

The MQPUT call puts a message on a queue, distribution list or to a topic. The queue, distribution list, or topic must already be open.

Syntax

MQPUT (*HCONN*, *HOBJ*, *MSGDSC*, *PMO*, *BUFLEN*, *BUFFER*, *CMPCOD*, *REASON*)

Usage notes

Topics

The following notes apply to the use of topics:

1. When using MQPUT to publish messages on a topic, where one or more subscribers to that topic cannot be given the publication due to a problem with their subscriber queue (for example it is full), the Reason code returned to the MQPUT call and the delivery behavior is dependent on the setting of the PMSGDLV or NPMSGDLV attributes on the TOPIC. Note that delivery of a publication to the dead letter queue when RODLQ is specified, or discarding the message when RODISC is specified, is considered a successful delivery of the message. If none of the publications are delivered, the MQPUT will return with RC2502. This can happen in the following cases:
 - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALL and any subscription (durable or not) has a queue which cannot receive the publication.
 - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLDUR and a durable subscription has a queue which cannot receive the publication.

The MQPUT can return with RCNONE even though publications could not be delivered to some subscribers in the following cases:

- A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLAVAIL and any subscription, durable or not, has a queue which cannot receive the publication.
 - A message is published to a TOPIC with PMSGDLV or NPMSGDLV (depending on the persistence of the message) set to ALLDUR and a non-durable subscription has a queue which cannot receive the publication.
2. If there are no subscribers to the topic being used, the message published is not sent to any queue and is discarded. It does not make any difference whether this message is persistent or non-persistent, or whether it has unlimited expiry or some small expiry time, it is still discarded if there are no subscribers. The exception to this is if the message is to be retained, in which case, although it is not sent to any subscribers' queues, it is stored against the topic to be delivered to any new subscriptions or to any subscribers that ask for retained publications using MQSUBRQ.

MQPUT and MQPUT1

Both the MQPUT and MQPUT1 calls can be used to put messages on a queue; which call to use depends on the circumstances

- The MQPUT call should be used when multiple messages are to be placed on the *same* queue.

An MQOPEN call specifying the OOOUT option is issued first, followed by one or more MQPUT requests to add messages to the queue; finally the queue is closed with an MQCLOSE call. This gives better performance than repeated use of the MQPUT1 call.

- The MQPUT1 call should be used when only *one* message is to be put on a queue.

This call encapsulates the MQOPEN, MQPUT, and MQCLOSE calls into a single call, minimizing the number of calls that must be issued.

Destination queues

If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if the following conditions are satisfied. Some conditions apply to both local and remote destination queues; other conditions apply only to remote destination queues.

Conditions for local and remote destination queues

- All of the MQPUT calls are within the same unit of work, or none of them is within a unit of work.

When messages are put onto a particular queue within a single unit of work, messages from other applications might be interspersed with the sequence of messages on the queue.

- All of the MQPUT calls are made using the same object handle *HOBJ*.

In some environments, message sequence is also preserved when different object handles are used, provided the calls are made from the same application. The meaning of "same application" is determined by the environment:

- On IBM i, the application is the job.

- The messages all have the same priority.

Additional conditions for remote destination queues

- There is only one path from the sending queue manager to the destination queue manager.

If there is a possibility that some messages in the sequence may go on a different path (for example, because of reconfiguration, traffic balancing, or path selection based on message size), the order of the messages at the destination queue manager cannot be guaranteed.

- Messages are not placed temporarily on dead-letter queues at the sending, intermediate, or destination queue managers.

If one or more of the messages is put temporarily on a dead-letter queue (for example, because a transmission queue or the destination queue is temporarily full), the messages can arrive on the destination queue out of sequence.

- The messages are either all persistent or all nonpersistent.

If a channel on the route between the sending and destination queue managers has its *CDNPM* attribute set to *NPFAST*, nonpersistent messages can jump ahead of persistent messages, resulting in the order of persistent messages relative to nonpersistent messages not being preserved. However, the order of persistent messages relative to each other, and of nonpersistent messages relative to each other, is preserved.

If these conditions are not satisfied, message groups can be used to preserve message order, but note that this requires both the sending and receiving applications to use the message-grouping support. For more information about message groups, see:

- *MDMFL* field in MQMD
- *PMLOGO* option in MQPMO
- *GMLOGO* option in MQGMO

Distribution lists

The following notes apply to the use of distribution lists.

1. Messages can be put to a distribution list using either a version-1 or a version-2 MQPMO. If a version-1 MQPMO is used (or a version-2 MQPMO with *PMREC* equal to zero), no put message records or response records can be provided by the application. This means that it will not be possible to identify the queues which encounter errors, if the message is sent successfully to some queues in the distribution list and not others.

If put message records or response records are provided by the application, the *PMVER* field must be set to *PMVER2*.

A version-2 MQPMO can also be used to send messages to a single queue that is not in a distribution list, by ensuring that *PMREC* is zero.

2. The completion code and reason code parameters are set as follows:

- If the puts to the queues in the distribution list all succeed or fail in the same way, the completion code and reason code parameters are set to describe the common result. The MQRR response records (if provided by the application) are not set in this case.

For example, if every put succeeds, the completion code is set to *CCOK* and the reason code is *RCNONE*; if every put fails because all of the queues are inhibited for puts, the parameters are set to *CCFAIL* and *RC2051*.

- If the puts to the queues in the distribution list do not all succeed or fail in the same way:
 - The completion code parameter is set to *CCWARN* if at least one put succeeded, and to *CCFAIL* if all failed.
 - The reason code parameter is set to *RC2136*.
 - The response records (if provided by the application) are set to the individual completion codes and reason codes for the queues in the distribution list.

If the put to a destination fails because the open for that destination failed, the fields in the response record are set to *CCFAIL* and *RC2137*; that destination is included in *PMIDC*.

3. If a destination in the distribution list resolves to a local queue, the message is placed on that queue in normal form (that is, not as a distribution-list message). If more than one destination resolves to the same local queue, one message is placed on the queue for each such destination.

If a destination in the distribution list resolves to a remote queue, a message is placed on the appropriate transmission queue. Where several destinations resolve to the same transmission queue, a single distribution-list message containing those destinations may be placed on the transmission queue, even if those destinations were not adjacent in the list of destinations provided by the application. However, this can be done only if the transmission queue supports distribution-list messages (see the *DistLists* queue attribute described in [“Attributes for queues” on page 1324](#)).

If the transmission queue does not support distribution lists, one copy of the message in normal form is placed on the transmission queue for each destination that uses that transmission queue.

If a distribution list with the application message data is too large for a transmission queue, the distribution list message is split up into smaller distribution-list messages, each containing fewer destinations. If the application message data only just fits on the queue, distribution-list messages cannot be used at all, and the queue manager generates one copy of the message in normal form for each destination that uses that transmission queue.

If different destinations have different message priority or message persistence (this can occur when the application specifies PRQDEF or PEQDEF), the messages are not held in the same distribution-list message. Instead, the queue manager generates as many distribution-list messages as are necessary to accommodate the differing priority and persistence values.

4. A put to a distribution list might result in:

- A single distribution-list message, or
- A number of smaller distribution-list messages, or
- A mixture of distribution list messages and normal messages, or
- Normal messages only.

Which of the previous occurs depends on whether:

- The destinations in the list are local, remote, or a mixture.
- The destinations have the same message priority and message persistence.
- The transmission queues can hold distribution-list messages.
- The transmission queues' maximum message lengths are large enough to accommodate the message in distribution-list form.

However, regardless of which of the above occurs, each *physical* message resulting (that is, each normal message or distribution-list message resulting from the put) counts as only *one* message when:

- Checking whether the application has exceeded the permitted maximum number of messages in a unit of work (see the *MaxUncommittedMsgs* queue manager attribute).
- Checking whether the triggering conditions are satisfied.
- Incrementing queue depths and checking whether the queues' maximum queue depth would be exceeded.

5. Any change to the queue definitions that would have caused a handle to become invalid had the queues been opened individually (for example, a change in the resolution path), does not cause the distribution-list handle to become invalid. However, it does result in a failure for that particular queue when the distribution-list handle is used on a subsequent MQPUT call.

Headers

If a message is put with one or more IBM MQ header structures at the beginning of the application message data, the queue manager performs certain checks on the header structures to verify that they are valid. If the queue manager detects an error, the call fails with an appropriate reason code. The checks performed vary according to the particular structures that are present. In addition, the checks are performed only if a version-2 or later MQMD is used on the MQPUT or MQPUT1 call; the checks are not performed if a version-1 MQMD is used, even if an MQMDE is present at the start of the application message data.

The following IBM MQ header structures are validated completely by the queue manager: MQDH, MQMDE.

For other IBM MQ header structures, the queue manager performs some validation, but does not check every field. Structures that are not supported by the local queue manager, and structures following the first MQDLH in the message, are not validated.

In addition to general checks on the fields in IBM MQ structures, the following conditions must be satisfied:

- An IBM MQ structure must not be split over two or more segments - the structure must be entirely contained within one segment.
- The sum of the lengths of the structures in a PCF message must equal the length specified by the *BUFLen* parameter on the MQPUT or MQPUT1 call. A PCF message is a message that has one of the following format names:
 - FMADMN
 - FMEVNT
 - FMPCF
- IBM MQ structures must not be truncated, except in the following situations where truncated structures are permitted:
 - Messages which are report messages.
 - PCF messages.
 - Messages containing an MQDLH structure. (Structures *following* the first MQDLH can be truncated; structures preceding the MQDLH cannot.)

Buffer

The *BUFFER* parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter should be declared instead as a structure, or as a field in a physical file. This will increase the maximum length possible to approximately 32 KB.

Parameters

The MQPUT call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HOBJ (10-digit signed integer) - input

Object handle.

This handle represents the queue to which the message is added, or the topic to which the message is published. The value of *HOBJ* was returned by a previous MQOPEN call that specified the OOOUT option.

MSGDSC (MQMD) - input/output

Message descriptor.

This structure describes the attributes of the message being sent, and receives information about the message after the put request is complete. See [“MQMD - Message descriptor” on page 1068](#) for details.

If the application provides a version-1 MQMD, the message data can be prefixed with an MQMDE structure in order to specify values for the fields that exist in the version-2 MQMD but not the

version-1. The *MDFMT* field in the MQMD must be set to FMMDE to indicate that an MQMDE is present. See “MQMDE - Message descriptor extension” on page 1111 for more details.

PMO (MQPMO) - input/output

Options that control the action of MQPUT.

See “MQPMO - Put-message options” on page 1131 for details.

BUFLEN (10-digit signed integer) - input

Length of the message in *BUFFER*.

Zero is valid, and indicates that the message contains no application data. The upper limit for *BUFLEN* depends on various factors:

- If the destination queue is a shared queue, the upper limit is 63 KB (64 512 bytes).
- If the destination is a local queue or resolves to a local queue (but is not a shared queue), the upper limit depends on whether:
 - The local queue manager supports segmentation.
 - The sending application specifies the flag that allows the queue manager to segment the message. This flag is MFSEGA, and can be specified either in a version-2 MQMD, or in an MQMDE used with a version-1 MQMD.

If both of these conditions are satisfied, *BUFLEN* cannot exceed 999 999 999 minus the value of the *MDOFF* field in MQMD. The longest logical message that can be put is therefore 999 999 999 bytes (when *MDOFF* is zero). However, resource constraints imposed by the operating system or environment in which the application is running may result in a lower limit.

If one or both of the previously described conditions are not satisfied, *BUFLEN* cannot exceed the smaller of the queue's *MaxMsgLength* attribute and queue manager's *MaxMsgLength* attribute.

- If the destination is a remote queue or resolves to a remote queue, the conditions for local queues apply, *but at each queue manager through which the message must pass in order to reach the destination queue* ; in particular:
 1. The local transmission queue used to store the message temporarily at the local queue manager
 2. Intermediate transmission queues (if any) used to store the message at queue managers on the route between the local and destination queue managers
 3. The destination queue at the destination queue manager

The longest message that can be put is therefore governed by the most restrictive of these queues and queue managers.

When a message is on a transmission queue, additional information resides with the message data, and this reduces the amount of application data that can be carried. In this situation it is recommended that LNMHD bytes be subtracted from the *MaxMsgLength* values of the transmission queues when determining the limit for *BUFLEN*.

Note: Only failure to comply with condition 1 can be diagnosed synchronously (with reason code RC2030 or RC2031) when the message is put. If conditions 2 or 3 are not satisfied, the message is redirected to a dead-letter (undelivered-message) queue, either at an intermediate queue manager or at the destination queue manager. If this happens, a report message is generated if one was requested by the sender.

BUFFER (1-byte bit string x BUFLEN) - input

Message data.

This is a buffer containing the application data to be sent. The buffer should be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment should be suitable for most messages (including messages containing MQ header structures), but some messages may require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If *BUFFER* contains character data, numeric data, or both, the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter should be set to the values appropriate to the data; this will enable the receiver of the message to convert the data (if necessary) to the character set and encoding used by the receiver.

Note: All of the other parameters on the MQPUT call must be in the character set given by the *CodedCharSetId* queue manager attribute, and encoding of the local queue manager given by the ENNAT.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2104

(2104, X'838') Report option in message descriptor not recognized.

RC2136

(2136, X'858') Multiple reason codes returned.

If *CMPCOD* is CCFAIL:

RC2004

(2004, X'7D4') Buffer parameter not valid.

RC2005

(2005, X'7D5') Buffer length parameter not valid.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2013

(2013, X'7DD') Expiry time not valid.

RC2014

(2014, X'7DE') Feedback code not valid.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2019

(2019, X'7E3') Object handle not valid.

RC2024

(2024, X'7E8') No more messages can be handled within current unit of work.

RC2026

(2026, X'7EA') Message descriptor not valid.

RC2027

(2027, X'7EB') Missing reply-to queue.

RC2029
(2029, X'7ED') Message type in message descriptor not valid.

RC2030
(2030, X'7EE') Message length greater than maximum for queue.

RC2031
(2031, X'7EF') Message length greater than maximum for queue manager.

RC2039
(2039, X'7F7') Queue not open for output.

RC2041
(2041, X'7F9') Object definition changed since opened.

RC2046
(2046, X'7FE') Options not valid or not consistent.

RC2047
(2047, X'7FF') Persistence not valid.

RC2048
(2048, X'800') Queue does not support persistent messages.

RC2050
(2050, X'802') Message priority not valid.

RC2051
(2051, X'803') Put calls inhibited for the queue.

RC2052
(2052, X'804') Queue has been deleted.

RC2053
(2053, X'805') Queue already contains maximum number of messages.

RC2056
(2056, X'808') No space available on disk for queue.

RC2058
(2058, X'80A') Queue manager name not valid or not known.

RC2059
(2059, X'80B') Queue manager not available for connection.

RC2061
(2061, X'80D') Report options in message descriptor not valid.

RC2071
(2071, X'817') Insufficient storage available.

RC2072
(2072, X'818') Syncpoint support not available.

RC2093
(2093, X'82D') Queue not open for pass all context.

RC2094
(2094, X'82E') Queue not open for pass identity context.

RC2095
(2095, X'82F') Queue not open for set all context.

RC2096
(2096, X'830') Queue not open for set identity context.

RC2097
(2097, X'831') Queue handle referred to does not save context.

RC2098
(2098, X'832') Context not available for queue handle referred to.

RC2101
(2101, X'835') Object damaged.

RC2102
(2102, X'836') Insufficient system resources available.

RC2135
(2135, X'857') Distribution header structure not valid.

RC2136
(2136, X'858') Multiple reason codes returned.

RC2137
(2137, X'859') Object not opened successfully.

RC2149
(2149, X'865') PCF structures not valid.

RC2154
(2154, X'86A') Number of records present not valid.

RC2156
(2156, X'86C') Response records not valid.

```

MQPUT1 - Put one message

The MQPUT1 call puts one message on a queue or distribution list, or to a topic. The queue, distribution list, or topic does not need to be open.

- [“Syntax” on page 1299](#)
- [“Usage notes” on page 1299](#)
- [“Parameters” on page 1300](#)
- [“RPG Declaration” on page 1305](#)

Syntax

MQPUT1 (*HCONN, OBJDSC, MSGDSC, PMO, BUFLN, BUFFER, CMPCOD, REASON*)

Usage notes

1. Both the MQPUT and MQPUT1 calls can be used to put messages on a queue; which call to use depends on the circumstances:
 - The MQPUT call should be used when multiple messages are to be placed on the *same* queue.
An MQOPEN call specifying the OOOUT option is issued first, followed by one or more MQPUT requests to add messages to the queue; finally the queue is closed with an MQCLOSE call. This gives better performance than repeated use of the MQPUT1 call.
 - The MQPUT1 call should be used when only *one* message is to be put on a queue.
This call encapsulates the MQOPEN, MQPUT, and MQCLOSE calls into a single call, minimizing the number of calls that must be issued.
2. If an application puts a sequence of messages on the same queue without using message groups, the order of those messages is preserved if certain conditions are satisfied. However, in most environments the MQPUT1 call does not satisfy these conditions, and so does not preserve message order. The MQPUT call must be used instead in these environments. See the usage notes in the description of the MQPUT call for details.
3. The MQPUT1 call can be used to put messages to distribution lists. For general information about this, see the usage notes for the MQOPEN and MQPUT calls.

The following differences apply when using the MQPUT1 call:

- a. If MQRN response records are provided by the application, they must be provided using the MQOD structure; they cannot be provided using the MQPMO structure.
 - b. The reason code RC2137 is never returned by MQPUT1 in the response records; if a queue fails to open, the response record for that queue contains the actual reason code resulting from the open operation.

If an open operation for a queue succeeds with a completion code of CCWARN, the completion code and reason code in the response record for that queue are replaced by the completion and reason codes resulting from the put operation.

As with the MQOPEN and MQPUT calls, the queue manager sets the response records (if provided) only when the outcome of the call is not the same for all queues in the distribution list; this is indicated by the call completing with reason code RC2136.
4. If the MQPUT1 call is used to put a message on a cluster queue, the call behaves as though OOBNDN had been specified on the MQOPEN call.
 5. If a message is put with one or more IBM MQ header structures at the beginning of the application message data, the queue manager performs certain checks on the header structures to verify that they are valid. For more information about this, see the usage notes for the MQPUT call.

6. If more than one of the warning situations arise (see the *CMPCOD* parameter), the reason code returned is the *first* one in the following list that applies:
 - a. RC2136
 - b. RC2242
 - c. RC2241
 - d. RC2049 or RC2104
7. The *BUFFER* parameter shown in the RPG programming example is declared as a string; this restricts the maximum length of the parameter to 256 bytes. If a larger buffer is required, the parameter should be declared instead as a structure, or as a field in a physical file. This will increase the maximum length possible to approximately 32 KB.

Parameters

The MQPUT1 call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

OBJDSC (MQOD) - input/output

Object descriptor.

This is a structure which identifies the queue to which the message is added. See [“MQOD - Object descriptor” on page 1117](#) for details.

The user must be authorized to open the queue for output. The queue must **not** be a model queue.

MSGDSC (MQMD) - input/output

Message descriptor.

This structure describes the attributes of the message being sent, and receives feedback information after the put request is complete. See [“MQMD - Message descriptor” on page 1068](#) for details.

If the application provides a version-1 MQMD, the message data can be prefixed with an MQMDE structure in order to specify values for the fields that exist in the version-2 MQMD but not the version-1. The *MDFMT* field in the MQMD must be set to FMMDE to indicate that an MQMDE is present. See [“MQMDE - Message descriptor extension” on page 1111](#) for more details.

PMO (MQPMO) - input/output

Options that control the action of MQPUT1.

See [“MQPMO - Put-message options” on page 1131](#) for details.

BUFLEN (10-digit signed integer) - input

Length of the message in *BUFFER*.

Zero is valid, and indicates that the message contains no application data. The upper limit depends on various factors; see the description of the *BUFLEN* parameter of the MQPUT call for further details.

BUFFER (1-byte bit string x BUFLen) - input

Message data.

This is a buffer containing the application message data to be sent. The buffer should be aligned on a boundary appropriate to the nature of the data in the message. 4-byte alignment should be suitable for most messages (including messages containing IBM MQ header structures), but some messages may require more stringent alignment. For example, a message containing a 64-bit binary integer might require 8-byte alignment.

If *BUFFER* contains character data, numeric data, or both, the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter should be set to the values appropriate to the data; this will enable the receiver of the message to convert the data (if necessary) to the character set and encoding used by the receiver.

Note: All of the other parameters on the MQPUT1 call must be in the character set given by the *CodedCharSetId* queue manager attribute and encoding of the local queue manager given by ENNAT.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2104

(2104, X'838') Report option in message descriptor not recognized.

RC2136

(2136, X'858') Multiple reason codes returned.

RC2049

(2049, X'801') Message Priority exceeds maximum value supported.

RC2241

(2241, X'8C1') Message group not complete.

RC2242

(2242, X'8C2') Logical message not complete.

If *CMPCOD* is CCFAIL:

RC2001

(2001, X'7D1') Alias base queue not a valid type.

RC2004

(2004, X'7D4') Buffer parameter not valid.

RC2005

(2005, X'7D5') Buffer length parameter not valid.

RC2009

(2009, X'7D9') Connection to queue manager lost.

- RC2013**
(2013, X'7DD') Expiry time not valid.
- RC2014**
(2014, X'7DE') Feedback code not valid.
- RC2017**
(2017, X'7E1') No more handles available.
- RC2018**
(2018, X'7E2') Connection handle not valid.
- RC2024**
(2024, X'7E8') No more messages can be handled within current unit of work.
- RC2026**
(2026, X'7EA') Message descriptor not valid.
- RC2027**
(2027, X'7EB') Missing reply-to queue.
- RC2029**
(2029, X'7ED') Message type in message descriptor not valid.
- RC2030**
(2030, X'7EE') Message length greater than maximum for queue.
- RC2031**
(2031, X'7EF') Message length greater than maximum for queue manager.
- RC2035**
(2035, X'7F3') Not authorized for access.
- RC2042**
(2042, X'7FA') Object already open with conflicting options.
- RC2043**
(2043, X'7FB') Object type not valid.
- RC2044**
(2044, X'7FC') Object descriptor structure not valid.
- RC2046**
(2046, X'7FE') Options not valid or not consistent.
- RC2047**
(2047, X'7FF') Persistence not valid.
- RC2048**
(2048, X'800') Queue does not support persistent messages.
- RC2050**
(2050, X'802') Message priority not valid.
- RC2051**
(2051, X'803') Put calls inhibited for the queue.
- RC2052**
(2052, X'804') Queue has been deleted.
- RC2053**
(2053, X'805') Queue already contains maximum number of messages.
- RC2056**
(2056, X'808') No space available on disk for queue.
- RC2057**
(2057, X'809') Queue type not valid.
- RC2058**
(2058, X'80A') Queue manager name not valid or not known.
- RC2059**
(2059, X'80B') Queue manager not available for connection.

RC2061
(2061, X'80D') Report options in message descriptor not valid.

RC2063
(2063, X'80F') Security error occurred.

RC2071
(2071, X'817') Insufficient storage available.

RC2072
(2072, X'818') Syncpoint support not available.

RC2082
(2082, X'822') Unknown alias base queue.

RC2085
(2085, X'825') Unknown object name.

RC2086
(2086, X'826') Unknown object queue manager.

RC2087
(2087, X'827') Unknown remote queue manager.

RC2091
(2091, X'82B') Transmission queue not local.

RC2092
(2092, X'82C') Transmission queue with wrong usage.

RC2097
(2097, X'831') Queue handle referred to does not save context.

RC2098
(2098, X'832') Context not available for queue handle referred to.

RC2101
(2101, X'835') Object damaged.

RC2102
(2102, X'836') Insufficient system resources available.

RC2135
(2135, X'857') Distribution header structure not valid.

RC2136
(2136, X'858') Multiple reason codes returned.

RC2149
(2149, X'865') PCF structures not valid.

RC2154
(2154, X'86A') Number of records present not valid.

RC2155
(2155, X'86B') Object records not valid.

RC2156
(2156, X'86C') Response records not valid.

RC2158
(2158, X'86E') Put message record flags not valid.

RC2159
(2159, X'86F') Put message records not valid.

RC2161
(2161, X'871') Queue manager quiescing.

RC2162
(2162, X'872') Queue manager shutting down.

RC2173
(2173, X'87D') Put-message options structure not valid.

RC2184

(2184, X'888') Remote queue name not valid.

RC2188

(2188, X'88C') Call rejected by cluster workload exit.

RC2189

(2189, X'88D') Cluster name resolution failed.

RC2195

(2195, X'893') Unexpected error occurred.

RC2196

(2196, X'894') Unknown transmission queue.

RC2197

(2197, X'895') Unknown default transmission queue.

RC2198

(2198, X'896') Default transmission queue not local.

RC2199

(2199, X'897') Default transmission queue usage error.

RC2258

(2258, X'8D2') Group identifier not valid.

RC2248

(2248, X'8C8') Message descriptor extension not valid.

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2249

(2249, X'8C9') Message flags not valid.

RC2250

(2250, X'8CA') Message sequence number not valid.

RC2251

(2251, X'8CB') Message segment offset not valid.

RC2252

(2252, X'8CC') Original length not valid.

RC2253

(2253, X'8CD') Length of data in message segment is zero.

RC2255

(2255, X'8CF') Unit of work not available for the queue manager to use.

RC2257

(2257, X'8D1') Wrong version of MQMD supplied.

RC2266

(2266, X'8DA') Cluster workload exit failed.

RC2269

(2269, X'8DD') Cluster resource error.

RC2270

(2270, X'8DE') No destination queues available.

RC2420

(2420) An MQPUT1 call was issued, but the message data contains an MQEPH structure that is not valid.

RC2551

(2551, X'9F7') Specified selection string is not available.

RC2554

(2554, X'9FA') Message content could not be parsed to determine whether the message should be delivered to a subscriber with an extended message selector.

RPG Declaration

```
C*.1.....2.....3.....4.....5.....6.....7..  
C          CALLP      MQPUT1(HCONN : OBJDSC : MSGDSC :

MQSET - Set object attributes

The MQSET call is used to change the attributes of an object represented by a handle. The object must be a queue.

- [“Syntax” on page 1305](#)
- [“Usage notes” on page 1305](#)
- [“Parameters” on page 1306](#)
- [“RPG Declaration” on page 1309](#)

Syntax

MQSET (*HCONN*, *HOBJ*, *SELCNT*, *SELS*, *IACNT*, *INTATR*, *CALEN*, *CHRATR*, *CMPCOD*, *REASON*)

Usage notes

1. Using this call, the application can specify an array of integer attributes, or a collection of character attribute strings, or both. If no errors occur, the attributes specified are all set simultaneously. If an error occurs (for example, if a selector is not valid, or an attempt is made to set an attribute to a value that is not valid), the call fails and no attributes are set.
2. The values of attributes can be determined using the MQINQ call ; see [“MQINQ - Inquire about object attributes” on page 1261](#) for details.
Note: Not all attributes with values that can be inquired upon using the MQINQ call can have their values changed using the MQSET call. For example, no process-object or queue manager attributes can be set with this call.
3. Attribute changes are preserved across restarts of the queue manager (other than alterations to temporary dynamic queues, which do not survive restarts of the queue manager).
4. You cannot change the attributes of a model queue using the MQSET call. However, if you open a model queue using the MQOPEN call with the MQOO_SET option, you can use the MQSET call to set the attributes of the dynamic local queue that is created by the MQOPEN call.
5. If the object being set is a cluster queue, there must be a local instance of the cluster queue for the open to succeed.

IBM i For more information about object attributes, see:

- “Attributes for queues” on page 1324
- “Attributes for namelists” on page 1352
- “Attributes for process definitions” on page 1353
- “Attributes for the queue manager” on page 1355

Parameters

The MQSET call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important: **IBM i** If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HOBJ (10-digit signed integer) - input

Object handle.

This handle represents the queue object with attributes that are to be set. The handle was returned by a previous MQOPEN call that specified the OOSSET option.

SELCNT (10-digit signed integer) - input

Count of selectors.

This is the count of selectors that are supplied in the *SELS* array. It is the number of attributes that are to be set. Zero is a valid value. The maximum number allowed is 256.

SELS (10-digit signed integer x SELCNT) - input

Array of attribute selectors.

This is an array of *SELCNT* attribute selectors; each selector identifies an attribute (integer or character) with a value that is to be set.

Each selector must be valid for the type of queue that *HOBJ* represents. Only certain IA* and CA* values are allowed; these values are listed later in this section.

Selectors can be specified in any order. Attribute values that correspond to integer attribute selectors (IA* selectors) must be specified in *INTATR* in the same order in which these selectors occur in *SELS*. Attribute values that correspond to character attribute selectors (CA* selectors) must be specified in *CHRATR* in the same order in which those selectors occur. IA* selectors can be interleaved with the CA* selectors; only the relative order within each type is important.

It is not an error to specify the same selector more than once; if this is done, the last value specified for a particular selector is the one that takes effect.

Note:

1. The integer and character attribute selectors are allocated within two different ranges; the IA* selectors reside within the range IAFRST through IALAST, and the CA* selectors within the range CAFRST through CALAST.

For each range, the constants IALSTU and CALSTU define the highest value that the queue manager will accept.

2. If all the IA* selectors occur first, the same element numbers can be used to address corresponding elements in the *SELS* and *INTATR* arrays.

The attributes that can be set are listed in the following table. No other attributes can be set using this call. For the CA* attribute selectors, the constant that defines the length in bytes of the string that is required in *CHRATR* is provided in parentheses.

Table 625. MQSET attribute selectors for queues		
Selector	Description	Note
CATRGD	Trigger data (LNTRGD).	“2” on page 1307
IADIST	Distribution list support.	“1” on page 1307
IAIGET	Whether get operations are allowed.	
IAIPUT	Whether put operations are allowed.	
IATRGC	Trigger control.	“2” on page 1307
IATRGD	Trigger depth.	“2” on page 1307
IATRGP	Threshold message priority for triggers.	“2” on page 1307
IATRGT	Trigger type.	“2” on page 1307

Notes:

1. Supported only on AIX, HP-UX, IBM i, Solaris, Windows, plus IBM MQ clients connected to these systems.
2. Not supported on VSE/ESA.

IACNT (10-digit signed integer) - input

Count of integer attributes.

This is the number of elements in the *INTATR* array, and must be at least the number of IA* selectors in the *SELS* parameter. Zero is a valid value if there are none.

INTATR (10-digit signed integer x IACNT) - input

Array of integer attributes.

This is an array of *IACNT* integer attribute values. These attribute values must be in the same order as the IA* selectors in the *SELS* array.

CALEN (10-digit signed integer) - input

Length of character attributes buffer.

This is the length in bytes of the *CHRATR* parameter, and must be at least the sum of the lengths of the character attributes specified in the *SELS* array. Zero is a valid value if there are no CA* selectors in *SELS*.

CHRATR (1-byte character string x CALEN) - input

Character attributes.

This is the buffer containing the character attribute values, concatenated together. The length of the buffer is given by the *CALEN* parameter.

The characters attributes must be specified in the same order as the CA* selectors in the *SELS* array. The length of each character attribute is fixed (see *SELS*). If the value to be set for an attribute contains fewer nonblank characters than the defined length of the attribute, the value in *CHRATR* must be padded to the right with blanks to make the attribute value match the defined length of the attribute.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2219

(2219, X'8AB') MQI call reentered before previous call complete.

RC2006

(2006, X'7D6') Length of character attributes not valid.

RC2007

(2007, X'7D7') Character attributes string not valid.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2019

(2019, X'7E3') Object handle not valid.

RC2020

(2020, X'7E4') Value for inhibit-get or inhibit-put queue attribute not valid.

RC2021

(2021, X'7E5') Count of integer attributes not valid.

RC2023

(2023, X'7E7') Integer attributes array not valid.

RC2040

(2040, X'7F8') Queue not open for set.

RC2041

(2041, X'7F9') Object definition changed since opened.

RC2101

(2101, X'835') Object damaged.

RC2052

(2052, X'804') Queue has been deleted.

RC2058

(2058, X'80A') Queue manager name not valid or not known.

RC2059

(2059, X'80B') Queue manager not available for connection.

RC2162

(2162, X'872') Queue manager shutting down.

RC2102

(2102, X'836') Insufficient system resources available.

RC2065

(2065, X'811') Count of selectors not valid.

RC2067

(2067, X'813') Attribute selector not valid.

RC2066

(2066, X'812') Count of selectors too large.

RC2071

(2071, X'817') Insufficient storage available.

RC2075

(2075, X'81B') Value for trigger-control attribute not valid.

RC2076

(2076, X'81C') Value for trigger-depth attribute not valid.

RC2077

(2077, X'81D') Value for trigger-message-priority attribute not valid.

RC2078

(2078, X'81E') Value for trigger-type attribute not valid.

RC2195

(2195, X'893') Unexpected error occurred.

RPG Declaration

```

C*..1.....2.....3.....4.....5.....6.....7..

```

MQSETMP - Set message handle property

The MQSETMP call sets or modifies a property of a message handle.

- [“Syntax” on page 1310](#)
- [“Usage notes” on page 1310](#)
- [“Parameters” on page 1311](#)
- [“RPG Declaration” on page 1314](#)

Syntax

MQSETMP (*Hconn*, *Hmsg*, *SetPropOpts*, *Name*, *PropDesc*, *Type*, *ValueLength*, *Value*, *CompCode*, *Reason*)

Usage notes

- You can use this call only when the queue manager itself coordinates the unit of work. This can be:
 - A local unit of work, where the changes affect only IBM MQ resources.
 - A global unit of work, where the changes can affect resources belonging to other resource managers, as well as affecting IBM MQ resources.

For further details about local and global units of work, see [“MQBEGIN - Begin unit of work” on page 1209](#).

- In environments where the queue manager does not coordinate the unit of work, use the appropriate back-out call instead of MQBACK. The environment might also support an implicit back out caused by the application terminating abnormally.
 - On z/OS, use the following calls:
 - Batch programs (including IMS batch DL/I programs) can use the MQBACK call if the unit of work affects only IBM MQ resources. However, if the unit of work affects both IBM MQ resources and resources belonging to other resource managers (for example, Db2), use the SRRBACK call provided by the z/OS Recoverable Resource Service (RRS). The SRRBACK call backs out changes to resources belonging to the resource managers that have been enabled for RRS coordination.
 - CICS applications must use the EXEC CICS SYNCPOINT ROLLBACK command to back out the unit of work. Do not use the MQBACK call for CICS applications.
 - IMS applications (other than batch DL/I programs) must use IMS calls such as ROLB to back out the unit of work. Do not use the MQBACK call for IMS applications (other than batch DL/I programs).
 - On IBM i, use this call for local units of work coordinated by the queue manager. This means that a commitment definition must not exist at job level, that is, the STRCMTCTL command with the CMTSCOPE(*JOB) parameter must not have been issued for the job.
- If an application ends with uncommitted changes in a unit of work, the disposition of those changes depends on whether the application ends normally or abnormally. See the usage notes in [“MQDISC - Disconnect queue manager” on page 1246](#) for further details.
- When an application puts or gets messages in groups or segments of logical messages, the queue manager retains information relating to the message group and logical message for the last successful MQPUT and MQGET calls. This information is associated with the queue handle, and includes such things as:
 - The values of the *GroupId*, *MsgSeqNumber*, *Offset*, and *MsgFlags* fields in MQMD.
 - Whether the message is part of a unit of work.
 - For the MQPUT call: whether the message is persistent or nonpersistent.

The queue manager keeps three sets of group and segment information, one set for each of the following:

- The last successful MQPUT call (this can be part of a unit of work).
- The last successful MQGET call that removed a message from the queue (this can be part of a unit of work).
- The last successful MQGET call that browsed a message on the queue (this cannot be part of a unit of work).

If the application puts or gets the messages as part of a unit of work, and the application then decides to back out the unit of work, the group and segment information is restored to the value that it had previously:

- The information associated with the MQPUT call is restored to the value that it had before the first successful MQPUT call for that queue handle in the current unit of work.
- The information associated with the MQGET call is restored to the value that it had before the first successful MQGET call for that queue handle in the current unit of work.

Queues that were updated by the application after the unit of work started, but outside the scope of the unit of work, do not have their group and segment information restored if the unit of work is backed out.

Restoring the group and segment information to its previous value when a unit of work is backed out allows the application to spread a large message group or large logical message consisting of many segments across several units of work, and to restart at the correct point in the message group or logical message if one of the units of work fails.

Using several units of work might be advantageous if the local queue manager has only limited queue storage. However, the application must maintain sufficient information to be able to restart putting or getting messages at the correct point if a system failure occurs.

For details of how to restart at the correct point after a system failure, see the PMLOGO option described in [PMOPT \(10 digit signed integer\)](#), and the GMLOGO option described in [GMOPT \(10 digit signed integer\)](#).

The remaining usage notes apply only when the queue manager coordinates the units of work:

- A unit of work has the same scope as a connection handle. All IBM MQ calls that affect a particular unit of work must be performed using the same connection handle. Calls issued using a different connection handle (for example, calls issued by another application) affect a different unit of work. See [HCONN \(10-digit signed integer\) - output](#) for information about the scope of connection handles.
- Only messages that were put or retrieved as part of the current unit of work are affected by this call.
- A long-running application that issues MQGET, MQPUT, or MQPUT1 calls within a unit of work, but that never issues a commit or backout call, can fill queues with messages that are not available to other applications. To guard against this possibility, the administrator must set the *MaxUncommittedMsgs* queue-manager attribute to a value that is low enough to prevent runaway applications filling the queues, but high enough to allow the expected messaging applications to work correctly.

Parameters

The MQSETMP call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager.

The value must match the connection handle that was used to create the message handle specified in the *HMSG* parameter.

If the message handle was created using HCUNAS, a valid connection must be established on the thread setting a property of the message handle, otherwise the call fails with reason code RC2009 .

HMSG (20-digit signed integer) - input

This is the message handle to be modified. The value was returned by a previous MQCRTMH call.

SETOPT (MQSMPO) - input

Control how message properties are set.

This structure allows applications to specify options that control how message properties are set. The structure is an input parameter on the MQSETMP call. See [MQSMPO](#) for further information.

PRNAME (MQCHARV) - input

This is the name of the property to set.

See [Property names](#) and [Property name restrictions](#) for further information about the use of property names.

PRPDSC (MQPD) - input/output

This structure is used to define the attributes of a property, including:

- what happens if the property is not supported
- what message context the property belongs to
- what messages the property is copied into as it flows

See [MQPD](#) for further information about this structure.

TYPE (10 digit signed integer) - input

The data type of the property being set. It can be one of the following:

TYPBOL

A boolean. *ValueLength* must be 4.

TYPBST

A byte string. *ValueLength* must be zero or greater.

TYPI8

An 8 bit signed integer. *ValueLength* must be 1.

TYPI16

A 16 bit signed integer. *ValueLength* must be 2.

TYPI32

A 32 bit signed integer. *ValueLength* must be 4.

TYPI64

A 64 bit signed integer. *ValueLength* must be 8.

TYPF32

A 32 bit floating-point number. *ValueLength* must be 4.

TYPF64

A 64 bit floating-point number. *ValueLength* must be 8.

TYPSTR

A character string. *ValueLength* must be zero or greater, or the special value VLNULL.

TYPNUL

The property exists but has a null value. *ValueLength* must be zero.

VALLEN (10-digit signed integer) - input

The length in bytes of the property value in the *Value* parameter.

Zero is valid only for null values or for strings or byte strings. Zero indicates that the property exists but that the value contains no characters or bytes.

The value must be greater than or equal to zero or the following special value if the *Type* parameter has TYPSTR set:

VLNULL

The value is delimited by the first null encountered in the string. The null is not included as part of the string. This value is invalid if TYPSTR is not also set.

Note: The null character used to terminate a string if VLNULL is set is a null from the character set of the Value.

VALUE (1-byte bit string x VALLEN) - input

The value of the property to be set. The buffer must be aligned on a boundary appropriate to the nature of the data in the value.

In the C programming language, the parameter is declared as a pointer-to-void; the address of any type of data can be specified as the parameter.

If *ValueLength* is zero, *Value* is not referred to. In this case, the parameter address passed by programs written in C or System/390 assembler can be null.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2421

(2421, X'0975') An MQRFH2 folder containing properties could not be parsed.

If *CMPCOD* is CCFAIL:

RC2204

(2204, X'089C') Adapter not available.

RC2130

(2130, X'852') Unable to load adapter service module.

RC2157

(2157, X'86D') Primary and home ASIDs differ.

RC2004

(2004, X'07D4') Value parameter not valid.

RC2005

(2005, X'07D5') Value length parameter not valid.

RC2219

(2219, X'08AB') MQI call entered before previous call completed.

RC2460

(2460, X'099C') Message handle pointer not valid.

RC2499

(2499, X'09C3') Message handle already in use.

RC2046

(2046, X'07FE') Options not valid or not consistent.

RC2482

(2482, X'09B2') Property descriptor structure not valid.

RC2442

(2442, X'098A') Invalid property name.

RC2473

(2473, X'09A9') Invalid property data type.

RC2472

(2472, X'09A8') Number format error encountered in value data.

RC2463

(2463, X'099F') Set message property options structure not valid.

RC2111

(2111, X'083F') Property name coded character set identifier not valid.

RC2071

(2071, X'817') Insufficient storage available.

RC2195

(2195, X'893') Unexpected error occurred.

See [“Return codes for IBM i \(ILE RPG\)” on page 1381](#) for more details.

MQSTAT - Retrieve status information

Use the MQSTAT call to retrieve status information. The type of status information returned is determined by the STYPE value specified on the call.

- [“Syntax” on page 1314](#)
- [“Usage notes” on page 1315](#)
- [“Parameters” on page 1315](#)
- [“RPG Declaration” on page 1316](#)

Syntax

MQSTAT (HCONN, STYPE, STAT, CMPCOD, REASON)

Usage notes

1. A call to MQSTAT specifying a type of STATAPT returns information about previous asynchronous MQPUT and MQPUT1 operations. The MQSTAT structure passed on the call is completed with the first recorded asynchronous warning or error information for that connection. If further errors or warnings follow the first, they do not normally alter these values. However, if an error occurs with a completion code of CCWARN, a subsequent failure with a completion code of CCFAIL is returned instead.
2. If no errors have occurred since the connection was established or since the last call to MQSTAT then a CMPCOD of CCOK and REASON of RCNONE are returned.
3. Counts of the number of asynchronous calls that have been processed under the connection handle are returned by using three counters; STSPSC, STSPWC, and STSPFC. These counters are incremented by the queue manager each time an asynchronous operation is processed successfully, has a warning, or fails (note that for accounting purposes a put to a distribution list counts once per destination queue rather than once per distribution list).
4. A successful call to MQSTAT results in any previous error information or counts being reset.

Parameters

The MQSTAT call has the following parameters:

Hconn (MQHCONN) - input

This handle represents the connection to the queue manager. The value of *Hconn* was returned by a previous MQCONN or MQCONNEX call.

STYPE (10-digit signed integer) - input

Type of status information being requested. The only valid value is:

STATAPT

Return information about previous asynchronous put operations.

STS (MQSTS) - input/output

Status information structure. See [“MQSTS - Status reporting structure” on page 1186](#) for details.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion.

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2374

(2374, X'946') API exit failed

RC2183

(2183, X'887') Unable to load API exit.

RC2219

(2219, X'8AB') MQI call entered before previous call complete.

RC2009

(2009, X'7D9') Connection to queue manager lost.

RC2203

(2203, X'89B') Connection shutting down.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2162

(2162, X'872') Queue manager stopping

RC2102

(2102, X'836') Insufficient system resources available.

RC2430

(2430, X'97E') Error with MQSTAT type.

RC2071

(2071, X'817') Insufficient storage available.

RC2424

(2424, X'978') Error with MQSTS structure

RC2195

(2195, X'893') Unexpected error occurred.

RC2298

(2298, X'8FA') The function requested is not available in the current environment.

MQSUB - Register Subscription

The MQSUB call registers the applications subscription to a particular topic.

- [“Syntax” on page 1316](#)
- [“Usage notes” on page 1317](#)
- [“Parameters” on page 1318](#)
- [“RPG Declaration” on page 1322](#)

Syntax

MQSUB (*HCONN*, *SUBDSC*, *HOBJ*, *HSUB*, *CMPCOD*, *REASON*)

Usage notes

- The subscription is made to a topic, named either using the short name of a pre-defined topic object, the full name of the topic string, or it is formed by the concatenation of two parts, as described in [“Using topic strings”](#) on page 554.
- The queue manager performs security checks when an MQSUB call is issued, to verify that the user identifier under which the application is running has the appropriate level of authority before access is permitted. The appropriate topic object is located either by a short name being provided in the call, or the nearest short name object in the topic hierarchy being found if a long name is provided. An authority check is made on this topic object to ensure authority to subscribe is set and on the destination queue to ensure that authority for output is set. If the SDMAN option is used, this means that an authority check is made on the managed queue name associated with this topic object, and if a non-managed queue is provided, this means that an authority check is made on the queue represented by the *HOBJ* parameter.
- The *HOBJ* returned on the MQSUB call when the SOMAN option is used, can be inquired in order to find out attributes such as the Backout threshold and the Excessive backout requeue name. You can also inquire the name of the managed queue, but you should not attempt to directly open this queue.
- Subscriptions can be grouped allowing only a single publication to be delivered to the group of subscriptions even where more than one of the group matched the publication. Subscriptions are grouped using the SOGRP option and in order to group subscriptions they must:
 - be using the same named queue (that is not using the SOMAN option) on the same queue manager - represented by the *HOBJ* parameter on the MQSUB call
 - share the same *SDCID*
 - be of the same *SDSL*

These attributes define the set of subscriptions considered to be in the group, and are also the attributes that cannot be altered if a subscription is grouped. Alteration of *SDSL* results in RC2512, and alteration of any of the others (which can be changed if a subscription is not grouped) results in RC2515.

- Fields in the MQSD are completed on return from an MQSUB call which uses the SORES option. The MQSD returned can be passed directly into an MQSUB call which uses the SOALT option with any changes you need to make to the subscription applied to the MQSD. Some fields have special considerations as noted in the table.

MQSD output from MQSUB	
Field name in MQSD	Special considerations
Access or creation options	None of these options are set on return from the MQSUB call. If you later reuse the MQSD in an MQSUB call the option you require must be explicitly set.
Durability options, Destination options, Registration Options & Wildcard options	These options will be set as appropriate
Publication options	These options will be set as appropriate, except for SONEWP which is only applicable to SOCRE.
Other options	These options are unchanged on return from an MQSUB call. They control how the API call is issued and are not stored with the subscription. They must be set as required on any subsequent MQSUB call reusing the MQSD.
ObjectName	This input only field is unchanged on return from an MQSUB call.

MQSD output from MQSUB (<i>continued</i>)	
Field name in MQSD	Special considerations
ObjectString	This input only field is unchanged on return from an MQSUB call. The Full topic name used is returned in the <i>SDRO</i> field, if a buffer is provided.
AlternateUserId and AlternateSecurityId	These input only fields are unchanged on return from an MQSUB call. They control how the API call is issued and are not stored with the subscription. They must set as required on any subsequent MQSUB call reusing the MQSD.
SubExpiry	On return from an MQSUB call using the SORES option this field will be set to the original expiry of the subscription and not the remaining expiry time. If you then reuse the MQSD in an MQSUB call using the SOALT option you will reset the expiry of the subscription to start counting down again.
SubName	This field is an input field on an MQSUB call and is not changed on output.
SubUserData and SelectionString	<p>These variable length fields will be returned on output from an MQSUB call using the SORES option, if a buffer is provided, and also a positive buffer length in <i>VCHRP</i>. If no buffer is provided only the length will be returned in the <i>VCHRL</i> field of the MQCHARV. If the buffer provided is smaller than the space required to return the field, only <i>VCHRP</i> bytes are returned in the provided buffer.</p> <p>If you later reuse the MQSD in an MQSUB call using the SOALT option and a buffer is not provided but a non-zero <i>VCHRL</i> is provided, if that length matches the existing length of the field, no alteration will made to the field.</p>
SubCorrelId and PubAccountingToken	<p>If you do not use SOSCID, then the <i>SDCID</i> will be generated by the queue manager. If you do not use SOSETI, then the <i>SDACC</i> will be generated by the queue manager.</p> <p>These fields will be returned in the MQSD from an MQSUB call using the SORES option. If they are generated by the queue manager, the generated value will be returned on an MQSUB call using the SOCRE or SOALT option.</p>
PubPriority, SubLevel & PubApplIdentityData	These fields will be returned in the MQSD.
ResObjectString	This output only field will be returned in the MQSD if a buffer is provided.

Parameters

The MQSUB call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

SUBDSC (MQSD) - input/output

This is a structure that identifies the object with use that is being registered by the application. See [“MQSD - Subscription descriptor” on page 1169](#) for more information.

HOBJ (10-digit signed integer) - input/output

This handle represents the access that has been established to obtain the messages sent to this subscription. These messages can either be stored on a specific queue or the queue manager can be asked to manage their storage without the need for a specific queue.

Object handle.

If a specific queue is to be used it must be associated with the subscription at creation time. This can be done in two ways:

- By providing this handle when calling MQSUB with the SDCRT option. If this handle is provided as an input parameter on the call, it must be a valid object handle returned from a previous MQOPEN call of a queue using at least one of OOINP*, OOOOUT (if a remote queue for example), or OOBRW option. If this is not the case, the call fails with RC2019. It cannot be an object handle to an alias queue which resolves to a topic object. If so, the call fails with RC2019
- By using the DEFINE SUB MQSC command and provided that command with the name of a queue object.

If the queue manager is to manage the storage of messages sent to this subscription, you should indicate this when the subscription is created, by using the SOMAN option and setting the parameter value to HONONE. The queue manager returns the handle as an output parameter on the call, and the handle that is returned is known as a managed handle. If HONONE is specified and SOMAN is not also specified, the call fails with RC2019.

A managed handle that is returned by the queue manager can be used on an MQGET or MQCB call, with or without browse options, on an MQINQ call, or on MQCLOSE. It cannot be used on MQPUT, MQSET, or on a subsequent MQSUB; attempting to do so fails with RC2039 for MQPUT, RC2040 for MQSET, or RC2038 for MQSUB.

If the SORES option in the *OPTS* field in the MQSD structure is used to resume this subscription, the handle can be returned to the application in this parameter if HONONE is specified. You can use this whether the subscription is using a managed handle or not. It can be useful for subscriptions created using DEFINE SUB if you want the handle to the subscription queue defined on the DEFINE SUB command. In the case where an administratively created subscription is being resumed, the queue is opened with OOINPQ and OOBRW. If other options are needed, the application must open the subscription queue explicitly and provide the object handle on the call. If there is a problem opening the queue the call will fail with RC2522. If the *HOBJ* is provided, it must be equivalent to the *HOBJ* in the original MQSUB call. This means if an object handle returned from an MQOPEN call is being provided, the handle must be to the same queue as previously used or the call fails with RC2019.

If this subscription is being altered, by using the SOALT option in the *OPTS* field in the MQSD structure, then a different *HOBJ* can be provided. Any publications that have been delivered to the queue

previously identified through this parameter remain on that queue and it is the responsibility of the application to retrieve those messages if the *HOBJ* parameter now represents a different queue.

The use of this parameter with various subscription options is summarized in the following table:

Options	Hobj	Description
SOCRT + SOMAN	Ignored on input	Creates a subscription with queue manager managed storage of messages.
SOCRT	Valid object handle	Creates a subscription providing a specific queue as the destination for messages.
SORES	HONONE	Resumes a previously created subscription (managed or not) and have the queue manager return the object handle for use by the application.
SORES	Valid, matching, object handle	Resumes a previously created subscription which uses a specific queue as the destination for messages and use an object handle with specific open options.
SOALT + SOMAN	HONONE	Alters an existing subscription which was previously using a specific queue, to now be managed.
SOALT	Valid object handle	Alters an existing subscription to use a specific queue (either from managed, or from a different specific queue).

Whether it was provided or returned, *HOBJ* must be specified on subsequent MQGET calls that you need to receive the publications.

The *HOBJ* handle ceases to be valid when the MQCLOSE call is issued on it, or when the unit of processing that defines the scope of the handle terminates. The scope of the object handle returned is the same as that of the connection handle specified on the call. See [HCONN](#) for information about handle scope. An MQCLOSE of the *HOBJ* handle has no effect on the *HSUB* handle.

HSUB (10-digit signed integer) - output

This handle represents the subscription that has been made. It can be used for two further operations:

- It can be used on a subsequent MQSUBRQ call to request that publications be sent when the SOPUBR option has been used when making the subscription.
- It can be used on a subsequent MQCLOSE call to remove the subscription that has been made. The *HSUB* handle ceases to be valid when the MQCLOSE call is issued, or when the unit of processing that defines the scope of the handle terminates. The scope of the object handle returned is the same as that of the connection handle specified on the call. An MQCLOSE of the *HSUB* handle has no effect on the *HOBJ* handle.

This handle cannot be passed to an MQGET or MQCB call. You must use the *HOBJ* parameter. Passing this handle to any other IBM MQ call results in RC2019.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion

CCWARN

Warning (partial completion)

CCFAIL

Call failed

REASON (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCFAIL:

RC2019

(2019 X'07E3') Object handle not valid

RC2046

(2046 X'07FE') Options not valid or not consistent

RC2085

(2085 X'0825') Object identified cannot be found

RC2161

(2161 X'0871') Queue manager quiescing

RC2298

(2298 X'08FA') Function not supported.

RC2424

(2424 X'0978') Subscription descriptor (MQSD) not valid

RC2425

(2441 X'979') Topic string not valid

RC2428

(2428 X'097C') Subscription name specified does not match existing subscriptions

RC2429

(2429 X'097D') Subscription name exists and is in use by another application

RC2431

(2431 X'097F') SubUserData field not valid

RC2432

(2432 X'0980') Subscription exists

RC2434

(2434 X'0982') Subscription name matches existing subscription

RC2440

(2440 X'0988') SubName field not valid

RC2441

(2441 X'0989') Objectstring field not valid

RC2435

(2435 X'0983') Attribute cannot be changed using SDALT, or subscription was created with SDIMM.

RC2436

(2436 X'0984') SODUR option not valid

RC2459

(2459, X'99B') Selection string syntax error.

RC2503

(2503 X'09C7') MQSUB calls are currently inhibited for the topics subscribed to.

RC2519

(2519, X'9D7') The selection string is not as specified in the description of how to use an MQCHARV structure.

RC2551

(2551, X'9F7') Specified selection string is not available.

RPG Declaration

```

C*.1.....2.....3.....4.....5.....6.....7..
C                                CALLP      MQSUB(HCONN : SUBDSC : HOBJ :
C                                HSUB : CMPCOD : REASON)

```

The prototype definition for the call is:

```

```

MQSUBRQ - Subscription Request

The MQSUBRQ call makes a request on a subscription.

- [“Syntax” on page 1322](#)
- [“Usage notes” on page 1322](#)
- [“Parameters” on page 1323](#)
- [“RPG Declaration” on page 1324](#)

Syntax

MQSUBRQ (*HCONN*, *HSUB*, *ACTION*, *SUBROPT*, *CMPCOD*, *REASON*)

Usage notes

The following usage notes apply to the use of SRAPUB:

1. If this verb completes successfully, the retained publications matching the subscription specified have been sent to the subscription and can be received by using MQGET or MQCB using the HOBJ returned on the original MQSUB verb that created the subscription.
2. If the topic subscribed to by the original MQSUB verb that created the subscription contained a wildcard, more than one retained publication might be sent. The number of publications sent as a result of this call is recorded in the *SRNMP* field in the *SBROPT* structure.
3. If this verb completes with a reason code of RC2437 then there were no currently retained publications for the topic specified.

4. If this verb completes with a reason code of RC2525 or RC2526 then there are currently retained publications for the topic specified but an error has occurred that that meant they were unable to be delivered.
5. The application must have a current subscription to the topic before it can make this call. If the subscription was made in a previous instance of the application and a valid handle to the subscription is not available, the application must first call MQSUB with the SORES option to obtain a handle to it for use in this call.
6. The publications are sent to the destination that is registered for use with the current subscription of this application. If the publications should be sent somewhere else, the subscription must first be altered using the MQSUB call with the SOALT option.

Parameters

The MQSUBRQ call has the following parameters:

HCONN (10-digit signed integer) - input

This handle represents the connection to the queue manager. The value of *HCONN* was returned by a previous MQCONN or MQCONNEX call.

On z/OS for CICS applications, and on IBM i for applications running in compatibility mode, the MQCONN call can be omitted, and the following value specified for *HCONN* :

HCDEFH

Default connection handle.

Important:  If you are still using compatibility mode, consider recompiling your application and using static bound calls instead. See [Compatibility mode for RPG applications on IBM i](#)

HSUB (10-digit signed integer) - input

This handle represents the subscription for which an update is to be requested. The value of *HSUB* was returned from a previous MQSUB call.

ACTION (10-digit signed integer) - input

This parameter controls the particular action that is being requested on the subscription. One (and only one) of the following must be specified:

SRAPUB

This action requests that an update publication be sent for the specified topic. This is normally used if the subscriber specified the option SOPUBR on the MQSUB call when it made the subscription. If the queue manager has a retained publication for the topic, this is sent to the subscriber. If not, the call fails. If an application is sent a publication which was retained, this is indicated by the MQIsRetained message property of that publication.

Since the topic in the existing subscription represented by the *HSUB* parameter can contain wildcards, the subscriber might receive multiple retained publications.

SBROPT (MQSRO) - input/output

These options control the action of MQSUBRQ, see [“MQSRO - Subscription request options” on page 562](#) for details.

CMPCOD (10-digit signed integer) - output

The completion code; it is one of the following:

CCOK

Successful completion

CCWARN

Warning (partial completion)

CCFAIL

Call failed

Reason (10-digit signed integer) - output

The reason code qualifying *CMPCOD*.

If *CPMCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CPMCOD* is CCFAIL:

RC2298

2298 (X'08FA') The function requested is not available in the current environment.

RC2437

2437 (X'0985') There are no retained publications currently stored for this topic.

RC2046

2046 (X'07FE') Options parameter or field contains options that are not valid, or a combination of options that is not valid.

RC2161

2161 (X'0871') Queue manager quiescing

RC2438

2438 (X'0986') On the MQSUBRQ call, the Subscription Request Options MQSRO is not valid.

RPG Declaration

```
C*.1.....2.....3.....4.....5.....6.....7..
C          CALLP      MQSUBRQ(HCONN : HSUB : ACTION :
C                               SBROPT : CMPCOD : REASON)
```

The prototype definition for the call is:

```

```

Attributes of objects

This collection of topics lists only those IBM MQ objects that can be the subject of an MQINQ function call, and gives details of the attributes that can be inquired on and the selectors to be used.

Attributes for queues

Use this information to learn about the different types of queue definitions and the attributes supported by each.

Types of queue: The queue manager supports the following types of queue definition:

Local queue

This is a physical queue that stores messages. The queue exists on the local queue manager.

Applications connected to the local queue manager can place messages on and remove messages from queues of this type. The value of the *QType* queue attribute is QTLOC.

Shared queue

This is a physical queue that stores messages. The queue exists in a shared repository that is accessible to all of the queue managers that belong to the queue-sharing group that owns the shared repository.

Applications connected to any queue manager in the queue-sharing group can place messages on and remove messages from queues of this type. Such queues are effectively the same as local queues. The value of the *QType* queue attribute is QTLOC.

- Shared queues are supported only on z/OS.

Cluster queue

This is a physical queue that stores messages. The queue exists either on the local queue manager, or on one or more of the queue managers that belong to the same cluster as the local queue manager.

Applications connected to the local queue manager can place messages on queues of this type, regardless of the location of the queue. If an instance of the queue exists on the local queue manager, the queue behaves in the same way as a local queue, and applications connected to the local queue manager can remove messages from the queue. The value of the *QType* queue attribute is QTCLUS.

Alias queue

This is not a physical queue - it is an alternative name for a local queue. The name of the local queue to which the alias resolves is part of the definition of the alias queue.

Applications connected to the local queue manager can place messages on and remove messages from alias queues - the messages are placed on and removed from the local queue to which the alias resolves. The value of the *QType* queue attribute is QTALS.

Remote queue

This is not a physical queue - it is the local definition of a queue that exists on a remote queue manager. The local definition of the remote queue contains information that tells the local queue manager how to route messages to the remote queue manager.

Applications connected to the local queue manager can place messages on remote queues - the messages are placed on the local transmission queue used to route messages to the remote queue manager. Applications cannot remove messages from remote queues. The value of the *QType* queue attribute is QTREM.

A remote queue definition can also be used for:

- Reply-queue aliasing

In this case the name of the definition is the name of a reply-to queue. For more information, see [Reply-to queue alias definitions](#).

- Queue-manager aliasing

In this case the name of the definition is an alias for a queue manager, and not the name of a queue. For more information, see [Queue manager alias definitions](#).

Model queue

This is not a physical queue - it is a set of queue attributes from which a local queue can be created.

Messages cannot be stored on queues of this type.

Some queue attributes apply to all types of queue; other queue attributes apply only to certain types of queue. The types of queue to which an attribute applies are indicated by the ✓ symbol in [Table 626 on page 1326](#) and subsequent tables.

[Table 626 on page 1326](#) summarizes the attributes that are specific to queues. The attributes are described in alphabetical order.

Note: The names of the attributes shown in this section are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [Script \(MQSC\) Commands](#) for details.

Table 626. Attributes for queues. The columns apply as follows:

- The column for local queues applies also to shared queues.
- The column for model queues indicates which attributes are inherited by the local queue created from the model queue.
- The column for cluster queues indicates the attributes that can be inquired when the cluster queue is opened for inquire alone, or for inquire and output. If the cluster queue is opened for inquire plus one or more of input, browse, or set, the column for local queues applies instead.

Attribute	Description	Local	Model	Alias	Remote	Cluster
AlterationDate	Date when definition was last changed	✓		✓	✓	
AlterationTime	Time when definition was last changed	✓		✓	✓	
BackoutRequeueQName	Excessive backout requeue queue name	✓	✓			
BackoutThreshold	Backout threshold	✓	✓			
BaseQName	Queue name to which alias resolves			✓		
ClusterChannelName	Cluster-sender channel name	✓	✓			
ClusterName	Name of cluster to which queue belongs	✓		✓	✓	
ClusterNamelist	Name of namelist object containing names of clusters to which queue belongs	✓		✓	✓	
CreationDate	Date the queue was created	✓				
CreationTime	Time the queue was created	✓				
CurrentQDepth	Current queue depth	✓				
DefBind	Default binding	✓		✓	✓	✓
DefinitionType	Queue definition type	✓	✓			
DefInputOpenOption	Default input open option	✓	✓			
DefPersistence	Default message persistence	✓	✓	✓	✓	✓
DefPriority	Default message priority	✓	✓	✓	✓	✓
DistLists	Distribution list support	✓	✓			

Table 626. Attributes for queues. The columns apply as follows:

- The column for local queues applies also to shared queues.
- The column for model queues indicates which attributes are inherited by the local queue created from the model queue.
- The column for cluster queues indicates the attributes that can be inquired when the cluster queue is opened for inquire alone, or for inquire and output. If the cluster queue is opened for inquire plus one or more of input, browse, or set, the column for local queues applies instead.

(continued)

Attribute	Description	Local	Model	Alias	Remote	Cluster
HardenGetBackout	Whether to maintain an accurate backout count	✓	✓			
InhibitGet	Controls whether get operations for the queue are allowed	✓	✓	✓		
InhibitPut	Controls whether put operations for the queue are allowed	✓	✓	✓	✓	✓
InitiationQName	Name of initiation queue	✓	✓			
MaxMsgLength	Maximum message length in bytes	✓	✓			
MaxQDepth	Maximum queue depth	✓	✓			
MediaLog	Identity of oldest log extent (or oldest journal receiver on IBM i) needed for media recovery of a specified queue	✓	✓			
MsgDeliverySequence	Message delivery sequence	✓	✓			
OpenInputCount	Number of opens for input	✓				
OpenOutputCount	Number of opens for output	✓				
ProcessName	Process name	✓	✓			
QDepthHighEvent	Controls whether Queue Depth High events are generated	✓	✓			
QDepthHighLimit	High limit for queue depth	✓	✓			
QDepthLowEvent	Controls whether Queue Depth Low events are generated	✓	✓			

Table 626. Attributes for queues. The columns apply as follows:

- The column for local queues applies also to shared queues.
- The column for model queues indicates which attributes are inherited by the local queue created from the model queue.
- The column for cluster queues indicates the attributes that can be inquired when the cluster queue is opened for inquire alone, or for inquire and output. If the cluster queue is opened for inquire plus one or more of input, browse, or set, the column for local queues applies instead.

(continued)

Attribute	Description	Local	Model	Alias	Remote	Cluster
QDepthLowLimit	Low limit for queue depth	✓	✓			
QDepthMaxEvent	Controls whether Queue Full events are generated	✓	✓			
QDesc	Queue description	✓	✓	✓	✓	✓
QName	Queue name	✓		✓	✓	✓
QServiceInterval	Target for queue service interval	✓	✓			
QServiceIntervalEvent	Controls whether Service Interval High or Service Interval OK events are generated	✓	✓			
QType	Queue type	✓		✓	✓	✓
RemoteQMgrName	Name of remote queue manager				✓	
RemoteQName	Name of remote queue				✓	
RetentionInterval	Retention interval	✓	✓			
Scope	Controls whether an entry for the queue also exists in a cell directory	✓		✓	✓	
Shareability	Queue shareability	✓	✓			
TriggerControl	Trigger control	✓	✓			
TriggerData	Trigger data	✓	✓			
TriggerDepth	Trigger depth	✓	✓			
TriggerMsgPriority	Threshold message priority for triggers	✓	✓			
TriggerType	Trigger type	✓	✓			
Usage	Queue usage	✓	✓			

Table 626. Attributes for queues. The columns apply as follows:

- The column for local queues applies also to shared queues.
- The column for model queues indicates which attributes are inherited by the local queue created from the model queue.
- The column for cluster queues indicates the attributes that can be inquired when the cluster queue is opened for inquire alone, or for inquire and output. If the cluster queue is opened for inquire plus one or more of input, browse, or set, the column for local queues applies instead.

(continued)

Attribute	Description	Local	Model	Alias	Remote	Cluster
<u>XmitQName</u>	Transmission queue name				✓	

AlterationDate (12-byte character string)

Date when definition was last changed.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes (for example, 1992-09-23↵↵, where ↵↵ represents two blank characters).

The values of certain attributes (for example, *CurrentQDepth*) change as the queue manager operates. Changes to these attributes do not affect *AlterationDate*.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

AlterationTime (8-byte character string)

Time when definition was last changed.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

This is the time when the definition was last changed. The format of the time is HH.MM.SS using the 24-hour clock, with a leading zero if the hour is less than 10 (for example 09.10.20). The time is local time.

The values of certain attributes (for example, *CurrentQDepth*) change as the queue manager operates. Changes to these attributes do not affect *AlterationTime*.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

BackoutRequeueQName (48-byte character string)

Excessive backout requeue queue name.

Local	Model	Alias	Remote	Cluster
✓	✓			

Applications running inside WebSphere Application Server and those that use the IBM MQ Application Server Facilities use this attribute to determine where messages that have been backed out should go. For all other applications, apart from allowing its value to be queried, the queue manager takes no action based on the value of the attribute.

To determine the value of this attribute, use the CABRQN selector with the MQINQ call. The length of this attribute is given by LNQN.

BackoutThreshold (10-digit signed integer)

Backout threshold.

Local	Model	Alias	Remote	Cluster
✓	✓			

Applications running inside WebSphere Application Server and those that use the IBM MQ Application Server Facilities use this attribute to determine if a message should be backed out. For all other applications, apart from allowing its value to be queried, the queue manager takes no action based on the value of the attribute.

To determine the value of this attribute, use the IABTHR selector with the MQINQ call.

BaseQName (48-byte character string)

The queue name to which the alias resolves.

Local	Model	Alias	Remote	Cluster
		✓		

This is the name of a queue that is defined to the local queue manager. (For more information about queue names, see the description of the *ODON* field in MQOD. The queue is one of the following types:

QTLOC

Local queue.

QTREM

Local definition of a remote queue.

QTCLUS

Cluster queue.

To determine the value of this attribute, use the CABASQ selector with the MQINQ call. The length of this attribute is given by LNQN.

BaseType (integer parameter structure)

The type of object to which the alias resolves.

Local	Model	Alias	Remote	Cluster
		✓		

This attribute can have one of the following values:

OTQ

Base object type is a queue

OTTOP

Base object type is a topic

CFStrucName (12-byte character string)

Coupling-facility structure name.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the name of the coupling-facility structure where the messages on the queue are stored. The first character of the name is in the range A through Z, and the remaining characters are in the range A through Z, 0 through 9, or blank.

The full name of the structure in the coupling facility is obtained by suffixing the value of the *QSGName* queue manager attribute with the value of the *CFStrucName* queue attribute.

This attribute applies only to shared queues; it is ignored if *QSGDisp* does not have the value QSGDSH.

To determine the value of this attribute, use the CACFSN selector with the MQINQ call. The length of this attribute is given by LNCFSN.

This attribute is supported only on z/OS.

ClusterChannelName (20-byte character string)

ClusterChannelName is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

Local	Model	Alias	Remote	Cluster
✓	✓			

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, *SYSTEM.CLUSTER.TRANSMIT.QUEUE*. The default configuration can be changed by modified by changing the queue manager attribute, **DefClusterXmitQueueType**. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the **DefClusterXmitQueueType** attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, *SYSTEM.CLUSTER.TRANSMIT.ChannelName*.

You can also set the transmission queue attribute *ClusterChannelName* attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the *ClusterChannelName* attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either *SYSTEM.CLUSTER.TRANSMIT.ChannelName* or *SYSTEM.CLUSTER.TRANSMIT.QUEUE*, depending on the value of the queue manager **DefClusterXmitQueueType** attribute.

By specifying asterisks, "*", in **ClusterChannelName**, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. **ClusterChannelName** is limited to a length of 20 characters: *MQ_CHANNEL_NAME_LENGTH*.

ClusterName (48-byte character string)

Name of cluster to which queue belongs.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

This is the name of the cluster to which the queue belongs. If the queue belongs to more than one cluster, *ClusterNameList* specifies the name of a namelist object that identifies the clusters, and *ClusterName* is blank. At least one of *ClusterName* and *ClusterNameList* must be blank.

To determine the value of this attribute, use the CACLN selector with the MQINQ call. The length of this attribute is given by LNCLUN.

ClusterNameList (48-byte character string)

Name of namelist object containing names of clusters to which queue belongs.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

This is the name of a namelist object that contains the names of clusters to which this queue belongs. If the queue belongs to only one cluster, the namelist object contains only one name. Alternatively, *ClusterName* can be used to specify the name of the cluster, in which case *ClusterNameList* is blank. At least one of *ClusterName* and *ClusterNameList* must be blank.

To determine the value of this attribute, use the CACLNL selector with the MQINQ call. The length of this attribute is given by LNNLN.

CreationDate (12-byte character string)

Date when queue was created.

Local	Model	Alias	Remote	Cluster
✓				

This is the date when the queue was created. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes (for example, 1992-09-23-- , where -- represents two blank characters).

- On IBM i, the creation date of a queue might differ from that of the underlying operating system entity (file or userspace) that represents the queue.

To determine the value of this attribute, use the CACRTD selector with the MQINQ call. The length of this attribute is given by LNCRTD.

CreationTime (8-byte character string)

Time when queue was created.

Local	Model	Alias	Remote	Cluster
✓				

This is the time when the queue was created. The format of the time is HH.MM.SS using the 24-hour clock, with a leading zero if the hour is less than 10 (for example 09.10.20). The time is local time.

- On IBM i, the creation time of a queue might differ from that of the underlying operating system entity (file or user space) that represents the queue.

To determine the value of this attribute, use the CACRTT selector with the MQINQ call. The length of this attribute is given by LNCRTT.

CurrentQDepth (10-digit signed integer)

Current queue depth.

Local	Model	Alias	Remote	Cluster
✓				

This is the number of messages currently on the queue. It is incremented during an MQPUT call, and during backout of an MQGET call. It is decremented during a nonbrowse MQGET call, and during backout of an MQPUT call. The effect of this is that the count includes messages that have been put on the queue within a unit of work, but which have not yet been committed, even though they are not eligible to be retrieved by the MQGET call. Similarly, it excludes messages that have been retrieved within a unit of work using the MQGET call, but which have yet to be committed.

The count also includes messages which have passed their expiry time but have not yet been discarded, although these messages are not eligible to be retrieved. See the *MDEXP* field described in [“MQMD - Message descriptor”](#) on page 1068.

Unit-of-work processing and the segmentation of messages can both cause *CurrentQDepth* to exceed *MaxQDepth*. However, this does not affect the retrievability of the messages - *all* messages on the queue can be retrieved using the MQGET call in the normal way.

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IACDEP selector with the MQINQ call.

DefBind (10-digit signed integer)

Default binding.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	✓

This attribute is the default binding that is used when OOBNDQ is specified on the MQOPEN call and the queue is a cluster queue. DefBind can have one of the following values:

BNDOPN

Binding fixed by MQOPEN call.

BNDNOT

Binding not fixed.

BNDGRP

Binding is not fixed by the MQOPEN call, but is fixed on MQPUT for all messages in a logical group.

To determine the value of this attribute, use the IADBND selector with the MQINQ call.

DefinitionType (10-digit signed integer)

Queue definition type.

Local	Model	Alias	Remote	Cluster
✓	✓			

This indicates how the queue was defined. The value is one of the following:

QDPRE

Predefined permanent queue.

The queue is a permanent queue created by the system administrator; only the system administrator can delete it.

Predefined queues are created using the DEFINE MQSC command, and can be deleted only by using the DELETE MQSC command. Predefined queues cannot be created from model queues.

Commands can be issued either by an operator, or by an authorized user sending a command message to the command input queue (see the *CommandInputQName* attribute described in [“Attributes for the queue manager”](#) on page 1355).

QDPERM

Dynamically defined permanent queue.

The queue is a permanent queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDPERM for the *DefinitionType* attribute.

This type of queue can be deleted using the MQCLOSE call. See [“MQCLOSE - Close object”](#) on page 1223 for more details.

The value of the *QSGDisp* attribute for a permanent dynamic queue is QSGDQM.

QDTEMP

Dynamically defined temporary queue.

The queue is a temporary queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDTEMP for the *DefinitionType* attribute.

This type of queue is deleted automatically by the MQCLOSE call when it is closed by the application that created it.

The value of the *QSGDisp* attribute for a temporary dynamic queue is QSGDQM.

QDSHAR

Dynamically defined shared queue.

The queue is a shared permanent queue that was created by an application issuing an MQOPEN call with the name of a model queue specified in the object descriptor MQOD. The model queue definition had the value QDSHAR for the *DefinitionType* attribute.

This type of queue can be deleted using the MQCLOSE call. See [“MQCLOSE - Close object”](#) on page 1223 for more details.

The value of the *QSGDisp* attribute for a shared dynamic queue is QSGDSH.

This attribute in a model queue definition does not indicate how the model queue was defined, because model queues are always predefined. Instead, the value of this attribute in the model queue is used to determine the *DefinitionType* of each of the dynamic queues created from the model queue definition using the MQOPEN call.

To determine the value of this attribute, use the IADEFT selector with the MQINQ call.

DefInputOpenOption (10-digit signed integer)

Default input open option.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the default way in which the queue should be opened for input. It applies if the OOINPQ option is specified on the MQOPEN call when the queue is opened. This can have one of the following values:

OOINPX

Open queue to get messages with exclusive access.

The queue is opened for use with subsequent MQGET calls. The call fails with reason code RC2042 if the queue is currently open by this or another application for input of any type (OOINPS or OOIINPX).

OOINPS

Open queue to get messages with shared access.

The queue is opened for use with subsequent MQGET calls. The call can succeed if the queue is currently open by this or another application with OOIINPS, but fails with reason code RC2042 if the queue is currently open with OOIINPX.

To determine the value of this attribute, use the IADINP selector with the MQINQ call.

DefPersistence (10-digit signed integer)

Default message persistence.

Local	Model	Alias	Remote	Cluster
✓	✓	✓	✓	✓

This is the default persistence of messages on the queue. It applies if PEQDEF is specified in the message descriptor when the message is put.

If there is more than one definition in the queue-name resolution path, the default persistence is taken from the value of this attribute in the *first* definition in the path at the time of the MQPUT or MQPUT1 call. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

This can have one of the following values:

PEPER

Message is persistent.

This means that the message survives system failures and restarts of the queue manager. Persistent messages cannot be placed on:

- Temporary dynamic queues
- Shared queues

Persistent messages can be placed on permanent dynamic queues, and predefined queues.

PENPER

Message is not persistent.

This means that the message does not normally survive system failures or restarts of the queue manager. This applies even if an intact copy of the message is found on auxiliary storage during restart of the queue manager.

In the special case of shared queues, nonpersistent messages *do* survive restarts of queue managers in the queue-sharing group, but do not survive failures of the coupling facility used to store messages on the shared queues.

Both persistent and nonpersistent messages can exist on the same queue.

To determine the value of this attribute, use the IADPER selector with the MQINQ call.

DefPriority (10-digit signed integer)

Default message priority.

Local	Model	Alias	Remote	Cluster
✓	✓	✓	✓	✓

This is the default priority for messages on the queue. This applies if PRQDEF is specified in the message descriptor when the message is put on the queue.

If there is more than one definition in the queue-name resolution path, the default priority for the message is taken from the value of this attribute in the *first* definition in the path at the time of the put operation. This could be:

- An alias queue
- A local queue
- A local definition of a remote queue
- A queue manager alias
- A transmission queue (for example, the *DefXmitQName* queue)

The way in which a message is placed on a queue depends on the value of the queue's *MsgDeliverySequence* attribute:

- If the *MsgDeliverySequence* attribute is MSPRIO, the logical position at which a message is placed on the queue is dependent on the value of the *MDPRI* field in the message descriptor.
- If the *MsgDeliverySequence* attribute is MSFIFO, messages are placed on the queue as though they had a priority equal to the *DefPriority* of the resolved queue, regardless of the value of the *MDPRI* field in the message descriptor. However, the *MDPRI* field retains the value specified by the application that put the message. See the *MsgDeliverySequence* attribute described in [“Attributes for queues”](#) on page 1324 for more information.

Priorities are in the range zero (lowest) through *MaxPriority* (highest); see the *MaxPriority* attribute described in [“Attributes for the queue manager”](#) on page 1355.

To determine the value of this attribute, use the IADPRI selector with the MQINQ call.

DefReadAhead (10-digit signed integer)

Specifies the default read ahead behavior for non-persistent messages delivered to the client.

Local	Model	Alias	Remote	Cluster
✓	✓	✓		

DefReadAhead can be set to one of the following values:

RAHNO

Non-persistent messages are not sent ahead to the client before an application requests them. A maximum of one non-persistent message can be lost if the client ends abnormally.

RAHYES

Non-persistent messages are sent ahead to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not consume all the messages it is sent.

RAHDIS

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

To determine the value of this attribute, use the IADRAH selector with the MQINQ call.

DefPResp (10-digit signed integer)

The default put response type (DEFPRESP) attribute defines the value used by applications when the PutResponseType within MQPMO has been set to PMRASQ. This attribute is valid for all queue types.

Local	Model	Alias	Remote	Cluster
✓	✓	✓	✓	✓

This can have one of the following values:

SYNC

The put operation is issued synchronously returning a response.

ASYNC

The put operation is issued asynchronously, returning a subset of MQMD fields.

To determine the value of this attribute, use the IADPRT selector with the MQINQ call.

DistLists (10-digit signed integer)

Distribution list support.

Local	Model	Alias	Remote	Cluster
✓	✓			

This indicates whether distribution-list messages can be placed on the queue. The attribute is set by a message channel agent (MCA) to inform the local queue manager whether the queue manager at the other end of the channel supports distribution lists. This latter queue manager (called the "partnering queue manager") is the one which next receives the message, after it has been removed from the local transmission queue by a sending MCA.

The attribute is set by the sending MCA whenever it establishes a connection to the receiving MCA on the partnering queue manager. In this way, the sending MCA can cause the local queue manager to place on the transmission queue only messages which the partnering queue manager can process correctly.

This attribute is primarily for use with transmission queues, but the processing described is performed regardless of the usage defined for the queue (see the *Usage* attribute).

This can have one of the following values:

DLSUPP

Distribution lists supported.

This indicates that distribution-list messages can be stored on the queue, and transmitted to the partnering queue manager in that form. This reduces the amount of processing required to send the message to multiple destinations.

DLNSUP

Distribution lists not supported.

This indicates that distribution-list messages cannot be stored on the queue, because the partnering queue manager does not support distribution lists. If an application puts a distribution-list message, and that message is to be placed on this queue, the queue manager splits the distribution-list message and places the individual messages on the queue instead. This increases the amount of processing required to send the message to multiple destinations, but ensures that the messages will be processed correctly by the partnering queue manager.

To determine the value of this attribute, use the IADIST selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

HardenGetBackout (10-digit signed integer)

Whether to maintain an accurate backout count.

Local	Model	Alias	Remote	Cluster
✓	✓			

For each message, a count is kept of the number of times that the message is retrieved by an MQGET call within a unit of work, and that unit of work later backed out. This count is available in the *MDBOC* field in the message descriptor after the MQGET call has completed.

The message backout count survives when the queue manager restarts. However, to ensure that the count is accurate, information has to be "hardened" (recorded on disk or other permanent storage device) each time a message is retrieved by an MQGET call within a unit of work for this queue. If this is not done, and a failure of the queue manager occurs together with backout of the MQGET call, the count might not be incremented.

Hardening information for each MQGET call within a unit of work, however, imposes a performance cost, and the *HardenGetBackout* attribute should be set to QABH only if the count has to be accurate.

- On IBM i, the message backout count is always hardened, regardless of the setting of this attribute.

The following values are possible:

QABH

Backout count remembered.

Hardening is used to ensure that the backout count for messages on this queue is accurate.

QABNH

Backout count might not be remembered.

Hardening is not used to ensure that the backout count for messages on this queue is accurate. The count might therefore be lower than it should be.

To determine the value of this attribute, use the IAHGB selector with the MQINQ call.

InhibitGet (10-digit signed integer)

Controls whether get operations for this queue are allowed.

Local	Model	Alias	Remote	Cluster
✓	✓	✓		

If the queue is an alias queue, get operations must be allowed for both the alias and the base queue at the time of the get operation, in order for the MQGET call to succeed. The value is one of the following:

QAGETI

Get operations are inhibited.

MQGET calls fail with reason code RC2016. This includes MQGET calls that specify GMBRWF or GMBRWN.

Note: If an MQGET call operating within a unit of work completes successfully, changing the value of the *InhibitGet* attribute after to QAGETI does not prevent the unit of work being committed.

QAGETA

Get operations are allowed.

To determine the value of this attribute, use the IAIGET selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

InhibitPut (10-digit signed integer)

Controls whether put operations for this queue are allowed.

Local	Model	Alias	Remote	Cluster
✓	✓	✓	✓	✓

If there is more than one definition in the queue-name resolution path, put operations must be allowed for *every* definition in the path (including any queue manager alias definitions) at the time of the put operation, in order for the MQPUT or MQPUT1 call to succeed. This can have one of the following values:

QAPUTI

Put operations are inhibited.

MQPUT and MQPUT1 calls fail with reason code RC2051.

Note: If an MQPUT call operating within a unit of work completes successfully, changing the value of the *InhibitPut* attribute later to QAPUTI does not prevent the unit of work being committed.

QAPUTA

Put operations are allowed.

To determine the value of this attribute, use the IAIPUT selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

InitiationQName (48-byte character string)

Name of initiation queue.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the name of a queue defined on the local queue manager; the queue must be of type QTLOC. The queue manager sends a trigger message to the initiation queue when application startup is required as a result of a message arriving on the queue to which this attribute belongs. The initiation queue must be monitored by a trigger monitor application which will start the appropriate application after receipt of the trigger message.

To determine the value of this attribute, use the CAINIQ selector with the MQINQ call. The length of this attribute is given by LNQN.

MaxMsgLength (10-digit signed integer)

Maximum message length in bytes.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is an upper limit for the length of the longest *physical* message that can be placed on the queue. However, because the *MaxMsgLength* queue attribute can be set independently of the *MaxMsgLength* queue manager attribute, the actual upper limit for the length of the longest physical message that can be placed on the queue is the lesser of those two values.

If the queue manager supports segmentation, it is possible for an application to put a *logical* message that is longer than the lesser of the two *MaxMsgLength* attributes, but only if the application specifies the MFSEGA flag in MQMD. If that flag is specified, the upper limit for the length of a logical message is 999 999 999 bytes, but typically, resource constraints imposed by the operating system or by the environment in which the application is running, results in a lower limit.

An attempt to place on the queue a message that is too long fails with reason code:

- RC2030 if the message is too large for the queue
- RC2031 if the message is too large for the queue manager, but not too large for the queue

The lower limit for the *MaxMsgLength* attribute is zero. The upper limit is determined by the environment:

- On IBM i, the maximum message length is 100 MB (104 857 600 bytes).

For more information, see the *BUFLen* parameter described in “MQPUT - Put message” on page 1289.

To determine the value of this attribute, use the IAMLEN selector with the MQINQ call.

MaxQDepth (10-digit signed integer)

Maximum queue depth.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the defined upper limit for the number of physical messages that can exist on the queue at any one time. An attempt to put a message on a queue that already contains *MaxQDepth* messages, fails with reason code RC2053.

Unit-of-work processing and the segmentation of messages can both cause the actual number of physical messages on the queue to exceed *MaxQDepth*. However, this does not affect the retrievability of the messages - *all* messages on the queue can be retrieved using the MQGET call in the normal way.

The value of this attribute is zero or greater. The upper limit is determined by the environment.

Note: It is possible for the storage space available to the queue to be exhausted even if there are fewer than *MaxQDepth* messages on the queue.

To determine the value of this attribute, use the IAMDEP selector with the MQINQ call.

MediaLog (10-digit signed integer)

Identity of the log extent (or journal receiver on IBM i) needed for media recovery of a particular queue.

Local	Model	Alias	Remote	Cluster
✓	✓			

On queue managers where circular logging is in use, the value is returned as a null string.

MsgDeliverySequence (10-digit signed integer)

Message delivery sequence.

Local	Model	Alias	Remote	Cluster
✓	✓			

This determines the order in which messages are returned to the application by the MQGET call:

MSFIFO

Messages are returned in FIFO order (first in, first out).

This means that an MQGET call will return the *first* message that satisfies the selection criteria specified on the call, regardless of the priority of the message.

MSPRIO

Messages are returned in priority order.

This means that an MQGET call will return the *highest-priority* message that satisfies the selection criteria specified on the call. Within each priority level, messages are returned in FIFO order (first in, first out).

If the relevant attributes are changed while there are messages on the queue, the delivery sequence is as follows:

- The order in which messages are returned by the MQGET call is determined by the values of the *MsgDeliverySequence* and *DefPriority* attributes in force for the queue at the time the message arrives on the queue:
 - If *MsgDeliverySequence* is MSFIFO when the message arrives, the message is placed on the queue as though its priority were *DefPriority*. This does not affect the value of the *MDPRI* field in the message descriptor of the message; that field retains the value it had when the message was first put.
 - If *MsgDeliverySequence* is MSPRIO when the message arrives, the message is placed on the queue at the place appropriate to the priority given by the *MDPRI* field in the message descriptor.

If the value of the *MsgDeliverySequence* attribute is changed while there are messages on the queue, the order of the messages on the queue is not changed.

If the value of the *DefPriority* attribute is changed while there are messages on the queue, the messages will not necessarily be delivered in FIFO order, even though the *MsgDeliverySequence* attribute is set to MSFIFO; those that were placed on the queue at the higher priority are delivered first.

To determine the value of this attribute, use the IAMDS selector with the MQINQ call.

OpenInputCount (10-digit signed integer)

Number of opens for input.

Local	Model	Alias	Remote	Cluster
✓				

This is the number of handles that are currently valid for removing messages from the queue with the MQGET call. It is the total number of such handles known to the *local* queue manager. If the queue is a shared queue, the count does not include opens for input that were performed for the queue at other queue managers in the queue-sharing group to which the local queue manager belongs.

The count includes handles where an alias queue which resolves to this queue was opened for input. The count does not include handles where the queue was opened for actions which did not include input (for example, a queue opened only for browse).

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IAOIC selector with the MQINQ call.

OpenOutputCount (10-digit signed integer)

Number of opens for output.

Local	Model	Alias	Remote	Cluster
✓				

This is the number of handles that are currently valid for adding messages to the queue with the MQPUT call. It is the total number of such handles known to the *local* queue manager; it does not include opens for output that were performed for this queue at remote queue managers. If the queue is a shared queue, the count does not include opens for output that were performed for the queue at other queue managers in the queue-sharing group to which the local queue manager belongs.

The count includes handles where an alias queue which resolves to this queue was opened for output. The count does not include handles where the queue was opened for actions which did not include output (for example, a queue opened only for inquire).

The value of this attribute fluctuates as the queue manager operates.

To determine the value of this attribute, use the IAOOC selector with the MQINQ call.

ProcessName (48-byte character string)

Process name.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the name of a process object that is defined on the local queue manager. The process object identifies a program that can service the queue.

To determine the value of this attribute, use the CAPRON selector with the MQINQ call. The length of this attribute is given by LNPRON.

QDepthHighEvent (10-digit signed integer)

Controls whether Queue Depth High events are generated.

Local	Model	Alias	Remote	Cluster
✓	✓			

A Queue Depth High event indicates that an application has put a message on a queue, which has caused the number of messages on the queue to become greater than or equal to the queue depth high threshold (see the *QDepthHighLimit* attribute).

Note: The value of this attribute can change dynamically.

QDepthHighEvent can have one of two values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDHE selector with the MQINQ call.

QDepthHighLimit (10-digit signed integer)

High limit for queue depth.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the threshold against which the queue depth is compared to generate a Queue Depth High event. This event indicates that an application has put a message on a queue, and this has caused the number of messages on the queue to become greater than or equal to the queue depth high threshold. See the *QDepthHighEvent* attribute.

The value is expressed as a percentage of the maximum queue depth (*MaxQDepth* attribute), and is in the range zero through 100. The default value is 80.

To determine the value of this attribute, use the IAQDHL selector with the MQINQ call.

QDepthLowEvent (10-digit signed integer)

Controls whether Queue Depth Low events are generated.

Local	Model	Alias	Remote	Cluster
✓	✓			

A Queue Depth Low event indicates that an application has retrieved a message from a queue, which has caused the number of messages on the queue to become less than or equal to the queue depth low threshold (see the *QDepthLowLimit* attribute).

Note: The value of this attribute can change dynamically.

QDepthLowEvent can have one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDLE selector with the MQINQ call.

QDepthLowLimit (10-digit signed integer)

Low limit for queue depth.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the threshold against which the queue depth is compared to generate a Queue Depth Low event. This event indicates that an application has retrieved a message from a queue, and this has caused the number of messages on the queue to become less than or equal to the queue depth low threshold. See the *QDepthLowEvent* attribute.

The value is expressed as a percentage of the maximum queue depth (*MaxQDepth* attribute), and is in the range zero through 100. The default value is 20.

To determine the value of this attribute, use the IAQDLL selector with the MQINQ call.

QDepthMaxEvent (10-digit signed integer)

Controls whether Queue Full events are generated.

Local	Model	Alias	Remote	Cluster
✓	✓			

A Queue Full event indicates that a put to a queue has been rejected because the queue is full, that is, the queue depth has already reached its maximum value.

Note: The value of this attribute can change dynamically.

This can have one of the following values:

EVARDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQDME selector with the MQINQ call.

QDesc (64-byte character string)

Queue description.

Local	Model	Alias	Remote	Cluster
✓	✓	✓	✓	✓

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contains only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

Note: If this field contains characters that are not in the queue manager's character set (as defined by the *CodedCharSetId* queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CAQD selector with the MQINQ call. The length of this attribute is given by LNQD.

QName (48-byte character string)

Queue name.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	✓

This is the name of a queue defined on the local queue manager. For more information about queue names, see [Rules for naming IBM MQ objects](#). All queues defined on a queue manager share the same queue namespace. Therefore, a QTLOC queue and a QTALS queue cannot have the same name.

To determine the value of this attribute, use the CAQN selector with the MQINQ call. The length of this attribute is given by LNQN.

QServiceInterval (10-digit signed integer)

Target for queue service interval.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the service interval used for comparison to generate Service Interval High and Service Interval OK events. See the *QServiceIntervalEvent* attribute.

The value is in units of milliseconds, and is in the range zero through 999 999 999.

To determine the value of this attribute, use the IAQSI selector with the MQINQ call.

QServiceIntervalEvent (10-digit signed integer)

Controls whether Service Interval High or Service Interval OK events are generated.

Local	Model	Alias	Remote	Cluster
✓	✓			

- A Service Interval High event is generated when a check indicates that no messages have been retrieved from the queue for at least the time indicated by the *QServiceInterval* attribute.
- A Service Interval OK event is generated when a check indicates that messages have been retrieved from the queue within the time indicated by the *QServiceInterval* attribute.

Note: The value of this attribute can change dynamically.

This attribute can have one of the following values:

QSIEHI

Queue Service Interval High events enabled.

- Queue Service Interval High events are **enabled** and
- Queue Service Interval OK events are **disabled**.

QSIEOK

Queue Service Interval OK events enabled.

- Queue Service Interval High events are **disabled** and
- Queue Service Interval OK events are **enabled**.

QSIENO

No queue service interval events enabled.

- Queue Service Interval High events are **disabled** and
- Queue Service Interval OK events are also **disabled**.

For shared queues, the value of this attribute is ignored; the value QSIENO is assumed.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAQSIE selector with the MQINQ call.

QSGDisp (10-digit signed integer)

Queue-sharing group disposition.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

This specifies the disposition of the queue. The value is one of the following:

QSGDQM

Queue manager disposition.

The object has queue manager disposition. This means that the object definition is known only to the local queue manager; the definition is not known to other queue managers in the queue-sharing group.

It is possible for each queue manager in the queue-sharing group to have an object with the same name and type as the current object, but these are separate objects and there is no correlation between them. Their attributes are not constrained to be the same as each other.

QSGDCP

Copied-object disposition.

The object is a local copy of a master object definition that exists in the shared repository. Each queue manager in the queue-sharing group can have its own copy of the object. Initially, all copies have the same attributes, but by using MQSC commands each copy can be altered so that its attributes differ from those of the other copies. The attributes of the copies are resynchronized when the master definition in the shared repository is altered.

QSGDSH

Shared disposition.

The object has shared disposition. This means that there exists in the shared repository a single instance of the object that is known to all queue managers in the queue-sharing group. When a queue manager in the group accesses the object, it accesses the single shared instance of the object.

To determine the value of this attribute, use the IAQSGD selector with the MQINQ call.

This attribute is supported only on z/OS.

QType (10-digit signed integer)

Queue type.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	✓

This attribute has one of the following values:

QTALS

Alias queue definition.

QTCLUS

Cluster queue.

QTLOC

Local queue.

QTREM

Local definition of a remote queue.

To determine the value of this attribute, use the IAQTYP selector with the MQINQ call.

RemoteQMgrName (48-byte character string)

Name of remote queue manager.

Local	Model	Alias	Remote	Cluster
			✓	

This is the name of the remote queue manager on which the queue *RemoteQName* is defined. If the *RemoteQName* queue has a *QSGDisp* value of *QSGDCP* or *QSGDSH*, *RemoteQMgrName* can be the name of the queue-sharing group that owns *RemoteQName*.

If an application opens the local definition of a remote queue, *RemoteQMgrName* must not be blank and must not be the name of the local queue manager. If *XmitQName* is blank, the local queue with same name as *RemoteQMgrName* is used as the transmission queue. If there is no queue with the name *RemoteQMgrName*, the queue identified by the *DefXmitQName* queue manager attribute is used.

If this definition is used for a queue manager alias, *RemoteQMgrName* is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if *XmitQName* is blank when the open occurs, there must be a local queue with the same name as *RemoteQMgrName*; this queue is used as the transmission queue.

If this definition is used for a reply-to alias, this name is the name of the queue manager which is to be the *MDRM*.

Note: No validation is performed on the value specified for this attribute when the queue definition is created or modified.

To determine the value of this attribute, use the *CARQMN* selector with the *MQINQ* call. The length of this attribute is given by *LNQMN*.

RemoteQName (48-byte character string)

Name of remote queue.

Local	Model	Alias	Remote	Cluster
			✓	

This is the name of the queue as it is known on the remote queue manager *RemoteQMgrName*.

If an application opens the local definition of a remote queue, when the open occurs *RemoteQName* must not be blank.

If this definition is used for a queue manager alias definition, when the open occurs *RemoteQName* must be blank.

If the definition is used for a reply-to alias, this name is the name of the queue that is to be the *MDRQ*.

Note: No validation is performed on the value specified for this attribute when the queue definition is created or modified.

To determine the value of this attribute, use the *CARQN* selector with the *MQINQ* call. The length of this attribute is given by *LNQN*.

RetentionInterval (10-digit signed integer)

Retention interval.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the time which the queue should be retained. After this time has elapsed, the queue is eligible for deletion.

The time is measured in hours, counting from the date and time when the queue was created. The creation date of the queue is recorded in the *CreationDate* and the create time of the queue is recorded in the *CreationTime* attribute.

This information is provided to enable a housekeeping application or the operator to identify and delete queues that are no longer required.

Note: The queue manager never tries to delete queues based on this attribute, or to prevent the deletion of queues with a retention interval that has not expired; it is the user's responsibility to cause any required action to be taken.

A realistic retention interval should be used to prevent the accumulation of permanent dynamic queues (see *DefinitionType*). However, this attribute can also be used with predefined queues.

To determine the value of this attribute, use the IARINT selector with the MQINQ call.

Scope (10-digit signed integer)

Controls whether an entry for this queue also exists in a cell directory.

Local	Model	Alias	Remote	Cluster
✓		✓	✓	

A cell directory is provided by an installable Name service. This can have one of the following values:

SCOQM

Queue-manager scope.

The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager which owns it. To open the queue for output from some other queue manager, either the name of the owning queue manager must be specified, or the other queue manager must have a local definition of the queue.

SCOCEL

Cell scope.

The queue definition has cell scope. This means that the queue definition is also placed in a cell directory available to all of the queue managers in the cell. The queue can be opened for output from any of the queue managers in the cell merely by specifying the name of the queue; the name of the queue manager which owns the queue need not be specified. However, the queue definition is not available to any queue manager in the cell which also has a local definition of a queue with that name, as the local definition takes precedence.

A cell directory is provided by an installable name service such as LDAP (Lightweight Directory Access Protocol). Note that IBM MQ no longer supports the DCE (Distributed Computing Environment) name service that was formerly used for inserting queue definitions into a DCE directory (also no longer supported).

Model and dynamic queues cannot have cell scope.

This value is only valid if a name service supporting a cell directory has been configured.

To determine the value of this attribute, use the IASCP selector with the MQINQ call.

Support for this attribute is subject to the following restrictions:

- On IBM i, the attribute is supported, but only SCOQM is valid.

Shareability (10-digit signed integer)

Whether queue can be shared for input.

Local	Model	Alias	Remote	Cluster
✓	✓			

This indicates whether the queue can be opened for input multiple times concurrently. This can have one of the following values:

QASHR

Queue is shareable.

Multiple opens with the OOINPS option are allowed.

QANSHR

Queue is not shareable.

An MQOPEN call with the OOINPS option is treated as OOINPX.

To determine the value of this attribute, use the IASHAR selector with the MQINQ call.

TriggerControl (10-digit signed integer)

Trigger control.

Local	Model	Alias	Remote	Cluster
✓	✓			

This controls whether trigger messages are written to an initiation queue, in order to cause an application to be started to service the queue. This is one of the following:

TCOFF

Trigger messages not required.

No trigger messages are to be written for this queue. The value of *TriggerType* is irrelevant in this case.

TCON

Trigger messages required.

Trigger messages are to be written for this queue, when the appropriate trigger events occur.

To determine the value of this attribute, use the IATRGC selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

TriggerData (64-byte character string)

Trigger data.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is free-format data that the queue manager inserts into the trigger message when a message arriving on this queue causes a trigger message to be written to the initiation queue.

The content of this data is of no significance to the queue manager. It is meaningful either to the trigger-monitor application which processes the initiation queue, or to the application which is started by the trigger monitor.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CATRGD selector with the MQINQ call. To change the value of this attribute, use the MQSET call. The length of this attribute is given by LNTRGD.

TriggerDepth (10-digit signed integer)

Trigger depth.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the number of messages of priority *TriggerMsgPriority* or greater that must be on the queue before a trigger message is written. This applies when *TriggerType* is set to TTDPTH. The value of *TriggerDepth* is one or greater. This attribute is not used otherwise.

To determine the value of this attribute, use the IATRGD selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

TriggerMsgPriority (10-digit signed integer)

Threshold message priority for triggers.

Local	Model	Alias	Remote	Cluster
✓	✓			

This is the message priority below which messages do not contribute to the generation of trigger messages (that is, the queue manager ignores these messages when determining whether a trigger message should be generated). *TriggerMsgPriority* can be in the range zero (lowest) through *MaxPriority* (highest; see [“Attributes for the queue manager”](#) on page 1355); a value of zero causes all messages to contribute to the generation of trigger messages.

To determine the value of this attribute, use the IATRGP selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

TriggerType (10-digit signed integer)

Trigger type.

Local	Model	Alias	Remote	Cluster
✓	✓			

This controls the conditions under which trigger messages are written as a result of messages arriving on this queue. The value is one of the following:

TTNONE

No trigger messages.

No trigger messages are written as a result of messages on this queue. This has the same effect as setting *TriggerControl* to TCOFF.

TTFIRST

Trigger message when queue depth goes from 0 to 1.

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue changes from 0 to 1.

TTEVRY

Trigger message for every message.

A trigger message is written whenever a message of priority *TriggerMsgPriority* or greater arrives on the queue.

TTDPTH

Trigger message when depth threshold exceeded.

A trigger message is written whenever the number of messages of priority *TriggerMsgPriority* or greater on the queue equals or exceeds *TriggerDepth*. After the trigger message has been written, *TriggerControl* is set to TCOFF to prevent further triggering until it is explicitly turned on again.

To determine the value of this attribute, use the IATRGT selector with the MQINQ call. To change the value of this attribute, use the MQSET call.

Usage (10-digit signed integer)

Queue usage.

Local	Model	Alias	Remote	Cluster
✓	✓			

This indicates what the queue is used for. The value is one of the following:

USNORM

Normal usage.

This is a queue that normal applications use when putting and getting messages; the queue is not a transmission queue.

USTRAN

Transmission queue.

This is a queue used to hold messages destined for remote queue managers. When a normal application sends a message to a remote queue, the local queue manager stores the message temporarily on the appropriate transmission queue in a special format. A message channel agent then reads the message from the transmission queue, and transports the message to the remote queue manager. For more information about transmission queues, see [Transmission queues](#).

Only privileged applications can open a transmission queue for OOOOUT to put messages on it directly. Only utility applications would normally be expected to do this. Care must be taken that the message data format is correct (see “MQXQH - Transmission-queue header” on page 1201), otherwise errors might occur during the transmission process. Context is not passed or set unless one of the PM* context options is specified.

To determine the value of this attribute, use the IAUSAG selector with the MQINQ call.

XmitQName (48-byte character string)

Transmission queue name.

Local	Model	Alias	Remote	Cluster
			✓	

If this attribute is nonblank when an open occurs, either for a remote queue or for a queue manager alias definition, it specifies the name of the local transmission queue to be used for forwarding the message.

If *XmitQName* is blank, the local queue with the same name as *RemoteQMGrName* is used as the transmission queue. If there is no queue with the name *RemoteQMGrName*, the queue identified by the *DefXmitQName* queue manager attribute is used.

This attribute is ignored if the definition is being used as a queue manager alias and *RemoteQMGrName* is the name of the local queue manager. It is also ignored if the definition is used as a reply-to queue alias definition.

To determine the value of this attribute, use the CAXQN selector with the MQINQ call. The length of this attribute is given by LNQN.

Attributes for namelists

This topic summarizes the attributes that are specific to namelists. The attributes are described in alphabetical order.

Note: The names of the attributes shown are the names used with the MQINQ and MQSET calls.

Attribute descriptions

A namelist object has the following attributes:

AlterationDate (12-byte character string)

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

AlterationTime (8-byte character string)

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

NameCount (10-digit signed integer)

Number of names in namelist.

This is greater than or equal to zero. The following value is defined:

NCMXNL

Maximum number of names in a namelist.

To determine the value of this attribute, use the IANAMC selector with the MQINQ call.

NamelistDesc (64-byte character string)

Namelist description.

This is a field that might be used for descriptive commentary; its value is established by the definition process. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contains only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, this field can contain DBCS characters (subject to a maximum field length of 64 bytes).

Note: If this field contains characters that are not in the queue manager's character set (as defined by the *CodedCharSetId* queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CALSTD selector with the MQINQ call.

The length of this attribute is given by LNNLD.

NamelistName (48-byte character string)

Namelist name.

This is the name of a namelist that is defined on the local queue manager.

Each namelist has a name that is different from the names of other namelists belonging to the queue manager, but might duplicate the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the CALSTN selector with the MQINQ call.

The length of this attribute is given by LNNLN.

Names (48-byte character string x NameCount)

A list of *NameCount* names.

Each name is the name of an object that is defined to the local queue manager. For more information about object names, see [Naming IBM MQ objects](#).

To determine the value of this attribute, use the CANAMS selector with the MQINQ call.

The length of each name in the list is given by LNOBJN.

Attributes for process definitions

This topic summarizes the attributes that are specific to process definitions. The attributes are described in alphabetical order.

Note: The names of the attributes shown are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [MQSC commands](#) for details.

Attribute descriptions

A process-definition object has the following attributes:

AlterationDate (12-byte character string)

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

AlterationTime (8-byte character string)

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

ApplId (256-byte character string)

Application identifier.

This is a character string that identifies the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *ApplId* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ requires *ApplId* to be the name of an executable program.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAAPPI selector with the MQINQ call. The length of this attribute is given by LNPROA.

ApplType (10-digit signed integer)

Application type.

This identifies the nature of the program to be started in response to the receipt of a trigger message. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

ApplType can have any value. You can use the following values for standard types; user-defined application types are restricted to values in the range ATUFST through ATULST:

ATCICS

CICS transaction.

AT400

IBM i application.

ATUFST

Lowest value for user-defined application type.

ATULST

Highest value for user-defined application type.

To determine the value of this attribute, use the IAAPPT selector with the MQINQ call.

EnvData (128-byte character string)

Environment data.

This is a character string that contains environment-related information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

The meaning of *EnvData* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends *EnvData* to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by *EnvData* with trailing blanks removed.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAENVD selector with the MQINQ call. The length of this attribute is given by LNPROE.

ProcessDesc (64-byte character string)

Process description.

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

Note: If this field contains characters that are not in the queue manager's character set (as defined by the *CodedCharSetId* queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

To determine the value of this attribute, use the CAPROD selector with the MQINQ call.

The length of this attribute is given by LNPROD.

ProcessName (48-byte character string)

Process name.

This is the name of a process definition that is defined on the local queue manager.

Each process definition has a name that is different from the names of other process definitions belonging to the queue manager. But the name of the process definition can be the same as the names of other queue manager objects of different types (for example, queues).

To determine the value of this attribute, use the CAPRON selector with the MQINQ call.

The length of this attribute is given by LNPRON.

UserData (128-byte character string)

User data.

This is a character string that contains user information pertaining to the application to be started. This information is for use by a trigger-monitor application that processes messages on the initiation queue, or the application which is started by the trigger monitor. The information is sent to the initiation queue as part of the trigger message.

The meaning of *UserData* is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ passes *UserData* to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing *UserData*), followed by one blank, followed by *EnvData* with trailing blanks removed.

The character string cannot contain any nulls. It is padded to the right with blanks if necessary.

To determine the value of this attribute, use the CAUSRD selector with the MQINQ call. The length of this attribute is given by LNPROU.

Attributes for the queue manager

A summary of queue manager attributes.

Some queue manager attributes are fixed for particular implementations, while others can be changed by using the MQSC command ALTER QMGR. The attributes can also be displayed by using the command DISPLAY QMGR. Most queue manager attributes can be inquired by opening a special OTQM object, and using the MQINQ call with the handle returned.

The following table summarizes the attributes that are specific to the queue manager. The attributes are described in alphabetical order.

Note: The names of the attributes shown in this section are the names used with the MQINQ and MQSET calls. When MQSC commands are used to define, alter, or display attributes, alternative short names are used; see [Script \(MQSC\) Commands](#) for more information.

Table 627. Attributes for the queue manager	
Attribute	Description
AlterationDate	Date when definition was last changed
AlterationTime	Time when definition was last changed
AuthorityEvent	Controls whether authorization (Not Authorized) events are generated
BridgeEvent	Controls whether IMS bridge events are generated
ChannelAutoDef	Controls whether automatic channel definition is permitted
ChannelAutoDefEvent	Controls whether channel automatic-definition events are generated
ChannelAutoDefExit	Name of user exit for automatic channel definition
ChannelEvent	Controls whether channel events are generated
ClusterCacheType	Controls whether the cluster cache is fixed in size or dynamically sized
ClusterWorkloadData	User data for cluster workload exit

<i>Table 627. Attributes for the queue manager (continued)</i>	
Attribute	Description
<u>ClusterWorkloadExit</u>	Name of user exit for cluster workload management
<u>ClusterWorkloadLength</u>	Maximum length of message data passed to cluster workload exit
<u>CodedCharSetId</u>	Coded character set identifier
<u>CommandEvent</u>	Controls whether command event messages are queued
<u>CommandInputQName</u>	Command input queue name
<u>CommandLevel</u>	Command level
<u>ConfigurationEvent</u>	Configuration event
<u>DeadLetterQName</u>	Name of dead-letter queue
<u>DefClusterXmitQueueType</u>	Default cluster transmission queue type
<u>DefXmitQName</u>	Default transmission queue name
<u>DistLists</u>	Distribution list support
<u>InhibitEvent</u>	Controls whether inhibit (Inhibit Get and Inhibit Put) events are generated
<u>LocalEvent</u>	Controls whether local error events are generated
<u>LoggerEvent</u>	Controls whether recovery log events are generated
<u>MaxHandles</u>	Maximum number of handles
<u>MaxMsgLength</u>	Maximum message length in bytes
<u>MaxPriority</u>	Maximum priority
<u>MaxUncommittedMsgs</u>	Maximum number of uncommitted messages within a unit of work
<u>PerformanceEvent</u>	Controls whether performance-related events are generated
<u>Platform</u>	Platform on which the queue manager is running
<u>PubSubMode</u>	Whether the publish/subscribe engine and queued publish/subscribe interface are running
<u>QMGrDesc</u>	Queue manager description
<u>QMGrIdentifier</u>	Unique internally-generated identifier of queue manager
<u>QMGrName</u>	Queue manager name
<u>RemoteEvent</u>	Controls whether remote error events are generated
<u>RepositoryName</u>	Name of cluster for which this queue manager provides repository services
<u>RepositoryNamelist</u>	Name of namelist object containing names of clusters for which this queue manager provides repository services
<u>SSLCRLNamelist</u>	Name of namelist object containing names of authentication information objects (See Note 1)
<u>SSLEvent</u>	Controls whether SSL events are generated
<u>SSLKeyRepository</u>	Location of SSL key repository (See Note 1)

Table 627. Attributes for the queue manager (continued)	
Attribute	Description
SSLKeyResetCount	Determines the number of non-encrypted bytes sent and received within an SSL conversation before the encryption key is renegotiated
StartStopEvent	Controls whether start and stop events are generated
SyncPoint	Syncpoint availability
TraceRouteRecording	Controls the recording of trace route information for messages
TreeLifeTime	The lifetime, in seconds, of non-administrative topics
TriggerInterval	Trigger-message interval
Notes: 1. This attribute cannot be inquired using the MQINQ call, and is not described in this section. For more information about this attribute, see Change Queue Manager .	

AlterationDate (12-byte character string)

Date when definition was last changed.

This is the date when the definition was last changed. The format of the date is YYYY-MM-DD, padded with two trailing blanks to make the length 12 bytes.

To determine the value of this attribute, use the CAALTD selector with the MQINQ call. The length of this attribute is given by LNDATE.

AlterationTime (8-byte character string)

Time when definition was last changed.

This is the time when the definition was last changed. The format of the time is HH.MM.SS.

To determine the value of this attribute, use the CAALTT selector with the MQINQ call. The length of this attribute is given by LNTIME.

AuthorityEvent (10-digit signed integer)

Controls whether authorization (Not Authorized) events are generated.

The AuthorityEvent attribute must be set to one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAAUTE selector with the MQINQ call.

BridgeEvent (character string)

This attribute determines whether IMS bridge event messages are put onto the SYSTEM.ADMIN.CHANNEL.EVENT queue. It is only supported on z/OS.

ChannelAutoDef (10-digit signed integer)

Controls whether automatic channel definition is permitted.

This attribute controls the automatic definition of channels of type CTCRCVR and CTSVCN. Note that the automatic definition of CTCLSD channels is always enabled. This can have one of the following values:

CHADDI

Channel auto-definition disabled.

CHADEN

Channel auto-definition enabled.

To determine the value of this attribute, use the IACAD selector with the MQINQ call.

ChannelAutoDefEvent (10-digit signed integer)

Controls whether channel automatic-definition events are generated.

This applies to channels of type CTCVR, CTSVCN, and CTCLSD. This can have one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Monitoring and performance](#).

To determine the value of this attribute, use the IACADE selector with the MQINQ call.

ChannelAutoDefExit (20-byte character string)

Name of user exit for automatic channel definition.

If this name is nonblank, and *ChannelAutoDef* has the value CHADEN, the exit is called each time that the queue manager is about to create a channel definition. This applies to channels of type CTCVR, CTSVCN, and CTCLSD. The exit can then do one of the following:

- Allow the creation of the channel definition to proceed without change.
- Modify the attributes of the channel definition that is created.
- Suppress creation of the channel entirely.

To determine the value of this attribute, use the CACADX selector with the MQINQ call. The length of this attribute is given by LNEXTN.

ChannelEvent (character string)

Determines whether channel event messages are generated.

This attribute determines whether channel event messages are put onto the SYSTEM.ADMIN.CHANNEL.EVENT queue, and if so, what type of messages are queued (for example 'channel started', 'channel stopped', 'channel not activated'). Before the implementation of this attribute, the only way of preventing channel event messages from being queued was to delete the target queue.

This attribute also allows you to collect IMS bridge events only (because you can now switch off channel events, they do not get put onto the same queue). The same applies to SSL events which can also be collected without having to collect channel events as well.

This attribute also allows you to collect significant events only (for example when channels have errors, not when they start and stop normally).

The value for the ChannelEvent attribute can be one of the following:

- EVREXP (only the following channel events are generated: RC2279, RC2283, RC2284, RC2295, RC2296).
- EVRENA (all channel events are generated; that is, in addition to the events generated by EVREXP, the RC2282, and RC2283 events are also generated).
- EVRDIS (no channel events are generated; this is the queue manager initial default value).

To determine the value of this attribute, use the IACHNE selector with the MQINQ call.

ClusterCacheType (32-byte character string)

Controls whether cluster cache is fixed size, or is dynamically sized.

This is a user-defined 32-byte character string that is passed to the cluster workload exit when it is called. If there is no data to pass to the exit, the string is blank.

To determine the value of this attribute, use the CACLWD selector with the MQINQ call.

ClusterWorkloadData (32-byte character string)

User data for cluster workload exit.

This is a user-defined 32-byte character string that is passed to the cluster workload exit when it is called. If there is no data to pass to the exit, the string is blank.

To determine the value of this attribute, use the CACLWD selector with the MQINQ call.

ClusterWorkloadExit (20-byte character string)

Name of user exit for cluster workload management.

If this name is not blank, the exit is called each time that a message is put to a cluster queue or moved from one cluster-sender queue to another. The exit can then either accept the queue instance selected by the queue manager as the destination for the message, or select another queue instance.

To determine the value of this attribute, use the CACLWX selector with the MQINQ call. The length of this attribute is given by LNEXTN.

ClusterWorkloadLength (10-digit signed integer)

Maximum length of message data passed to cluster workload exit.

This is the maximum length of message data that is passed to the cluster workload exit. The actual length of data passed to the exit is the minimum of the following:

- The length of the message.
- The queue manager's *MaxMsgLength* attribute.
- The *ClusterWorkloadLength* attribute.

To determine the value of this attribute, use the IACLWL selector with the MQINQ call.

CodedCharSetId (10-digit signed integer)

Coded character set identifier.

This defines the character set used by the queue manager for all character string fields defined in the MQI such as the names of objects, and queue creation date and time. The character set must be one that has single-byte characters for the characters that are valid in object names. It does not apply to application data carried in the message. The value depends on the environment:

- On IBM i, the value is that which is set in the environment when the queue manager is first created.

To determine the value of this attribute, use the IACCSI selector with the MQINQ call.

CommandEvent (integer)

Controls whether messages are put onto a local queue when commands are issued.

This controls whether messages are written to a new event queue, SYSTEM.ADMIN.COMMAND.EVENT, whenever commands are issued. This feature is useful for command tracking notification, and for problem diagnosis. To inquire about the CommandEvent queue manager attribute, use the new attribute selector iacev with one of the following values:

- EVRENA - command event messages are generated and put onto the queue for all successful commands.
- EVND - command event messages are generated and put onto the queue for all successful commands other than the DISPLAY (MQSC) command, and the Inquire (PCF) command.
- EVRDIS - command event messages are not generated or put onto the queue (this is the queue manager's initial default value).

To determine the value of this attribute, use the CMDEV selector with the MQINQ call.

CommandInputQName (48-byte character string)

Command input queue name.

CommandInputQName is the name of the command input queue defined on the local queue manager. It is a queue to which users can send commands, if authorized to do so. The name of the queue depends on the environment:

- On IBM i, the name of the queue is SYSTEM.ADMIN.COMMAND.QUEUE, and only PCF commands can be sent to it. However, an MQSC command can be sent to this queue if the MQSC command is enclosed within a PCF command of type CMESC. For more information about the Escape command, see [Escape](#).

To determine the value of this attribute, use the CACMDQ selector with the MQINQ call. The length of this attribute is given by LNQN.

CommandLevel (10-digit signed integer)

Command Level. This indicates the level of system control commands supported by the queue manager.

The level is one of the following values:

CML700

Level 700 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i Version 7 Release 0

CML701

Level 701 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i Version 7 Release 0 Modification 1

CML71

Level 71 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i Version 7 Release 1

CML800

Level 800 of system control commands.

This value is returned by the following applications:

- IBM MQ for IBM i
 - Version 8.0

The set of system control commands that corresponds to a particular value of the *CommandLevel* attribute varies according to the value of the *Platform* attribute; both must be used to decide which system control commands are supported.

To determine the value of this attribute, use the IACMDL selector with the MQINQ call.

ConfigurationEvent

Controls whether configuration events are generated and sent to the SYSTEM.ADMIN.CONFIG.EVENT queue default object.

The ConfigurationEvent attribute can be one of the following values:

- EVRENA
- EVRDIS

If the ConfigurationEvent attribute is set to EVRENA, and certain commands are successfully issued by runmqsc or PCF, configuration events are generated and sent to the SYSTEM.ADMIN.CONFIG.EVENT queue. Events for the following commands are issued, even if an alter command does not change the object involved. The commands for which configuration events are generated and sent are:

- DEFINE/ALTER AUTHINFO
- DEFINE/ALTER CHANNEL
- DEFINE/ALTER NAMELIST
- DEFINE/ALTER PROCESS
- DEFINE/ALTER QLOCAL (unless it is a temporary dynamic queue)
- DEFINE/ALTER QMODEL/QALIAS/QREMOTE
- DELETE AUTHINFO
- DELETE CHANNEL
- DELETE NAMELIST
- DELETE PROCESS
- DELETE QLOCAL (unless it is a temporary dynamic queue)
- DELETE QMODEL/QALIAS/QREMOTE
- ALTER QMGR (unless the CONFIGEV attribute is disabled and is not changed to enabled)
- REFRESH QMGR
- An MQSET call, other than for a temporary dynamic queue.

Events are not generated (if enabled) in the following circumstances:

- The command or MQSET call fails.
- The queue manager cannot put the event message on the event queue. The command should still complete successfully.
- Temporary dynamic queues.
- Internal attribute changes done directly or implicitly (not by MQSET or command); this affects TRIGGER, CURDEPTH, IPPROCS, OPPROCS, QDPHIEV, QDPLOEV, QDPMAXEV, QSVCI EV.
- When the configuration event queue is changed, although it an event message will be generated for that change when a Refresh is requested.
- Clustering changes by the commands REFRESH/RESET CLUSTER and RESUME/SUSPEND QMGR.
- Creating or deleting a queue manager.

DeadLetterQName (48-byte character string)

Name of dead-letter (undelivered-message) queue.

This is the name of a queue defined on the local queue manager. Messages are sent to this queue if they cannot be routed to their correct destination.

For example, messages are put on this queue when:

- A message arrives at a queue manager, destined for a queue that is not yet defined on that queue manager
- A message arrives at a queue manager, but the queue for which it is destined cannot receive it because, possibly:
 - The queue is full
 - Put requests are inhibited
 - The sending node does not have authority to put messages on the queue

Applications can also put messages on the dead-letter queue.

Report messages are treated in the same way as ordinary messages; if the report message cannot be delivered to its destination queue (typically the queue specified by the *MDRQ* field in the message descriptor of the original message), the report message is placed on the dead-letter (undelivered-message) queue.

Note: Messages that have passed their expiry time (see the *MDEXP* field described in “MQMD - Message descriptor” on page 1068) are **not** transferred to this queue when they are discarded. However, an expiration report message (ROEXP) is still generated and sent to the *MDRQ* queue, if requested by the sending application.

Messages are not put on the dead-letter (undelivered-message) queue when the application that issued the put request has been notified synchronously of the problem with the reason code returned by the MQPUT or MQPUT1 call (for example, a message put on a local queue for which put requests are inhibited).

Messages on the dead-letter (undelivered-message) queue sometimes have their application message data prefixed with an MQDLH structure. This structure contains extra information that indicates why the message was placed on the dead-letter (undelivered-message) queue. See “MQDLH - Dead-letter header” on page 1023 for more details of this structure.

This queue must be a local queue, with a *Usage* attribute of USNORM.

If a dead-letter (undelivered-message) queue is not supported by a queue manager, or one has not been defined, the name is all blanks. All IBM MQ queue managers support a dead-letter (undelivered-message) queue, but by default it is not defined.

If the dead-letter (undelivered-message) queue is not defined, or it is full, or unusable for some other reason, a message which would have been transferred to it by a message channel agent is retained instead on the transmission queue.

To determine the value of this attribute, use the CADLQ selector with the MQINQ call. The length of this attribute is given by LNQN.

DefClusterXmitQueueType (10-digit signed integer)

The DefClusterXmitQueueType attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

The values of **DefClusterXmitQueueType** are MQCLXQ_SCTQ or MQCLXQ_CHANNEL.

MQCLXQ_SCTQ

All cluster-sender channels send messages from SYSTEM.CLUSTER.TRANSMIT.QUEUE. The correlID of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined. This behavior is implicit in versions of IBM WebSphere MQ, earlier than Version 7.5. In earlier versions, the queue manager attribute DefClusterXmitQueueType was not present.

MQCLXQ_CHANNEL

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE.

If the queue manager attribute, DefClusterXmitQueueType, is set to CHANNEL, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

To query the value, call MQINQ, or send an Inquire Queue Manager (MQCMD_INQUIRE_Q_MGR) PCF command, setting the MQIA_DEF_CLUSTER_XMIT_Q_TYPE selector. To change the value, send a Change Queue Manager (MQCMD_CHANGE_Q_MGR) PCF command, setting the MQIA_DEF_CLUSTER_XMIT_Q_TYPE selector.

Related reference

[Change Queue Manager](#)

[Inquire Queue Manager](#)

[“MQINQ - Inquire about object attributes” on page 1261](#)

The MQINQ call returns an array of integers and a set of character strings containing the attributes of an object.

DefXmitQName (48-byte character string)

Default transmission queue name.

This is the name of the transmission queue that is used for the transmission of messages to remote queue managers, if there is no other indication of which transmission queue to use.

If there is no default transmission queue, the name is entirely blank. The initial value of this attribute is blank.

To determine the value of this attribute, use the CADXQN selector with the MQINQ call. The length of this attribute is given by LNQN.

DistLists (10-digit signed integer)

Distribution list support.

This indicates whether the local queue manager supports distribution lists on the MQPUT and MQPUT1 calls. This can have one of the following values:

DLSUPP

Distribution lists supported.

DLNSUP

Distribution lists not supported.

To determine the value of this attribute, use the IADIST selector with the MQINQ call.

InhibitEvent (10-digit signed integer)

Controls whether inhibit (Inhibit Get and Inhibit Put) events are generated.

This can have one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Monitoring and performance](#).

To determine the value of this attribute, use the IAINHE selector with the MQINQ call.

LocalEvent (10-digit signed integer)

Controls whether local error events are generated.

The value is one of the following:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#)

To determine the value of this attribute, use the IALCLE selector with the MQINQ call.

LoggerEvent (10-digit signed integer)

Controls whether recovery logger events are generated.

This can have one of the following values:

ENABLED

Logger events are generated.

DISABLED

Logger events are not generated. This is the queue managers initial default value.

For more information about events, see [Monitoring and performance](#).

MaxHandles (10-digit signed integer)

Maximum number of handles.

This is the maximum number of open handles that any one task can use concurrently. Each successful MQOPEN call for a single queue (or for an object that is not a queue) uses one handle. That handle becomes available for reuse when the object is closed. However, when a distribution list is opened, each queue in the distribution list is allocated a separate handle, and so that MQOPEN call uses as many handles as there are queues in the distribution list. This must be taken into account when deciding on a suitable value for *MaxHandles*.

The MQPUT1 call performs an MQOPEN call as part of its processing; as a result, MQPUT1 uses as many handles as MQOPEN would, but the handles are used only for the duration of the MQPUT1 call itself.

The value is in the range 1 through 999 999 999. On IBM i, the default value is 256.

To determine the value of this attribute, use the IAMHND selector with the MQINQ call.

MaxMsgLength (10-digit signed integer)

Maximum message length in bytes.

This is the length of the longest *physical* message that can be handled by the queue manager. However, because the *MaxMsgLength* queue manager attribute can be set independently of the *MaxMsgLength* queue attribute, the longest physical message that can be placed on a queue is the lesser of those two values.

If the queue manager supports segmentation, it is possible for an application to put a *logical* message that is longer than the lesser of the two *MaxMsgLength* attributes, but only if the application specifies the MFSEGA flag in MQMD. If that flag is specified, the upper limit for the length of a logical message is 999 999 999 bytes, but typically, resource constraints imposed by the operating system or by the environment in which the application is running, will result in a lower limit.

The lower limit for the *MaxMsgLength* attribute is 32 KB (32 768 bytes). On IBM i, the maximum message length is 100 MB (104 857 600 bytes).

To determine the value of this attribute, use the IAMLEN selector with the MQINQ call.

MaxPriority (10-digit signed integer)

Maximum priority.

This is the maximum message priority supported by the queue manager. Priorities range from zero (lowest) to *MaxPriority* (highest).

To determine the value of this attribute, use the IAMPRI selector with the MQINQ call.

MaxUncommittedMsgs (10-digit signed integer)

Maximum number of uncommitted messages within a unit of work.

This is the maximum number of uncommitted messages that can exist within a unit of work. The number of uncommitted messages is the sum of the following since the start of the current unit of work:

- Messages put by the application with the PMSYP option
- Messages retrieved by the application with the GMSYP option
- Trigger messages and COA report messages generated by the queue manager for messages put with the PMSYP option
- COD report messages generated by the queue manager for messages retrieved with the GMSYP option

The following are *not* counted as uncommitted messages:

- Messages put or retrieved by the application outside a unit of work
- Trigger messages or COA/COD report messages generated by the queue manager as a result of messages put or retrieved outside a unit of work
- Expiration report messages generated by the queue manager (even if the call causing the expiration report message specified GMSYP)
- Event messages generated by the queue manager (even if the call causing the event message specified PMSYP or GMSYP)

Note:

1. Exception report messages are generated by the Message Channel Agent (MCA), or by the application, and so are treated in the same way as ordinary messages put or retrieved by the application.
2. When a message or segment is put with the PMSYP option, the number of uncommitted messages is incremented by one regardless of how many physical messages actually result from the put. (More than one physical message might result if the queue manager needs to subdivide the message or segment.)
3. When a distribution list is put with the PMSYP option, the number of uncommitted messages is incremented by one *for each physical message that is generated*. This can be as small as one, or as great as the number of destinations in the distribution list.

The lower limit for this attribute is 1; the upper limit is 999 999 999.

To determine the value of this attribute, use the IAMUNC selector with the MQINQ call.

PerformanceEvent (10-digit signed integer)

Controls whether performance-related events are generated.

PerformanceEvent can have one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IAPFME selector with the MQINQ call.

Platform (10-digit signed integer)

Platform on which the queue manager is running.

This indicates the operating system on which the queue manager is running. The value is:

PL400

IBM i.

PubSubMode (10-digit signed integer)

Whether the publish/subscribe engine and the queued publish/subscribe interface are running, therefore allowing applications to publish/subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface.

This can have one of the following values:

PSMCP

The publish/subscribe engine is running. It is therefore possible to publish/subscribe by using the application programming interface. The queued publish/subscribe interface is not running, therefore any message that is put to the queues that are monitored by the queued publish/subscribe interface is not acted on. This setting is used for compatibility with WebSphere Message Broker V6 or earlier versions using this queue manager, because it must read the same queues from which the queued publish/subscribe interface normally reads.

PSMDS

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish/subscribe by using the application programming interface. Any publish/subscribe messages that are put to the queues that are monitored by the queued publish/subscribe interface are not acted on.

PSMEN

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish/subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface. This is the queue manager's initial default value.

To determine the value of this attribute, use the PSMODE selector with the MQINQ call.

QMGrDesc (64-byte character string)

Queue manager description.

This is a field that can be used for descriptive commentary. The content of the field is of no significance to the queue manager, but the queue manager might require that the field contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, this field can contain DBCS characters (subject to a maximum field length of 64 bytes).

Note: If this field contains characters that are not in the queue manager's character set (as defined by the *CodedCharSetId* queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

On IBM i, the default value is blanks.

To determine the value of this attribute, use the CAQMD selector with the MQINQ call. The length of this attribute is given by LNQMD.

QMGrIdentifier (48-byte character string)

Unique internally-generated identifier of queue manager.

This is an internally-generated unique name for the queue manager.

To determine the value of this attribute, use the CAQMID selector with the MQINQ call. The length of this attribute is given by LNQMID.

QMGrName (48-byte character string)

Queue manager name.

This is the name of the local queue manager, that is, the name of the queue manager to which the application is connected.

The first 12 characters of the name are used to construct a unique message identifier (see the *MDMID* field described in “MQMD - Message descriptor” on page 1068). Queue managers that can intercommunicate must therefore have names that differ in the first 12 characters, in order for message identifiers to be unique in the queue manager network.

To determine the value of this attribute, use the CAQMN selector with the MQINQ call. The length of this attribute is given by LNQMN.

RemoteEvent (10-digit signed integer)

Controls whether remote error events are generated.

The value is one of the following:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IARMTE selector with the MQINQ call.

RepositoryName (48-byte character string)

Name of cluster for which this queue manager provides repository services.

This is the name of a cluster for which this queue manager provides a repository-manager service. If the queue manager provides this service for more than one cluster, *RepositoryNameList* specifies the name of a namelist object that identifies the clusters, and *RepositoryName* is blank. At least one of *RepositoryName* and *RepositoryNameList* must be blank.

To determine the value of this attribute, use the CARPN selector with the MQINQ call. The length of this attribute is given by LNQMNM.

RepositoryNameList (48-byte character string)

Name of namelist object containing names of clusters for which this queue manager provides repository services.

This is the name of a namelist object that contains the names of clusters for which this queue manager provides a repository-manager service. If the queue manager provides this service for only one cluster, the namelist object contains only one name. Alternatively, *RepositoryName* can be used to specify the name of the cluster, in which case *RepositoryNameList* is blank. At least one of *RepositoryName* and *RepositoryNameList* must be blank.

To determine the value of this attribute, use the CARPNL selector with the MQINQ call. The length of this attribute is given by LNNLN.

SSLEvent (character string)

Determines whether SSL events are generated.

The value is one of the following:

- EVRENA (MQINQ/PCF/config event) ENABLED (MQSC): SSL events are generated (that is, the RC2371 event is generated).
- EVRDIS (MQINQ/PCF/config event) DISABLED (MQSC): SSL events are not generated. This is the queue manager's initial default value.

To determine the value of this attribute, use the IASSLE selector with the MQINQ call.

SSLKeyResetCount (integer)

Determines the total number of non-encrypted bytes that are sent and received within an SSL conversation, before the secret key is renegotiated. The number of bytes includes control information sent by the message channel agent (MCA).

This value is only used by SSL channel MCAs which initiate communication from this queue manager (that is, the sender channel MCA in a sender and receiver channel pairing).

If the value of this attribute is greater than 0, and channel heartbeats are enabled for a channel, the secret key is also renegotiated before data is sent or received following a channel heartbeat. The count of bytes until the next secret key renegotiation is reset after each successful renegotiation occurs.

The value can be in the range 0 through 999 999 999. A value of 0 for this attribute indicates that the secret key is never renegotiated. If you specify an SSL/TLS secret key reset count in the range 1 byte through 32 KB, SSL/TLS channels will use a secret key reset count of 32 KB. This is to avoid the processing cost of excessive key resets which would occur for small SSL/TLS secret key reset values.

When the SSL server is an IBM MQ queue manager, and both secret key reset and channel heartbeats are enabled, renegotiation occurs immediately after each channel heartbeat.

To determine the value of this attribute, use the IASSRC selector with the MQINQ call.

StartStopEvent (10-digit signed integer)

Controls whether start and stop events are generated.

This attribute can have one of the following values:

EVRDIS

Event reporting disabled.

EVRENA

Event reporting enabled.

For more information about events, see [Event monitoring](#).

To determine the value of this attribute, use the IASSE selector with the MQINQ call.

SyncPoint (10-digit signed integer)

Syncpoint availability.

This indicates whether the local queue manager supports units of work and syncpointing with the MQGET, MQPUT, and MQPUT1 calls.

SPAVL

Units of work and syncpointing available.

SPNAVL

Units of work and syncpointing not available.

To determine the value of this attribute, use the IASYNC selector with the MQINQ call.

TraceRouteRecording (10-digit signed integer)

This controls whether information about messages is recorded as they flow through a queue manager.

The value is one of the following:

- RECDD: no appending to trace route messages is allowed
- RECDQ: messages are put onto a fixed named queue
- RECDM: determine using message (this is the initial default setting)

To prevent the trace route message from remaining in the system, set an expiry value on it that is greater than zero, and specify the RODISC report option. To prevent report or reply messages remaining in the system, set the report option ROPDAE. For more information, see [“Report options and message flags” on page 1388](#).

To determine the value of this attribute, use the IATRGI selector with the MQINQ call.

TreeLifeTime (10-digit signed integer)

The lifetime, in seconds, of non-administrative topics.

Non-administrative topics are those created when an application publishes to, or subscribes as, a topic string that does not exist as an administrative node. When this non-administrative node no longer has any active subscriptions, this parameter determines how long the queue manager will wait before removing that node. Only non-administrative topics that are in use by a durable subscription remain after the queue manager is recycled.

Specify a value in the range 0 through 604 000. A value of 0 means that non-administrative topics are not removed by the queue manager. The queue manager's initial default value is 1800.

To determine the value of this attribute, use the IATRLFT selector with the MQINQ call.

TriggerInterval (10-digit signed integer)

Trigger-message interval.

This is a time interval (in milliseconds) used to restrict the number of trigger messages. This is relevant only when the *TriggerType* is TTFRST. In this case, trigger messages are normally generated only when a suitable message arrives on the queue, and the queue was previously empty. Under certain circumstances, however, an additional trigger message can be generated with TTFRST triggering even if the queue was not empty. These additional trigger messages are not generated more often than every *TriggerInterval* milliseconds.

For more information about triggering, see [Triggering channels](#).

The value is in the range zero through 999 999 999. The default value is 999 999 999.

To determine the value of this attribute, use the IATRGI selector with the MQINQ call.

Applications

This information describes the sample programs delivered with IBM MQ for IBM i for RPG. Also, learn how to build executable applications from the programs you write.

Building your application

The IBM i publications describe how to build executable applications from the programs you write. This topic describes the additional tasks, and the changes to the standard tasks, you must perform when building IBM MQ for IBM i applications to run under IBM i.

In addition to coding the MQI calls in your source code, you must add the appropriate language statements to include the IBM MQ for IBM i copy files for the RPG language. You should make yourself familiar with the contents of these files; their names, and a brief description of their contents are given in the following text.

IBM MQ copy files

IBM MQ for IBM i provides copy files to assist you with writing your applications in the RPG programming language. They are suitable for use with the WebSphere Development toolset (5722 WDS) ILE RPG 4 Compiler.

The copy files that IBM MQ for IBM i provides to assist with the writing of channel exits are described in [Channel-exit programs for messaging channels](#).

The names of the IBM MQ for IBM i copy files for RPG have the prefix CMQ. They have a suffix of G or H. There are separate copy files containing the named constants, and one file for each of the structures. The copy files are listed in [“Language considerations” on page 971](#).

Note: For ILE RPG/400, they are supplied as members of file QRPGLSRC in library QMQM.

The structure declarations do not contain DS statements. This allows the application to declare a data structure (or a multiple-occurrence data structure) by coding the DS statement and using the /COPY statement to copy in the remainder of the declaration:

For ILE RPG/400 the statement is:

```
D*..1.....2.....3.....4.....5.....6.....7
D* Declare an MQMD data structure
D MQMD          DS
D/COPY CMQMDG
```

Preparing your programs to run

To create an executable IBM MQ for IBM i application, you have to compile the source code you have written.

To do this for ILE RPG/400, you can use the typical IBM i commands, CRTRPGMOD and CRTPGM.

After creating your *MODULE, you need to specify BNDSRVPGM (QMQM/LIBMQM) in the CRTPGM command. This includes the various IBM MQ procedures in your program.

Make sure that the library containing the copy files (QMQM) is in the library list when you perform the compilation.

For further information concerning programming considerations, including client modes, see [“Language considerations” on page 971](#).

Interfaces to the IBM i external syncpoint manager

IBM MQ for IBM i uses native IBM i commitment control as an external syncpoint coordinator.

See the *IBM i Programming: Backup and Recovery Guide* for more information about the commitment control capabilities of IBM i.

To start the IBM i commitment control facilities, use the STRCMTCTL system command. To end commitment control, use the ENDCMTCTL system command.

Note: The default value of *Commitment definition scope* is *ACTGRP. This must be defined as *JOB for IBM MQ for IBM i. For example:

```
STRCMTCTL LCKLVL(*ALL) CMTSCOPE(*JOB)
```

If you call MQPUT, MQPUT1, or MQGET, specifying PMSYP or GMSYP, after starting commitment control, IBM MQ for IBM i adds itself as an API commitment resource to the commitment definition. This is typically the first such call in a job. While there are any API commitment resources registered under a particular commitment definition, you cannot end commitment control for that definition.

IBM MQ for IBM i removes its registration as an API commitment resource when you disconnect from the queue manager, provided there are no pending MQI operations in the current unit of work.

If you disconnect from the queue manager while there are pending MQPUT, MQPUT1, or MQGET operations in the current unit of work, IBM MQ for IBM i remains registered as an API commitment resource so that it is notified of the next commit or rollback. When the next syncpoint is reached, IBM MQ commits or rolls back the changes as required. It is possible for an application to disconnect and reconnect to a queue manager during an active unit of work and perform further MQGET and MQPUT operations inside the same unit of work (this is a pending disconnect).

If you attempt to issue an ENDCMTCTL system command for that commitment definition, message CPF8355 is issued, indicating that pending changes were active. This message also appears in the job log when the job ends. To avoid this, ensure that you commit or roll back all pending IBM MQ operations, and that you disconnect from the queue manager. Thus, using COMMIT or ROLLBACK commands before ENDCMTCTL should enable end-commitment control to complete successfully.

When IBM i commitment control is used as an external syncpoint coordinator, MQCMIT, MQBACK, and MQBEGIN calls might not be issued. Calls to these functions fail with the reason code RC2012.

To commit or roll back (that is, to back out) your unit of work, use one of the programming languages that supports the commitment control. For example:

- CL commands: COMMIT and ROLLBACK
- ILE C Programming Functions: _Rcommit and _Rrollback
- RPG/400: COMMIT and ROLBK
- COBOL/400: COMMIT and ROLLBACK

Syncpoints in CICS for IBM i applications

IBM MQ for IBM i participates in units of work with CICS. You can use the MQI within a CICS application to put and get messages inside the current unit of work.

You can use the EXEC CICS SYNCPOINT command to establish a syncpoint that includes the IBM MQ for IBM i operations. To back out all changes up to the previous syncpoint, you can use the EXEC CICS SYNCPOINT ROLLBACK command.

If you use MQPUT, MQPUT1, or MQGET with the PMSYP, or GMSYP, option set in a CICS application, you cannot log off CICS until IBM MQ for IBM i has removed its registration as an API commitment resource. Therefore, you should commit or back out any pending put or get operations before you disconnect from the queue manager. This will allow you to log off CICS.

Sample programs on IBM i

This topic describes the sample programs delivered with IBM MQ for IBM i for RPG. The samples demonstrate typical uses of the Message Queue Interface (MQI).

The samples are not intended to demonstrate general programming techniques, so some error checking that you may want to include in a production program has been omitted. However, these samples are suitable for use as a base for your own message queuing programs.

The source code for all the samples is provided with the product; this source includes comments that explain the message queuing techniques demonstrated in the programs.

There is one set of ILE sample programs:

1. Programs using prototyped calls to the MQI (static bound calls)

The source exists in QMQMSAMP/QRPGLESRC. The members are named AMQ3xxx4, where xxx indicates the sample function. Copy members exist in QMQM/QRPGLESRC. Each member name has a suffix of G or H.

Table 628 on page 1371 gives a complete list of the sample programs delivered with IBM MQ for IBM i, and shows the names of the programs in each of the supported programming languages. Notice that their names all start with the prefix AMQ, the fourth character in the name indicates the programming language.

Table 628. Names of the sample programs	
	RPG (ILE)
Put samples	AMQ3PUT4
Browse samples	AMQ3GBR4
Get samples	AMQ3GET4
Request samples	AMQ3REQ4
Echo samples	AMQ3ECH4
Inquire samples	AMQ3INQ4
Set samples	AMQ3SET4
Trigger Monitor sample	AMQ3TRG4
Trigger Server sample	AMQ3SRV4

In addition to these, the IBM MQ for IBM i sample option includes a sample data file, AMQSDATA, which can be used as input to certain sample programs and sample CL programs that demonstrate administration tasks. The CL samples are described in [Administering IBM i](#). You could use the sample CL program to create queues to use with the sample programs described in this topic.

For information about how to run the sample programs, see [“Preparing and running the sample programs on IBM i”](#) on page 1372.

Features demonstrated in the sample programs on IBM i

A table that shows the techniques demonstrated by the IBM MQ for IBM i sample programs.

Some techniques occur in more than one sample program, but only one program is listed in the table. All the samples open and close queues using the MQOPEN and MQCLOSE calls, so these techniques are not listed separately in the table.

<i>Table 629. Sample programs demonstrating use of the MQI</i>	
Technique	RPG (ILE)
Using the MQCONN and MQDISC calls	AMQ3ECH4 or AMQ3INQ4
Implicitly connecting and disconnecting	AMQ3PUT4
Putting messages using the MQPUT call	AMQ3PUT4
Putting a single message using the MQPUT1 call	AMQ3ECH4 or AMQ3INQ4
Replying to a request message	AMQ3INQ4
Getting messages (no wait)	AMQ3GBR4
Getting messages (wait with a time limit)	AMQ3GET4
Getting messages (with data conversion)	AMQ3ECH4
Browsing a queue	AMQ3GBR4
Using a shared input queue	AMQ3INQ4
Using an exclusive input queue	AMQ3REQ4
Using the MQINQ call	AMQ3INQ4
Using the MQSET call	AMQ3SET4
Using a reply-to queue	AMQ3REQ4
Requesting exception messages	AMQ3REQ4
Accepting a truncated message	AMQ3GBR4
Using a resolved queue name	AMQ3GBR4
Trigger processing	AMQ3SRV4 or AMQ3TRG4

Note: All the sample programs produce a spool file that contains the results of the processing.

Preparing and running the sample programs on IBM i

Before you can run the IBM MQ for IBM i sample programs, you must compile them as you would any other IBM MQ for IBM i applications. To do so, you can use the IBM i commands CRTRPGMOD and CRTPGM.

When you create the AMQ3xxx4 programs, you must specify BNDSRVPGM(QMQM/LIBMQM) in the CRTPGM command. Doing so includes the various IBM MQ procedures in your program.

The sample programs are provided in library QMQMSAMP as members of QRPGLSRC. They use the copy files provided in library QMQM, so make sure that this library is in the library list when you compile them. The RPG compiler gives information messages because the samples do not use many of the variables that are declared in the copy files.

Running the sample programs

You can use your own queues when you run the samples, or you can compile and run AMQSAMP4 to create some sample queues. The source for this program is shipped in file QCLSRC in library QMQMSAMP. It can be compiled using the CRTCLPGM command.

To call one of the sample programs, use a command like:

```
CALL PGM(QMQMSAMP/AMQ3PUT4) PARM('Queue_Name','Queue_Manager_Name')
```

Where `Queue_Name` and `Queue_Manager_Name` must be 48 characters in length, which you achieve by padding the `Queue_Name` and `Queue_Manager_Name` with the required number of blanks.

For the Inquire and Set sample programs, the sample definitions created by AMQSAMP4 cause the C versions of these samples to be triggered. If you want to trigger the RPG versions, you must change the process definitions `SYSTEM.SAMPLE.ECHOPROCESS` and `SYSTEM.SAMPLE.INQPROCESS` and `SYSTEM.SAMPLE.SETPROCESS`. You can use the `CHGMQMPRC` command (described in [Change MQ Process \(CHGMQMPRC\)](#)) to do so, or edit and run AMQSAMP4 with the alternative definition.

The Put sample program on IBM i

The Put sample program, AMQ3PUT4, puts messages on a queue using the MQPUT call.

To start the program, call the program and give the name of your target queue as a program parameter. The program puts a set of fixed messages on the queue; these messages are taken from the data block at the end of the program source code. A sample put program is AMQ3PUT4 in library QMQMSAMP.

Using this example program, the command is:

```
CALL PGM(QMQMSAMP/AMQ3PUT4) PARM('Queue_Name','Queue_Manager_Name')
```

Where `Queue_Name` and `Queue_Manager_Name` *must* be 48 characters in length, which you achieve by padding the `Queue_Name` and `Queue_Manager_Name` with the required number of blanks.

Design of the Put sample program

The program uses the MQOPEN call with the OOOUT option to open the target queue for putting messages. The results are output to a spool file. If it cannot open the queue, the program writes an error message containing the reason code returned by the MQOPEN call. To keep the program simple, on this and on subsequent MQI calls, the program uses default values for many of the options.

For each line of data contained in the source code, the program reads the text into a buffer and uses the MQPUT call to create a datagram message containing the text of that line. The program continues until either it reaches the end of the input or the MQPUT call fails. If the program reaches the end of the input, it closes the queue using the MQCLOSE call.

The Browse sample program on IBM i

The Browse sample program, AMQ3GBR4, browses messages on a queue using the MQGET call.

The program retrieves copies of all the messages on the queue you specify when you call the program; the messages remain on the queue. You could use the supplied queue `SYSTEM.SAMPLE.LOCAL`; run the Put sample program first to put some messages on the queue. You could use the queue `SYSTEM.SAMPLE.ALIAS`, which is an alias name for the same local queue. The program continues until it reaches the end of the queue or an MQI call fails.

An example of a command to call the RPG program is:

```
CALL PGM(QMQMSAMP/AMQ3GBR4) PARM('Queue_Name','Queue_Manager_Name')
```

Where `Queue_Name` and `Queue_Manager_Name` *must* be 48 characters in length, which you achieve by padding the `Queue_Name` and `Queue_Manager_Name` with the required number of blanks. Therefore, if you are using `SYSTEM.SAMPLE.LOCAL` as your target queue, you will need 29 blank characters.

Design of the Browse sample program

The program opens the target queue using the MQOPEN call with the OOBROW option. If it cannot open the queue, the program writes an error message to its spool file, containing the reason code returned by the MQOPEN call.

For each message on the queue, the program uses the MQGET call to copy the message from the queue, then displays the data contained in the message. The MQGET call uses these options:

GMBRWN

After the MQOPEN call, the browse cursor is positioned logically before the first message in the queue, so this option causes the *first* message to be returned when the call is first made.

GMNWT

The program does not wait if there are no messages on the queue.

GMATM

The MQGET call specifies a buffer of fixed size. If a message is longer than this buffer, the program displays the truncated message, together with a warning that the message has been truncated.

The program demonstrates how you must clear the *MDMID* and *MDCID* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The program continues to the end of the queue; here, the MQGET call returns the RC2033 (no message available) reason code and the program displays a warning message. If the MQGET call fails, the program writes an error message that contains the reason code in its spool file.

The program then closes the queue using the MQCLOSE call.

The Get sample program on IBM i

The Get sample program, AMQ3GET4, gets messages from a queue using the MQGET call.

When the program is called, it removes messages from the specified queue. You could use the supplied queue SYSTEM.SAMPLE.LOCAL; run the Put sample program first to put some messages on the queue. You could use the SYSTEM.SAMPLE.ALIAS queue, which is an alias name for the same local queue. The program continues until the queue is empty or an MQI call fails.

An example of a command to call the RPG program is:

```
CALL PGM(QMQMSAMP/AMQ3GET4) PARM('Queue_Name','Queue_Manager_Name')
```

where Queue_Name and Queue_Manager_Name *must* be 48 characters in length, which you achieve by padding the Queue_Name and Queue_Manager_Name with the required number of blanks. Therefore, if you are using SYSTEM.SAMPLE.LOCAL as your target queue, you will need 29 blank characters.

Design of the Get sample program

The program opens the target queue for getting messages; it uses the MQOPEN call with the OOINPQ option. If it cannot open the queue, the program writes an error message containing the reason code returned by the MQOPEN call in its spool file.

For each message on the queue, the program uses the MQGET call to remove the message from the queue; it then displays the data contained in the message. The MQGET call uses the GMWT option, specifying a wait interval (*GMWT*) of 15 seconds, so that the program waits for this period if there is no message on the queue. If no message arrives before this interval expires, the call fails and returns the RC2033 (no message available) reason code.

The program demonstrates how you must clear the *MDMID* and *MDCID* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The MQGET call specifies a buffer of fixed size. If a message is longer than this buffer, the call fails and the program stops.

The program continues until either the MQGET call returns the RC2033 (no message available) reason code or the MQGET call fails. If the call fails, the program displays an error message that contains the reason code.

The program then closes the queue using the MQCLOSE call.

The Request sample program on IBM i

The Request sample program, AMQ3REQ4, demonstrates client/server processing. The sample is the client that puts request messages on a queue that is processed by a server program. It waits for the server program to put a reply message on a reply-to queue.

The Request sample puts a series of request messages on a queue using the MQPUT call. These messages specify SYSTEM.SAMPLE.REPLY as the reply-to queue. The program waits for reply messages, then displays them. Replies are sent only if the target queue (which we will call the *server queue*) is being processed by a server application, or if an application is triggered for that purpose (the Inquire and Set sample programs are designed to be triggered). The sample waits 5 minutes for the first reply to arrive (to allow time for a server application to be triggered) and 15 seconds for subsequent replies, but it can end without getting any replies.

To start the program, call the program and give the name of your target queue as a program parameter. The program puts a set of fixed messages on the queue; these messages are taken from the data block at the end of the program source code.

Design of the Request sample program

The program opens the server queue so that it can put messages. It uses the MQOPEN call with the OOOOUT option. If it cannot open the queue, the program displays an error message containing the reason code returned by the MQOPEN call.

The program then opens the reply-to queue called SYSTEM.SAMPLE.REPLY so that it can get reply messages. For this, the program uses the MQOPEN call with the OOINPX option. If it cannot open the queue, the program displays an error message containing the reason code returned by the MQOPEN call.

For each line of input, the program then reads the text into a buffer and uses the MQPUT call to create a request message containing the text of that line. On this call the program uses the ROEXCD report option to request that any report messages sent about the request message will include the first 100 bytes of the message data. The program continues until either it reaches the end of the input or the MQPUT call fails.

The program then uses the MQGET call to remove reply messages from the queue, and displays the data contained in the replies. The MQGET call uses the GMWT option, specifying a wait interval (*GMWT*) of 5 minutes for the first reply (to allow time for a server application to be triggered) and 15 seconds for subsequent replies. The program waits for these periods if there is no message on the queue. If no message arrives before this interval expires, the call fails and returns the RC2033 (no message available) reason code. The call also uses the GMATM option, so messages longer than the declared buffer size are truncated.

The program demonstrates how you must clear the *MDMID* and *MDCOD* fields of the MQMD structure after each MQGET call because the call sets these fields to the values contained in the message it retrieves. Clearing these fields means that successive MQGET calls retrieve messages in the order in which the messages are held in the queue.

The program continues until either the MQGET call returns the RC2033 (no message available) reason code or the MQGET call fails. If the call fails, the program displays an error message that contains the reason code.

The program then closes both the server queue and the reply-to queue using the MQCLOSE call. Table 630 on page 1375 shows the changes to the Echo sample program that are necessary to run the Inquire and Set sample programs.

Note: The details for the Echo sample program are included as a reference.

<i>Table 630. Client/Server sample program details</i>		
Program name	SYSTEM/SAMPLE queue	Program started
Echo	ECHO	AMQ3ECH4
Inquire	INQ	AMQ3INQ4

Table 630. Client/Server sample program details (continued)		
Program name	SYSTEM/SAMPLE queue	Program started
Set	SET	AMQ3SET4

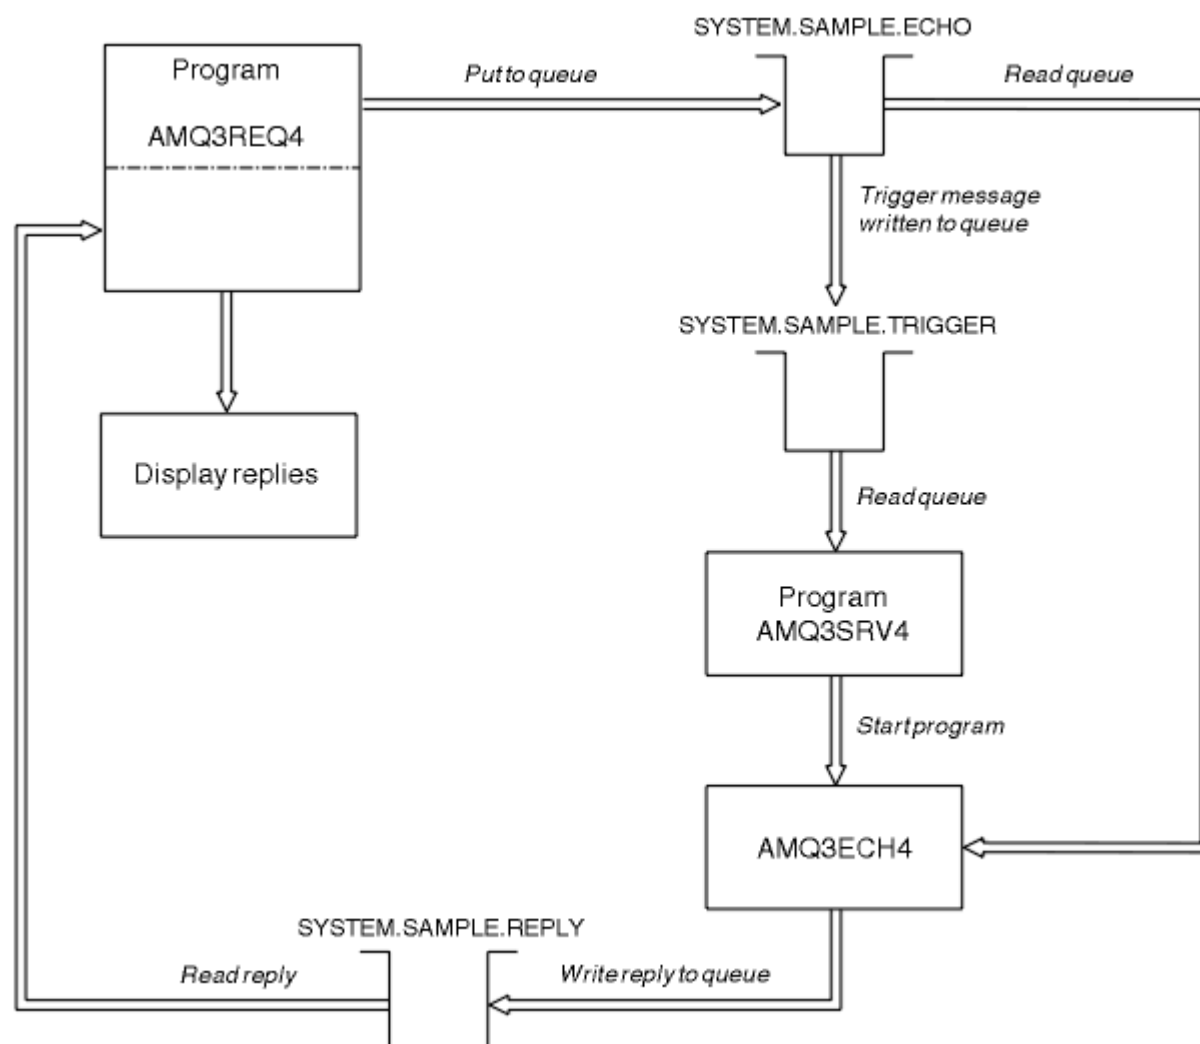

Figure 9. Sample Client/Server (Echo) program flowchart

Using triggering with the Request sample

To run the sample using triggering, start the trigger server program, AMQ3SRV4, against the required initiation queue in one job, then start AMQ3REQ4 in another job.

This means that the trigger server is ready when the Request sample program sends a message.

Note:

1. The samples use the SYSTEM SAMPLE TRIGGER queue as the initiation queue for SYSTEM.SAMPLE.ECHO, SYSTEM.SAMPLE.INQ, or SYSTEM.SAMPLE.SET local queues. Alternatively, you can define your own initiation queue.
2. The sample definitions created by AMQSAMP4 cause the C version of the sample to be triggered. If you want to trigger the RPG version, you must change the process definitions SYSTEM.SAMPLE.ECHOPROCESS and SYSTEM.SAMPLE.INQPROCESS and SYSTEM.SAMPLE.SETPROCESS. You can use the CHGMQMPCRC command (see [Change MQ Process \(CHGMQMPCRC\)](#) for more details) to do this, or edit and run your own version of AMQSAMP4.
3. You must compile the trigger server program from the source provided in QMQMSAMP/QRPGLESRC.

Depending on the trigger process you want to run, AMQ3REQ4 should be called with the parameter specifying request messages to be placed on one of these sample server queues:

- SYSTEM.SAMPLE.ECHO (for the Echo sample programs)
- SYSTEM.SAMPLE.INQ (for the Inquire sample programs)
- SYSTEM.SAMPLE.SET (for the Set sample programs)

A flow chart for the SYSTEM.SAMPLE.ECHO program is shown in [Figure 9 on page 1376](#). Using the example the command to issue the RPG program request to this server is:

```
CALL PGM(QMQMSAMP/AMQ3REQ4) PARM('SYSTEM.SAMPLE.ECHO  
+ 30 blank characters','Queue_Manager_Name')
```

because the queue name and queue manager name *must* be 48 characters in length.

Note: This sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, server applications are not triggered by the messages you send.

If you want to attempt further examples, you can try the following variations:

- Use AMQ3TRG4 instead of AMQ3SRV4 to submit the job instead, but potential job submission delays could make it less easy to follow what is happening.
- Use the SYSTEM.SAMPLE.INQ and SYSTEM.SAMPLE.SET sample queues. Using the example data file, the commands to issue the RPG program requests to these servers are:

```
CALL PGM(QMQMSAMP/AMQ3INQ4) PARM('SYSTEM.SAMPLE.INQ  
+ 31 blank characters')  
CALL PGM(QMQMSAMP/AMQ3SET4) PARM('SYSTEM.SAMPLE.SET  
+ 31 blank characters')
```

because the queue name *must* be 48 characters in length.

These sample queues also have a trigger type of FIRST.

The Echo sample program on IBM i

The Echo sample programs return the message send to a reply queue. The program is named AMQ3ECH4

For the triggering process to work, you must ensure that the Echo sample program you want to use is triggered by messages arriving on queue SYSTEM.SAMPLE.ECHO. To do this, specify the name of the Echo sample program you want to use in the *AppLId* field of the process definition SYSTEM.SAMPLE.ECHOPROCESS. (For this, you can use the CHGMQMPCRC command, described in [Administering IBM i](#).) The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Echo sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays could make it less easy to follow what is happening.

Use the Request sample programs to send messages to queue SYSTEM.SAMPLE.ECHO. The Echo sample programs send a reply message containing the data in the request message to the reply-to queue specified in the request message.

Design of the Echo sample program

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although this is not necessary for IBM MQ for IBM i, this means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message and displays a warning message.

For each request message removed from the request queue, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the contents of the request message.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

This program can also respond to messages sent to the queue from platforms other than IBM MQ for IBM i, although no sample is supplied for this situation. To make the ECHO program work, you:

- Write a program, correctly specifying the *Format*, *Encoding*, and *CCSID* fields, to send text request messages.

The ECHO program requests the queue manager to perform message data conversion, if this is needed.

- Specify CONVERT(*YES) on the IBM MQ for IBM i sending channel, if the program you have written does not provide similar conversion for the reply.

The Inquire sample program on IBM i

The Inquire sample program, AMQ3INQ4, inquires about some of the attributes of a queue using the MQINQ call.

The program is intended to run as a triggered program, so its only input is an MQTMC (trigger message) structure. This structure contains the name of a target queue with attributes that are to be inquired upon.

For the triggering process to work, you must ensure that the Inquire sample program is triggered by messages arriving on queue SYSTEM.SAMPLE.INQ. To do so, specify the name of the Inquire sample program in the *AppId* field of the SYSTEM.SAMPLE.INQPROCESS process definition. (For this, you can use the CHGMQMPCRC command, described in [Change MQ Process \(CHGMQMPCRC\)](#)). The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Inquire sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays might make it less easy to follow what is happening.

Use the Request sample program to send request messages, each containing just a queue name, to queue SYSTEM.SAMPLE.INQ. For each request message, the Inquire sample program sends a reply message containing information about the queue specified in the request message. The replies are sent to the reply-to queue specified in the request message.

Design of the Inquire sample program

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although not necessary for IBM MQ for IBM i, this design feature means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message, and displays a warning message.

For each request message removed from the request queue, the program reads the name of the queue (which we will call the *target queue*) contained in the data and opens that queue using the MQOPEN call with the OOINQ option. The program then uses the MQINQ call to inquire about the values of the *InhibitGet*, *CurrentQDepth*, and *OpenInputCount* attributes of the target queue.

If the MQINQ call is successful, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the values of the three attributes.

If the MQOPEN or MQINQ call is unsuccessful, the program uses the MQPUT call to put a *report* message on the reply-to queue. In the *MDFB* field of the message descriptor of this report message is the reason code returned by either the MQOPEN or MQINQ call, depending on which one failed.

After the MQINQ call, the program closes the target queue using the MQCLOSE call.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

The Set sample program on IBM i

The Set sample program, AMQ3SET4, inhibits put operations on a queue by using the MQSET call to change the queue's *InhibitPut* attribute.

The program is intended to run as a triggered program, so its only input is an MQTMC (trigger message) structure that contains the name of a target queue with attributes that are to be inquired upon.

For the triggering process to work, you must ensure that the Set sample program is triggered by messages arriving on queue SYSTEM.SAMPLE.SET. To do this, specify the name of the Set sample program in the *AppLId* field of the process definition SYSTEM.SAMPLE.SETPROCESS. (For this, you can use the CHGMQMPPRC command, described in the *Administering IBM i*.) The sample queue has a trigger type of FIRST, so if there are already messages on the queue before you run the Request sample, the Set sample is not triggered by the messages you send.

When you have set the definition correctly, first start AMQ3SRV4 in one job, then start AMQ3REQ4 in another. You could use AMQ3TRG4 instead of AMQ3SRV4, but potential job submission delays could make it less easy to follow what is happening.

Use the Request sample program to send request messages, each containing just a queue name, to queue SYSTEM.SAMPLE.SET. For each request message, the Set sample program sends a reply message containing a confirmation that put operations have been inhibited on the specified queue. The replies are sent to the reply-to queue specified in the request message.

Design of the Set sample program

When the program is triggered, it explicitly connects to the default queue manager using the MQCONN call. Although this is not necessary for IBM MQ for IBM i, this means you could use the same program on other platforms without changing the source code.

The program then opens the queue named in the trigger message structure it was passed when it started. (For clarity, we will call this the *request queue*.) The program uses the MQOPEN call to open this queue for shared input.

The program uses the MQGET call to remove messages from this queue. This call uses the GMATM and GMWT options, with a wait interval of 5 seconds. The program tests the descriptor of each message to see if it is a request message; if it is not, the program discards the message and displays a warning message.

For each request message removed from the request queue, the program reads the name of the queue (which we will call the *target queue*) contained in the data and opens that queue using the MQOPEN call with the OOSSET option. The program then uses the MQSET call to set the value of the *InhibitPut* attribute of the target queue to QAPUTI.

If the MQSET call is successful, the program uses the MQPUT call to put a reply message on the reply-to queue. This message contains the string PUT inhibited.

If the MQOPEN or MQSET call is unsuccessful, the program uses the MQPUT call to put a *report* message on the reply-to queue. In the *MDFB* field of the message descriptor of this report message is the reason code returned by either the MQOPEN or MQSET call, depending on which one failed.

After the MQSET call, the program closes the target queue using the MQCLOSE call.

When there are no messages remaining on the request queue, the program closes that queue and disconnects from the queue manager.

The Triggering sample programs on IBM i

IBM MQ for IBM i supplies two Triggering sample programs that are written in ILE/RPG.

The programs are:

AMQ3TRG4

This is a trigger monitor for the IBM i environment. It submits an IBM i job for the application to be started, but this means that there is additional processing cost associated with each trigger message.

AMQ3SRV4

This is a trigger server for the IBM i environment. For each trigger message, this server runs the start command in its own job to start the specified application. The trigger server can call CICS transactions.

C language versions of these samples are also available as executable programs in library QMQM, called AMQSTRG4 and AMQSERV4.

The AMQ3TRG4 sample trigger monitor on IBM i

AMQ3TRG4 is a trigger monitor. It takes one parameter: the name of the initiation queue it is to serve. AMQSAMP4 defines a sample initiation queue, SYSTEM.SAMPLE.TRIGGER, that you can use when you try the sample programs.

AMQ3TRG4 submits an IBM i job for each valid trigger message it gets from the initiation queue.

Design of the trigger monitor

The trigger monitor opens the initiation queue and gets messages from the queue, specifying an unlimited wait interval.

The trigger monitor submits an IBM i job to start the application specified in the trigger message, and passes an MQTMC (a character version of the trigger message) structure. The environment data in the trigger message is used as job submission parameters.

Finally, the program closes the initiation queue.

The AMQ3SRV4 sample trigger server

AMQ3SRV4 is a trigger server. It takes one parameter: the name of the initiation queue it is to serve. AMQSAMP4 defines a sample initiation queue, SYSTEM.SAMPLE.TRIGGER, that you can use when you try the sample programs.

For each trigger message, AMQ3SRV4 runs a start command in its own job to start the specified application.

Using the example trigger queue the command to issue is:

```
CALL PGM(QMQM/AMQ3SRV4) PARM('Queue Name')
```

Where Queue Name *must* be 48 characters in length, which you achieve by padding the queue name with the required number of blanks. Therefore, if you are using SYSTEM.SAMPLE.TRIGGER as your target queue, you will need 28 blank characters.

Design of the trigger server

The design of the trigger server is like that of the trigger monitor, except the trigger server:

- Allows CICS as well as IBM i applications
- Does not use the environment data from the trigger message
- Calls IBM i applications in its own job (or uses STRCICSUSR to start CICS applications) rather than submitting an IBM i job
- Opens the initiation queue for shared input, so many trigger servers can run at the same time

Note: Programs started by AMQ3SRV4 must not use the MQDISC call because this will stop the trigger server. If programs started by AMQ3SRV4 use the MQCONN call, they will get the RC2002 reason code.

Ending the Triggering sample programs on IBM i

A trigger monitor program can be ended by the sysrequest option 2 (ENDRQS) or by inhibiting gets from the trigger queue.

If the sample trigger queue is used the command is:

```
CHGMQM QNAME('SYSTEM.SAMPLE.TRIGGER') GETENBL(*NO)
```

Note: To start triggering again on this queue, you *must* enter the command:

```
CHGMQM QNAME('SYSTEM.SAMPLE.TRIGGER') GETENBL(*YES)
```

Running the samples using remote queues on IBM i

You can demonstrate remote queuing by running the samples on connected message queue managers.

Program AMQSAMP4 provides a local definition of a remote queue (SYSTEM.SAMPLE.REMOTE) that uses a remote queue manager named OTHER. To use this sample definition, change OTHER to the name of the second message queue manager you want to use. You must also set up a message channel between your two message queue managers; for information about how to do so, see [Channel-exit programs for messaging channels](#).

The Request sample program puts its own local queue manager name in the *MDRM* field of messages it sends. The Inquire and Set samples send reply messages to the queue and message queue manager named in the *MDRQ* and *MDRM* fields of the request messages they process.

Return codes for IBM i (ILE RPG)

This information describes the return codes associated with the MQI and MQAI.

The return codes associated with:

- Programmable Command Format (PCF) commands are listed in [Programmable command formats reference](#).
- C++ calls are listed in [Using C++](#).

For each call, a completion code and a reason code are returned by the queue manager or by an exit routine, to indicate the success or failure of the call.

Applications must not depend upon errors being checked for in a specific order, except where specifically noted. If more than one completion code or reason code could arise from a call, the particular error reported depends on the implementation.

Completion codes for IBM i (ILE RPG)

The completion code parameter (*CMPCOD*) allows the caller to see quickly whether the call completed successfully, completed partially, or failed.

CCOK

(MQCC_OK on other platforms)

Successful completion.

The call completed fully; all output parameters have been set. The *REASON* parameter always has the value RCNONE in this case.

CCWARN

(MQCC_WARN on other platforms)

Warning (partial completion).

The call completed partially. Some output parameters might have been set in addition to the *CMPCOD* and *REASON* output parameters. The *REASON* parameter gives additional information about the partial completion.

CCFAIL

(MQCC_FAIL on other platforms)

Call failed.

The processing of the call did not complete, and the state of the queue manager is normally unchanged; exceptions are specifically noted. The *CMPCOD* and *REASON* output parameters have been set; other parameters are unchanged, except where noted.

The reason might be a fault in the application program, or it might be a result of some situation external to the program, for example the user's authority might have been revoked. The *REASON* parameter gives additional information about the error.

Reason codes for IBM i (ILE RPG)

The reason code parameter (*REASON*) is a qualification to the completion code parameter (*CMPCOD*).

If there is no special reason to report, RCNONE is returned. A successful call returns CCOK and RCNONE.

If the completion code is either CCWARN or CCFAIL, the queue manager always reports a qualifying reason; details are given under each call description.

Where user exit routines set completion codes and reasons, they should adhere to these rules. In addition, any special reason values defined by user exits should be less than zero, to ensure that they do not conflict with values defined by the queue manager. Exits can set reasons already defined by the queue manager, where these are appropriate.

Reason codes also occur in:

- The *DLREA* field of the MQDLH structure
- The *MDFB* field of the MQMD structure

The full list of reason codes is in [API completion and reason codes](#) in .

To find your IBM i reason code in that list, remove the "RC" from the front, for example RC2002 becomes 2002. Also the completion codes there are shown as they are on other platforms:

Table 631.	
IBM i	Other platforms
CCOK	MQCC_OK
CCWARN	MQCC_WARN
CCFAIL	MQCC_FAIL

Rules for validating MQI options for IBM i (ILE RPG)

This topic gives information about the situations that produce an RC2046 reason code from an MQOPEN, MQPUT, MQPUT1, MQGET, or MQCLOSE call.

MQOPEN call on IBM i

For the options of the MQOPEN call:

- *At least one* of the following must be specified:
 - OOBROW
 - OOINPQ
 - OOINPX
 - OOINPS
 - OOINQ

- OOOOUT
- OOSSET
- Only *one* of the following is allowed:
 - OOINPQ
 - OOINPX
 - OOINPS
- Only *one* of the following is allowed:
 - OOBNDQ
 - OOBNDN
 - OOBNDQ

Note: The options listed previously are mutually exclusive. However, because the value of OOBNDQ is zero, specifying it with either of the other two bind options does not result in reason code RC2046. OOBNDQ is provided to aid program documentation.

- If OOSAVA is specified, one of the OOINP* options must also be specified.
- If one of the OOSSET* or OOPAS* options is specified, OOOOUT must also be specified.

MQPUT call on IBM i

For the put-message options:

- The combination of PMSYP and PMNSYP is not allowed.
- Only *one* of the following is allowed:
 - PMDEFC
 - PMNOC
 - PMPASA
 - PMPASI
 - PMSETA
 - PMSETI
- PMALTU is not allowed (it is valid only on the MQPUT1 call).

MQPUT1 call on IBM i

For the put-message options, the rules are the same as for the MQPUT call, except for the following options:

- PMALTU is allowed.
- PMLOGO is *not* allowed.

MQGET call on IBM i

For the get-message options:

- Only *one* of the following options is allowed:
 - GMNSYP
 - GMSYP
 - GMPSYP
- Only *one* of the following options is allowed:
 - GMBRWF

- GMBRWC
- GMBRWN
- GMMUC
- GMSYP is not allowed with any of the following options:
 - GMBRWF
 - GMBRWC
 - GMBRWN
 - GMLK
 - GMUNLK
- GMPSP is not allowed with any of the following options:
 - GMBRWF
 - GMBRWC
 - GMBRWN
 - GMCMPM
 - GMUNLK
- If GMLK is specified, one of the following options must also be specified:
 - GMBRWF
 - GMBRWC
 - GMBRWN
- If GMUNLK is specified, only the following options are allowed:
 - GMNSYP
 - GMNWT

MQCLOSE call on IBM i

- For the options of the MQCLOSE call. The combination of CODEL and COPURG is not allowed.
- Only one of the following is allowed:
 - COKPSB
 - CORMSB

MQSUB call on IBM i

For the options of the MQSUB call:

- At least one of the following must be specified:
- At least one of the following must be specified:
 - SOALT
 - SORES
 - SOCRT
- Only one of the following is allowed:
 - SODUR
 - SONDUR

Note: The options listed previously are mutually exclusive. However, as the value of SONDUR is zero, specifying it with SODUR does not result in reason code RC2046. SONDUR is provided to aid program documentation.

- The combination of SOGRP and SOMAN is not allowed.

- SOGRP requires SOSCID to be specified.
- Only one of the following is allowed: SOAUID SOFUID
- The combination of SONEWP and SOPUBR is not allowed.
- SONEWP is only allowed in combination with SOCRT.
- Only one of the following is allowed:
 - SOWCHR
 - SOWTOP

Machine encodings on IBM i

Use this information to learn about the structure of the *MDENC* field in the message descriptor.

For more information about the message descriptor, see [“MQMD - Message descriptor”](#) on page 1068.

The *MDENC* field is a 32-bit integer that is divided into four separate subfields; these subfields identify:

- The encoding used for binary integers
- The encoding used for packed-decimal integers
- The encoding used for floating-point numbers
- Reserved bits

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined:

ENIMSK

Mask for binary-integer encoding.

This subfield occupies bit positions 28 through 31 within the *MDENC* field.

ENDMSK

Mask for packed-decimal-integer encoding.

This subfield occupies bit positions 24 through 27 within the *MDENC* field.

ENFMSK

Mask for floating-point encoding.

This subfield occupies bit positions 20 through 23 within the *MDENC* field.

ENRMSK

Mask for reserved bits.

This subfield occupies bit positions 0 through 19 within the *MDENC* field.

Binary-integer encoding

Valid values for binary-integer encoding.

The following values are valid for the binary-integer encoding:

ENIUND

Undefined integer encoding.

Binary integers are represented using an encoding that is undefined.

ENINOR

Normal integer encoding.

Binary integers are represented in the conventional way:

- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address.

- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address.

ENIREV

Reversed integer encoding.

Binary integers are represented in the same way as ENINOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENINOR.

Packed-decimal-integer encoding

Valid values for packed-decimal-integer encoding

The following values are valid for the packed-decimal-integer encoding:

ENDUND

Undefined packed-decimal encoding.

Packed-decimal integers are represented using an encoding that is undefined.

ENDNOR

Normal packed-decimal encoding.

Packed-decimal integers are represented in the conventional way:

- Each decimal digit in the printable form of the number is represented in packed decimal by a single hexadecimal digit in the range X'0' through X'9'. Each hexadecimal digit occupies 4 bits, and so each byte in the packed decimal number represents two decimal digits in the printable form of the number.
- The least significant byte in the packed-decimal number is the byte which contains the least significant decimal digit. Within that byte, the most significant 4 bits contain the least significant decimal digit, and the least significant 4 bits contain the sign. The sign is either X'C' (positive), X'D' (negative), or X'F' (unsigned).
- The least significant byte in the number has the highest address of any of the bytes in the number; the most significant byte has the lowest address.
- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address.

ENDREV

Reversed packed-decimal encoding.

Packed-decimal integers are represented in the same way as ENDNOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENDNOR.

Floating-point encoding

Valid values for floating-point encoding

The following values are valid for the floating-point encoding:

ENFUND

Undefined floating-point encoding.

Floating-point numbers are represented using an encoding that is undefined.

ENFNOR

Normal IEEE (The Institute of Electrical and Electronics Engineers) float encoding.

Floating-point numbers are represented using the standard IEEE floating-point format, with the bytes arranged as follows:

- The least significant byte in the mantissa has the highest address of any of the bytes in the number; the byte containing the exponent has the lowest address
- The least significant bit in each byte is next to the byte with the next higher address; the most significant bit in each byte is next to the byte with the next lower address

Details of the IEEE float encoding might be found in IEEE Standard 754.

ENFREV

Reversed IEEE float encoding.

Floating-point numbers are represented in the same way as ENFNOR, but with the bytes arranged in reverse order. The bits within each byte are arranged in the same way as ENFNOR.

ENF390

System/390 architecture float encoding.

Floating-point numbers are represented using the standard System/390 floating-point format; this is also used by System/370.

Constructing encodings

To construct a value for the *MDENC* field in MQMD, the relevant constants that describe the required encodings should be added.

Be sure to combine only one of the ENI* encodings with one of the END* encodings and one of the ENF* encodings.

Analyzing encodings

The *MDENC* field contains subfields; because of this, applications that need to examine the integer, packed decimal, or float encoding should use the technique described in this topic.

Using arithmetic

The following steps should be performed using integer arithmetic:

1. Select one of the following values, according to the type of encoding required:

- 1 for the binary integer encoding
- 16 for the packed decimal integer encoding
- 256 for the floating point encoding

Call the value A.

2. Divide the value of the *MDENC* field by A ; call the result B.

3. Divide B by 16; call the result C.

4. Multiply C by 16 and subtract from B ; call the result D.

5. Multiply D by A ; call the result E.

6. E is the encoding required, and can be tested for equality with each of the values that is valid for that type of encoding.

Summary of machine architecture encodings

A table summarizing encodings for machine architectures.

Encodings for machine architectures are shown in [Table 632 on page 1387](#).

<i>Table 632. Summary of encodings for machine architectures</i>			
Machine architecture	Binary integer encoding	Packed-decimal integer encoding	Floating-point encoding
IBM i	normal	normal	IEEE normal
Intel x86	reversed	reversed	IEEE reversed
PowerPC	normal	normal	IEEE normal

Table 632. Summary of encodings for machine architectures (continued)			
Machine architecture	Binary integer encoding	Packed-decimal integer encoding	Floating-point encoding
System/390	normal	normal	System/390

Report options and message flags

This topic concerns the *MDREP* and *MDMFL* fields that are part of the message descriptor MQMD specified on the MQGET, MQPUT, and MQPUT1 calls.

For more information about the message descriptor, see [“MQMD - Message descriptor”](#) on page 1068. This information describes:

- The structure of the report field and how the queue manager processes it
- How an application should analyze the report field
- The structure of the message-flags field

Structure of the report field

The *MDREP* field is a 32-bit integer that is divided into three separate subfields.

These subfields identify:

- Report options that are rejected if the local queue manager does not recognize them
- Report options that are always accepted, even if the local queue manager does not recognize them
- Report options that are accepted only if certain other conditions are satisfied

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. Note that the bits in a subfield are not necessarily adjacent. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

RORUM

Mask for unsupported report options that are rejected.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will cause the MQPUT or MQPUT1 call to fail with completion code CCFAIL and reason code RC2061.

This subfield occupies bit positions 3, and 11 through 13.

ROAUM

Mask for unsupported report options that are accepted.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls. Completion code CCWARN with reason code RC2104 are returned in this case.

This subfield occupies bit positions 0 through 2, 4 through 10, and 24 through 31.

The following report options are included in this subfield:

- ROCMTC
- RODLQ
- RODISC
- ROEXC
- ROEXCD
- ROEXCF
- ROEXP

- ROEXPD
- ROEXPF
- RONAN
- RONMI
- RONONE
- ROPAN
- ROPCI
- ROPMI

ROAUXM

Mask for unsupported report options that are accepted only in certain circumstances.

This mask identifies the bit positions within the *MDREP* field where report options which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ODMN* and *ODON* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code CCWARN with reason code RC2104 are returned if these conditions are satisfied, and CCFAIL with reason code RC2061 if not.

This subfield occupies bit positions 14 through 23.

The following report options are included in this subfield:

- ROCOA
- ROCOAD
- ROCOAF
- ROCOD
- ROCODD
- ROCODF

If there are any options specified in the *MDREP* field which the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MDREP* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

If CCWARN is returned, it is not defined which reason code is returned if other warning conditions exist.

The ability to specify and have accepted report options which are not recognized by the local queue manager is useful when it is necessary to send a message with a report option which will be recognized and processed by a *remote* queue manager.

Analyzing the report field

The MDREP field contains subfields. Because of this, some applications need to check whether the sender of the message requested a particular report. Those applications should use the technique described in this topic.

Using arithmetic

The following steps should be performed using integer arithmetic:

1. Select one of the following values, according to the type of report to be checked:
 - ROCOA for COA report

- ROCOD for COD report
- ROEXC for exception report
- ROEXP for expiration report

Call the value A.

2. Divide the *MDREP* field by A ; call the result B.
3. Divide B by 8 ; call the result C.
4. Multiply C by 8 and subtract from B ; call the result D.
5. Multiply D by A ; call the result E.
6. Test E for equality with each of the values that is possible for that type of report.

For example, if A is ROEXC, test E for equality with each of the following to determine what was specified by the sender of the message:

- RONONE
- ROEXC
- ROEXCD
- ROEXCF

The tests can be performed in whatever order is most convenient for the application logic.

The following pseudocode illustrates this technique for exception report messages:

```
A = ROEXC
B = Report/A
C = B/8
D = B - C*8
E = D*A
```

A similar method can be used to test for the ROPMI or ROPCI options; select as the value A whichever of these two constants is appropriate, and then proceed as described previously, but replacing the value 8 in the previous steps by the value 2.

Structure of the message-flags field

The *MDMFL* field is a 32-bit integer that is divided into three separate subfields.

These subfields identify:

- Message flags that are rejected if the local queue manager does not recognize them
- Message flags that are always accepted, even if the local queue manager does not recognize them
- Message flags that are accepted only if certain other conditions are satisfied

Note: All subfields in *MDMFL* are reserved for use by the queue manager.

Each subfield is identified by a bit mask which has 1-bits in the positions corresponding to the subfield, and 0-bits elsewhere. The bits are numbered such that bit 0 is the most significant bit, and bit 31 the least significant bit. The following masks are defined to identify the subfields:

MFRUM

Mask for unsupported message flags that are rejected.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will cause the MQPUT or MQPUT1 call to fail with completion code CCFAIL and reason code RC2249.

This subfield occupies bit positions 20 through 31.

The following message flags are included in this subfield:

- MFLMIG
- MFLSEG

- MFMIG
- MFSEG
- MFSEGA
- MFSEGI

MFAUM

Mask for unsupported message flags that are accepted.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls. The completion code is CCOK.

This subfield occupies bit positions 0 through 11.

MFAUXM

Mask for unsupported message flags that are accepted only in certain circumstances.

This mask identifies the bit positions within the *MDMFL* field where message flags which are not supported by the local queue manager will nevertheless be accepted on the MQPUT or MQPUT1 calls *provided* that both of the following conditions are satisfied:

- The message is destined for a remote queue manager.
- The application is not putting the message directly on a local transmission queue (that is, the queue identified by the *ODMN* and *ODON* fields in the object descriptor specified on the MQOPEN or MQPUT1 call is not a local transmission queue).

Completion code CCOK is returned if these conditions are satisfied, and CCFAIL with reason code RC2249 if not.

This subfield occupies bit positions 12 through 19.

If there are flags specified in the *MDMFL* field that the queue manager does not recognize, the queue manager checks each subfield in turn by using the bitwise AND operation to combine the *MDMFL* field with the mask for that subfield. If the result of that operation is not zero, the completion code and reason codes described previously are returned.

Data conversion

This topic describes the interface to the data-conversion exit, and the processing performed by the queue manager when data conversion is required.

The data-conversion exit is invoked as part of the processing of the MQGET call in order to convert the application message data to the representation required by the receiving application. Conversion of the application message data is optional - it requires the GMCONV option to be specified on the MQGET call.

The following are described:

- The processing performed by the queue manager in response to the GMCONV option; see [“Conversion processing” on page 1392](#).
- Processing conventions used by the queue manager when processing a built-in format; these conventions are recommended for user-written exits too. See [“Processing conventions” on page 1393](#).
- Special considerations for the conversion of report messages; see [“Conversion of report messages” on page 1397](#).
- The parameters passed to the data-conversion exit; see [“MQCONVX - Data conversion exit” on page 1407](#).
- A call that can be used from the exit in order to convert character data between different representations; see [“MQXCNVC - Convert characters” on page 1402](#).
- The data-structure parameter which is specific to the exit; see [“MQDXP - Data-conversion exit parameter” on page 1398](#).

Conversion processing

This information describes the processing performed by the queue manager in response to the GMCONV option.

The queue manager performs the following actions if the GMCONV option is specified on the MQGET call, and there is a message to be returned to the application:

1. If one or more of the following is true, no conversion is necessary:

- The message data is already in the character set and encoding required by the application issuing the MQGET call. The application must set the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter of the MQGET call to the values required, before issuing the call.
- The length of the message data is zero.
- The length of the *BUFFER* parameter of the MQGET call is zero.

In these cases the message is returned without conversion to the application issuing the MQGET call; the *MDCSI* and *MDENC* values in the *MSGDSC* parameter are set to the values in the control information in the message, and the call completes with one of the following combinations of completion code and reason code:

Completion code

Reason code

CCOK

RCNONE

CCWARN

RC2079

CCWARN

RC2080

The following steps are performed only if the character set or encoding of the message data differs from the corresponding value in the *MSGDSC* parameter, and there is data to be converted:

1. If the *MDFMT* field in the control information in the message has the value FMNONE, the message is returned unconverted, with completion code CCWARN and reason code RC2110.

In all other cases conversion processing continues.

2. The message is removed from the queue and placed in a temporary buffer which is the same size as the *BUFFER* parameter. For browse operations, the message is copied into the temporary buffer, instead of being removed from the queue.

3. If the message has to be truncated to fit in the buffer, the following is done:

- If the GMATM option was *not* specified, the message is returned unconverted, with completion code CCWARN and reason code RC2080.
- If the GMATM option was specified, the completion code is set to CCWARN, the reason code is set to RC2079, and conversion processing continues.

4. If the message can be accommodated in the buffer without truncation, or the GMATM option was specified, the following is done:

- If the format is a built-in format, the buffer is passed to the queue manager's data-conversion service.
- If the format is not a built-in format, the buffer is passed to a user-written exit which has the same name as the format. If the exit cannot be found, the message is returned unconverted, with completion code CCWARN and reason code RC2110.

If no error occurs, the output from the data-conversion service or from the user-written exit is the converted message, plus the completion code and reason code to be returned to the application issuing the MQGET call.

5. If the conversion is successful, the queue manager returns the converted message to the application. In this case, the completion code and reason code returned by the MQGET call will typically be one of the following combinations:

Completion code

Reason code

CCOK

RCNONE

CCWARN

RC2079

However, if the conversion is performed by a user-written exit, other reason codes can be returned, even when the conversion is successful.

If the conversion fails (for whatever reason), the queue manager returns the unconverted message to the application, with the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter set to the values in the control information in the message, and with completion code CCWARN.

Processing conventions

When converting a built-in format, the queue manager follows the processing conventions described in this topic.

Consider applying these conventions to user-written exits, although this is not enforced by the queue manager. The built-in formats converted by the queue manager are:

Built in formats
FMADMN
FMMDE
FMCICS
FMPCF
FMCMDB1
FMRMH
FMCMDB2
FMRFH
FMDLH
FMRFH2
FMDH
FMSTR
FMEVNT
FMTM
FMIMS
FMXQH
FMIMVS

1. If the message expands during conversion, and exceeds the size of the *BUFFER* parameter, the following is done:
 - If the GMATM option was *not* specified, the message is returned unconverted, with completion code CCWARN and reason code RC2120.

- If the GMATM option was specified, the message is truncated, the completion code is set to CCWARN, the reason code is set to RC2079, and conversion processing continues.
2. If truncation occurs (either before or during conversion), it is possible for the number of valid bytes returned in the *BUFFER* parameter to be *less than* the length of the buffer.

This can occur, for example, if a 4-byte integer or a DBCS character straddles the end of the buffer. The incomplete element of information is not converted, and so those bytes in the returned message do not contain valid information. This can also occur if a message that was truncated before conversion shrinks during conversion.

If the number of valid bytes returned is less than the length of the buffer, the unused bytes at the end of the buffer are set to nulls.
 3. If an array or string straddles the end of the buffer, as much of the data as possible is converted; only the particular array element or DBCS character which is incomplete is not converted - preceding array elements or characters are converted.
 4. If truncation occurs (either before or during conversion), the length returned for the *DATLEN* parameter is the length of the *unconverted* message before truncation.
 5. When strings are converted between single-byte character sets (SBCS), double-byte character sets (DBCS), or multi-byte character sets (MBCS), the strings can expand or contract.
 - In the PCF formats FMADMN, FMEVNT, and FMPCF, the strings in the MQCFST and MQCFSL structures expand or contract as necessary to accommodate the string after conversion.

For the string-list structure MQCFSL, the strings in the list might expand or contract by different amounts. If this happens, the queue manager pads the shorter strings with blanks to make them the same length as the longest string after conversion.
 - In the format FMRMH, the strings addressed by the *RMSEO*, *RMSNO*, *RMDEO*, and *RMDNO* fields expand or contract as necessary to accommodate the strings after conversion.
 - In the format FMRFH, the *RFNVS* field expands or contracts as necessary to accommodate the name/value pairs after conversion.
 - In structures with fixed field sizes, the queue manager allows strings to expand or contract within their fixed fields, if no significant information is lost. In this regard, trailing blanks and characters following the first null character in the field are treated as insignificant.
 - If the string expands, but only insignificant characters need to be discarded to accommodate the converted string in the field, the conversion succeeds and the call completes with CCOK and reason code RCNONE (assuming no other errors).
 - If the string expands, but the converted string requires significant characters to be discarded in order to fit in the field, the message is returned unconverted and the call completes with CCWARN and reason code RC2190.

Note: Reason code RC2190 results in this case whether the GMATM option was specified.

 - If the string contracts, the queue manager pads the string with blanks to the length of the field.
 6. For messages consisting of one or more IBM MQ header structures followed by user data, it is possible for one or more of the header structures to be converted, while the remainder of the message is not. However, with two exceptions, the *MDCSI* and *MDENC* fields in each header structure always correctly indicate the character set and encoding of the data that follows the header structure.

The two exceptions are the MQCIH and MQIIH structures, where the values in the *MDCSI* and *MDENC* fields in those structures are not significant. For those structures, the data following the structure is in the same character set and encoding as the MQCIH or MQIIH structure itself.
 7. If the *MDCSI* or *MDENC* fields in the control information of the message being retrieved, or in the *MSGDSC* parameter, specify values which are undefined or not supported, the queue manager might ignore the error if the undefined or unsupported value does not need to be used in converting the message.

For example, if the *MDENC* field in the message specifies an unsupported float encoding, but the message contains only integer data, or contains floating-point data which does not require

conversion (because the source and target float encodings are identical), the error might or might not be diagnosed.

If the error is diagnosed, the message is returned unconverted, with completion code CCWARN and one of the RC2111, RC2112, RC2113, RC2114 or RC2115, RC2116, RC2117, RC2118 reason codes (as appropriate); the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter are set to the values in the control information in the message.

If the error is not diagnosed and the conversion completes successfully, the values returned in the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter, are those specified by the application issuing the MQGET call.

8. In all cases, if the message is returned to the application unconverted the completion code is set to CCWARN, and the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter are set to the values appropriate to the unconverted data. This is done for FMNONE also.

The *REASON* parameter is set to a code that indicates why the conversion could not be carried out, unless the message also had to be truncated; reason codes related to truncation take precedence over reason codes related to conversion. (To determine if a truncated message was converted, check the values returned in the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter.)

When an error is diagnosed, either a specific reason code is returned, or the general reason code RC2119. The reason code returned depends on the diagnostic capabilities of the underlying data-conversion service.

9. If completion code CCWARN is returned, and more than one reason code is relevant, the order of precedence is as follows:

- a. The following reason takes precedence over all others:
 - RC2079
- b. Next in precedence is the following reason:
 - RC2110
- c. The order of precedence within the remaining reason codes is not defined.

10. On completion of the MQGET call:

- The following reason code indicates that the message was converted successfully:
 - RCNONE
- The following reason code indicates that the message *may* have been converted successfully (check the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter to find out):
 - RC2079
- All other reason codes indicate that the message was not converted.

The following processing is specific to the built-in formats; it is not applicable to user-defined formats:

1. Except for the following formats:

- FMADMN
- FMEVNT
- FMIMVS
- FMPCF
- FMSTR

none of the built-in formats can be converted from or to character sets that do not have SBCS characters for the characters that are valid in queue names. If an attempt is made to perform such a conversion, the message is returned unconverted, with completion code CCWARN and reason code RC2111 or RC2115, as appropriate.

The Unicode character set UCS-2 is an example of a character set that does not have SBCS characters for the characters that are valid in queue names.

2. If the message data for a built-in format is truncated, fields within the message which contain lengths of strings, or counts of elements or structures, are *not* adjusted to reflect the length of the data returned to the application; the values returned for such fields within the message data are the values applicable to the message *before truncation*.

When processing messages such as a truncated FMADMN message, care must be taken to ensure that the application does not attempt to access data beyond the end of the data returned.

3. If the format name is FMDLH, the message data begins with an MQDLH structure, and this may be followed by zero or more bytes of application message data. The format, character set, and encoding of the application message data are defined by the *DLFMT*, *DLCSI*, and *DLENC* fields in the MQDLH structure at the start of the message. Since the MQDLH structure and application message data can have different character sets and encodings, it is possible for one, other, or both of the MQDLH structure and application message data to require conversion.

The queue manager converts the MQDLH structure first, as necessary. If conversion is successful, or the MQDLH structure does not require conversion, the queue manager checks the *DLCSI* and *DLENC* fields in the MQDLH structure to see if conversion of the application message data is required. If conversion is required, the queue manager invokes the user-written exit with the name given by the *DLFMT* field in the MQDLH structure, or performs the conversion itself (if *DLFMT* is the name of a built-in format).

If the MQGET call returns a completion code of CCWARN, and the reason code is one of those indicating that conversion was not successful, one of the following applies:

- The MQDLH structure could not be converted. In this case the application message data will not have been converted either.
- The MQDLH structure was converted, but the application message data was not.

The application can examine the values returned in the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter, and those in the MQDLH structure, in order to determine which of the previous applies.

4. If the format name is FMXQH, the message data begins with an MQXQH structure, and this may be followed by zero or more bytes of additional data. This additional data is typically the application message data (which may be of zero length), but there can also be one or more further IBM MQ header structures present, at the start of the additional data.

The MQXQH structure must be in the character set and encoding of the queue manager. The format, character set, and encoding of the data following the MQXQH structure are given by the *MDFMT*, *MDCSI*, and *MDENC* fields in the MQMD structure contained *within* the MQXQH. For each subsequent IBM MQ header structure present, the *MDFMT*, *MDCSI*, and *MDENC* fields in the structure describe the data that follows that structure; that data is either another IBM MQ header structure, or the application message data.

If the GMCONV option is specified for an FMXQH message, the application message data and certain of the MQ header structures are converted, *but the data in the MQXQH structure is not*. On return from the MQGET call, therefore:

- The values of the *MDFMT*, *MDCSI*, and *MDENC* fields in the *MSGDSC* parameter, describe the data in the MQXQH structure, and *not* the application message data; the values will therefore *not* be the same as those specified by the application that issued the MQGET call.

The effect of this is that an application which repeatedly gets messages from a transmission queue with the GMCONV option specified must reset the *MDCSI* and *MDENC* fields in the *MSGDSC* parameter to the values necessary for the application message data, before each MQGET call.

- The values of the *MDFMT*, *MDCSI*, and *MDENC* fields in the last MQ header structure present describe the application message data. If there are no other IBM MQ header structures present, the application message data is described by these fields in the MQMD structure within the MQXQH structure. If conversion is successful, the values will be the same as those specified in the *MSGDSC* parameter by the application that issued the MQGET call.

If the message is a distribution-list message, the MQXQH structure is followed by an MQDH structure (plus its arrays of MQOR and MQPMR records), which in turn may be followed by zero or more further

IBM MQ header structures and zero or more bytes of application message data. Like the MQXQH structure, the MQDH structure must be in the character set and encoding of the queue manager, and it is not converted on the MQGET call, even if the GMCONV option is specified.

The processing of the MQXQH and MQDH structures described previously are primarily intended for use by message channel agents when they get messages from transmission queues.

Conversion of report messages

A report message can contain varying amounts of application message data, according to the report options specified by the sender of the original message.

In particular, a report message can contain either:

1. No application message data
2. Some of the application message data from the original message

This occurs when the sender of the original message specifies RO*D and the message is longer than 100 bytes.

3. All of the application message data from the original message

This occurs when the sender of the original message specifies RO*F, or specifies RO*D and the message is 100 bytes or shorter.

When the queue manager or message channel agent generates a report message, it copies the format name from the original message into the *MDFMT* field in the control information in the report message. The format name in the report message might therefore imply a length of data which is different from the length present in the report message (cases 1 and 2 described previously).

If the GMCONV option is specified when the report message is retrieved:

- For case 1 described previously, the data-conversion exit will not be invoked (because the report message will have no data).
- For case 3 described previously, the format name correctly implies the length of the message data.
- But for case 2 described previously, the data-conversion exit will be invoked to convert a message which is *shorter* than the length implied by the format name.

In addition, the reason code passed to the exit will typically be RCNONE (that is, the reason code will not indicate that the message has been truncated). This happens because the message data was truncated by the *sender* of the report message, and not by the receiver's queue manager in response to the MQGET call.

Because of these possibilities, the data-conversion exit should *not* use the format name to deduce the length of data passed to it; instead the exit should check the length of data provided, and be prepared to convert *less* data than the length implied by the format name. If the data can be converted successfully, completion code CCOK and reason code RCNONE should be returned by the exit. The length of the message data to be converted is passed to the exit as the *INLEN* parameter.

Product-sensitive programming interface

If a report message contains information about an activity that has taken place, it is known as an activity report. Examples of activities are:

- an MCA sending a message from a queue down a channel
- an MCA receiving a message from a channel and putting it onto a queue
- an MCA dead-letter queuing an undeliverable message
- an MCA getting a message off a queue and discarding it
- a dead-letter handler placing a message back on a queue
- the command server processing a PCF request - a broker processing a publish request
- a user application getting a message from a queue - a user application browsing a message on a queue

Any application, including the queue manager, can add some of the message data to the activity report following the report header. The amount of data that should be supplied if some is sent is not fixed, and is decided by the application. The information returned should be useful to the application processing the activity report. Queue manager activity reports will return with them any standard IBM MQ header structures (beginning 'MQH') contained in the original message. This includes, for example, any MQRFH2 headers that were included in the original message. Also the queue manager will return an MQCFH header found, but not the PCF parameters associated with it. This gives monitoring applications an idea of what the message was about.

MQDXP - Data-conversion exit parameter

Data-conversion exit parameter block.

Overview

Purpose: The MQDXP structure is a parameter that the queue manager passes to the data-conversion exit when the exit is invoked to convert the message data as part of the processing of the MQGET call. See the description of the MQCONVX call for details of the data conversion exit.

Character set and encoding: Character data in MQDXP is in the character set of the local queue manager; this is given by the *CodedCharSetId* queue manager attribute. Numeric data in MQDXP is in the native machine encoding; this is given by ENNAT.

Usage: Only the *DXLEN*, *DXCC*, *DXREA* and *DXRES* fields in MQDXP might be changed by the exit; changes to other fields are ignored. However, the *DXLEN* field *cannot* be changed if the message being converted is a segment that contains only part of a logical message.

When control returns to the queue manager from the exit, the queue manager checks the values returned in MQDXP. If the values returned are not valid, the queue manager continues processing as though the exit had returned XRFAIL in *DXRES* ; however, the queue manager ignores the values of the *DXCC* and *DXREA* fields returned by the exit in this case, and uses instead the values those fields had on *input* to the exit. The following values in MQDXP cause this processing to occur:

- *DXRES* field not XROK and not XRFAIL
- *DXCC* field not CCOK and not CCWARN
- *DXLEN* field less than zero, or *DXLEN* field changed when the message being converted is a segment that contains only part of a logical message.
- [“Fields” on page 1398](#)
- [“RPG declaration \(copy file CMQDXPH\)” on page 1402](#)

Fields

The MQDXP structure contains the following fields; the fields are described in **alphabetical order**:

DXAOP (10-digit signed integer)

Application options.

This is a copy of the *GMOPT* field of the MQGMO structure specified by the application issuing the MQGET call. The exit may need to examine these to ascertain whether the GMATM option was specified.

This is an input field to the exit.

DXCC (10-digit signed integer)

Completion code.

When the exit is invoked, this contains the completion code that will be returned to the application that issued the MQGET call, if the exit chooses to do nothing. It is always CCWARN, because either the message was truncated, or the message requires conversion and this has not yet been done.

On output from the exit, this field contains the completion code to be returned to the application in the *CMPCOD* parameter of the MQGET call; only CCOK and CCWARN are valid. See the description of the *DXREA* field for suggestions on how the exit should set this field on output.

This is an input/output field to the exit.

DXCSI (10-digit signed integer)

Character set required by application.

This is the coded character-set identifier of the character set required by the application issuing the MQGET call; see the *MDCSI* field in the MQMD structure for more details. If the application specifies the special value CSQM on the MQGET call, the queue manager changes this to the actual character-set identifier of the character set used by the queue manager, before invoking the exit.

If the conversion is successful, the exit should copy this to the *MDCSI* field in the message descriptor.

This is an input field to the exit.

DXENC (10-digit signed integer)

Numeric encoding required by application.

This is the numeric encoding required by the application issuing the MQGET call; see the *MDENC* field in the MQMD structure for more details.

If the conversion is successful, the exit should copy this to the *MDENC* field in the message descriptor.

This is an input field to the exit.

DXHCN (10-digit signed integer)

Connection handle.

This is a connection handle which can be used on the MQXCNVC call. This handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

DXLEN (10-digit signed integer)

Length in bytes of message data.

When the exit is invoked, this field contains the original length of the application message data. If the message was truncated in order to fit into the buffer provided by the application, the size of the message provided to the exit will be *smaller* than the value of *DXLEN*. The size of the message provided to the exit is always given by the *INLEN* parameter of the exit, irrespective of any truncation that may have occurred.

Truncation is indicated by the *DXREA* field having the value RC2079 on input to the exit.

Most conversions will not need to change this length, but an exit can do so if necessary; the value set by the exit is returned to the application in the *DATLEN* parameter of the MQGET call. However, this length *cannot* be changed if the message being converted is a segment that contains only part of a logical message. This is because changing the length would cause the offsets of later segments in the logical message to be incorrect.

Note that, if the exit wants to change the length of the data, be aware that the queue manager has already decided whether the message data will fit into the application's buffer, based on the length of the *unconverted* data. This decision determines whether the message is removed from the queue (or the browse cursor moved, for a browse request), and is not affected by any change to the data length caused by the conversion. For this reason it is recommended that conversion exits do not cause a change in the length of the application message data.

If character conversion does imply a change of length, a string can be converted into another string with the same length in bytes, truncating trailing blanks, or padding with blanks as necessary.

The exit is not invoked if the message contains no application message data; hence *DXLEN* is always greater than zero.

This is an input/output field to the exit.

DXREA (10-digit signed integer)

Reason code qualifying *DXCC*.

When the exit is invoked, this contains the reason code that will be returned to the application that issued the MQGET call, if the exit chooses to do nothing. Among possible values are RC2079, indicating that the message was truncated in order to fit into the buffer provided by the application, and RC2119, indicating that the message requires conversion but that this has not yet been done.

On output from the exit, this field contains the reason to be returned to the application in the *REASON* parameter of the MQGET call; the following is recommended:

- If *DXREA* had the value RC2079 on input to the exit, the *DXREA* and *DXCC* fields should not be altered, irrespective of whether the conversion succeeds or fails.

(If the *DXCC* field is not CCOK, the application which retrieves the message can identify a conversion failure by comparing the returned *MDENC* and *MDCSI* values in the message descriptor with the values requested; in contrast, the application cannot distinguish a truncated message from a message that just fitted the buffer. For this reason, RC2079 should be returned in preference to any of the reasons that indicate conversion failure.)

- If *DXREA* had any other value on input to the exit:
 - If the conversion succeeds, *DXCC* should be set to CCOK and *DXREA* set to RCNONE.
 - If the conversion fails, or the message expands and has to be truncated to fit in the buffer, *DXCC* should be set to CCWARN (or left unchanged), and *DXREA* set to one of the values in the following list, to indicate the nature of the failure.

Note that, if the message after conversion is too big for the buffer, it should be truncated only if the application that issued the MQGET call specified the GMATM option:

- If it did specify that option, reason RC2079 should be returned.
- If it did not specify that option, the message should be returned unconverted, with reason code RC2120.

The reason codes in the following list are recommended for use by the exit to indicate the reason that conversion failed, but the exit can return other values from the set of RC* codes if deemed appropriate. In addition, the range of values RC0900 through RC0999 are allocated for use by the exit to indicate conditions that the exit wants to communicate to the application issuing the MQGET call.

Note: If the message cannot be converted successfully, the exit *must* return XRFAIL in the *DXRES* field, in order to cause the queue manager to return the unconverted message. This is true regardless of the reason code returned in the *DXREA* field.

RC0900

(900, X'384') Lowest value for application-defined reason code.

RC0999

(999, X'3E7') Highest value for application-defined reason code.

RC2120

(2120, X'848') Converted data too big for buffer.

RC2119

(2119, X'847') Message data not converted.

RC2111

(2111, X'83F') Source coded character set identifier not valid.

RC2113

(2113, X'841') Packed-decimal encoding in message not recognized.

RC2114

(2114, X'842') Floating-point encoding in message not recognized.

RC2112

(2112, X'840') Source integer encoding not recognized.

RC2115

(2115, X'843') Target coded character set identifier not valid.

RC2117

(2117, X'845') Packed-decimal encoding specified by receiver not recognized.

RC2118

(2118, X'846') Floating-point encoding specified by receiver not recognized.

RC2116

(2116, X'844') Target integer encoding not recognized.

RC2079

(2079, X'81F') Truncated message returned (processing completed).

This is an input/output field to the exit.

DXRES (10-digit signed integer)

Response from exit.

This is set by the exit to indicate the success or otherwise of the conversion. It must be one of the following:

XROK

Conversion was successful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *DXCC* field on output from the exit
- The value of the *DXREA* field on output from the exit
- The value of the *DXLEN* field on output from the exit
- The contents of the exit's output buffer *OUTBUF*. The number of bytes returned is the lesser of the exit's *OUTLEN* parameter, and the value of the *DXLEN* field on output from the exit

If the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter are *both* unchanged, the queue manager returns:

- The value of the *MDENC* and *MDCSI* fields in the MQDXP structure on *input* to the exit

If one or both of the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter has been changed, the queue manager returns:

- The value of the *MDENC* and *MDCSI* fields in the exit's message descriptor parameter on output from the exit
-

XRFAIL

Conversion was unsuccessful.

If the exit specifies this value, the queue manager returns the following to the application that issued the MQGET call:

- The value of the *DXCC* field on output from the exit
- The value of the *DXREA* field on output from the exit
- The value of the *DXLEN* field on *input* to the exit
- The contents of the exit's input buffer *INBUF*. The number of bytes returned is given by the *INLEN* parameter

If the exit has altered *INBUF*, the results are undefined.

DXRES is an output field from the exit.

DXSID (4-byte character string)

Structure identifier.

The value must be:

DXSIDV

Identifier for data conversion exit parameter structure.

This is an input field to the exit.

DXVER (10-digit signed integer)

Structure version number.

The value must be:

DXVER1

Version number for data-conversion exit parameter structure.

The following constant specifies the version number of the current version:

DXVERC

Current version of data-conversion exit parameter structure.

Note: When a new version of this structure is introduced, the layout of the existing part is not changed. The exit should therefore check that the *DXVER* field is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

DXXOP (10-digit signed integer)

Reserved.

This is a reserved field; its value is 0.

MQXCNCV - Convert characters

The MQXCNCV call converts characters from one character set to another.

This call is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces. Note: This call can be used only from a data-conversion exit.

- [“Syntax” on page 1403](#)
- [“Parameters” on page 1403](#)
- [“RPG invocation \(ILE\)” on page 1407](#)

Syntax

MQXCNVC (*HCONN, OPTS, SRCCSI, SRCLEN, SRCBUF, TGTCSI, TGTLEN, TGTBUF, DATLEN, CMPCOD, REASON*)

Parameters

The MQXCNVC call has the following parameters:

HCONN (10-digit signed integer) - input

Connection handle.

This handle represents the connection to the queue manager. It should normally be the handle passed to the data-conversion exit in the *DXHCN* field of the MQDXP structure; this handle is not necessarily the same as the handle specified by the application which issued the MQGET call.

On IBM i, the following special value can be specified for *HCONN*:

HCDEFH

Default connection handle.

OPTS (10-digit signed integer) - input

Options that control the action of MQXCNVC.

Zero or more of the options described later in this section can be specified. If more than one is required, the values can be added (do not add the same constant more than once).

Default-conversion option: The following option controls the use of default character conversion:

DCCDEF

Default conversion.

This option specifies that default character conversion can be used if one or both of the character sets specified on the call is not supported. This allows the queue manager to use an installation-specified default character set that approximates the specified character set, when converting the string.

Note: The result of using an approximate character set to convert the string is that some characters may be converted incorrectly. This can be avoided by using in the string only characters which are common to both the specified character set and the default character set.

The default character sets are defined by a configuration option when the queue manager is installed or restarted.

If DCCDEF is not specified, the queue manager uses only the specified character sets to convert the string, and the call fails if one or both of the character sets is not supported.

Padding option: The following option allows the queue manager to pad the converted string with blanks or discard insignificant trailing characters, in order to make the converted string fit the target buffer:

DCCFIL

Fill target buffer.

This option requests that conversion take place in such a way that the target buffer is filled completely:

- If the string contracts when it is converted, trailing blanks are added in order to fill the target buffer.
- If the string expands when it is converted, trailing characters that are not significant are discarded to make the converted string fit the target buffer. If this can be done successfully, the call completes with CCOK and reason code RCNONE.

If there are too few insignificant trailing characters, as much of the string as will fit is placed in the target buffer, and the call completes with CCWARN and reason code RC2120.

Insignificant characters are:

- Trailing blanks
- Characters following the first null character in the string (but excluding the first null character itself)
- If the string, *TGTCSI*, and *TGTLEN* are such that the target buffer cannot be set completely with valid characters, the call fails with CCFAIL and reason code RC2144. This can occur when *TGTCSI* is a pure DBCS character set (such as UCS-2), but *TGTLEN* specifies a length that is an odd number of bytes.
- *TGTLEN* can be less than or greater than *SRCLLEN*. On return from MQXCNCV, *DATLEN* has the same value as *TGTLEN*.

If this option is not specified:

- The string is allowed to contract or expand within the target buffer as required. Insignificant trailing characters are not added or discarded.

If the converted string fits in the target buffer, the call completes with CCOK and reason code RCNONE.

If the converted string is too large for the target buffer, as much of the string as will fit is placed in the target buffer, and the call completes with CCWARN and reason code RC2120. Note that fewer than *TGTLEN* bytes can be returned in this case.

- *TGTLEN* can be less than or greater than *SRCLLEN*. On return from MQXCNCV, *DATLEN* is less than or equal to *TGTLEN*.

Encoding options: The following options can be used to specify the integer encodings of the source and target strings. The relevant encoding is used *only* when the corresponding character set identifier indicates that the representation of the character set in main storage is dependent on the encoding used for binary integers. This affects only certain multibyte character sets (for example, UCS-2 character sets).

The encoding is ignored if the character set is a single-byte character set (SBCS), or a multibyte character set with representation in main storage that is not dependent on the integer encoding.

Only one of the DCCS* values should be specified, combined with one of the DCCT* values:

DCCSNA

Source encoding is the default for the environment and programming language.

DCCSNO

Source encoding is normal.

DCCSRE

Source encoding is reversed.

DCCSUN

Source encoding is undefined.

DCCTNA

Target encoding is the default for the environment and programming language.

DCCTNO

Target encoding is normal.

DCCTRE

Target encoding is reversed.

DCCTUN

Target encoding is undefined.

The encoding values defined previously can be added directly to the *OPTS* field. However, if the source or target encoding is obtained from the *MDENC* field in the MQMD or other structure, the following processing must be done:

1. The integer encoding must be extracted from the *MDENC* field by eliminating the float and packed-decimal encodings; see [“Analyzing encodings” on page 1387](#) for details of how to do this.
2. The integer encoding resulting from step 1 must be multiplied by the appropriate factor before being added to the *OPTS* field. These factors are:

DCCSFA

Factor for source encoding

DCCTFA

Factor for target encoding

If not specified, the encoding options default to undefined (DCC*UN). In most cases, this does not affect the successful completion of the MQXCNVC call. However, if the corresponding character set is a multibyte character set with representation that is dependent on the encoding (for example, a UCS-2 character set), the call fails with reason code RC2112 or RC2116 as appropriate.

Default option: If none of the options described previously is specified, the following option can be used:

DCCNON

No options specified.

DCCNON is defined to aid program documentation. It is not intended that this option be used with any other, but as its value is zero, such use cannot be detected.

SRCCSI (10-digit signed integer) - input

Coded character set identifier of string before conversion.

This is the coded character set identifier of the input string in *SRCBUF*.

SRCLLEN (10-digit signed integer) - input

Length of string before conversion.

This is the length in bytes of the input string in *SRCBUF* ; it must be zero or greater.

SRCBUF (1-byte character string x SRCLLEN) - input

String to be converted.

This is the buffer containing the string to be converted from one character set to another.

TGTCSI (10-digit signed integer) - input

Coded character set identifier of string after conversion.

This is the coded character set identifier of the character set to which *SRCBUF* is to be converted.

TGTLEN (10-digit signed integer) - input

Length of output buffer.

This is the length in bytes of the output buffer *TGTBUF* ; it must be zero or greater. It can be less than or greater than *SRCLLEN*.

TGTBUF (1-byte character string x TGTLEN) - output

String after conversion.

This is the string after it has been converted to the character set defined by *TGTCSI*. The converted string can be shorter or longer than the unconverted string. The *DATLEN* parameter indicates the number of valid bytes returned.

DATLEN (10-digit signed integer) - output

Length of output string.

This is the length of the string returned in the output buffer *TGTBUF*. The converted string can be shorter or longer than the unconverted string.

CMPCOD (10-digit signed integer) - output

Completion code.

It is one of the following:

CCOK

Successful completion.

CCWARN

Warning (partial completion).

CCFAIL

Call failed.

REASON (10-digit signed integer) - output

Reason code qualifying *CMPCOD*.

If *CMPCOD* is CCOK:

RCNONE

(0, X'000') No reason to report.

If *CMPCOD* is CCWARN:

RC2120

(2120, X'848') Converted data too large for buffer.

If *CMPCOD* is CCFAIL:

RC2010

(2010, X'7DA') Data length parameter not valid.

RC2150

(2150, X'866') DBCS string not valid.

RC2018

(2018, X'7E2') Connection handle not valid.

RC2046

(2046, X'7FE') Options not valid or not consistent.

RC2102

(2102, X'836') Insufficient system resources available.

RC2145

(2145, X'861') Source buffer parameter not valid.

RC2111

(2111, X'83F') Source coded character set identifier not valid.

RC2112

(2112, X'840') Source integer encoding not recognized.

RC2143

(2143, X'85F') Source length parameter not valid.

RC2071

(2071, X'817') Insufficient storage available.

RC2146

(2146, X'862') Target buffer parameter not valid.

RC2115

(2115, X'843') Target coded character set identifier not valid.

RC2116

(2116, X'844') Target integer encoding not recognized.

RC2144

(2144, X'860') Target length parameter not valid.

RC2195

(2195, X'893') Unexpected error occurred.

For more information about these reason codes, see [“Return codes for IBM i \(ILE RPG\)” on page 1381](#).

MQCONVX - Data conversion exit

This call definition describes the parameters that are passed to the data-conversion exit.

No entry point called MQCONVX is provided by the queue manager (see usage note [“11” on page 1409](#)).

This definition is part of the IBM MQ Data Conversion Interface (DCI), which is one of the IBM MQ framework interfaces.

- [“Syntax” on page 1408](#)
- [“Usage notes” on page 1408](#)
- [“Parameters” on page 1409](#)
- [“RPG invocation \(ILE\)” on page 1410](#)

Syntax

MQCONVX (MQDXP, MQMD, INLEN, INBUF, OUTLEN, OUTBUF)

Usage notes

1. A data-conversion exit is a user-written exit which receives control during the processing of an MQGET call. The function performed by the data-conversion exit is defined by the provider of the exit; however, the exit must conform to the rules described here, and in the associated parameter structure MQDXP.

The programming languages that can be used for a data-conversion exit are determined by the environment.

2. The exit is invoked only if *all* of the following are true:
 - The GMCONV option is specified on the MQGET call
 - The *MDFMT* field in the message descriptor is not FMNONE
 - The message is not already in the required representation; that is, one or both of the message's *MDCSI* and *MDENC* is different from the value specified by the application in the message descriptor supplied on the MQGET call
 - The queue manager has not already done the conversion successfully
 - The length of the application's buffer is greater than zero
 - The length of the message data is greater than zero
 - The reason code so far during the MQGET operation is RCNONE or RC2079

3. When an exit is being written, consideration should be given to coding the exit in a way that will allow it to convert messages that have been truncated. Truncated messages can arise in the following ways:

- The receiving application provides a buffer that is smaller than the message, but specifies the GMATM option on the MQGET call.

In this case, the *DXREA* field in the *MQDXP* parameter on input to the exit will have the value RC2079.

- The sender of the message truncated it before sending it. This can happen with report messages, for example (see [“Conversion of report messages” on page 1397](#) for more details).

In this case, the *DXREA* field in the *MQDXP* parameter on input to the exit will have the value RCNONE (if the receiving application provided a buffer that was large enough for the message).

Thus the value of the *DXREA* field on input to the exit cannot always be used to decide whether the message has been truncated.

The distinguishing characteristic of a truncated message is that the length provided to the exit in the *INLEN* parameter will be *less than* the length implied by the format name contained in the *MDFMT* field in the message descriptor. The exit should therefore check the value of *INLEN* before attempting to convert any of the data; the exit *should not* assume that the full amount of data implied by the format name has been provided.

If the exit has *not* been written to convert truncated messages, and *INLEN* is less than the value expected, the exit should return XRFAIL in the *DXRES* field of the *MQDXP* parameter, with the *DXCC* field set to CCWARN and the *DXREA* field set to RC2110.

If the exit *has* been written to convert truncated messages, the exit should convert as much of the data as possible (see next usage note), taking care not to attempt to examine or convert data beyond the end of *INBUF*. If the conversion completes successfully, the exit should leave the *DXREA* field in the *MQDXP* parameter unchanged. This returns RC2079 if the message was truncated by the receiver's queue manager, and RCNONE if the message was truncated by the sender of the message.

It is also possible for a message to expand *during* conversion, to the point where it is bigger than *OUTBUF*. In this case the exit must decide whether to truncate the message; the *DXAOP* field in the *MQDXP* parameter will indicate whether the receiving application specified the GMATM option.

4. Generally it is recommended that all of the data in the message provided to the exit in *INBUF* is converted, or that none of it is. An exception to this, however, occurs if the message is truncated, either before conversion or during conversion; in this case there may be an incomplete item at the end of the buffer (for example: one byte of a double-byte character, or 3 bytes of a 4-byte integer). In this situation it is recommended that the incomplete item should be omitted, and unused bytes in *OUTBUF* set to nulls. However, complete elements or characters within an array or string *should* be converted.
5. When an exit is needed for the first time, the queue manager attempts to load an object that has the same name as the format (apart from extensions). The object loaded must contain the exit that processes messages with that format name. It is recommended that the exit name, and the name of the object that contain the exit, should be identical, although not all environments require this.
6. A new copy of the exit is loaded when an application attempts to retrieve the first message that uses that *MDFMT* since the application connected to the queue manager. A new copy might also be loaded at other times, if the queue manager has discarded a previously loaded copy. For this reason, an exit should not attempt to use static storage to communicate information from one invocation of the exit to the next - the exit may be unloaded between the two invocations.
7. If there is a user-supplied exit with the same name as one of the built-in formats supported by the queue manager, the user-supplied exit does not replace the built-in conversion routine. The only circumstances in which such an exit is invoked are:
 - If the built-in conversion routine cannot handle conversions to or from either the *MDCSI* or *MDENC* involved, or
 - If the built-in conversion routine has failed to convert the data (for example, because there is a field or character which cannot be converted).
8. The scope of the exit is environment-dependent. *MDFMT* names should be chosen so as to minimize the risk of clashes with other formats. It is recommended that they start with characters that identify the application defining the format name.
9. The data-conversion exit runs in an environment like that of the program which issued the *MQGET* call; environment includes address space and user profile (where applicable). The program could be a message channel agent sending messages to a destination queue manager that does not support message conversion. The exit cannot compromise the queue manager's integrity, since it does not run in the queue manager's environment.
10. The only *MQI* call which can be used by the exit is *MQXCNVC*; attempting to use other *MQI* calls fails with reason code RC2219, or other unpredictable errors.
11. No entry point called *MQCONVX* is provided by the queue manager. The name of the exit should be the same as the format name (the name contained in the *MDFMT* field in *MQMD*), although this is not required in all environments.

Parameters

The *MQCONVX* call has the following parameters:

MQDXP (MQDXP) - input/output

Data-conversion exit parameter block.

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate the outcome of the conversion. See [“MQDXP - Data-conversion exit parameter”](#) on page 1398 for details of the fields in this structure.

MQMD (MQMD) - input/output

Message descriptor.

On input to the exit, this is the message descriptor that would be returned to the application if no conversion were performed. It therefore contains the *MDFMT*, *MDENC*, and *MDCSI* of the unconverted message contained in *INBUF*.

Note: The *MQMD* parameter passed to the exit is always the most recent version of *MQMD* supported by the queue manager which invokes the exit. If the exit is intended to be portable between different environments, the exit should check the *MDVER* field in *MQMD* to verify that the fields that the exit needs to access are present in the structure.

On IBM i, the exit is passed a version-2 *MQMD*.

On output, the exit should change the *MDENC* and *MDCSI* fields to the values requested by the application, if conversion was successful; these changes will be reflected back to the application. Any other changes that the exit makes to the structure are ignored; they are not reflected back to the application.

If the exit returns *XROK* in the *DXRES* field of the *MQDXP* structure, but does not change the *MDENC* or *MDCSI* fields in the message descriptor, the queue manager returns for those fields the values that the corresponding fields in the *MQDXP* structure had on input to the exit.

INLEN (10-digit signed integer) - input

Length in bytes of *INBUF*.

This is the length of the input buffer *INBUF*, and specifies the number of bytes to be processed by the exit. *INLEN* is the lesser of the length of the message data before conversion, and the length of the buffer provided by the application on the *MQGET* call.

The value is always greater than zero.

INBUF (1-byte bit string x INLEN) - input

Buffer containing the unconverted message.

This contains the message data before conversion. If the exit is unable to convert the data, the queue manager returns the contents of this buffer to the application after the exit has completed.

Note: The exit should not alter *INBUF*; if this parameter is altered, the results are undefined.

OUTLEN (10-digit signed integer) - input

Length in bytes of *OUTBUF*.

This is the length of the output buffer *OUTBUF*, and is the same as the length of the buffer provided by the application on the *MQGET* call.

The value is always greater than zero.

OUTBUF (1-byte bit string x OUTLEN) - output

Buffer containing the converted message.

On output from the exit, if the conversion was successful (as indicated by the value *XROK* in the *DXRES* field of the *MQDXP* parameter), *OUTBUF* contains the message data to be delivered to the application, in the requested representation. If the conversion was unsuccessful, any changes that the exit has made to this buffer are ignored.

RPG invocation (ILE)

```
C*..1.....2.....3.....4.....5.....6.....7..
C          CALLP      exitname(MQDXP : MQMD : INLEN :
C                               INBUF : OUTLEN : OUTBUF)
```

The prototype definition for the call is:

```
D*..1.....2.....3.....4.....5.....6.....7..
Dexitname      PR          EXTPROC('exitname')
D* Data-conversion exit parameter block
```

```

D MQDXP                                44A
D* Message descriptor
D MQMD                                364A
D* Length in bytes of INBUF
D INLEN                                10I 0 VALUE
D* Buffer containing the unconverted message
D INBUF                                *   VALUE
D* Length in bytes of OUTBUF
D OUTLEN                                10I 0 VALUE
D* Buffer containing the converted message
D OUTBUF                                *   VALUE

```

End of product-sensitive programming interface

SOAP reference

IBM MQ transport for SOAP reference information arranged alphabetically.

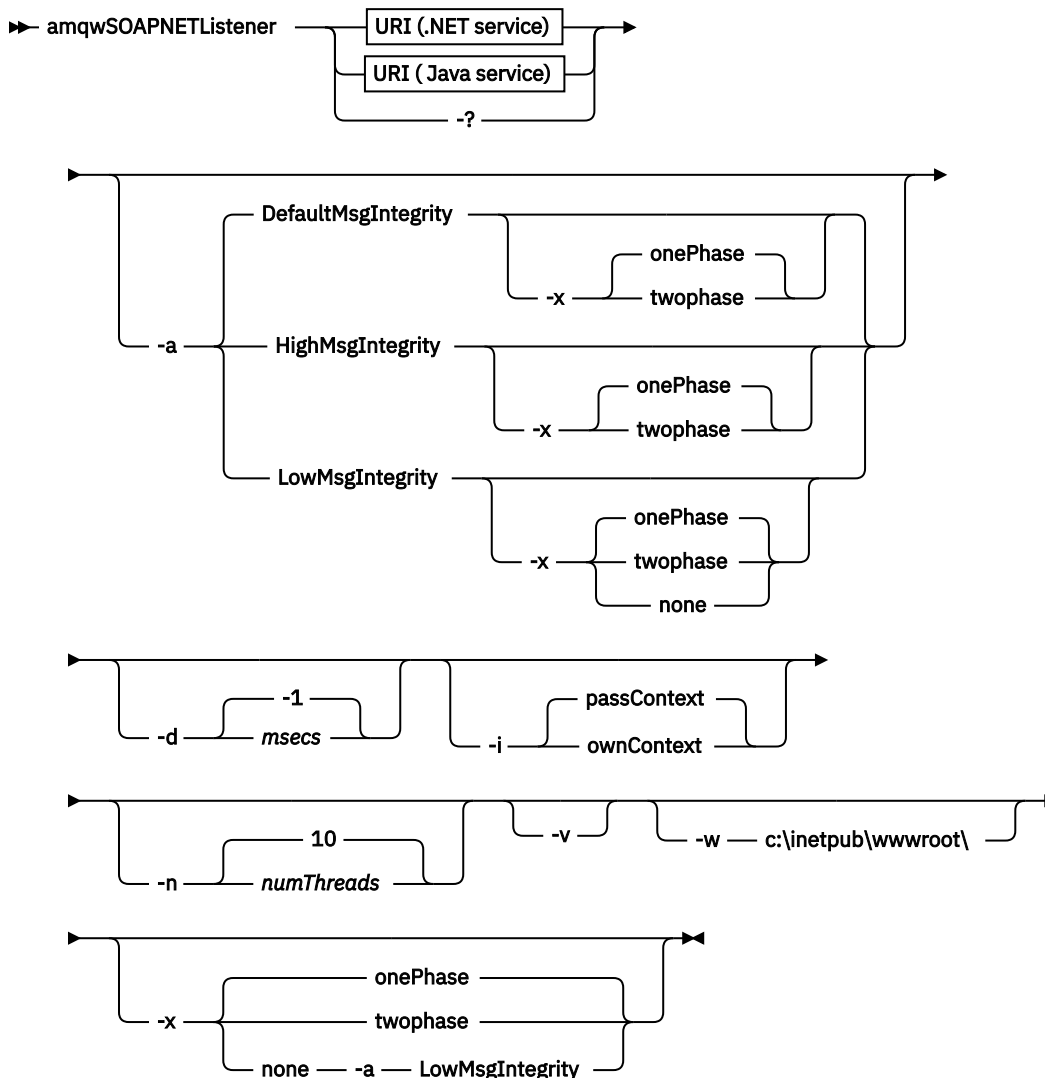

amqwSOAPNETListener: IBM MQ SOAP listener for .NET Framework 1 or 2

Syntax and parameters for the IBM MQ SOAP listener for .NET Framework 1 or 2.

Purpose

Starts the IBM MQ SOAP listener for .NET Framework 1 or 2.

.NET

Required parameters

URI *platform*

See [“URI syntax and parameters for Web service deployment”](#) on page 1447.

-?

Print out help text describing how the command is used.

Optional parameters

-a *integrityOption*

integrityOption specifies the behavior of IBM MQ SOAP listeners if it is not possible to put a failed request message on the dead-letter queue. *integrityOption* can take one of the following values:

DefaultMsgIntegrity

For non-persistent messages, the listener displays a warning message and continues to execute with the original message being discarded. For persistent messages, it displays an error message, backs out the request message so it remains on the request queue and exits. *DefaultMsgIntegrity* applies if the -a option is omitted, or if *integrityOption* is not specified.

LowMsgIntegrity

For both persistent and non-persistent messages, the listener displays a warning and continues to execute, discarding the message.

HighMsgIntegrity

For both persistent and non-persistent messages, the listener displays an error message, backs out the request message so it remains on the request queue and exits.

The deployment utility checks for the compatibility of the -x and -a flags. If -x none is specified, then -a LowMsgIntegrity must be specified. If the flags are incompatible the deployment utility exits with an error message and with no deployment steps having been undertaken.

-d *msecs*

msecs specifies the number of milliseconds for the IBM MQ SOAP listener to stay alive if request messages have been received on any thread. If *msecs* is set to -1, the listener stays alive indefinitely.

-i *Context*

Context specifies whether the listeners pass identity context. *Context* takes the following values:

passContext

Set the identity context of the original request message into the response message. The SOAP listener checks that it has authority to save the context from the request queue and to pass it to the response queue. It makes the checks at run time when opening the request queue to save context, and the response queue to pass context. If it does not have the required authority, or the MQOPEN call fails, and the response message is not processed. The response message is put on the dead-letter queue with the dead-letter header containing the return code from the failed MQOPEN. The listener then continues to process subsequent incoming messages as normal.

ownContext

The SOAP listener does not pass context. The returned context reflects the user ID under which the listener is running rather than the user ID which created the original request message.

The fields in the origin context are set by the queue manager, and not by the SOAP listener.

-n *numThreads*

numThreads specifies the number of threads in the generated startup scripts for the IBM MQ SOAP listener. The default is 10. Consider increasing this number if you have high message throughput.

-v

-v sets verbose output from external commands. Error messages are always displayed. Use -v to output commands that you can tailor to create customized deployment scripts.

-w *serviceDirectory*

serviceDirectory is the directory containing the web service.

-x *transactionality*

transactionality specifies the type of transactional control for the listener. *transactionality* can be set to one of the following values:

onePhase

IBM MQ one-phase support is used. If the system fails during processing, the request message is redelivered to the application. IBM MQ transactions ensure that the response messages are written exactly once.

twoPhase

Two-phase support is used. If the service is written appropriately the message is delivered exactly once, coordinated with other resources, within a single committed execution of the service. This option applies to server bindings connections only.

none

No transactional support. If the system fails during processing, the request message can be lost, even if persistent. The service might or might not have executed, and response, report or dead-letter messages might or might not be written.

The deployment utility checks for the compatibility of the -x and -a flags. See the description of the -a flag for details.

.NET Example

```
amqwSOAPNETlistener
-u "jms:/queue?destination=myQ&connectionFactory=()
&targetService=myService&initialContextFactory=com.ibm.mq.jms.Nojndi"
-w C:/wmqsoap/demos
-n 20
```

amqswsd1: generate WSDL for .NET Framework 1 or 2 service

amqswsd1 takes a Web service written for .NET Framework 1 or 2, and generates the WSDL for the class, inserting the URI you provide for the IBM MQ transport for SOAP into the generated WSDL.

Purpose

Use **amqswsd1** to generate WSDL containing the URI of the service deployed to IBM MQ. Use the WSDL to generate client proxies.

➡ **amqswsd1** — *escapedUri* — *className* — .asmx — *className* — .wsdl ➡

Parameters

***escapedUri* (Input)**

The URI of the service, with all "&" escaped to "&". For example:

```
"jms:/queue?destination=REQUESTDOTNET
&initialContextFactory=com.ibm.mq.jms.Nojndi
&connectionFactory=(connectQueueManager(QM1)binding(server))
&targetService=Quote.asmx"
```

***className.asmx* (Input)**

The service class.

***className.wsdl* (Output)**

The service WSDL.

Description

If the class is implemented using the code-behind programming model, you must build *className.dll* and store it in *./bin*.

amqwclientconfig: create Axis 1.4 Web services client deployment descriptor for IBM MQ transport for SOAP

amqwclientconfig creates the `client-config.wsdd` Axis 1.4 client deployment descriptor file.

Purpose

It adds the `jms:/transport` to the descriptor, and registers `java:com.ibm.mq.soap.transport.jms.WMQSender` as the class to handle SOAP requests for the `jms:transport`.

Syntax

➤ `amqwclientconfig` ➤

Description

amqwclientconfig calls **amqwsetcp** to set the CLASSPATH and runs the command:

```
java org.apache.axis.utils.Admin client "%WMQSOAP_HOME%\bin\amqwclientTransport.wsdd"
```

amqwdeployWMQService: deploy Web service utility

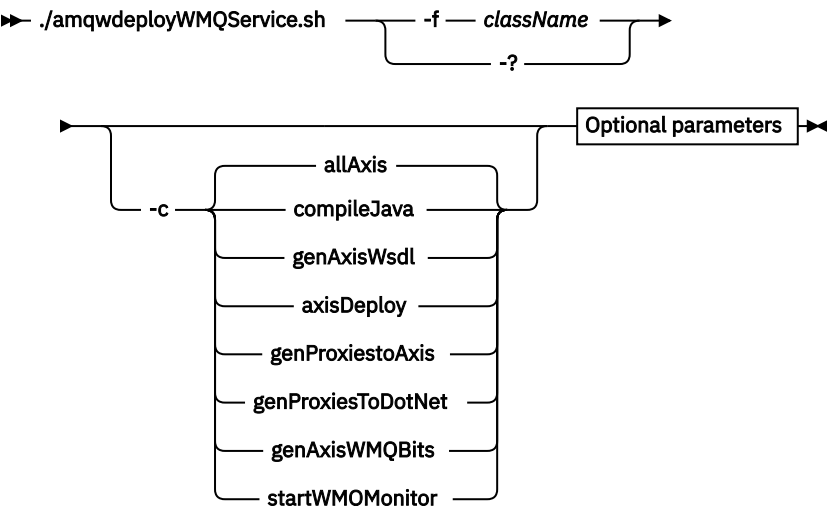

The deployment utility prepares a service class for use as a Web service using IBM MQ as the transport.

Purpose

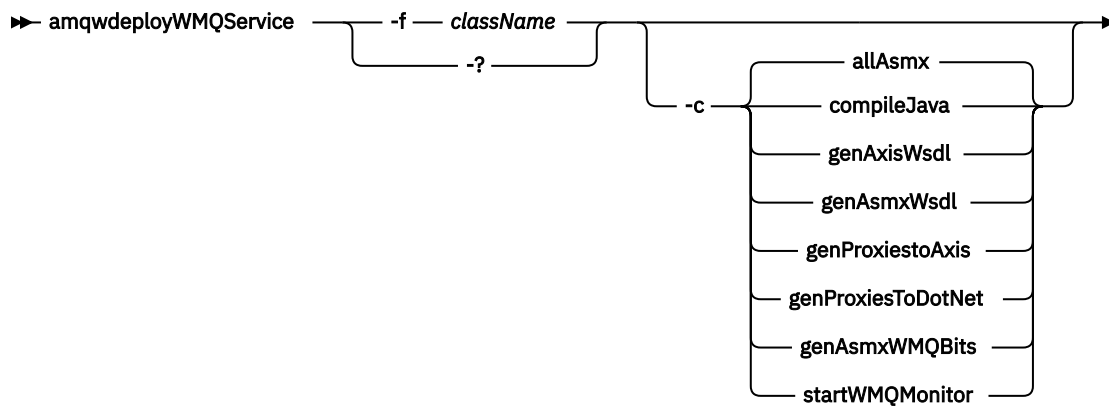

Use the deployment utility to generate the files that are needed to deploy an Axis 1.4, .NET Framework 1 or .NET Framework 2 service. Use the files to deploy a service invoked by IBM MQ. The files generated by **amqwdeployWMQService** are shown in [“Output files from amqwdeployWMQService” on page 1419](#).

Syntax diagram

UNIX and Linux systems

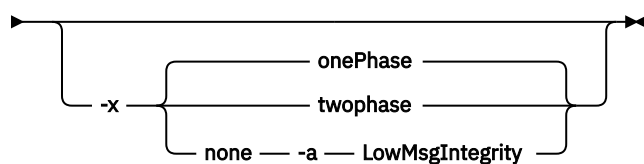

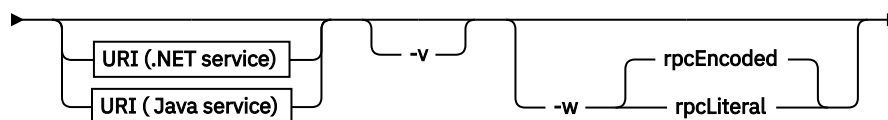

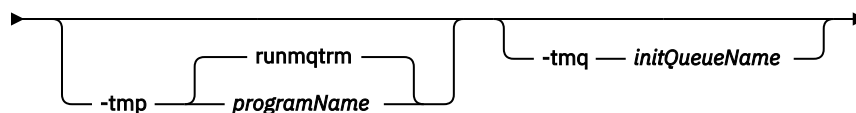

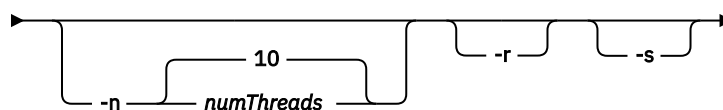

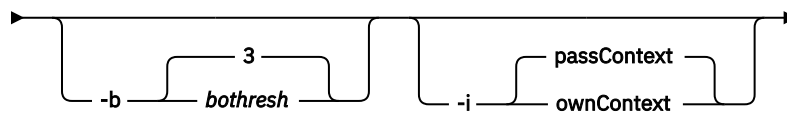

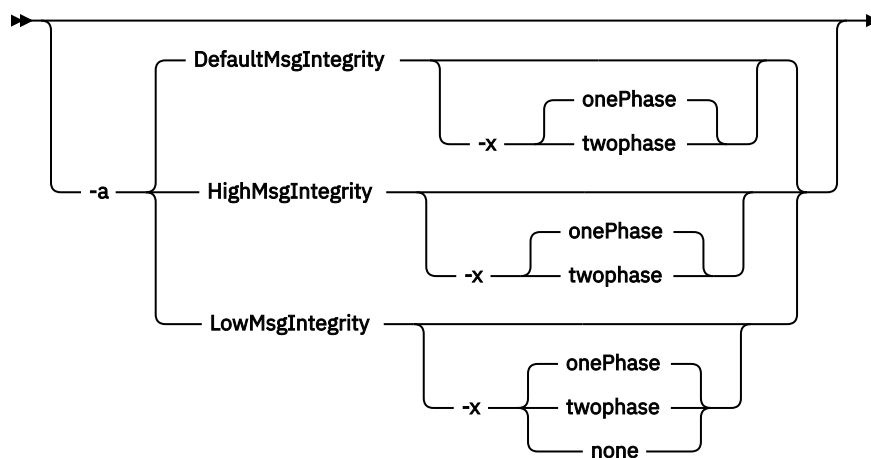

Windows

Optional parameters

Optional parameters

Required parameters

-f *className*

className is the name of the class to be deployed. For Axis services *className* is the Java source file, and for .NET services, the .asmx file. Figure 10 on page 1416 illustrates the deployment of an Axis service and Figure 11 on page 1416 of a .NET service.

```
amqwdeployMQService -f javaDemos/service/StockQuoteAxis.java
```

Figure 10. Example deployment of Axis service

```
amqwdeployMQService -f StockQuoteDotNet.asmx
```

Figure 11. Example deployment of .NET service

For Java, *className* must be fully qualified by the package name. It can be specified as a path name with directory separators or as a class name with period separators. The generated class is located in `./generated/client/remote/path name`. For a .NET service, although the directory can be specified, generated Java proxies are always located in `./generated/client/remote/dotNetService`.

If you specify a URI with the -u option and within the URI specify *targetService*, the deployment utility checks the *className*. *className* must match *targetService*. If the class and service do not match, the deployment utility displays an error message and exits.

-?

Print out help text describing how the command is used.

Optional parameters

-a *integrityOption*

integrityOption specifies the behavior of IBM MQ SOAP listeners if it is not possible to put a failed request message on the dead-letter queue. *integrityOption* can take one of the following values:

DefaultMsgIntegrity

For non-persistent messages, the listener displays a warning message and continues to execute with the original message being discarded. For persistent messages, it displays an error message, backs out the request message so it remains on the request queue and exits. DefaultMsgIntegrity applies if the -a option is omitted, or if *integrityOption* is not specified.

LowMsgIntegrity

For both persistent and non-persistent messages, the listener displays a warning and continues to execute, discarding the message.

HighMsgIntegrity

For both persistent and non-persistent messages, the listener displays an error message, backs out the request message so it remains on the request queue and exits.

The deployment utility checks for the compatibility of the -x and -a flags. If -x none is specified, then -a LowMsgIntegrity must be specified. If the flags are incompatible the deployment utility exits with an error message and with no deployment steps having been undertaken.

-b *bothresh*

bothresh specifies the backout threshold setting for the request queue. The default is 3.

-c *operation*

operation specifies which part of the deployment process to execute. *operation* is one of the following options:

allAxis

Perform all compile and setup steps for an Axis or Java service ⁵.

⁵ Default if *className* has a .java extension

compileJava

Compile the Java service: .java to .class.

genAxisWsd1

Generate WSDL: .class to .wsdl.

axisDeploy

Deploy the class file: .wsdl to .wsdd, apply .wsdd.

genProxiestoAxis

Generate proxies: .wsdl to .java and .class.

genAxisWMQBits

Set up IBM MQ queues, IBM MQ SOAP listeners and triggers for an Axis service.

allAsmx

Perform all setup steps for a .NET service ⁶.

genAsmxWsd1

Generate WSDL: .asmx to .wsdl.

genProxiesToDotNet

Generate proxies: .wsdl to .java, .class, .cs and .vb.

genAsmxWMQBits

Set up IBM MQ queues, IBM MQ SOAP listeners and triggers

startWMQMonitor

Start the trigger monitor for IBM MQ SOAP services.

Note: `runmqtrm` runs under the mqm user ID. If security is an issue, you must ensure that the listeners are started under appropriate user IDs.

-i Context

Context specifies whether the listeners pass identity context. *Context* takes the following values:

passContext

Set the identity context of the original request message into the response message. The SOAP listener checks that it has authority to save the context from the request queue and to pass it to the response queue. It makes the checks at run time when opening the request queue to save context, and the response queue to pass context. If it does not have the required authority, or the MQOPEN call fails, and the response message is not processed. The response message is put on the dead-letter queue with the dead-letter header containing the return code from the failed MQOPEN. The listener then continues to process subsequent incoming messages as normal.

ownContext

The SOAP listener does not pass context. The returned context reflects the user ID under which the listener is running rather than the user ID which created the original request message.

The fields in the origin context are set by the queue manager, and not by the SOAP listener.

-n numThreads

numThreads specifies the number of threads in the generated startup scripts for the IBM MQ SOAP listener. The default is 10. Consider increasing this number if you have high message throughput.

-r

-r specifies that any existing request or trigger monitor queue definitions are replaced. Trigger monitor queues are replaced only if *-tmq* is also specified. Queues are re-created with standard default attributes and existing messages on the queues are deleted. If the *-r* option is not used then any existing queue definitions are not altered and existing messages are not deleted. By not specifying *-r*, you ensure that any customized queue attributes are preserved.

-s

Configure the listener to run as an IBM MQ service. If *-s* and *-tmq* are both specified, the deployment utility displays an error message and exits.

⁶ Default if *className* has a .asmx extension.

-tmp *programName*

programName specifies the name of a trigger monitor program. Use `-tmp programName` in a UNIX or Linux environment as an alternative to using **runmqtrm**. Programs it initiates run under mqm authority.

For example:

```
amqwdployWmqService -f javaDemos/service/StockQuoteAxis.java
-tmq trigger.monitor.queue -tmp trigmon
```

-tmq *queueName*

queueName specifies a trigger monitor queue name. IBM MQ process definitions are created to configure automatic triggering of IBM MQ SOAP listeners with the associated trigger monitor queue name. If the option is not specified then no triggering configuration is defined by the deployment utility. If `-s` and `-tmq` are both specified, the deployment utility displays an error message and exits.

URI *platform*

See [“URI syntax and parameters for Web service deployment” on page 1447](#).

-v

`-v` sets verbose output from external commands. Error messages are always displayed. Use `-v` to output commands that you can tailor to create customized deployment scripts.

-w

`-w` controls the style of WSDL to generate. The default is `rpcEnclosed`, for compatibility with previous releases of IBM MQ transport for SOAP. Use `rpcLiteral` to create WSDL compatible with Axis2 client proxy generation. `rpcEnclosed` is not compatible with WS-I recommendations.

-x *transactionality*

transactionality specifies the type of transactional control for the listener. *transactionality* can be set to one of the following values:

onePhase

IBM MQ one-phase support is used. If the system fails during processing, the request message is redelivered to the application. IBM MQ transactions ensure that the response messages are written exactly once.

twoPhase

Two-phase support is used. If the service is written appropriately the message is delivered exactly once, coordinated with other resources, within a single committed execution of the service. This option applies to server bindings connections only.

none

No transactional support. If the system fails during processing, the request message can be lost, even if persistent. The service might or might not have executed, and response, report or dead-letter messages might or might not be written.

The deployment utility checks for the compatibility of the `-x` and `-a` flags. See the description of the `-a` flag for details.

Errors

On Windows, if errors are reported from **amqswsd1**, try issuing the following command to register `.asmx` files as services.

```
%windir%\Microsoft.NET\Framework/ version number /aspnet_regiis.exe -ir
```

The problem typically occurs on systems where IIS has not been installed, or IIS has been installed after .NET. The problem is encountered when **amqswsd1** generates the `.wsdl` files.

Note: The registry keys are also required to permit the listener to invoke the services. If you use your own customized deployment procedures, you might not encounter the problem until run time.

Output files from amqwdeployWMQService

A list of the directories and files output from **amqwdeployWMQService**

Table 633. Output files from amqwdeployWMQService			
Output s	Descriptio n	Output directory	Filename
.class	Compiled Java source file	./generated/server/server package	classname.class
.wsdl	Service description	./generated	className Axis_Wmq.wsdl className DotNet_Wmq.wsdl
.wsdd	Axis client and service deployment files	./	client-config.wsdd server-config.wsdd
		./generated/server/server package	className _deploy.wsdd className _undeploy.wsdd

Scripts (.cmd and .sh)	Listener scripts	/generated/server	startWMQJListener.cmd startWMQJListener.sh startWMQNListener.cmd endWMQJListener.cmd endWMQJListener.sh endWMQNListener.cmd

Usage notes for amqwdeployWMQService

Describes the tasks performed by **amqwdeployWMQService**.

The deployment utility performs the following actions.

1. Checks paths to the following files:

- axis.jar.
- WMQSOAP_HOME/java/lib/com.ibm.mq.soap.jar.
- On Windows, csc.exe

2. On Windows, uses either %SystemRoot%\Microsoft.NET\Framework\v1.1.432 or, if the C# compiler is installed, the path to csc.exe as the path to the .NET Framework.

Note: If you have Microsoft Visual Studio 2008 installed (Version 9), wsdl.exe is not in the path to csc.exe. You need to add the path to the .NET framework to your Path variable; for example:

```
Set Path=C:\WINDOWS\Microsoft.NET\Framework\v2.0.50727;%Path%
```

3. Creates the ./generated directory, and required subdirectories, if they do not exist.

4. For Java services, compiles the source into *className.class*.

5. Generates WSDL.

6. For Java services, creates deployment descriptor files *className_deploy.wsdd* and *className_undeploy.wsdd*

7. For Java services, creates or updates the Axis deployment descriptor file, server-config.wsdd.

8. Generates the client proxies for Java, C# and Visual Basic from the WSDL.

Note: On Windows, the deploy utility generates proxies for Visual Basic and C# regardless of the language in which the service is written. The WSDL and the proxies generated from it include the appropriate URI to call the service:

```
a. jms:/queue?destination=SOAPN.demos@WMQSOAP.DEMO.QM
&connectionFactory=(connectQueueManager(WMQSOAP.DEMO.QM))
&initialContextFactory=com.ibm.mq.jms.Nojndi
&targetService=StockQuoteDotNet.asmx
&replyDestination=SYSTEM.SOAP.RESPONSE.QUEUE
```

Figure 12. Example URI in generated .NET client to call .NET service

```
b. jms:/queue?destination=SOAPJ.demos@WMQSOAP.DEMO.QM
&connectionFactory=(connectQueueManager(WMQSOAP.DEMO.QM))
&initialContextFactory=com.ibm.mq.jms.Nojndi
&targetService=soap.server.StockQuoteAxis.java
&replyDestination=SYSTEM.SOAP.RESPONSE.QUEUE
```

Figure 13. Example URI in generated .NET client to call Axis 1 service

9. Compiles the Java proxies.
 10. Creates an IBM MQ queue, *requestQueue* to hold requests for the service. The default queue name is of the form SOAPJ. *directory* , or you can specify *requestQueue* in the -u URI option.
 11. Creates command and shell script files to start the IBM MQ SOAP listeners that process the request queue.
 12. If the -tmq option has been used, the deployment utility creates IBM MQ definitions to trigger IBM MQ SOAP listener processes automatically.
 - The deployment utility uses the APPLICID attribute of the **runmqsc** DEFINE PROCESS command to contain a command to start the listener. The command has the name of the deployment directory embedded in it. The APPLICID field has a maximum length of 256, which limits the maximum length of the deployment directory. The directory limit for Java services is as follows:
 - UNIX and Linux systems: 218
 - Windows: 197 minus the length of the request queue name.
- For .NET services, the directory limit is as follows:
- Windows: 209 minus length of the service name, minus the .asmx extension.
- The deployment utility checks whether the limit for APPLICID is exceeded. If the limit is exceeded, the utility does not attempt to define the triggering process. It displays an error message and the deployment process fails without performing any deployment steps.

The following examples show the configuration and start commands generated by the deployment utility to start an IBM MQ SOAP listener.

```
DEFINE PROCESS(requestQueue) APPLICID(applicIDStr) REPLACE
ALTER QLOCAL (requestQueue) TRIGTYPE(FIRST) TRIGGER
PROCESS(requestQueue) INITQ(initQueueName) TRIGMPRI(0)
```

Figure 14. IBM MQ configuration commands to trigger a SOAP listener.

```
applicIDStr = start "Java WMQSoapListener -requestQueue"
               /min .\generated\server\startWMQJListener.cmd;
```

Figure 15. Starting Axis SOAP listener on Windows

```
applicIDStr = start "WMQAsmxListener -className\
               /min .\generated\server\startWMQNListener.cmd;
```

Figure 16. Starting .NET SOAP listener on Windows

```
applicIDStr = xterm -iconic -T \"Java WMQSoapListener_requestQueue\"
               -e ./generated/server/startWMQJListener.sh & #
```

Figure 17. Starting Axis SOAP listener on UNIX and Linux systems

amqwRegisterdotNet: register IBM MQ transport for SOAP to .NET

Register IBM MQ transport for SOAP to the global assembly cache on .NET.

Purpose

amqwRegisterdotNet registers the IBM MQ SOAP sender, SOAP listener, and WSDL processor with .NET Framework 1 or 2.

Syntax

➤ amqwRegisterdotNet ➤

Description

amqwRegisterdotNet is run automatically during installation. You do not need to run it again if the .NET Framework you are using was installed before IBM MQ transport for SOAP. You can run it as many times as you want. Use it to reregister IBM MQ transport for SOAP with different .NET Framework versions.

Note: On Windows 2003 Server, you must also run the **aspnet_regiis** utility, even if you are not deploying to Internet Information Server (IIS). The location of the **aspnet_regiis.exe** utility might vary with different versions of the Microsoft.NET Framework, but it is typically located in: %SystemRoot%/Microsoft.NET/Framework/version number/aspnet_regiis. If multiple versions are installed, use **aspnet_regiis** for the version of .NET Framework you are using.

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the

editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

(b) You must cause any modified files to carry prominent notices stating that You changed the files; and

(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special,

incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

you may not use this file except in compliance with the License.
You may obtain a copy of the License at

<http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

MQMD SOAP settings

The IBM MQ SOAP sender and IBM MQ SOAP listener create a message descriptor (**MQMD**). The topic describes the fields you must set in the MQMD if you create your own SOAP sender or listener.

Purpose

The values set in the **MQMD** control the exchange of messages between the IBM MQ SOAP sender, the IBM MQ SOAP listener, and the SOAP client program. If you create your own SOAP sender or listener, follow the rules in [Table 634 on page 1426](#).

Description

Table 634 on page 1426 describes how the **MQMD** fields are set by the IBM MQ SOAP sender and IBM MQ SOAP listener. If you write your own sender or listener you must set these fields in accordance with the rules for exchanging messages. The IBM MQ SOAP listener conforms to typical IBM MQ message exchange protocols. If you write your own sender to work with the IBM MQ SOAP listeners, you can set different **MQMD** values.

In Table 634 on page 1426, the values in the Setting column are organized as follows:

Request, One way

Settings made by IBM MQ SOAP sender.

Response, Report

Settings made by IBM MQ SOAP listener in response to IBM MQ SOAP sender request.

ALL

Settings made by both the IBM MQ SOAP sender and IBM MQ SOAP listener.

Customized sender

You can write your own sender. Typically, a customized sender overrides the standard report options.

Table 634. MQMD SOAP settings		
Field name	Setting	Values
<i>StrucId</i>	ALL MQMD_STRUC_ID	'MD-1' 1
<i>Version</i>	ALL MQMD_VERSION_2	2
<i>Report</i>	ALL MQRO_NONE + MQRO_NEW_MSG_ID + MQRO_COPY_MSG_ID_TO_CORREL_ID + MQRO_EXCEPTION + MQRO_EXPIRY + MQRO_DISCARD Customized sender See “Customized report options” on page 1430	52428800
<i>MsgType</i>	Request MQMT_REQUEST Response MQMT_REPLY Report MQMT_REPORT One way MQMT_DATAGRAM	MQMT_REQUEST 1 MQMT_REPLY 2 MQMT_REPORT 4 MQMT_DATAGRAM 8
<i>Expiry</i>	Request, One way Specified by Expiry option in URI. Defaults to MQEI_UNLIMITED. Response Value of Expiry in request message Report MQEI_UNLIMITED	MQEI_UNLIMITED -1

<i>Offset</i>	Request, One way, Report Not used Response Field is copied from the request message	0
<i>MsgFlags</i>	Request, One way, Report MQMF_NONE Response Field is copied from the request message	MQMF_NONE 0 See “MsgFlags (MQLONG)” on page 417
<i>OriginalLength</i>	Request, One way, Response MQOL_UNDEFINED Report Length of original request message	MQOL_UNDEFINED -1

Table 634. MQMD SOAP settings (continued)

Field name	Setting	Values
Notes: <ol style="list-style-type: none"> 1. The symbol ~ represents a single blank character. 2. The value Null string or blanks denotes the null string in C, and blank characters in other programming languages. 		

Customized report options

You can write your own SOAP sender and use it with the supplied listeners. Typically you might write a sender to change the choice of report options. The IBM MQ SOAP listeners support most combinations of report options, as described in the following lists.

- Report options supported by IBM MQ SOAP listeners:
 - MQRO_EXCEPTION
 - MQRO_EXCEPTION_WITH_DATA
 - MQRO_EXCEPTION_WITH_FULL_DATA
 - MQRO_DEAD_LETTER_Q
 - MQRO_DISCARD_MSG
 - MQRO_NONE
 - MQRO_NEW_MSG_ID
 - MQRO_PASS_MSG_ID
 - MQRO_COPY_MSG_ID_TO_CORREL_ID
 - MQRO_PASS_CORREL_ID
- Report options supported by the queue manager:
 - MQRO_COA
 - MQRO_COA_WITH_DATA
 - MQRO_COA_WITH_FULL_DATA
 - MQRO_COD
 - MQRO_COD_WITH_DATA
 - MQRO_COD_WITH_FULL_DATA
 - MQRO_EXPIRATION
 - MQRO_EXPIRATION_WITH_DATA
 - MQRO_EXPIRATION_WITH_FULL_DATA
- The following report options are not supported by the IBM MQ SOAP listeners.
 - MQRO_PAN
 - MQRO_NAN

The behavior of IBM MQ SOAP listeners in response to combinations of MQRO_EXCEPTION_* and MQRO_DISCARD is described in [Table 635 on page 1431](#).

The notation MQRO_EXCEPTION_* indicates the use of either MQRO_EXCEPTION, MQRO_EXCEPTION_WITH_DATA or MQRO_EXCEPTION_WITH_FULL_DATA.

runivt: IBM MQ transport for SOAP installation verification test

An installation verification test suite (IVT) is provided with IBM MQ transport for SOAP. **runivt** runs a number of demonstration applications and ensures that the environment is correctly set up after installation.

Purpose

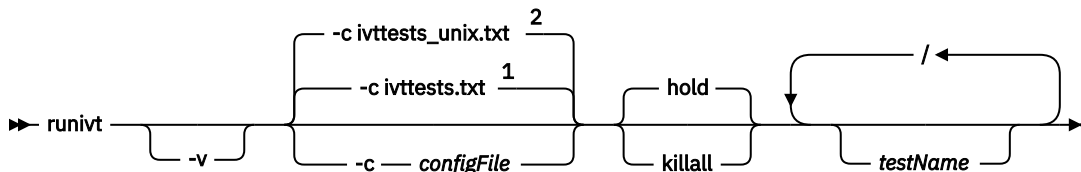

The **runivt** command uses the sample programs provided with the IBM MQ transport for SOAP to send Web service requests from clients to services. It runs tests for Axis 1.4, .NET Framework 1, and .NET Framework 2. The tests are configured in a test script file. The default test script file for Windows runs a combination of tests between Java and .NET clients and services.

Description

runivt must be run from its own directory.

The command starts listeners in a different command window. For this reason, you must run the command from an X Window System session on UNIX and Linux systems.

runivt syntax

Notes:

¹ Default on Windows

² Default on UNIX and Linux systems

runivt parameters

-v

Verbose mode. Write fuller error messages to the console.

-c configFile

A configuration file defining the tests to be run. The default configuration file supplied with Windows, UNIX or Linux systems is used by default.

hold

Leave the listener running after the tests complete

killall

End the listener when the tests complete

testName

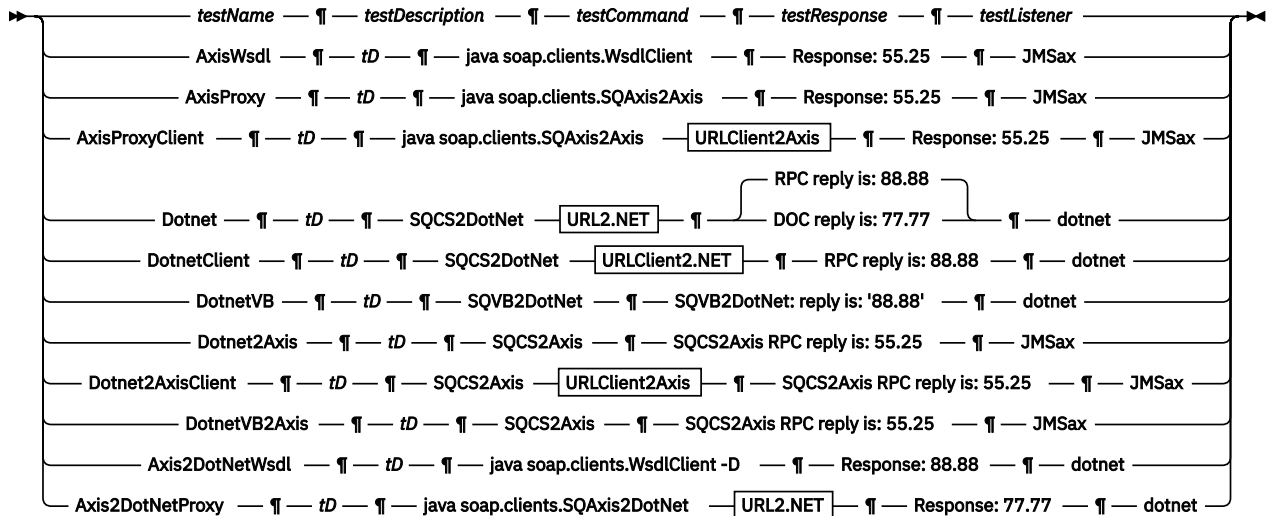

A space separated list of the tests to run. The test names are selected from the configuration file. If no names are specified then all the tests in the configuration file are run.

Configuration file

Each configuration file parameter is a separate line of the file. Leave a blank line between each group of parameters.

The parameters in the `ivttests.txt` parameter file are listed.

configFile syntax

URLClient2Axis

URL2.NET

URLClient2.NET

Common URL

```

jms:/queue?destination=SOAPJ.demos@WMQSOAP.DEMO.QM — & — initialContextFactory — = —>
com.ibm.mq.jms.Nojndi — & — connectionFactory — = —>
connectQueueManager — ( — WMQSOAP.DEMO.QM — ) —>
  
```

Client connection

```

clientConnection — ( — localhost%25289414WMQSOAP.DEMO.QM%2529 — ) — clientChannel —>
( — TESTCHANNEL — ) —>
  
```

Target service

```

& — targetService — = — StockQuoteDotNet.asmx —>
  
```

configFile parameters

testName

The name of the test. Use *testName* in the **runivt** command

testDescription

Documentation about the test

testCommand

The command executed by the **runivt** command to make the client request.

testResponse

The exact response string returned by the client request to the console. For the test to succeed *testResponse* must match the actual response.

testListener

The name of the IBM MQ SOAP listener that is started by **runivt** to process the SOAP request. **dotnet** and **JMSax** are synonyms for the supplied listeners, **amqwSOAPNETlistener** and **SimpleJavaListener**.

Examples

```
runivt
```

Figure 18. run all the default tests

```
runivt dotnet
```

Figure 19. run a specific test from the default tests

```
runivt -c mytests.txt
```

Figure 20. run a set of custom tests

[Verifying the IBM MQ transport for SOAP](#)

Secure Web services over IBM MQ transport for SOAP

You might secure Web services that use the IBM MQ transport for SOAP in one of two ways. Either create an SSL channel between the client and server, or use Web services security.

SSL and the IBM MQ transport for SOAP

The IBM MQ transport for SOAP provides several SSL options that can be specified for use with client channel configured to run in SSL mode. The options differ between the .NET and Java environments. The IBM MQ SOAP senders and listeners process only the SSL options that are applicable to their particular environment. They ignore options that are not applicable.

The presence or absence of the `sslCipherSpec` option for .NET clients and the `sslCipherSuite` option for Java clients determines whether SSL is used or not. If the option is not specified in the URI then by default SSL is not used and all other SSL options are ignored. All SSL options are optional except where indicated.

For IBM MQ clients, set the SSL attributes in the URI or channel definition table. On the server, set the attributes using the facilities of IBM MQ.

By default, the standard IBM MQ SSL option, `SSLCAUTH`, is set when enabling SSL on the channel. Clients must authenticate themselves before SSL communication can commence. If `SSLCAUTH` is not set, SSL communications are established without client authentication.

To authenticate themselves, clients must have a certificate assigned in their key repository that is acceptable to the queue manager. For additional security, IBM MQ channels can be configured to accept only certificates from a restricted list. The list is restricted by checking the distinguished name of the certificate against the peer name attribute of the channel.

If you use Java, the first SSL connection from an IBM MQ SOAP client causes the following SSL parameters to be fixed. The same values are used in subsequent connections using the same client process:

- `sslKeyStore`
- `sslKeyStorePassword`
- `sslTrustStore`
- `sslTrustStorePassword`

- `sslFipsRequired`
- `sslLDAPCRLservers`

The effect of varying these parameters on subsequent connections from this client is undefined.

If you use .NET, the first SSL connection from an IBM MQ SOAP client causes the following SSL parameters to be fixed. The same values are used in subsequent connections using the same client process:

- `sslKeyRepository`
- `sslCryptoHardware`
- `sslFipsRequired`
- `sslLDAPCRLservers`

The effect of varying these parameters on subsequent connections from this client is undefined. These parameters are reset if all SSL connections become inactive and a new SSL connection is made.

The following properties can also be specified as system properties:

- `sslKeyStore`
- `sslKeyStorePassword`
- `sslTrustStore`
- `sslTrustStorePassword`

If they are specified both as system properties and in the URI, and the values differ, the deployment utility displays a warning. The URI values take precedence.

[SSL connection factory parameters in the IBM MQ Web services URI](#)

Add SSL options to the list of connection factory options in the IBM MQ Web services URI.

[Federal Information Processing Standards \(FIPS\) for UNIX, Linux and Windows](#)

SSL connection factory parameters in the IBM MQ Web services URI

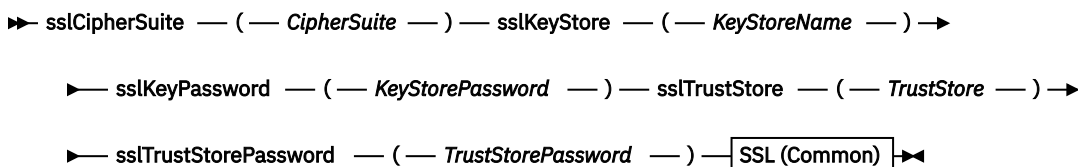

Add SSL options to the list of connection factory options in the IBM MQ Web services URI.

Purpose

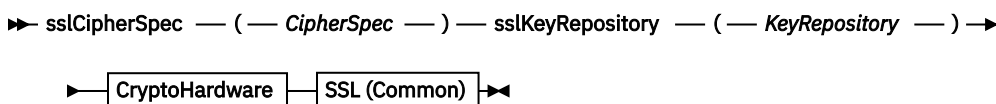

You can use a secure connection between an IBM MQ Web services client and the queue manager hosting the web service. The SSL options control how SSL is configured on the IBM MQ MQI client-server channel connection.

Syntax diagram

SSL (Java)

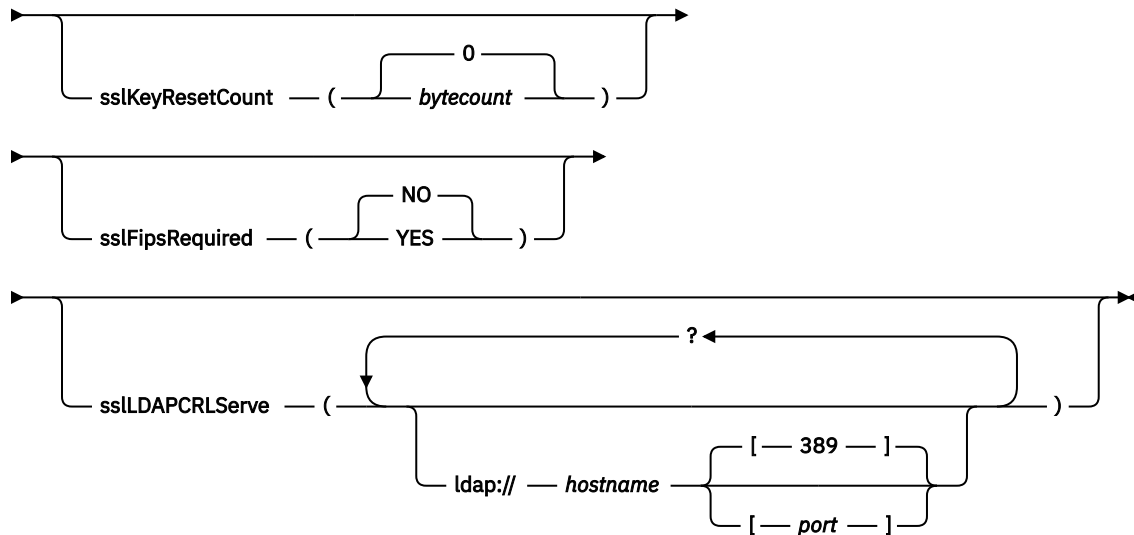

SSL (.NET)

SSL (Common)

➤ `sslCipherPeerName` — (— *PeerName* —) ➔

CryptoHardware

➤ `sslCryptoHardware` — = — *PKCS #11 Path and file name* — ; — *PKCS #11 token label* — ; ➔

➤ *PKCS #11 token password* — ; — *symmetric cipher setting* — ; ➤

Required SSL parameters (Common)

`sslPeerName` (*peerName*)

peerName specifies the `sslPeerName` used on the channel.

Required SSL parameters (Java)

`sslCipherSuite` (*CipherSuite*)

CipherSuite specifies the `sslCipherSuite` used on the channel. The `CipherSuite` specified by the client must match the `CipherSuite` specified on the server connection channel.

`sslKeyStore` (*KeyStoreName*)

KeyStoreName specifies the `sslKeyStoreName` used on the channel. The keystore holds the private key of the client used to authenticate the client to the server. The keystore is optional if the SSL connection is configured to accept anonymous client connections.

`sslKeyStorePassword` (*KeyStorePassword*)

KeyStorePassword specifies the `sslKeyStorePassword` used on the channel.

`sslTrustStore` (*TrustStoreName*)

TrustStoreName specifies the `sslTrustStoreName` used on the channel. The truststore holds the public certificate of the server, or its key chain, to authenticate the server to the client. The truststore is optional if the root certificate of a certificate authority is used to authenticate the server. In Java, root certificates are held in the JRE certificate store, `cacerts`.

`sslTrustStorePassword` (*TrustStorePassword*)

TrustStorePassword specifies the `sslTrustStorePassword` used on the channel.

Required SSL parameters (.NET)

`sslCipherSpec` (*CipherSpec*)

CipherSpec specifies the `sslCipherSpec` used on the channel. If the option is specified then SSL is used on the client channel.

sslKeyRepository (*KeyRepository*)

KeyRepository specifies the sslCipherSpec used on the channel where SSL keys and certificates are stored. *KeyRepository* is specified in stem format, that is, a full path with file name but with the file extension omitted. The effect of setting sslKeyRepository is the same as setting the KeyRepository field in the **MQSCO** structure on an MQCONN call.

Optional SSL parameters (.NET)**sslCryptoHardware (*CryptoHardware*)**

CryptoHardware specifies the sslCryptoHardware used on the channel. The possible values for this field, and the effect of setting it, are the same as for the CryptoHardware field of the **MQSCO** structure on an MQCONN.

Optional SSL parameters (Common)**sslKeyResetCount (*bytecount*)**

bytecount specifies the number of bytes passed across an SSL channel before the SSL secret key must be renegotiated. To disable the renegotiation of SSL keys omit the field or set it to zero. Zero is the only value supported in some environments, see [Renegotiating the secret key in IBM MQ classes for Java](#) . The effect of setting sslKeyResetCount is the same as setting the KeyResetCount field in the **MQSCO** structure on an MQCONN call.

sslFipsRequired (*fipsCertified*)

fipsCertified specifies whether *CipherSpec* or *CipherSuite* must use FIPS-certified cryptography in IBM MQ on the channel. The effect of setting *fipsCertified* is the same as setting the FipsRequired field of the **MQSCO** structure on an MQCONN call.

sslLDAPCRLServers (*LDAPServerList*)

LDAPServerList specifies a list of LDAP servers to be used for Certificate Revocation List checking.

For SSL enabled client connections, *LDAPServerList* is a list of LDAP servers to be used for Certificate Revocation List (CRL) checking. The certificate provided by the queue manager is checked against one of the listed LDAP CRL servers; if found, the connection fails. Each LDAP server is tried in turn until connectivity is established to one of them. If it is impossible to connect to any of the servers, the certificate is rejected. Once a connection has been successfully established to one of them, the certificate is accepted or rejected depending on the CRLs present on that LDAP server.

If *LDAPServerList* is blank, the certificate belonging to the queue manager is not checked against a Certificate Revocation List. An error message is displayed if the supplied list of LDAP URIs is not valid. The effect of setting this field is the same as that of including MQAIR records and accessing them from an **MQSCO** structure on an MQCONN.

SimpleJavaListener: IBM MQ SOAP Listener for Axis 1.4

Syntax and parameters for the IBM MQ SOAP listener for Axis 1.4.

Purpose

Starts the IBM MQ SOAP listener for Axis 1.4.

Java

Required parameters

URI platform

See [“URI syntax and parameters for Web service deployment”](#) on page 1447.

-?

Print out help text describing how the command is used.

Optional parameters

-a integrityOption

integrityOption specifies the behavior of IBM MQ SOAP listeners if it is not possible to put a failed request message on the dead-letter queue. *integrityOption* can take one of the following values:

DefaultMsgIntegrity

For non-persistent messages, the listener displays a warning message and continues to execute with the original message being discarded. For persistent messages, it displays an error message, backs out the request message so it remains on the request queue and exits. DefaultMsgIntegrity applies if the -a option is omitted, or if *integrityOption* is not specified.

LowMsgIntegrity

For both persistent and non-persistent messages, the listener displays a warning and continues to execute, discarding the message.

HighMsgIntegrity

For both persistent and non-persistent messages, the listener displays an error message, backs out the request message so it remains on the request queue and exits.

The deployment utility checks for the compatibility of the -x and -a flags. If -x none is specified, then -a LowMsgIntegrity must be specified. If the flags are incompatible the deployment utility exits with an error message and with no deployment steps having been undertaken.

-d msecs

msecs specifies the number of milliseconds for the IBM MQ SOAP listener to stay alive if request messages have been received on any thread. If *msecs* is set to -1, the listener stays alive indefinitely.

-i Context

Context specifies whether the listeners pass identity context. *Context* takes the following values:

passContext

Set the identity context of the original request message into the response message. The SOAP listener checks that it has authority to save the context from the request queue and to pass it to the response queue. It makes the checks at run time when opening the request queue to save context, and the response queue to pass context. If it does not have the required authority, or the MQOPEN call fails, and the response message is not processed. The response message is put on the dead-letter queue with the dead-letter header containing the return code from the failed MQOPEN. The listener then continues to process subsequent incoming messages as normal.

ownContext

The SOAP listener does not pass context. The returned context reflects the user ID under which the listener is running rather than the user ID which created the original request message.

The fields in the origin context are set by the queue manager, and not by the SOAP listener.

-n numThreads

numThreads specifies the number of threads in the generated startup scripts for the IBM MQ SOAP listener. The default is 10. Consider increasing this number if you have high message throughput.

-v

-v sets verbose output from external commands. Error messages are always displayed. Use -v to output commands that you can tailor to create customized deployment scripts.

-w serviceDirectory

serviceDirectory is the directory containing the web service.

-x transactionality

transactionality specifies the type of transactional control for the listener. *transactionality* can be set to one of the following values:

onePhase

IBM MQ one-phase support is used. If the system fails during processing, the request message is redelivered to the application. IBM MQ transactions ensure that the response messages are written exactly once.

twoPhase

Two-phase support is used. If the service is written appropriately the message is delivered exactly once, coordinated with other resources, within a single committed execution of the service. This option applies to server bindings connections only.

none

No transactional support. If the system fails during processing, the request message can be lost, even if persistent. The service might or might not have executed, and response, report or dead-letter messages might or might not be written.

The deployment utility checks for the compatibility of the -x and -a flags. See the description of the -a flag for details.

Java Example

```
java com.ibm.mq.soap.transport.jms.SimpleJavaListener
-u "jms:/queue?destination=myQ&connectionFactory=()
```

```
&initialContextFactory=com.ibm.mq.jms.NoJndi"
-n 20
```

IBM MQ SOAP listeners

An IBM MQ SOAP listener reads an incoming SOAP request from the queue specified as the destination in the URI. It checks the format of the request message and then invokes a Web service using the Web services infrastructure. An IBM MQ SOAP listener returns any response or error from a Web service using the reply destination queue in the URI. It returns IBM MQ reports to the reply queue.

The term listener is used here in its standard Web services sense. It is distinct from the standard IBM MQ listener invoked by the **runmqcls** command.

Description

The Java SOAP listener is implemented as a Java class and run services using Axis 1.4. The .NET listener is a console application and runs .NET Framework 1 or .NET Framework 2 services. For .NET Framework 3 services, use the IBM MQ custom channel for Microsoft Windows Communication Foundation (WCF).

The deployment utility creates scripts to start Java or .NET SOAP listeners automatically. A SOAP Listener can be started manually using either the **amqSOAPNETListener** command, or by calling the `SimpleJavaListener` class. You can configure the IBM MQ SOAP listener to be started as an IBM MQ service by setting the **-s** option in the deployment utility. Alternatively, start listeners using triggering, or use the start and end listener scripts generated by the deployment utility. You can configure triggering manually, or use the **-tmq** and **-tmp** deployment options to configure triggering automatically. You can end a listener by setting the request queue to GET (DISABLED).

Table 636. Command scripts generated by the deployment utility			
Web service Infrastructure	UNIX and Linux systems	Windows Java	Windows.NET
Start listener	<code>startWMQJListener.sh</code>	<code>startWMQJListener.cmd</code>	<code>startWMQNListener.cmd</code>
Stop listener	<code>endWMQJListener.sh</code>	<code>endWMQJListener.cmd</code>	<code>endWMQNListener.cmd</code>
Define listener service	<code>defineWMQJListener.sh</code>	<code>defineWMQJListener.cmd</code>	<code>defineWMQNListener.cmd</code>

The IBM MQ SOAP listener passes the `endpointURL` and `soapAction` fields from the SOAP message to the SOAP infrastructure. The listener invokes the service through the Web Services infrastructure and waits for the response. The listener does not validate `endpointURL` and `soapAction`. The fields are set by the IBM MQ SOAP sender from the data that is provided in the URI set by a SOAP client.

The listener creates the response message and sends it to the reply destination supplied in the request message URI. In addition, the listener sets the correlation ID in the response message according to the report option in the request message. It returns the expiry, persistence, and priority settings from the request message. The listener also sends report messages back to clients in some circumstances.

If there are format errors in the SOAP request, the listener returns a report message to the client using the reply destination queue. The queue manager also returns report messages to the client using the reply destination queue, if a report has been requested. Full report messages are written to the response queue, in response to a number of events:

- An exception.
- Message expiry.
- Format of the request message is not recognized.
- Failure of the integrity check of the **MQRFH2** header.
- The format of the main message body is not **MQFMT_NONE**.

- The backout/retry threshold is exceeded while the IBM MQ SOAP listener is processing the request.

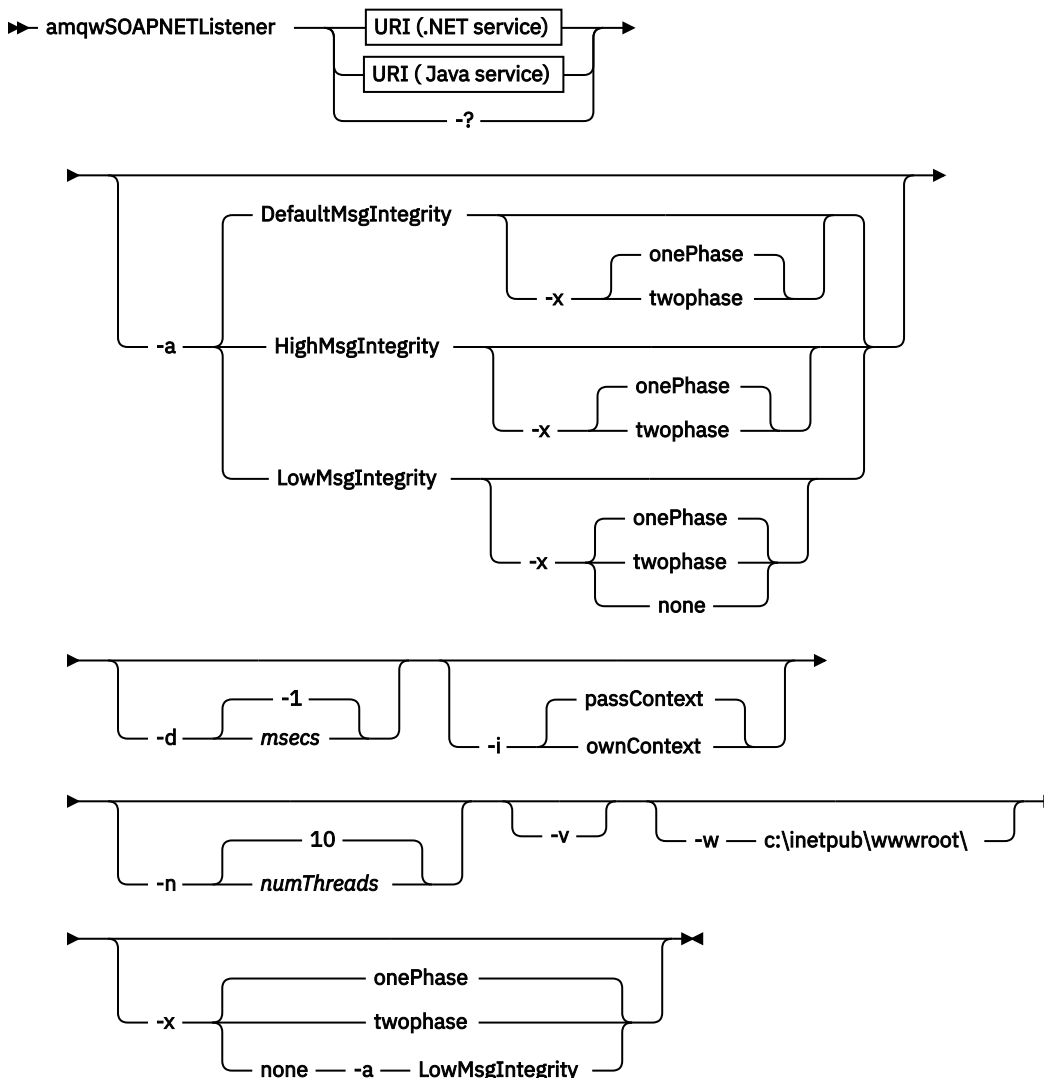

The IBM MQ SOAP sender sets MQRO_EXCEPTION_WITH_FULL_DATA and MQRO_EXPIRATION_WITH_FULL_DATA report options. As a result of the report options set by the IBM MQ SOAP sender, the report message contains the entire originating request message. The IBM MQ SOAP sender also sets the MQRO_DISCARD option, which causes the message to be discarded after a report message has been returned. If the report options do not meet your requirements, write your own senders to use different MQRO_EXCEPTION and MQRO_DISCARD report options. If the SOAP request is sent by a different sender that did not set MQRO_DISCARD, the failing message is written to the dead letter queue (DLQ).

If the listener generates a report message but fails in the process of sending the report, the report message is sent to the DLQ. Ensure that your DLQ handler handles these messages correctly.

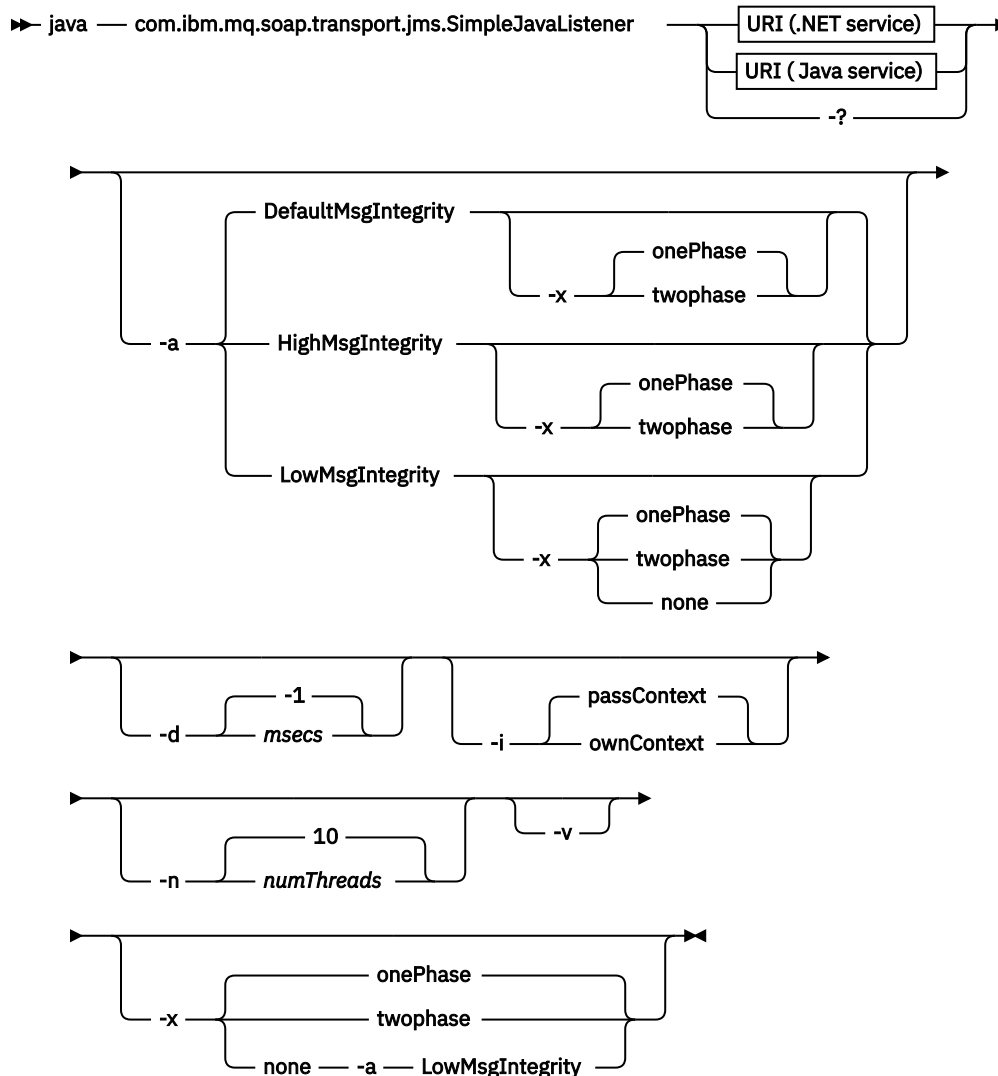

If an error occurs when attempting to write to the dead-letter queue a message is written to the IBM MQ error log. Whether the listener continues to process more messages depends on which message persistence and transactional options are selected. If the listener is running in one-phase transactional mode and is processing a non-persistent request message, the original message is discarded. The IBM MQ SOAP listener continues to execute. If the request message is persistent the request message is backed out to the request queue and the listener exits. The request queue is set to get-inhibited to prevent an accidental triggered restart.

Syntax diagram

.NET

Java

Required parameters

URI platform

See [“URI syntax and parameters for Web service deployment”](#) on page 1447.

-?

Print out help text describing how the command is used.

Optional parameters

-a integrityOption

integrityOption specifies the behavior of IBM MQ SOAP listeners if it is not possible to put a failed request message on the dead-letter queue. *integrityOption* can take one of the following values:

DefaultMsgIntegrity

For non-persistent messages, the listener displays a warning message and continues to execute with the original message being discarded. For persistent messages, it displays an error message, backs out the request message so it remains on the request queue and exits. DefaultMsgIntegrity applies if the -a option is omitted, or if *integrityOption* is not specified.

LowMsgIntegrity

For both persistent and non-persistent messages, the listener displays a warning and continues to execute, discarding the message.

HighMsgIntegrity

For both persistent and non-persistent messages, the listener displays an error message, backs out the request message so it remains on the request queue and exits.

The deployment utility checks for the compatibility of the -x and -a flags. If -x none is specified, then -a LowMsgIntegrity must be specified. If the flags are incompatible the deployment utility exits with an error message and with no deployment steps having been undertaken.

-d msec

msec specifies the number of milliseconds for the IBM MQ SOAP listener to stay alive if request messages have been received on any thread. If *msec* is set to -1, the listener stays alive indefinitely.

-i Context

Context specifies whether the listeners pass identity context. *Context* takes the following values:

passContext

Set the identity context of the original request message into the response message. The SOAP listener checks that it has authority to save the context from the request queue and to pass it to the response queue. It makes the checks at run time when opening the request queue to save context, and the response queue to pass context. If it does not have the required authority, or the MQOPEN call fails, and the response message is not processed. The response message is put on the dead-letter queue with the dead-letter header containing the return code from the failed MQOPEN. The listener then continues to process subsequent incoming messages as normal.

ownContext

The SOAP listener does not pass context. The returned context reflects the user ID under which the listener is running rather than the user ID which created the original request message.

The fields in the origin context are set by the queue manager, and not by the SOAP listener.

-n numThreads

numThreads specifies the number of threads in the generated startup scripts for the IBM MQ SOAP listener. The default is 10. Consider increasing this number if you have high message throughput.

-v

-v sets verbose output from external commands. Error messages are always displayed. Use -v to output commands that you can tailor to create customized deployment scripts.

-w serviceDirectory

serviceDirectory is the directory containing the web service.

-x transactionality

transactionality specifies the type of transactional control for the listener. *transactionality* can be set to one of the following values:

onePhase

IBM MQ one-phase support is used. If the system fails during processing, the request message is redelivered to the application. IBM MQ transactions ensure that the response messages are written exactly once.

twoPhase

Two-phase support is used. If the service is written appropriately the message is delivered exactly once, coordinated with other resources, within a single committed execution of the service. This option applies to server bindings connections only.

none

No transactional support. If the system fails during processing, the request message can be lost, even if persistent. The service might or might not have executed, and response, report or dead-letter messages might or might not be written.

The deployment utility checks for the compatibility of the -x and -a flags. See the description of the -a flag for details.

.NET Example

```
amqwSOAPNETlistener  
-u "jms:/queue?destination=myQ&connectionFactory=()
```

```
&targetService=myService&initialContextFactory=com.ibm.mq.jms.NoJndi"  
-w C:/wmqsoap/demos  
-n 20
```

Java Example

```
java com.ibm.mq.soap.transport.jms.SimpleJavaListener  
-u "jms:/queue?destination=myQ&connectionFactory=()  
&initialContextFactory=com.ibm.mq.jms.NoJndi"  
-n 20
```

IBM MQ transport for SOAP sender

Sender classes are provided for Axis and .NET Framework 1 and .NET Framework 2. The sender constructs a SOAP request and puts it on a queue, it then blocks until it has read a response from the response queue. You can alter the behavior of the classes by passing different URIs from a SOAP client. For .NET Framework 3 use IBM MQ custom channel for Microsoft Windows Communication Foundation (WCF).

Purpose

The IBM MQ SOAP sender puts a SOAP request to invoke a Web service onto an IBM MQ request queue. The sender sets fields in the **MQRFH2** header according to options specified in the URI, or according to defaults.

If you need to change the behavior of a sender beyond what is possible using the URI options, write your own sender. Your sender can work with the IBM MQ transport for SOAP listeners, or with other SOAP environments. Your sender must construct SOAP messages in the format defined by IBM MQ. The format is supported by the IBM MQ SOAP listener, and also SOAP listeners provided by WebSphere Application Server and CICS. Your sender must follow the rules for an IBM MQ requestor. The IBM MQ SOAP listener returns reply and report messages. See [“MQMD SOAP settings” on page 1425](#) for details how to set the report options in the **MQMD**. The report options control the report messages returned by the IBM MQ SOAP listener.

Description

The IBM MQ SOAP Java sender is registered with the Axis host environment for the `jms:` URI prefix. The sender is implemented in the class `com.ibm.mq.soap.transport.jms.WMQSender`, which is derived from `org.apache.axis.handlers.BasicHandler`. If the Axis host environment detects a `jms:` URI prefix it invokes the `com.ibm.mq.soap.transport.jms.WMQSender` class. The class blocks after placing the message until it has read a response from the response queue. If no response is received within a timeout interval the sender throws an exception. If a response is received within the timeout interval the response message is returned to the client using the Axis framework. Your client application must be able to handle these response messages.

For Microsoft .NET Framework 1 and .NET Framework 2 services, the IBM MQ SOAP sender is implemented in the class `IBM.WMQSOAP.MQWebRequest`, which is derived from `System.Net.WebRequest` and `System.Net.IWebRequestCreate`. If .NET Framework 1 or .NET Framework 2 detects a `jms:` URI prefix it invokes the `IBM.WMQSOAP.MQWebRequest` class. The sender creates an `MQWebResponse` object to read the response message from the response queue and return it to the client.

`com.ibm.mq.soap.transport.jms.WMQSender` is a final class, and `IBM.WMQSOAP.MQWebRequest` is sealed. You cannot modify their behavior by creating subclasses.

Parameters

Set the URI to control the behavior of the IBM MQ SOAP sender in a Web service SOAP client. The deployment utility creates Web service client stubs incorporating the URI options supplied to the deployment utility.

Use a channel definition table with the IBM MQ SOAP transport for SOAP sender

A client connection channel definition is an alternative to setting connection properties in the `ConnectionFactory` attribute of the Web service URI. The connection properties are `clientChannel`, `clientConnection`, and `SSL` parameters.

Description

Create the client channel description table by defining client connections. Even if a Web services client connects to different queue managers, create all the connections in the connection table on a single queue manager. The default name and location of the connection table is *queue manager directory/@ipcc/AMQCLCHL.TAB*.

Pass the location of the connection table to a Java client by setting the `com.ibm.mq.soap.transport.jms.mqchlurl` system property.

Pass the location of the connection table to a .NET client by setting the `MQCHLLIB` and `MQCHLTAB` environment variables.

You might provide both a channel connection table and channel connection parameters in the `ConnectionFactory` attribute of the Web service URI. The values set in the `ConnectionFactory` take precedence over the values in the channel definition table.

Using a channel definition table in Java

```
java -Dcom.ibm.msg.client.config.location=file:/C:/mydir/myjms.config MyAppClass
```

Figure 21. Starting Java client using a configuration file

```
com.ibm.mq.soap.transport.jms.mqchlurl=file:/C:/ibm/wmq/qmgrs/QM1/@ipcc/AMQCLCHL.TAB
```

Figure 22. *myjms.config*

Transactions

Use the `-x` option when starting the listener, to run Web services transactionally. Select the integrity of messages by setting the `persistence` option in the service URI.

Web services

Use the `-x` option when starting the listener, to run Web services transactionally. On .NET Framework 1 and 2 the SOAP listener uses Microsoft Transaction Coordinator (MTS). On Axis 1.4, the SOAP listener uses queue manager coordinated transactions.

Web service clients

The SOAP senders are not transactional.

IBM MQ bindings

You can set the binding type for the SOAP sender. It can connect as an IBM MQ server application, or as a client application. You can also bind the SOAP sender as an XA-client on .NET.

Message persistence

Select the level of persistence by setting the `Persistence` option in the URI.

Web service transactions

You can use Web service transactions, because the SOAP sender is not transactional. If you write your own SOAP sender, and intend to use Web service transactions, do not create a transactional SOAP sender.

You cannot send the request message and receive the reply message in the same transaction. The send and receive must not be coordinated by the Web service transaction.

URI syntax and parameters for Web service deployment

The syntax and parameters to deploy an IBM MQ Web service are defined in a URI. The deployment utility generates a default URI based on the name of the Web service. You can override the defaults by defining your own URI as a parameter to the deployment utility. The deployment utility incorporates the URI in the generated Web service client stubs.

Purpose

A web service is specified using a Universal Resource Identifier (URI). The syntax diagram specifies the URI that is supported in the IBM MQ transport for SOAP. The URI controls over IBM MQ -specific SOAP parameters and options used to access target services. The URI is compatible with Web services hosted by .NET, Apache Axis 1, WebSphere Application Server, CICS.

Description

The URI is incorporated into the Web service client classes generated by the deployment utility. The client passes the URI to IBM MQ SOAP Sender in an IBM MQ message. The URI controls the processing performed by both the IBM MQ SOAP Sender and IBM MQ SOAP listener.

Syntax

The URI syntax is as follows:

```
jms:/queue?name=value&name=value...
```

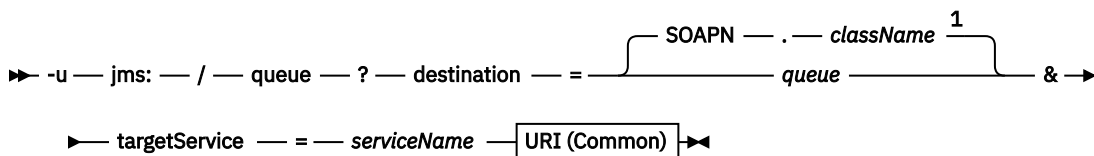

where name is a parameter name and *value* is an appropriate value, and the name = *value* element can be repeated any number of times with the second and subsequent occurrences being preceded by an ampersand (&).

Parameter names are case-sensitive, as are names of IBM MQ objects. If any parameter is specified more than once, the final occurrence of the parameter takes effect. Client applications can override a generated parameter by appending another copy of the parameter to the URI. If any additional unrecognized parameters are included, they are ignored.

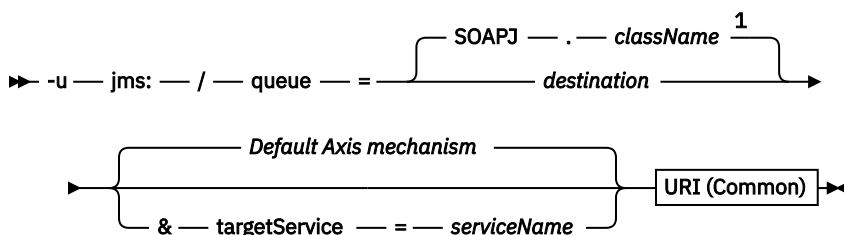

If you store a URI in an XML string, you must represent the ampersand character as & . Similarly, if a URI is coded in a script, take care to escape characters such as & that would otherwise be interpreted by the shell.

Syntax diagram

URI (.NET service)

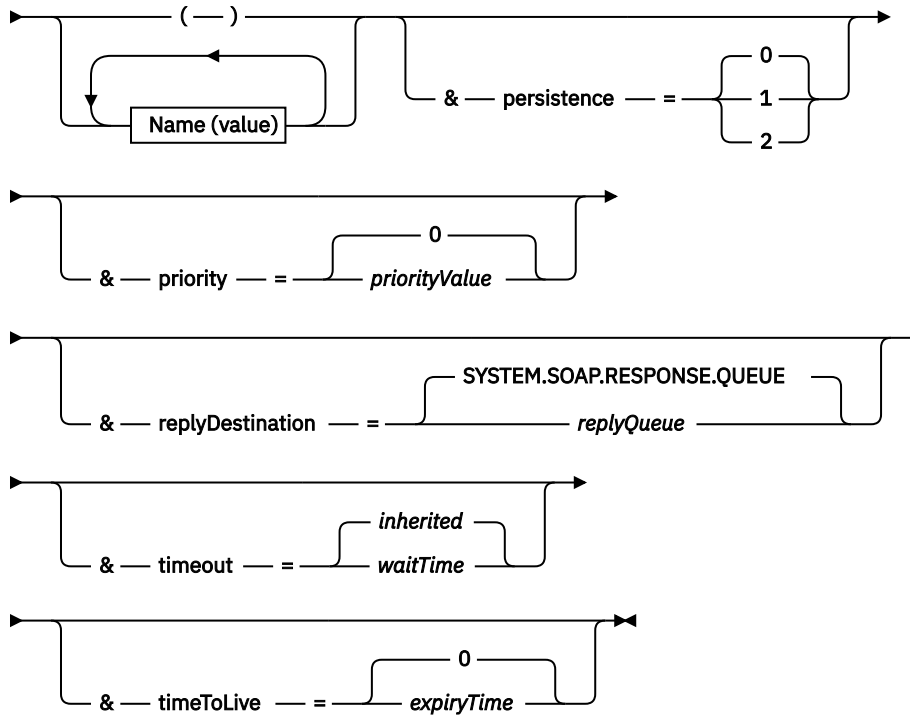

URI (Java service)

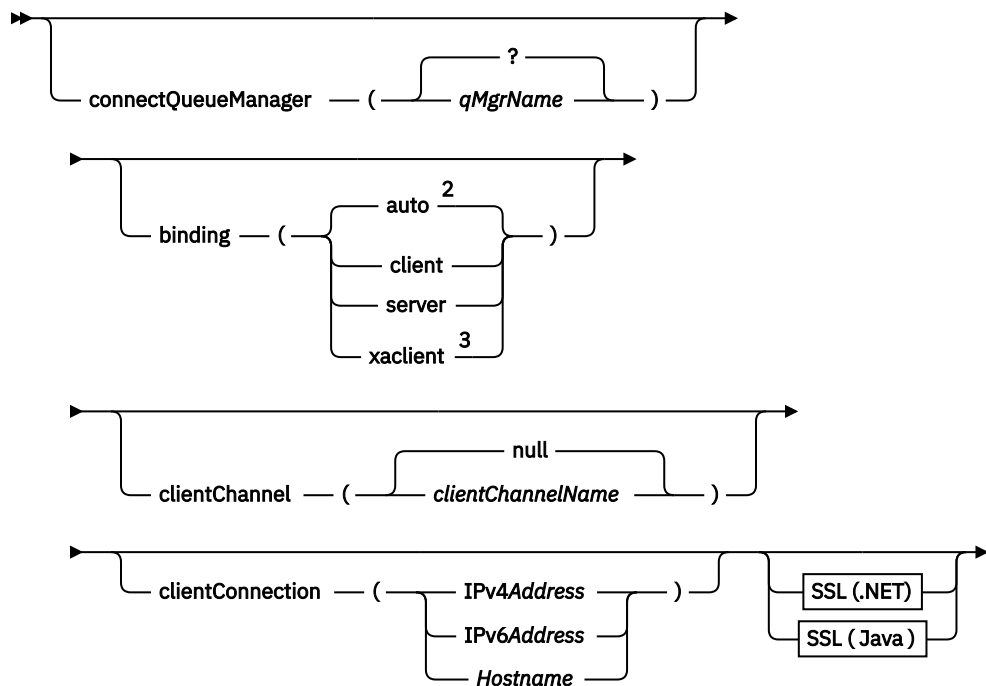

URI (Common)

►► & — initialContextFactory — = — com.ibm.mq.jms.Nojndi — & — connectionFactory — = —►

Name (value)

Notes:

- ¹ The queue manager transforms *className* to a queue name following the steps described in [“Destination to queue name transformation”](#) on page 1449
- ² `client` is the default if other options appropriate for a client are specified; for example `clientConnection`.
- ³ `xacient` applies to .NET only

Destination to queue name transformation

1. *className* is prefixed with SOAPJ . for Java services or with SOAPN . for .NET services.
2. The file extension is removed from the full path name given in the *className* parameter.
3. The resulting string is truncated to no more than 48 characters
4. Directory separator characters are replaced with period characters.
5. Embedded spaces are replaced with underscore characters.
6. The colon following a drive prefix letter is replaced with a period for a .NET service.

Note: In some environments, a queue name generated by the deployment utility might not be unique. The deployment utility makes checks whether to create the queue. You might choose to override the deployment utility by restructuring the deployment directory hierarchy, or by customizing the supplied deployment process.

Required URI parameters

destination = queue

queue is the name of the request destination. It can be a queue or a queue alias. If it is queue alias, the alias can resolve to a topic.

- If the -u parameter is omitted *queue* is generated from *classname* using the steps described in [“Destination to queue name transformation” on page 1449](#).
- If the -u parameter is specified *queue* is required and must be the first parameter of the URI after the initial `jms: / queue ?` string. Specify either an IBM MQ queue name, or a queue name and queue manager name connected by an @ symbol, for example SOAPN.trandemos@WMQSOAP.DEMO.QM.
- The deployment utility checks whether the queue name, generated or provided, matches the name of an existing queue. The action taken is described in [Table 637 on page 1449](#).

Table 637. queue validation			
Listener script exists?	Listener script exists in the ./generated/server directory		Listener script does not exist in the ./generated/server directory
Queue in listener script matches queue ?	queue does not match request queue being used in listener script	queue matches request queue being used in listener script	
queue exists	<ul style="list-style-type: none"> – Deployment exits with an error. – The service has already been deployed in ./generated/server, but using a different queue. 	<ul style="list-style-type: none"> – Deployment continues normally. – The service has already been deployed in ./generated/server 	<ul style="list-style-type: none"> – Deployment exits with an error. – The listener startup script is not found in ./generated/server, but queue is in use by a different service or application.
queue does not exist		<ul style="list-style-type: none"> – Deployment continues with a warning. – The previous deployment might have failed, because the startup is valid, but queue is missing. 	<ul style="list-style-type: none"> – Deployment continues normally. – No service has been deployed from this directory.

&connectionFactory = *Name(value)*

Name is one of the following parameters:

- [connectQueueManager\(qMgrName\)](#)
- [binding\(bindingType\)](#)
- [clientChannel\(channel\)](#)
- [clientConnection\(connection\)](#)
- [“Required SSL parameters \(Java \)” on page 1437](#)

See [“Connection factory parameters” on page 1451](#) for a description of the values of these parameters.

&targetService = *serviceName*

⁹ On .NET, *serviceName* is the name of a .NET service located in the deployment directory, for example: `targetService=myService.asmx`. In the .NET environment, the `targetService` parameter makes it possible for a single IBM MQ SOAP listener to be able to process requests for multiple services. These services must be deployed from the same directory.

Optional URI parameters**&initialContextFactory = *contextFactory***

contextFactory is required and must be set to `com.ibm.mq.jms.NoJndi`. Make sure `NoJndi.jar` is in the class path for a WebSphere Application Server Web services client. `NoJndi.jar` returns Java objects based on the contents of the `connectionFactory` and `destination` parameters, rather than by reference to a directory.

&targetService = *serviceName*

¹⁰ On Axis, *serviceName* is the fully qualified name of a Java service, for example: `targetService=javaDemos.service.StockQuoteAxis`. If `targetService` is not specified, a service is loaded using the default Axis mechanism.

&persistence = *messagePersistence*

messagePersistence takes one of the following values:

- 0**
Persistence is inherited from the queue definition.
- 1**
The message is non-persistent.
- 2**
The message is persistent

&priority = *priorityValue*

priorityValue is in the range 0 - 9. 0 is low priority. The default value is environment-specific, which in the case of IBM MQ is 0.

&replyDestination = *replyToQueue*

The queue at the client side to be used for the response message. The default reply queue is `SYSTEM.SOAP.RESPONSE.QUEUE`.

- Run the `setupWMQSOAP` script to create the default IBM MQ SOAP objects.
- Specify a model queue for *replyToQueue* to create either a temporary or permanent dynamic response queue. For both temporary and permanent dynamic response queues, a separate instance of dynamic queue is created for each request. If any of the following events happen the queue is deleted:
 - The response arrives and is processed.
 - The request times out.

⁹ .NET service only

¹⁰ Java service only

- The requesting program terminates.

For the best performance, use temporary dynamic queues rather than permanent dynamic queues. Do not send a persistent request message to a URI with a temporary dynamic queue. The IBM MQ listener SOAP fails to process the message and outputs an error. The client times out waiting for the reply.

- The `setupWMQSOAP` script creates a default permanent dynamic model queue called `SYSTEM.SOAP.MODEL.RESPONSE.QUEUE`.

&timeout = *waitTime*

The time, in milliseconds, that the client waits for a response message. *waitTime* overrides values set by the infrastructure or client application. If not specified the application value, if specified, or infrastructure default is inherited.

Note: No relationship is enforced between timeout and timeToLive.

&timeToLive = *expiryTime*

expiryTime is the time, specified in milliseconds, before the message expires. The default is zero, which indicates an unlimited lifetime.

Note: No relationship is enforced between timeout and timeToLive.

Connection factory parameters

connectQueueManager (*qMgrName*)

qMgrName specifies the queue manager to which the client connects. The default is blank.

binding (*bindingType*)

bindingType specifies how the client is connected to *qMgrName*. The default is `auto`. *bindingType* takes the following values:

auto

The sender tries the following connection types, in order:

1. If other options appropriate to a client connection are specified, the sender uses a client binding. The other options are `clientConnection` or `clientChannel`.
2. Use a server connection.
3. Use a client connection.

Use `binding (auto)` in the *URI* if there is no local queue manager at the SOAP client. A client connection is built for the SOAP client.

client

Use `binding (client)` in the *URI* to build a client configuration for the SOAP sender.

server

Use `binding (server)` in the *URI* to build a server configuration for the SOAP sender. If the connection has client type parameters the connection fails and an error is displayed by the IBM MQ SOAP sender. Client type parameters are `clientConnection`, `clientChannel`, or SSL parameters.

xaclient

`xaclient` is applicable only on .NET and not for Java clients. Use an XA-client connection.

clientChannel (*channel*)

The SOAP client uses *channel* to make an IBM MQ client connection. *channel* must match the name of a server connection channel, unless channel auto definition is enabled at the server. `clientChannel` is a required parameter, unless you have provided a Client Connection Definition table (CCDT).

Provide a CCDT in Java by setting `com.ibm.mq.soap.transport.jms.mqchlurl`. In .NET set the `MQCHLLIB` and `MQCHLTAB` environment variables; see [“Use a channel definition table with the IBM MQ SOAP transport for SOAP sender” on page 1446](#).

clientConnection (connection)

The SOAP client uses *connection* to make an IBM MQ client connection. The default hostname is localhost, and default port is 1414. If *connection* is a TCP/IP address, it takes one of three formats, and can be suffixed with a port number.

JMS clients can either use the format : hostname:port or 'escape' the brackets using the format %X where X is the hexadecimal value that represents the bracket character in the code page of the URI. For example, in ASCII, %28 and %29 for (and) respectively.

.Net clients can use the brackets explicitly : hostname(port) or use the 'escaped' format.

IPv4 address

For example, 192.0.2.0.

IPv6 address

For example, 2001:DB8:0:0:0:0:0:0.

Host name

For example, www.example.com%281687%29, www.example.com:1687, or www.example.com(1687).

SSL platform

See [“Required SSL parameters \(Java \)” on page 1437](#)

Sample URIs

Note:

1. & in the URI is encoded as &
2. All the parameter listed previously are applicable to the clients.
3. Only **destination**, **connectionFactory** and **initialContextFactory** are applicable to the WCF service.

```
jms:/queue?  
destination=myQ&amp;connectionFactory=()&amp;initialContextFactory=com.ibm.mq.jms.Nojndi
```

Figure 23. URI for an Axis service, supplying only required parameters

```
jms:/queue?destination=myQ&amp;connectionFactory=()&amp;targetService=MyService.asmx  
&amp;initialContextFactory=com.ibm.mq.jms.Nojndi
```

sslPeerName(CN=MQ Test 1,O=IBM,S=Hampshire,C=GB)  
&amp;initialContextFactory=com.ibm.mq.jms.Nojndi
```

Figure 26. URI for an Axis service, supplying the sslPeerName option of the connectionFactory parameter

The Nojndi mechanism

The Nojndi mechanism enables JMS programs, which use JNDI interfaces, to use the same URI as IBM MQ programs, which do not use JNDI.

You can use the IBM MQ transport for SOAP to invoke Web services on WebSphere Application Server. WebSphere Application Server SOAP over JMS looks up the JMS resources using JNDI. The Web service client might be running on .NET, or using Axis 1.4, to invoke the Web service and not using JNDI. To use

the same URL for the client and server, it must provide the same information whether the environment is using JNDI or not.

The URI passed to the IBM MQ transport for SOAP by a Web service client contains a specific IBM MQ queue manager and queue names. These names are parsed and used directly by IBM MQ SOAP support.

The `Nojndi` mechanism directs the `initialContextFactory` used by a JMS program to `com.ibm.mq.jms.Nojndi`. The `com.ibm.mq.jms.Nojndi` class is an implementation of the JNDI interface that returns the `connectionFactory` and destination from the URL as `ConnectionFactory` and `Queue` Java objects. If the JMS implementation is IBM MQ, `MQConnectionFactory` and `MQQueue` inherit from the `ConnectionFactory` and `Queue` classes.

By using the `Nojndi` mechanism, you are able to provide the same connection information to WebSphere Application server and .NET using the same URL.

W3C SOAP over JMS URI for the IBM MQ Axis 2 client

Define a W3C SOAP over JMS URI to call a Web service from an Axis 2 client using IBM MQ JMS as the SOAP transport. The Web service must be provided by a server that supports IBM MQ JMS and the W3C SOAP over JMS candidate recommendation for the SOAP/JMS binding.

Description

The W3C candidate recommendation defines the SOAP over JMS binding; [SOAP over Java Message Service 1.0](#). Also useful for its examples is [URI Scheme for Java\(tm\) Message Service 1.0](#)¹¹.

Use the syntax diagram to create W3C SOAP over JMS URIs that are syntactically correct, and are accepted by the IBM MQ Axis 2 client. It is limited to defining the URI that is accepted by the IBM MQ Axis 2 client. It is a subset of the W3C recommendation in two respects:

1. The `jms-variant` topic is not supported, and must not be specified in a URI passed to the IBM MQ Axis 2 client.
2. The following properties are omitted from the syntax diagram because they are JMS properties, and not part of the URI.
 - a. `bindingVersion`
 - b. `contentType`
 - c. `soapAction`
 - d. `requestURI`
 - e. `isFault`

The JMS properties are set by the Axis 2 client or the server.

The diagram extends the W3C recommendation by defining a custom parameter, `connectionFactory`. `connectionFactory` is used as an alternative to JNDI to specify how the Axis 2 client connects to a queue manager using a queue.

The IBM MQ Axis 2 client only accepts properties as part of the URI passed to the client by the client application or as environment variables. The IBM MQ Axis 2 client has no capability to process a WSDL document. The client application or a development tool might process the WSDL and create the URI to pass to the Axis 2 client. An IBM MQ Axis 2 client application cannot set the JMS message properties directly.

Syntax

¹¹ Look for *URI Scheme for JMS*, in the W3C specification references, for the latest draft.

In accordance with the W3C recommendation, all the parameters can be obtained from environment variables. The environment variable names are formed by prefacing the parameter name with soapjms_. The syntax is: soapjms_ *parameterName* ; for example,

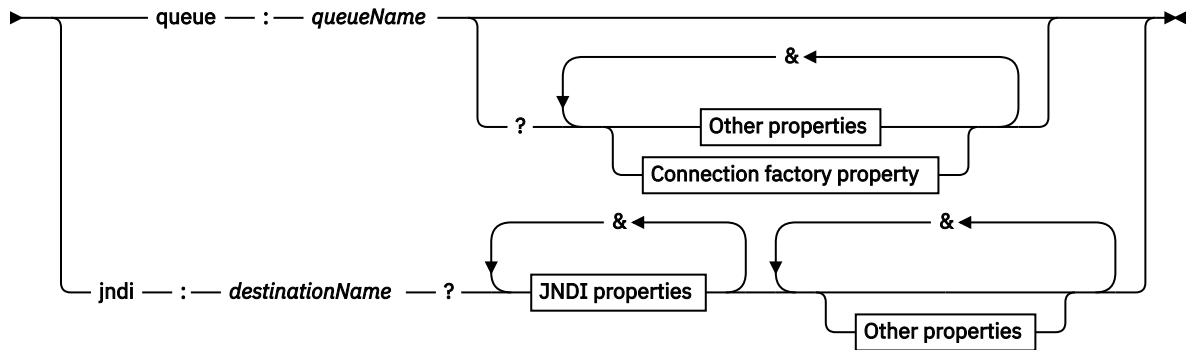

```
set soapjms_targetServer=com.example.org.stockquote
```

If a parameter is set using an environment variable it overrides the value set in the URI.

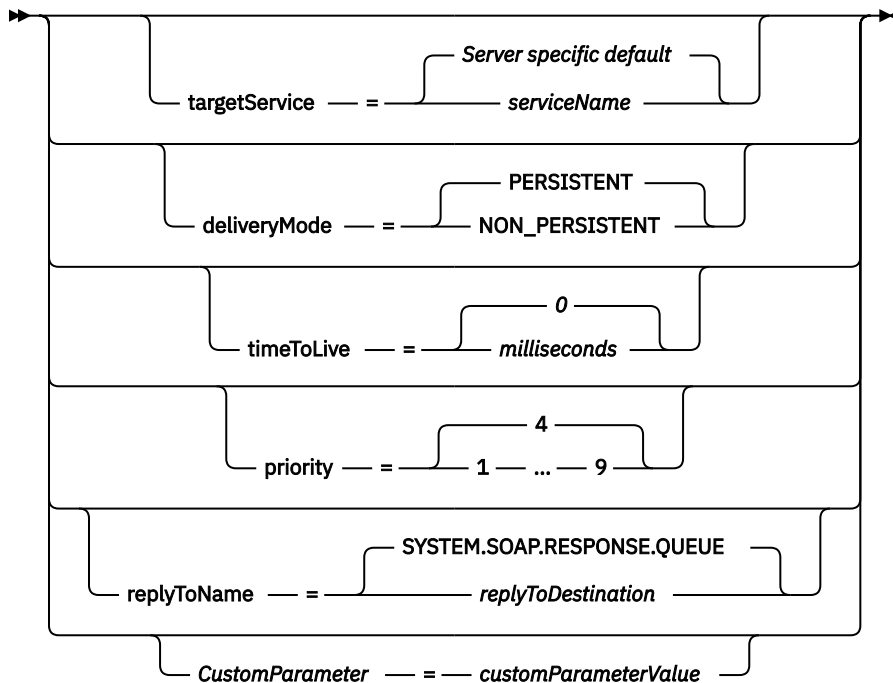

In accordance with the W3C recommendation, all the parameters can be repeated. The last instance of a parameter is used, unless overridden by an environment variable.

SSL property

➤ `sslCipherSuite` — (`cipherSuite`) ➔

Notes:

¹ `jndiConnectionFactoryName`, `jndiConnectionFactoryName` and `jndiURL` are all required parameters. `jndi-ContextParameter` is optional.

Parameters

connectionFactory = *connectionFactoryParameterList*

connectionFactoryParameterList are parameters that qualify how the Axis 2 client connects to a queue manager when the destination variant is queue.

connectionFactory must not be specified with the jndi destination variant.

The parameters are not passed to the server in the request URI.

If connectionFactory is omitted, the queue must belong to a default queue manager running on the same server as the Axis 2 client.

The *connectionFactoryParameterList*:

binding (*bindingType*)

bindingType specifies how the client is connected to *qMgrName*. The default is auto. *bindingType* takes the following values:

auto

The sender tries the following connection types, in order:

1. If other options appropriate to a client connection are specified, the sender uses a client binding. The other options are clientConnection or clientChannel.
2. Use a server connection.
3. Use a client connection.

Use binding (auto) in the *URI* if there is no local queue manager at the SOAP client. A client connection is built for the SOAP client.

client

Use binding (client) in the *URI* to build a client configuration for the SOAP sender.

server

Use binding (server) in the *URI* to build a server configuration for the SOAP sender. If the connection has client type parameters the connection fails and an error is displayed by the IBM MQ SOAP sender. Client type parameters are clientConnection, clientChannel, or SSL parameters.

xaclient

xaclient is applicable only on .NET and not for Java clients. Use an XA-client connection.

clientChannel (*channel*)

The SOAP client uses *channel* to make an IBM MQ client connection. *channel* must match the name of a server connection channel, unless channel auto definition is enabled at the server. clientChannel is a required parameter, unless you have provided a Client Connection Definition table (CCDT).

Provide a CCDT in Java by setting `com.ibm.mq.soap.transport.jms.mqchlurl`. In .NET set the MQCHLLIB and MQCHLTAB environment variables; see [“Use a channel definition table with the IBM MQ SOAP transport for SOAP sender” on page 1446](#).

clientConnection (*connection*)

The SOAP client uses *connection* to make an IBM MQ client connection. The default hostname is localhost, and default port is 1414. If *connection* is a TCP/IP address, it takes one of three formats, and can be suffixed with a port number.

JMS clients can either use the format : hostname:port or 'escape' the brackets using the format %X where X is the hexadecimal value that represents the bracket character in the code page of the URI. For example, in ASCII, %28 and %29 for (and) respectively.

.Net clients can use the brackets explicitly : hostname(port) or use the 'escaped' format.

IPv4 address

For example, 192.0.2.0.

IPv6 address

For example, 2001:DB8:0:0:0:0:0:0.

Host name

For example, `www.example.com%281687%29`, `www.example.com:1687`, or `www.example.com(1687)`.

sslCipherSuite (*CipherSuite*)

CipherSuite specifies the sslCipherSuite used on the channel. The CipherSuite specified by the client must match the CipherSuite specified on the server connection channel.

sslFipsRequired (*fipsCertified*)

fipsCertified specifies whether *CipherSpec* or *CipherSuite* must use FIPS-certified cryptography in IBM MQ on the channel. The effect of setting *fipsCertified* is the same as setting the *FipsRequired* field of the **MQSCO** structure on an MQCONN call.

sslKeyStore (*KeyStoreName*)

KeyStoreName specifies the sslKeyStoreName used on the channel. The keystore holds the private key of the client used to authenticate the client to the server. The keystore is optional if the SSL connection is configured to accept anonymous client connections.

sslKeyResetCount (*bytecount*)

bytecount specifies the number of bytes passed across an SSL channel before the SSL secret key must be renegotiated. To disable the renegotiation of SSL keys omit the field or set it to zero. Zero is the only value supported in some environments, see [Renegotiating the secret key in IBM MQ classes for Java](#) . The effect of setting sslKeyResetCount is the same as setting the KeyResetCount field in the **MQSCO** structure on an MQCONN call.

sslKeyStorePassword (*KeyStorePassword*)

KeyStorePassword specifies the sslKeyStorePassword used on the channel.

sslLDAPCRLServers (*LDAPServerList*)

LDAPServerList specifies a list of LDAP servers to be used for Certificate Revocation List checking.

For SSL enabled client connections, *LDAPServerList* is a list of LDAP servers to be used for Certificate Revocation List (CRL) checking. The certificate provided by the queue manager is checked against one of the listed LDAP CRL servers; if found, the connection fails. Each LDAP server is tried in turn until connectivity is established to one of them. If it is impossible to connect to any of the servers, the certificate is rejected. Once a connection has been successfully established to one of them, the certificate is accepted or rejected depending on the CRLs present on that LDAP server.

If *LDAPServerList* is blank, the certificate belonging to the queue manager is not checked against a Certificate Revocation List. An error message is displayed if the supplied list of LDAP URIs is not valid. The effect of setting this field is the same as that of including MQAIR records and accessing them from an **MQSCO** structure on an MQCONN.

sslPeerName (*peerName*)

peerName specifies the sslPeerName used on the channel.

sslTrustStore (*TrustStoreName*)

TrustStoreName specifies the sslTrustStoreName used on the channel. The truststore holds the public certificate of the server, or its key chain, to authenticate the server to the client. The truststore is optional if the root certificate of a certificate authority is used to authenticate the server. In Java, root certificates are held in the JRE certificate store, `cacerts`.

sslTrustStorePassword (*TrustStorePassword*)

TrustStorePassword specifies the sslTrustStorePassword used on the channel.

CustomParameter = customParameterValue

CustomParameter is the user-defined name of a custom parameter, and *customParameterValue* is the value of the parameter.

Custom parameters that are not used by the Axis 2 client are sent by the Axis 2 client to the SOAP server. Consult the server documentation. *connectionFactory* is a custom parameter that is used by the Axis 2 client and is not passed to the server.

CustomParameter must not match the name of an existing parameter.

If *CustomParameter* starts with the string *jndi* - it is used in looking up a JNDI destination; see [jndi](#).

deliveryMode = *deliveryMode*

deliveryMode sets the message persistence. The default is PERSISTENT.

jndi : *destinationName*

destinationName is a JNDI destination name that maps to a JMS queue. If the *jndi* destination variant is specified, you must provide a *destinationName*.

jndiConnectionFactoryName = *connectionFactoryName*

connectionFactoryName sets the JNDI name of the connection factory. If the destination variant is *jndi*, *connectionFactoryName* must be provided.

jndiInitialContextFactory = *contextFactoryName*

contextFactoryName sets the JNDI name of the initial context factory. If the destination variant is *jndi*, *contextFactoryName* must be provided. See [Using JNDI to retrieve administered objects in a JMS application](#).

jndiURL = *providerURL*

jndiURL sets the URL name of the JNDI provider. If the destination variant is *jndi*, *jndiURL* must be specified.

jndi- ContextParameter = *contextParameterValue*

jndi- ContextParameter is the user-defined name of a custom parameter that used to pass information to the JNDI provider. *contextParameterValue* is the information that is passed.

priority = *priorityValue*

priorityValue sets the JMS message priority. 0 is low, 9 is high. The default value is 4.

queue : *queueName*

queueName is the name of a JMS queue on which the SOAP request is placed. If the queue variant is specified, a queue name must be provided. If the queue does not belong to a default queue manager on the same server as the client, set the [connectionFactory](#) parameter.

replyToName = *replyToDestination*

replyToDestination sets the destination queue name. If the destination variant is *jndi*, the name is a JNDI name that must map to a queue. If the variant is *queue* the name is a JMS queue. The default value is SYSTEM.SOAP.RESPONSE.QUEUE.

targetService = *serviceName*

The name used by the SOAP server to start the target Web service.

On Axis, *serviceName* is the fully qualified name of a Java service, for example:

`targetService=www.example.org.StockQuote`. If *targetService* is not specified, a service is loaded using the default Axis mechanism.

timeToLive = *milliseconds*

Set *milliseconds* to the time before the message expires. The default, 0, is the message never expires.

Examples

```
jms:jndi:REQUESTQ
?jndiURL=file:/C:/JMSAdmin
&jndiInitialContextFactory=com.sun.jndi.fscontext.RefFSContextFactory
&jndiConnectionFactoryName=ConnectionFactory
&replyToName=RESPONSEQ
&deliveryMode(NON_PERSISTENT)
```

Figure 27. Use *jms:jndi* to send a SOAP/JMS request

```
jms:queue:SOAPJ.demos
?connectionFactory=connectQueueManager(QM1)
Bind(Client)
ClientChannel(SOAPClient)
ClientConnection(www.example.org(1418))
&deliveryMode(NON_PERSISTENT)
```

Figure 28. Use `jms:queue` to send a SOAP/JMS request

Supported Web services

Code that has been written to run as a Web service does not need to be modified to use the IBM MQ transport for SOAP. You do need to deploy services differently to run with the IBM MQ transport for SOAP rather than using HTTP.

Description

V 8.0.0.2 From IBM MQ 8.0.0, Fix Pack 2, the IBM MQ transport for SOAP is deprecated. For more information, see [Deprecations: IBM MQ transport SOAP client and HTTP Bridge](#).

The IBM MQ transport for SOAP provides a SOAP listener to run services for .NET Framework 1 and .NET 2, and for Axis 1.4. The IBM MQ custom channel for Microsoft Windows Communication Foundation runs services for .NET Framework 3. WebSphere Application Server and CICS provide support for running services over IBM MQ transport for SOAP. Create a custom Export to use WebSphere Enterprise Service Bus or WebSphere Process Server.

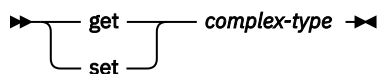

The IBM MQ SOAP listener can process SOAP requests transactionally. Run **amqwdployWMQService** using the `-x` option. The two-phase option is only supported for listeners using server bindings. Other environments might provide transactional support for the IBM MQ transport for SOAP. Consult their documentation.

IBM MQ transport for SOAP currently does not support the emerging industry standard SOAP over JMS protocol that has been submitted to W3C. You can distinguish a SOAP/JMS message written to the new standard by looking for the JMS BindingVersion property. IBM MQ transport for SOAP does not set the BindingVersion property.

Axis 1.4

A Java class can typically be used without modification. The types of any arguments to the methods in the web service must be supported by the Axis engine. Refer to Axis documentation for further details. If the service uses a complex object as an argument, or returns one, that object must comply to the Java bean specification. See the examples in [Figure 31 on page 1461](#), [Figure 32 on page 1461](#), and [Figure 33 on page 1461](#):

1. Have a public parameter-less constructor.
2. Any complex types of the bean must have public getters and setters of the form:

Prepare the service for deployment using the **amqwdployWMQService** utility. The service is invoked by the IBM MQ SOAP listener which uses `axis.jar` to run the service.

The only two-phase transaction manager supported for Axis 1.4 is IBM MQ.

The supplied deployment utility does not support the case where a service returns an object in a different package to the service itself. To use an object returned in a different package, write your own deployment utility. You can base your deployment utility on the supplied sample, or capture the commands it produces, using the `-v` option. Amend the commands to produce a tailored script.

If the service uses classes that are external to the Axis infrastructure and the IBM MQ SOAP run time environment, you must set the correct CLASSPATH. To change CLASSPATH, amend the generated script that starts or defines the listeners to include the services required, in one of the following ways:

- Amend the CLASSPATH directly in the script after the call to **amqwsetcp**.
- Create a service-specific script to customize the CLASSPATH and invoke this script in the generated script after the call to **amqwsetcp**.
- Create a customized deployment process to customize the CLASSPATH in the generated script automatically.

.NET Framework 1 and .NET Framework 2

A service that has already been prepared as an HTTP Web service does not need to be modified for use as an IBM MQ Web service. It needs to be deployed using the **amqwdeployWMQService** utility.

The only two-phase transaction manager supported for .NET Framework 1 and .NET 2 is Microsoft Transaction Server (MTS).

If the service code has not been prepared as an HTTP Web service you must convert it to a Web service. Declare the class as a web service and identify how the parameters of each method are formatted. You must check that any arguments to the methods of the service are compatible with the environment. Figure 29 on page 1461 and Figure 30 on page 1461 show a .NET class that has been prepared as a web service. The additions made are shown in bold type.

Figure 29 on page 1461 uses the code-behind programming model for a .NET Web service. In the code-behind model, the source for the service is separated from the .asmx file. The .asmx file declares the name of the associated source file with the Codebehind keyword. IBM MQ has samples of both inline and code-behind .NET Web services.

.NET Web services source must be compiled before deployment by the **amqwdeployWMQService** deployment utility. The service is compiled into a library (.dll). The library must be placed in the . /bin subdirectory of the deployment directory.

.NET Framework 3

Create an IBM MQ custom channel for Microsoft Windows Communication Foundation (WCF) to invoke services deployed to .NET Framework 3. See [Developing WCF applications with IBM MQ](#) for a description of how to configure WCF to use the IBM MQ transport for SOAP.

WebSphere Application Server

You can invoke web services hosted by WebSphere Application Server using the IBM MQ Transport for SOAP. See [Using SOAP over JMS to transport web services](#).

You need to modify the WSDL generated by deployment of a JMS service to WebSphere Application Server in order to generate a Web services client. The WSDL created by deployment to WebSphere Application Server includes a URI with a JNDI reference to the JMS InitialContextFactory. You need to modify the JNDI reference to Nojndi and provide connection attributes as described in [“URI syntax and parameters for Web service deployment” on page 1447](#).

CICS

You can invoke CICS applications using the IBM MQ Transport for SOAP. See [Configuring your CICS system for Web services](#).

WebSphere Enterprise Service Bus and WebSphere Process Server for Multiplatforms

WebSphere ESB and WebSphere Process Server for Multiplatforms support SOAP over JMS, with a ready built binding, only when using the default WebSphere Application Server messaging provider. Create a custom binding for JMS to support IBM MQ transport for SOAP. See [JMS data bindings](#).

Example

```
<%@ WebService Language="C#" CodeBehind="Quote.aspx.cs" Class="Quote.QuoteDotNet" %>
```

Figure 29. Service definition for .NET Framework 2: *Quote.aspx*

```
<%@ WebService Language="C#" CodeBehind="Quote.aspx.cs" Class="Quote.QuoteDotNet" %>
using System;
using System.Web;
using System.Web.Services;
using System.Web.Services.Protocols;

namespace Quote {
    [WebService(Namespace = "http://www.example.org/")]
    [WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
    public class QuoteDotNet : System.Web.Services.WebService {
        [WebMethod]
        public string getQuote(String symbol){
            return symbol.ToUpper();
        }
    }
}
```

Figure 30. Service implementation for .NET Framework 2: *Quote.aspx.cs*

```
package org.example.www;
public interface CustomerInfoInterface extends java.rmi.Remote {
    public org.example.www.CustomerRecord
        getCustomerName(org.example.www.CustomerRecord request)
        throws java.rmi.RemoteException, org.example.www.GetCustomerName_faultMsg;
}
```

Figure 31. Java JAX-RPC service interface using a complex type

```
package org.example.www;
public class CustomerInfoPortImpl implements org.example.www.CustomerInfoInterface{
    public org.example.www.CustomerRecord
        getCustomerName(org.example.www.CustomerRecord request)
        throws java.rmi.RemoteException, org.example.www.GetCustomerName_faultMsg {
        request.setName(request.getID().toString());
        return request;
    }
}
```

Figure 32. Java JAX-RPC service implementation using a complex type

```
package org.example.www;
public class CustomerRecord {
    private java.lang.String name;
    private java.lang.Integer ID;
    public CustomerRecord() {}
    public java.lang.String getName() {
        return name;
    }
    public void setName(java.lang.String name) {
        this.name = name;
    }
    public java.lang.Integer getID() {
        return ID;
    }
    public void setID(java.lang.Integer ID) {
        this.ID = ID;
    }
}
```

Figure 33. Java JAX-RPC service bean implementation of a complex type

IBM MQ transport for SOAP Web service clients

You can reuse an existing SOAP over HTTP client with IBM MQ transport for SOAP. You must make some small modifications to the code and build process to convert the client to work with IBM MQ transport for SOAP.

Coding

JAX-RPC clients must be written in Java. .NET Framework 1 and 2 clients can be written in any language that uses the Common Language Runtime. Code examples are provided in C# and Visual Basic.

The level of transactional support depends on the client environment and the pattern of the SOAP interaction. The SOAP request and SOAP reply can not be part of the same atomic transaction.

You must call `IBM.WMQSOAP.Register.Extension()` in a .NET Framework 1, .NET Framework 2 client. In a JAX-RPC Java Web service client call `com.ibm.mq.soap.Register.extension` to register the IBM MQ SOAP sender. The method registers the IBM MQ transport for SOAP sender as the handler for SOAP messages using the `jms: protocol`.

To create a .NET Framework 3 client, generate a Windows Communication Foundation client proxy using the **svcutil** tool; see [Generating a WCF client proxy and application configuration files using the svcutil tool with metadata from a running service](#).

Libraries required to build and run .NET Framework 1 and 2 clients

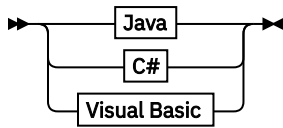

- `amqsoap`
- `System`
- `System.Web.Services`
- `System.Xml`

Libraries required to build and run Axis 1.4 clients

- `MQ_Install\java\lib\com.ibm.mq.soap.jar;`
- `MQ_Install\java\lib\com.ibm.mq.commonservices.jar;`
- `MQ_Install\java\lib\soap\axis.jar;`
- `MQ_Install\java\lib\soap\jaxrpc.jar`
- `MQ_Install\java\lib\soap\saa.jar;`
- `MQ_Install\java\lib\soap\commons-logging-1.0.4.jar;`
- `MQ_Install\java\lib\soap\commons-discovery-0.2.jar;`
- `MQ_Install\java\lib\soap\wsdl4j-1.5.1.jar;`
- `MQ_Install\java\jre\lib\xml.jar;`
- `MQ_Install\java\lib\soap\servlet.jar;`
- `MQ_Install\java\lib\com.ibm.mq.jar;`
- `MQ_Install\java\lib\com.ibm.mq.headers.jar;`
- `MQ_Install\java\lib\com.ibm.mq.pcf.jar;`
- `MQ_Install\java\lib\com.ibm.mq.jmqi.jar;`

Note: From IBM MQ 8.0, `ldap.jar`, `jndi.jar` and `jta.jar` have been removed from this list as they are now part of the JDK.

Register SOAP extension

Java

➔ `com.ibm.mq.soap.Register.extension()` ➔

C#

➔ `IBM.WMQSOAP.Register.Extension();` ➔

Visual Basic

➔ `IBM.WMQSOAP.Register.Extension` ➔

Client examples

Figure 34 on page 1463 is an example of a .NET Framework 1 or .NET Framework 2 C# client that uses the inline programming model. The **IBM.WMQSOAP.Register.Extension()** method registers the IBM MQ SOAP sender with .NET as the `jms:` protocol handler.

```
using System;
namespace QuoteClientProgram {
    class QuoteMain {
        static void Main(string[] args) {
            try {
                IBM.WMQSOAP.Register.Extension();
                Quote q = new Quote();
                Console.WriteLine("Response is: " + q.getQuote("ibm"));
            } catch (Exception e) {
                Console.WriteLine("Exception is: " + e);
            }
        }
    }
}
```

Figure 34. C# Web service client sample

Figure 35 on page 1463 is an example of a Java client that uses the JAX-RPC static proxy client interface. The **com.ibm.mq.soap.Register.extension();** method registers the IBM MQ SOAP sender with the service proxy to handle the `jms:` protocol.

```
package org.example.www;
import com.ibm.mq.soap.Register;
public class QuoteClient {
    public static void main(String[] args) {
        try {
            Register.extension();
            QuoteSOAPImplServiceLocator locator = new QuoteSOAPImplServiceLocator();
            System.out.println("Response = "
                + locator.getOrgExampleWwwQuoteSOAPImpl_Wmq().getQuote("IBM"));
        } catch (Exception e) {
            System.out.println("Exception = " + e.getMessage());
        }
    }
}
```

IBM MQ .NET classes and interfaces are listed alphabetically. The properties, methods and constructors are described.

[“IBM MQ C++ classes” on page 1820](#)

The IBM MQ C++ classes encapsulate the IBM MQ Message Queue Interface (MQI). There is a single C++ header file, **imqi.hpp**, which covers all of these classes.

[IBM MQ Classes for JMS](#)

MQIEP structure

The MQIEP structure contains an entry point for each function call that exits are permitted to make.

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQIEP_STRUC_ID

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQIEP_VERSION_1

Version 1 structure version number.

MQIEP_CURRENT_VERSION

Current version of the structure.

StrucLength

Type: MQLONG

Size of the MQIEP structure in bytes. The value is as follows:

MQIEP_LENGTH_1**Flags**

Type: MQLONG

Provides information about the function addresses. A flag to indicate if the library is threaded can be used with a flag to indicate if the library is a client or server library.

The following value is used to specify no library information:

MQIEPF_NONE

One of the following values is used to specify if the shared library is threaded or non-threaded:

MQIEPF_NON_THREADED_LIBRARY

A non-threaded shared library

MQIEPF_THREADED_LIBRARY

A threaded shared library

One of the following values is used to specify if the shared library is a client or a server shared library:

MQIEPF_CLIENT_LIBRARY

A client shared library

MQIEPF_LOCAL_LIBRARY

A server shared library

Reserved

Type: MQPTR

MQBACK_Call

Type: PMQ_BACK_CALL

Address of the MQBACK call.

MQBEGIN_Call

Type: PMQ_BEGIN_CALL

Address of the MQBEGIN call.

MQBUFMH_Call

Type: PMQ_BUFMH_CALL

Address of the MQBUFMH call.

MQCB_Call

Type: PMQ_CB_CALL

Address of the MQCB call.

MQCLOSE_Call

Type: PMQ_CLOSE_CALL

Address of the MQCLOSE call.

MQCMIT_Call

Type: PMQ_CMIC_CALL

Address of the MQCMIT call.

MQCONN_Call

Type: PMQ_CONN_CALL

Address of the MQCONN call.

MQCONNX_Call

Type: PMQ_CONNX_CALL

Address of the MQCONNX call.

MQCRTMH_Call

Type: PMQ_CRTMH_CALL

Address of the MQCRTMH call.

MQCTL_Call

Type: PMQ_CTL_CALL

Address of the MQCTL call.

MQDISC_Call

Type: PMQ_DISC_CALL

Address of the MQDISC call.

MQDLTMH_Call

Type: PMQ_DLTMH_CALL

Address of the MQDLTMH call.

MQDLTMP_Call

Type: PMQ_DLTMP_CALL

Address of the MQDLTMP call.

MQGET_Call

Type: PMQ_GET_CALL

Address of the MQGET call.

MQINQ_Call

Type: PMQ_INQ_CALL

Address of the MQINQ call.

MQINQMP_Call

Type: PMQ_INQMP_CALL

Address of the MQINQMP call.

MQMHBUF_Call

Type: PMQ_MHBUF_CALL

Address of the MQMHBUF call.

MQOPEN_Call

Type: PMQ_OPEN_CALL

Address of the MQOPEN call.

MQPUT_Call

Type: PMQ_PUT_CALL

Address of the MQPUT call.

MQPUT1_Call

Type: PMQ_PUT1_CALL

Address of the MQPUT1 call.

MQSET_Call

Type: PMQ_SET_CALL

Address of the MQSET call.

MQSETMP_Call

Type: PMQ_SETMP_CALL

Address of the MQSETMP call.

MQSTAT_Call

Type: PMQ_STAT_CALL

Address of the MQSTAT call.

MQSUB_Call

Type: PMQ_SUB_CALL

Address of the MQSUB call.

MQSUBRQ_Call

Type: PMQ_SUBRQ_CALL

Address of the MQSUBRQ call.

MQXCNVC_Call

Type: PMQ_XCNVC_CALL

Address of the MQXCNVC call.

MQXCLWLN_Call

Type: PMQ_XCLWLN_CALL

Address of the MQXCLWLN call.

MQXDX_Call

Type: PMQ_XDX_CALL

Address of the MQXDX call.

MQXEP_Call

Type: PMQ_XEP_CALL

Address of the MQXEP call.

MQZEP_Call

Type: PMQ_ZEP_CALL

Address of the MQZEP call.

    PMQ_INQMP_CALL MQINQMP_Call;  /* Address of MQINQMP */
    PMQ_MHBUF_CALL MQMHBUF_Call;  /* Address of MQMHBUF */
    PMQ_OPEN_CALL MQOPEN_Call;    /* Address of MQOPEN */
    PMQ_PUT_CALL  MQPUT_Call;     /* Address of MQPUT */
    PMQ_PUT1_CALL MQPUT1_Call;    /* Address of MQPUT1 */
    PMQ_SET_CALL  MQSET_Call;     /* Address of MQSET */
    PMQ_SETMP_CALL MQSETMP_Call;  /* Address of MQSETMP */
    PMQ_STAT_CALL MQSTAT_Call;    /* Address of MQSTAT */
    PMQ_SUB_CALL  MQSUB_Call;     /* Address of MQSUB */
}
```

```

PMQ_SUBRQ_CALL    MQSUBRQ_Call;    /* Address of MQSUBRQ */
PMQ_XCLWLN_CALL   MQXCLWLN_Call;   /* Address of MQXCLWLN */
PMQ_XCNVC_CALL    MQXCNVC_Call;    /* Address of MQXCNVC */
PMQ_XDX_CALL      MQXDX_Call;      /* Address of MQXDX */
PMQ_XEP_CALL      MQXEP_Call;      /* Address of MQXEP */
PMQ_ZEP_CALL      MQZEP_Call;      /* Address of MQZEP */
};

```

Data-conversion exit reference

For z/OS, you must write data-conversion exits in assembler language. For other platforms, it is recommended that you use the C programming language.

To help you to create a data-conversion exit program, the following are supplied:

- A skeleton source file
- A convert characters call
- A utility that creates a fragment of code that performs data conversion on data type structures This utility takes C input only. On z/OS, it produces assembler code.

For the procedure for writing the programs see:

-  [Writing a data-conversion exit program for IBM MQ for IBM i](#)
-  [Writing a data-conversion exit program for IBM MQ for z/OS](#)
- [Writing a data-conversion exit for IBM MQ on UNIX and Linux systems](#)
- [Writing a data-conversion exit for IBM MQ for Windows](#)

Skeleton source file

These can be used as your starting point when writing a data-conversion exit program.

The files supplied are listed in [Table 638 on page 1468](#).

Table 638. Skeleton source files	
Platform	File
AIX	amqsvfc0.c
IBM i	QMQMSAMP/QCSRC(AMQSVFC4)
HP-UX	amqsvfc0.c
Linux	amqsvfc0.c
z/OS	CSQ4BAX8 (“1” on page 1469) CSQ4BAX9 (“2” on page 1469) CSQ4CAX9 (“3” on page 1469)
Solaris	amqsvfc0.c
Windows systems	amqsvfc0.c

Table 638. Skeleton source files (continued)	
Platform	File
Notes: <ol style="list-style-type: none"> 1. Illustrates the MQXCVNC call. 2. A wrapper for the code fragments generated by the utility for use in all environments except CICS. 3. A wrapper for the code fragments generated by the utility for use in the CICS environment. 	

Convert characters call

Use the MQXCNVC (convert characters) call from within a data-conversion exit program to convert character message data from one character set to another. For certain multibyte character sets (for example, UCS-2 character sets), the appropriate options must be used.

No other MQI calls can be made from within the exit; an attempt to make such a call fails with reason code MQRC_CALL_IN_PROGRESS.

See “MQXCNVC - Convert characters” on page 882 for further information on the MQXCNVC call and appropriate options.

Utility for creating conversion-exit code

Use this information to learn more about creating conversion-exit code.

The commands for creating conversion-exit code are:

IBM i

CVTMQMMDTA (Convert IBM MQ Data Type)

Windows, UNIX and Linux systems

crtmqcvx (Create IBM MQ conversion-exit)

z/OS

z/OS

CSQUCVX

The command for your platform produces a fragment of code that performs data conversion on data type structures, for use in your data-conversion exit program. The command takes a file containing one or more C language structure definitions.

z/OS

 On z/OS, it then generates a data set containing assembler code fragments and conversion functions. On other platforms, it generates a file with a C function to convert each structure definition. On z/OS, the utility requires access to the LE/370 runtime library SCEERUN.

Invoking the CSQUCVX utility on z/OS

z/OS

Figure 36 on page 1469 shows an example of the JCL used to invoke the CSQUCVX utility.

```
//CVX      EXEC  PGM=CSQUCVX
//STEPLIB DD  DISP=SHR,DSN=thlqual.SCSQANLE
//          DD  DISP=SHR,DSN=thlqual.SCSQLOAD
//          DD  DISP=SHR,DSN=le370qual.SCEERUN
//SYSPRINT DD  SYSOUT=*
//CSQUINP DD  DISP=SHR,DSN=MY.MQSERIES.FORMATS(MSG1)
//CSQUOUT DD  DISP=OLD,DSN=MY.MQSERIES.EXIT(S(MSG1)
```

Figure 36. Sample JCL used to invoke the CSQUCVX utility

z/OS data definition statements

The CSQUCVX utility requires DD statements with the following DDnames:

Table 639. Data definition statement names and descriptions	
DD statement	Description
SYSPRINT	Specifies a data set or print spool class for reports and error messages.
CSQUINP	Specifies the partitioned data set containing the definitions of the data structures to be converted.
CSQUOUT	Specifies the partitioned data set where the conversion code fragments are to be written. The logical record length (LRECL) must be 80 and the record format (RECFM) must be FB.

Error messages in Windows, UNIX and Linux systems

The `crtmqcvx` command returns messages in the range AMQ7953 through AMQ7970.

These messages are listed in [Messages and reason codes IBM MQ Messages](#).

There are two main types of error:

- Major errors, such as syntax errors, when processing cannot continue.

A message is displayed on the screen giving the line number of the error in the input file. The output file might have been partially created.

- Other errors when a message is displayed stating that a problem has been found but that parsing of the structure can continue.

The output file has been created and contains error information about the problems that have occurred. This error information is prefixed by `#error` so that the code produced is not accepted by any compiler without intervention to rectify the problems.

Valid syntax

Your input file for the utility must conform to the C language syntax.

If you are unfamiliar with C, refer to the [C example](#) in this topic.

In addition, be aware of the following rules:

- `typedef` is recognized only before the `struct` keyword.
- A structure tag is required on your structure declarations.
- You can use empty square brackets `[]` to denote a variable length array or string at the end of a message.
- Multidimensional arrays and arrays of strings are not supported.
- The following additional data types are recognized:
 - `MQBOOL`
 - `MQBYTE`
 - `MQCHAR`
 - `MQFLOAT32`
 - `MQFLOAT64`
 - `MQSHORT`
 - `MQLONG`

- MQINT8
- MQUINT8
- MQINT16
- MQUINT16
- MQINT32
- MQUINT32
- MQINT64
- MQUINT64

MQCHAR fields are code page converted, but MQBYTE, MQINT8 and MQUINT8 are left untouched. If the encoding is different, MQSHORT, MQLONG, MQINT16, MQUINT16, MQINT32, MQUINT32, MQINT64, MQUINT64, MQFLOAT32, MQFLOAT64 and MQBOOL are converted accordingly.

- Do *not* use the following types of data:

- double
- pointers
- bit-fields

This is because the utility for creating conversion-exit code does not provide the facility to convert these data types. To overcome this, you can write your own routines and call them from the exit.

Other points to note:

- Do not use sequence numbers in the input data set.
- If there are fields for which you want to provide your own conversion routines, declare them as MQBYTE, and then replace the generated CMQXCFBA macros with your own conversion code.

C example

```
struct TEST { MQLONG    SERIAL_NUMBER;
              MQCHAR    ID[5];
              MQINT16   VERSION;
              MQBYTE    CODE[4];
              MQLONG    DIMENSIONS[3];
              MQCHAR    NAME[24];
            } ;
```

This corresponds to the following declarations in other programming languages:

COBOL

```
10 TEST.
  15 SERIAL-NUMBER PIC S9(9) BINARY.
  15 ID            PIC X(5).
  15 VERSION      PIC S9(4) BINARY.
  * CODE IS NOT TO BE CONVERTED
  15 CODE         PIC X(4).
  15 DIMENSIONS   PIC S9(9) BINARY OCCURS 3 TIMES.
  15 NAME         PIC X(24).
```

System/390

```
TEST          EQU *
SERIAL_NUMBER DS F
ID            DS CL5
VERSION       DS H
CODE          DS XL4
DIMENSIONS    DS 3F
NAME          DS CL24
```

PL/I

Supported on z/OS only

```
DCL 1 TEST,
  2 SERIAL_NUMBER  FIXED BIN(31),
  2 ID              CHAR(5),
  2 VERSION         FIXED BIN(15),
  2 CODE            CHAR(4),      /* not to be converted */
  2 DIMENSIONS(3)   FIXED BIN(31),
  2 NAME            CHAR(24);
```

MQ_PUBLISH_EXIT - Publish exit

The MQ_PUBLISH_EXIT call can inspect and alter messages delivered to subscribers.

Purpose

Use the publish exit to inspect and alter messages delivered to subscribers:

- Examine the contents of a message published to each subscriber
- Modify the contents of a message published to each subscriber
- Alter the queue to which a message is put
- Stop the delivery of a message to a subscriber

This exit is not available on IBM MQ for z/OS.

Syntax

MQ_PUBLISH_EXIT (*ExitParms*, *PubContext*, *SubContext*)

Parameters

ExitParms (MQPSXP) - Input/Output

ExitParms contains information about the invocation of the exit.

PubContext (MQPBC) - Input

PubContext contains contextual information about the publisher of the publication.

SubContext (MQSBC) - Input/Output

SubContext contains contextual information about the subscriber receiving the publication.

MQPSXP - Publish exit data structure

The MQPSXP structure describes the information that is passed to and returned from the publish exit.

Table 640 on page 1472 summarizes the fields in the structure:

Table 640. Fields in MQPSXP	
Field	Description
<u>StrucID</u>	Structure identifier
<u>Version</u>	Structure version number
<u>ExitId</u>	Type of exit that is being called
<u>ExitReason</u>	Reason for calling the exit
<u>ExitResponse</u>	Response from the exit
<u>ExitResponse2</u>	Secondary response from exit
<u>Feedback</u>	Feedback code

Table 640. Fields in MQPSXP (continued)	
Field	Description
<u>ExitUserArea</u>	Exit user area
<u>ExitData</u>	Exit data
<u>QMgrName</u>	Name of local queue manager
<u>Hconn</u>	Connection handle
<u>MsgDescPtr</u>	Address of message descriptor (MQMD)
<u>MsgHandle</u>	Handle to message properties (MQHMSG)
<u>MsgInPtr</u>	Address of input message
<u>MsgInLength</u>	Length of input message
<u>MsgOutPtr</u>	Address of output message
<u>MsgOutLength</u>	Length of output message
<u>pEntryPoints</u>	Address of the MQIEP structure

Fields

StrucID (MQCHAR4)

StrucID is the structure identifier. The value is as follows:

MQPSXP_STRUCID

MQPSXP_STRUCID is the identifier for the publish exit parameter structure. For the C programming language, the constant MQPSXP_STRUC_ID_ARRAY is also defined; it has the same value as MQPSXP_STRUC_ID, but is an array of characters instead of a string.

StrucID is an input field to the exit.

Version (MQLONG)

Version is the structure version number. The value is as follows:

MQPSXP_VERSION_1

MQPSXP_VERSION_1 is the Version 1 publish exit parameter structure. The constant MQPSXP_CURRENT_VERSION is also defined with the same value.

Version is an input field to the exit.

ExitId (MQLONG)

ExitId is the type of exit that is being called. The value is as follows:

MQXT_PUBLISH_EXIT

Publish exit.

ExitId is an input field to the exit.

ExitReason (MQLONG)

ExitReason is the reason for calling the exit. The possible values are:

MQXR_INIT

The exit for this connection is called for initialization. The exit might acquire and initialize the resources that it needs; for example, main storage.

MQXR_TERM

The exit for this connection is called because the exit is about to be stopped. The exit must free any resources that it has acquired since it was initialized; for example, main storage.

MQXR_PUBLICATION

The exit is called by the queue manager before it puts a publication onto a message queue of a subscriber. The exit can change the message, not put the message on the queue, or halt publication.

ExitReason is an input field to the exit.

ExitResponse (MQLONG)

Set *ExitResponse* in the exit to specify how processing must continue. *ExitResponse* is one of the following values:

MQXCC_OK

Set MQXCC_OK to continue processing normally. Set MQXCC_OK in response to any values of *ExitReason*.

If *ExitReason* has the value MQXR_PUBLICATION, the *DestinationQName* and *DestinationQMGrName* fields of the MQSBC structure identify the destination to which the message is sent.

MQXCC_FAILED

Set MQXCC_FAILED to stop the publish operation. The completion code MQCC_FAILED and reason code 2557 (09FD) (RC2557): MQRC_PUBLISH_EXIT_ERROR is set on return from the exit.

MQXCC_SUPPRESS_FUNCTION

Set MQXCC_SUPPRESS_FUNCTION to stop normal processing of the message. Only set MQXCC_SUPPRESS_FUNCTION if *ExitReason* has the value MQXR_PUBLICATION.

The message continues to be processed by the queue manager according to the MQRO_DISCARD_MSG option in the *Report* field in the message descriptor of the message.

- If the MQRO_DISCARD_MSG option is specified, the message is not delivered to the subscriber.
- If the MQRO_DISCARD_MSG option is not specified, the message is placed on the dead-letter queue. If there is no dead-letter queue, or the message cannot be placed successfully on the dead-letter queue, the publication is not delivered to the subscriber. The delivery of the publication to other subscribers depends on the values of the PMSGDLV and NPMSGDLV topic object attributes. For an explanation of these attributes, see the parameter descriptions for the [DEFINE TOPIC](#) command.

ExitResponse is an output field from the exit.

ExitResponse2 (MQLONG)

ExitResponse2 is reserved for future use.

Feedback (MQLONG)

Feedback is the feedback code to be used if the exit returns MQXCC_SUPPRESS_FUNCTION in *ExitResponse*.

On input to the exit, *Feedback* always has the value MQFB_NONE. If the exit returns MQXCC_SUPPRESS_FUNCTION, set *Feedback* to the value to be used for the message when the queue manager places it on the dead-letter queue. On return from the exit, if *Feedback* has the original value MQFB_NONE, the queue manager sets *Feedback* to MQFB_STOPPED_BY_PUBSUB_EXIT.

Feedback is an input/output field to the exit.

ExitUserArea (MQBYTE16)

ExitUserArea is a field that is available for the exit to use. Each connection has a separate *ExitUserArea*. The length of *ExitUserArea* is given by MQ_EXIT_USER_AREA_LENGTH.

The *ExitReason* field has the value MQXR_INIT on the first invocation of the exit. *ExitUserArea* is initialized to MQXUA_NONE on the first invocation of the exit for a connection. Subsequent changes to *ExitUserArea* are preserved across invocations of the exit.

ExitUserArea is an input/output field to the exit.

ExitData (MQCHAR32)

ExitData is fixed exit data defined by the *PublishExitData* parameter of the stanza in the initialization file of the queue manager. The data is padded with blanks to the full length of the field. If there is no fixed exit data defined in the initialization file, *ExitData* is blank. The length of *ExitData* is given by MQ_EXIT_DATA_LENGTH.

ExitData is an input field to the exit.

QMgrName (MQCHAR48)

QMgrName is the name of the local queue manager. The name is padded with blanks to the full length of the field. The length of this field is given by MQ_Q_MGR_NAME_LENGTH.

QMgrName is an input field to the exit.

Hconn (MQHCONN)

Hconn is the handle representing a connection to the queue manager. Only use *Hconn* as a parameter to the MQSETMP, MQINQMMP, or MQDLTMP message property function calls to work with message properties.

Hconn is an input field to the exit.

MsgDescPtr (PMQMD)

MsgDescPtr is the address of message descriptor (MQMD) of the message being processed, and is a copy of the MQMD returned from the MQPUT call. The exit can change the contents of the message descriptor. Any change to the contents of the message descriptor must be done with care. In particular, in the case where the *SubType* field of the MQSBC structure is of value MQSUBTYPE_PROXY, the *CorrelId* field in the message descriptor must not be changed.

No message descriptor is passed to the exit if *ExitReason* is MQXR_INIT or MQXR_TERM; in these cases, *MsgDescPtr* is the null pointer.

MsgDescPtr is an input field to the exit.

MsgHandle (MQHMSG)

MsgHandle is the handle to message properties. Only use *MsgHandle* with the MQSETMP, MQINQMMP, or MQDLTMP message property function calls to work with message properties.

MsgHandle is an input field to the exit.

MsgInPtr (PMQVOID)

MsgInPtr is the address of the input message data. The contents of the buffer addressed by *MsgInPtr* can be modified by the exit; see [MsgOutPtr](#).

MsgInPtr is an input field to the exit.

MsgInLength (MQLONG)

MsgInLength is the length in bytes of the message data passed to the exit. The address of the data is given by *MsgInPtr*.

MsgInLength is an input field to the exit.

MsgOutPtr (PMQVOID)

MsgOutPtr is the address of a buffer containing message data that is returned from the exit. On entry to the exit, *MsgOutPtr* is null. On return from the exit, if the value is still null, the queue manager sends the message specified by *MsgInPtr*, with the length given by *MsgInLength*.

If the exit modifies the message data, use one of the following procedures:

- If the length of the data does not change, the data can be modified in the buffer addressed by *MsgInPtr*. In this case, do not change *MsgOutPtr* and *MsgOutLength*.
- If the modified data is shorter than the original data, the data can be modified in the buffer addressed by *MsgInPtr*. In this case *MsgOutPtr* must be set to the address of the input message buffer, and *MsgOutLength* set to the new length of the message data.
- If the modified data is, or might be, longer than the original data, the exit must obtain a new message buffer. Copy the modified data into it. Set *MsgOutPtr* to the address of the new buffer, and

set *MsgOutLength* to the length of the new message data. The exit is responsible for freeing the buffer addressed by *MsgOutPtr* when the exit is next called.

Note: *MsgOutPtr* is always the null pointer on input to the exit, and not the address of a previously obtained message buffer. To free the previously obtained buffer, the exit must save its address and length. Save the information either in *ExitUserArea*, or in a control block that has its address saved in *ExitUserArea*.

MsgOutPtr is an input/output field to the exit.

MsgOutLength (MQLONG)

MsgOutLength is the length in bytes of the message data returned by the exit. On input to the exit, this field is always zero. On return from the exit, this field is ignored if *MsgOutPtr* is null. See *MsgOutPtr* for information about modifying the message data.

MsgOutLength is an input/output field to the exit.

pEntryPoints (PMQIEP)

pEntryPoints is the address of an MQIEP structure through which MQI and DCI calls can be made.

C language declaration - MQPSXP

```
typedef struct tagMQPSXP {
    MQCHAR4      StrucId;           /* Structure identifier */
    MQLONG       Version;          /* Structure version number */
    MQLONG       ExitId;           /* Type of exit */
    MQLONG       ExitReason;        /* Reason for invoking exit */
    MQLONG       ExitResponse;      /* Response from exit */
    MQLONG       ExitResponse2;     /* Reserved */
    MQLONG       Feedback;          /* Feedback code */
    MQBYTE16     ExitUserArea;      /* Exit user area */
    MQCHAR32     ExitData;          /* Exit data */
    MQCHAR48     QMgrName;          /* Name of local queue manager */
    MQHCONN      Hconn;            /* Connection handle */
    MQHMSG       MsgHandle;         /* Handle to message properties */
    PMQMD        MsgDescPtr;        /* Address of message descriptor */
    PMQVOID      MsgInPtr;          /* Address of input message data */
    MQLONG       MsgInLength;       /* Length of input message data */
    PMQVOID      MsgOutPtr;         /* Address of output message data */
    MQLONG       MsgOutLength;      /* Length of output message data */
    /* Ver:1 */
    PMQIEP       pEntryPoints;      /* Address of the MQIEP structure */
    /* Ver:2 */
} MQPSXP;
```

MQPBC - Publication context data structure

The MQPBC structure contains the contextual information, relating to the publisher of the publication, that is passed to the publish exit.

Table 641 on page 1476 summarizes the fields in the structure:

Table 641. Fields in MQPBC	
Field	Description
<u>StrucID</u>	Structure identifier
<u>Version</u>	Structure version number
<u>PubTopicString</u>	Publish topic string
<u>MsgDescPtr</u>	Address of message descriptor (MQMD)

Fields

StrucID (MQCHAR4)

StrucID is the structure identifier. The value is as follows:

MQPBC_STRUCID

MQPBC_STRUCID is the identifier for the publication context structure. For the C programming language, the constant MQPBC_STRUC_ID_ARRAY is also defined; it has the same value as MQPBC_STRUC_ID, but is an array of characters instead of a string.

StrucID is an input field to the exit.

Version (MQLONG)

Version is the structure version number. The value is as follows:

MQPBC_VERSION_1

MQPBC_VERSION_1 is the Version 1 publish exit parameter structure.

MQPBC_VERSION_2

MQPBC_VERSION_2 is the Version 2 publish exit parameter structure. The constant MQPBC_CURRENT_VERSION is also defined with the same value.

Version is an input field to the exit.

PubTopicString (MQCHARV)

PubTopicString is the topic string being published to.

PubTopicString is an input field to the exit.

MsgDescPtr (PMQMD)

MsgDescPtr is the address of a copy of the message descriptor (MQMD) for the message being processed.

MsgDescPtr is an input field to the exit.

C language declaration - MQPBC

```
typedef struct tagMQPBC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQCHARV    PubTopicString;    /* Publish topic string */
    PMQMD      MsgDescPtr;       /* Address of message descriptor */
} MQPBC;
```

MQSBC - Subscription context data structure

The MQSBC structure contains the contextual information, relating to the subscriber that is receiving the publication, that is passed to the publish exit.

Table 642 on page 1477 summarizes the fields in the structure:

Table 642. Fields in MQSBC	
Field	Description
<i>StrucID</i>	Structure identifier
<i>Version</i>	Structure version number
<i>DestinationQMgrName</i>	Name of destination queue manager
<i>DestinationQName</i>	Name of destination queue
<i>SubType</i>	Type of subscription
<i>SubOptions</i>	Subscription options
<i>ObjectName</i>	Object name
<i>ObjectString</i>	Object string
<i>SubTopicString</i>	Subscription topic string
<i>SubName</i>	Subscription name

Table 642. Fields in MQSBC (continued)	
Field	Description
<i>SubId</i>	Subscription identifier
<i>SelectionString</i>	Address of selection string
<i>SubLevel</i>	Subscription level
<i>PSPProperties</i>	Publish/subscribe properties

Fields

StrucID (MQCHAR4)

Structure identifier. The value is as follows:

MQSBC_STRUCID

MQSBC_STRUCID is the identifier for the publish exit parameter structure. For the C programming language, the constant MQSBC_STRUC_ID_ARRAY is also defined; MQSBC_STRUC_ID_ARRAY has the same value as MQSBC_STRUC_ID, but is an array of characters instead of a string.

StrucID is an input field to the exit.

Version (MQLONG)

Structure version number. The value is as follows:

MQSBC_VERSION_1

Version 1 publish exit parameter structure. The constant MQSBC_CURRENT_VERSION is also defined with the same value.

Version is an input field to the exit.

DestinationQMGrName (MQCHAR48)

DestinationQMGrName is the name of the queue manager to which the message is being sent. The name is padded with blanks to the full length of the field. The name can be altered by the exit. The length of this field is given by MQ_Q_MGR_NAME_LENGTH.

DestinationQMGrName is an input/output field to the exit; see [note](#).

DestinationQName (MQCHAR48)

DestinationQName is the name of the queue to which the message is being sent. The name is padded with blanks to the full length of the field. The name can be altered by the exit. The length of this field is given by MQ_Q_NAME_LENGTH.

DestinationQName is an input/output field to the exit; see [note](#).

SubType (MQLONG)

SubType indicates how the subscription was created. Valid values are MQSUBTYPE_API, MQSUBTYPE_ADMIN and MQSUBTYPE_PROXY ; see [Inquire Subscription Status \(Response\)](#).

SubType is an input field to the exit.

SubOptions (MQLONG)

SubOptions are the subscription options; see “Options (MQLONG)” on [page 542](#) for a description of values this field can take.

SubOptions is an input field to the exit.

ObjectName (MQCHAR48)

ObjectName is the name of the topic object as defined on the local queue manager. The length of this field is given by MQ_TOPIC_NAME_LENGTH. The object name is the name of the administrative topic object that the queue manager has associated with the topic string. Even if the subscriber provided a topic object as part of the subscription, the *ObjectName* might be a different topic object. The association of a topic object with a subscription depends upon the full resolution of *SubTopicString*.

ObjectName is an input field to the exit.

ObjectString (MQCHARV)

ObjectString is the full topic string of the publication that was subscribed to. Any wildcards in the original subscription string are resolved. It is different to the MQSD subscription *ObjectString* field described in [“ObjectString \(MQCHARV\)”](#) on page 541, which might contain wildcards, and is exclusive of any object name provided by the subscriber.

ObjectString is an input field to the exit.

SubTopicString (MQCHARV)

SubTopicString is the complete topic string as supplied by the subscriber. *SubTopicString* is the combination of the topic string defined in a topic object, and a topic string. A subscriber must provide either a topic object, a topic string, or both. If the subscriber provides a topic string, it might contain wildcards.

SubTopicString is an input field to the exit.

SubName (MQCHARV)

SubName is the subscription name that is provided either by the subscriber, or is a generated name.

SubName is an input field to the exit.

SubId (MQBYTE 24)

SubId is the unique internal subscription identifier.

SubId is an input field to the exit.

SelectionString (MQCHARV)

SelectionString is the selection criteria used when subscribing for messages from a topic; see [Selectors](#).

SelectionString is an input field to the exit.

SubLevel (MQLONG)

SubLevel is the interception level associated with the subscription; see [“SubLevel \(MQLONG\)”](#) on page 552 for further details.

SubLevel is an input field to the exit.

PSPProperties (MQLONG)

PSPProperties are the publish/subscribe properties. They specify how publish/subscribe related message properties are added to messages sent to this subscription. Possible values are MQPSPROP_NONE, MQPSPROP_COMPAT, MQPSPROP_RFH2, MQPSPROP_MSGPROP. See [Optional parameters \(Change, Copy, and Create Subscription\)](#) for a description of these values.

PSPProperties is an input field to the exit.

Note: Authorization checks are only performed on the original values of *DestinationQMGrName* and *DestinationQName* before they are passed to the publish exit. No new authorization checks are performed when the exit changes the destination queue, either by changing *DestinationQMGrName* or *DestinationQName*.

C language declaration - MQSBC

```
typedef struct tagMQSBC {
    MQCHAR4      StructId;           /* Structure identifier */
    MQLONG       Version;            /* Structure version number */
    MQCHAR48     DestinationQMGrName; /* Destination queue manager */
    MQCHAR48     DestinationQName;   /* Destination queue name */
    MQLONG       SubType;            /* Type of subscription */
    MQLONG       SubOptions;         /* Subscription options */
    MQCHAR48     ObjectName;         /* Object name */
    MQCHARV      ObjectString;       /* Object string */
    MQCHARV      SubTopicString;     /* Subscription topic string */
    MQCHARV      SubName;           /* Subscription name */
    MQBYTE24     SubId;             /* Subscription identifier */
    MQCHARV      SelectionString;    /* Subscription selection string */
    MQLONG       SubLevel;          /* Subscription level */
}
```

```

MQLONG      PSProperties;      /* Publish/subscribe properties */
} MQSBC;

```

Channel-exit calls and data structures

This collection of topics provide reference information about the special IBM MQ calls and data structures that you can use when you write channel exit programs.

This information is product-sensitive programming interface information. You can write IBM MQ user exits in the following programming languages:

Platform	Programming languages
IBM MQ for z/OS	Assembler and C (which must conform to the C system programming environment for system exits, described in the <i>z/OS C/C++ Programming Guide</i> .)
IBM MQ for IBM i	ILE C, ILE COBOL, and ILE RPG
All other IBM MQ platforms	C

You can also write user exits in Java for use only with Java and JMS applications. For more information about creating and using channel exits with the IBM MQ classes for Java, see [Using channel exits in IBM MQ classes for Java](#) and for IBM MQ classes for JMS, see [Using channel exits with IBM MQ classes for JMS](#).

You cannot write IBM MQ user exits in TAL or Visual Basic. However, a declaration for the MQCD structure is provided in Visual Basic for use on the MQCONN call from an IBM MQ MQI client program.

In a number of cases in the descriptions that follow, parameters are arrays or character strings with a size that is not fixed. For these parameters, a lowercase "n" is used to represent a numeric constant. When the declaration for that parameter is coded, the "n" must be replaced by the numeric value required. For further information about the conventions used in these descriptions, see the [“Elementary data types”](#) on [page 231](#).

Data definition files

Data definition files are supplied with IBM MQ for each of the supported programming languages. For details of these files, see [Copy, header, include, and module files](#).

MQ_CHANNEL_EXIT - Channel exit

The MQ_CHANNEL_EXIT call describes the parameters that are passed to each of the channel exits called by the Message Channel Agent.

No entry point called MQ_CHANNEL_EXIT is provided by the queue manager; the name MQ_CHANNEL_EXIT is of no special significance since the names of the channel exits are provided in the channel definition MQCD.

There are five types of channel exit:

- Channel security exit
- Channel message exit
- Channel send exit
- Channel receive exit
- Channel message-retry exit

The parameters are similar for each type of exit, and the description given here applies to all of them, except where specifically noted.

Syntax

MQ_CHANNEL_EXIT (*ChannelExitParms*, *ChannelDefinition*, *DataLength*,
AgentBufferLength, *AgentBuffer*, *ExitBufferLength*, *ExitBufferAddr*)

Parameters

The MQ_CHANNEL_EXIT call has the following parameters.

ChannelExitParms (MQCXP) - input/output

Channel exit parameter block.

This structure contains additional information relating to the invocation of the exit. The exit sets information in this structure to indicate how the MCA proceeds.

ChannelDefinition (MQCD) - input/output

Channel definition.

This structure contains parameters set by the administrator to control the behavior of the channel.

DataLength (MQLONG) - input/output

Length of data.

The data depends on the type of exit:

- For a channel security exit, when the exit is invoked this parameter contains the length of any security message in the *AgentBuffer* field, if *ExitReason* is MQXR_SEC_MSG. It is zero if there is no message. The exit must set this field to the length of any security message to be sent to its partner if it sets *ExitResponse* to MQXCC_SEND_SEC_MSG or MQXCC_SEND_AND_REQUEST_SEC_MSG. The message data is in either *AgentBuffer* or *ExitBufferAddr*.

The content of security messages is the sole responsibility of the security exits.
- For a channel message exit, when the exit is invoked this parameter contains the length of the message (including the transmission queue header). The exit must set this field to the length of the message in either *AgentBuffer* or *ExitBufferAddr* that is to proceed. This must be greater than or equal to the length of the transmission queue header (MQXQH).
- For a channel send or channel receive exit, when the exit is invoked this parameter contains the length of the transmission. The exit must set this field to the length of the transmission in either *AgentBuffer* or *ExitBufferAddr* that is to proceed.

If a security exit sends a message, and there is no security exit at the other end of the channel, or the other end sets an *ExitResponse* of MQXCC_OK, the initiating exit is re-invoked with MQXR_SEC_MSG and a null response (*DataLength*=0).

AgentBufferLength (MQLONG) - input

Length of agent buffer.

This parameter can be greater than *DataLength* on invocation.

For channel message, send, and receive exits, any unused space on invocation can be used by the exit to expand the data in place. If this is done, the *DataLength* parameter must be set appropriately by the exit.

In the C programming language, this parameter is passed by address.

AgentBuffer (MQBYTE x AgentBufferLength) - input/output

Agent buffer.

The contents of this parameter depend upon the exit type:

- For a channel security exit, on invocation of the exit it contains a security message if *ExitReason* is MQXR_SEC_MSG. To send a security message back, the exit can either use this buffer or its own buffer (*ExitBufferAddr*).
- For a channel message exit, on invocation of the exit this parameter contains:
 - The transmission queue header (MQXQH), which includes the message descriptor (which itself contains the context information for the message), immediately followed by
 - The message data

If the message is to proceed, the exit can do one of the following:

- Leave the contents of the buffer untouched
- Modify the contents in place (returning the new length of the data in *DataLength* ; this must not be greater than *AgentBufferLength*)
- Copy the contents to the *ExitBufferAddr*, making any required changes

Any changes that the exit makes to the transmission queue header are not checked; however, erroneous modifications might mean that the message cannot be put at the destination.

- For a channel send or receive exit, on invocation of the exit this contains the transmission data. The exit can do one of the following:
 - Leave the contents of the buffer untouched
 - Modify the contents in place (returning the new length of the data in *DataLength* ; this must not be greater than *AgentBufferLength*)
 - Copy the contents to the *ExitBufferAddr*, making any required changes

The first 8 bytes of the data must not be changed by the exit.

ExitBufferLength (MQLONG) - input/output

Length of exit buffer.

On the first invocation of the exit, this parameter is set to zero. Thereafter whatever value is passed back by the exit, on each invocation, is presented to the exit next time it is invoked. The value is not used by the MCA.

Note: This parameter must not be used by exits written in programming languages which do not support the pointer data type.

ExitBufferAddr (MQPTR) - input/output

Address of exit buffer.

This parameter is a pointer to the address of a buffer of storage managed by the exit, where it can choose to return message or transmission data (depending upon the type of exit) to the agent if the buffer of the agent is or might not be large enough, or if it is more convenient for the exit to do so.

On the first invocation of the exit, the address passed to the exit is null. Thereafter whatever address is passed back by the exit, on each invocation, is presented to the exit the next time it is invoked.

If *ExitBufferAddr* is null the data used is taken from the *AgentBuffer* parameter.

If *ExitBufferAddr* is not null the data used is taken from the buffer pointed to by the *ExitBufferAddr* parameter.

Note: This parameter must not be used by exits written in programming languages that do not support the pointer data type.

C invocation

```
exitname (&ChannelExitParms, &ChannelDefinition,
&DataLength, &AgentBufferLength, AgentBuffer,
&ExitBufferLength, &ExitBufferAddr);
```

The parameters passed to the exit are declared as follows:

```
MQCXP  ChannelExitParms;  /* Channel exit parameter block */
MQCD   ChannelDefinition; /* Channel definition */
MQLONG DataLength;        /* Length of data */
MQLONG AgentBufferLength; /* Length of agent buffer */
MQBYTE AgentBuffer[n];    /* Agent buffer */
MQLONG ExitBufferLength;  /* Length of exit buffer */
MQPTR  ExitBufferAddr;    /* Address of exit buffer */
```

COBOL invocation

```
CALL 'exitname' USING CHANNELEXITPARMS, CHANNELDEFINITION,
                     DATALENGTH, AGENTBUFFERLENGTH, AGENTBUFFER,
                     EXITBUFFERLENGTH, EXITBUFFERADDR.
```

The parameters passed to the exit are declared as follows:

```
** Channel exit parameter block
01 CHANNELEXITPARMS.
   COPY CMQCXPV.
** Channel definition
01 CHANNELDEFINITION.
   COPY CMQCDV.
** Length of data
01 DATALENGTH      PIC S9(9) BINARY.
** Length of agent buffer
01 AGENTBUFFERLENGTH PIC S9(9) BINARY.
** Agent buffer
01 AGENTBUFFER       PIC X(n).
** Length of exit buffer
01 EXITBUFFERLENGTH  PIC S9(9) BINARY.
** Address of exit buffer
01 EXITBUFFERADDR    POINTER.
```

RPG invocation (ILE)

```
C*..1.....2.....3.....4.....5.....6.....7..
C                                CALLP      exitname(MQCXP : MQCD : DATLEN :
C                                ABUFL : ABUF : EBUFL :
C                                EBUF)
```

The prototype definition for the call is:

```
D*..1.....2.....3.....4.....5.....6.....7..
Dexitname      PR                EXTPROC('exitname')
D* Channel exit parameter block
D MQCXP                160A
D* Channel definition
D MQCD                1328A
D* Length of data
D DATLEN              10I 0
D* Length of agent buffer
D ABUFL              10I 0
D* Agent buffer
D ABUF                *   VALUE
D* Length of exit buffer
D EBUFL              10I 0
D* Address of exit buffer
D EBUF                *
```

System/390 assembler invocation

```
CALL EXITNAME, (CHANNELEXITPARMS, CHANNELDEFINITION, DATALENGTH, X
               AGENTBUFFERLENGTH, AGENTBUFFER, EXITBUFFERLENGTH, X
               EXITBUFFERADDR)
```

The parameters passed to the exit are declared as follows:

CHANNELEXITPARMS	CMQCXPA	,	Channel exit parameter block
CHANNELDEFINITION	CMQCDA	,	Channel definition
DATALength	DS	F	Length of data
AGENTBUFFERLENGTH	DS	F	Length of agent buffer
AGENTBUFFER	DS	CL(n)	Agent buffer
EXITBUFFERLENGTH	DS	F	Length of exit buffer
EXITBUFFERADDR	DS	F	Address of exit buffer

Usage notes

1. The function performed by the channel exit is defined by the provider of the exit. The exit, however, must conform to the rules defined here and in the associated control block, the MQCXP.
2. The *ChannelDefinition* parameter passed to the channel exit might be one of several versions. See the *Version* field in the MQCD structure for more information.
3. If the channel exit receives an MQCD structure with the *Version* field set to a value greater than MQCD_VERSION_1, the exit must use the *ConnectionName* field in MQCD, in preference to the *ShortConnectionName* field.
4. In general, channel exits are allowed to change the length of message data. This can arise as a result of the exit adding data to the message, or removing data from the message, or compressing or encrypting the message. However, special restrictions apply if the message is a segment that contains only part of a logical message. In particular, there must be no net change in the length of the message as a result of the actions of complementary sending and receiving exits.

For example, it is permissible for a sending exit to shorten the message by compressing it, but the complementary receiving exit must restore the original length of the message by decompressing it, so that there is no net change in the length of the message.

This restriction arises because changing the length of a segment would cause the offsets of later segments in the message to be incorrect, and this would inhibit the ability of the queue manager to recognize that the segments formed a complete logical message.

MQ_CHANNEL_AUTO_DEF_EXIT - Channel auto-definition exit

The MQ_CHANNEL_AUTO_DEF_EXIT call describes the parameters that are passed to the channel auto-definition exit called by the Message Channel Agent.

No entry point called MQ_CHANNEL_AUTO_DEF_EXIT is provided by the queue manager; the name MQ_CHANNEL_AUTO_DEF_EXIT is of no special significance because the names of the auto-definition exits are provided in the queue manager.

Syntax

MQ_CHANNEL_AUTO_DEF_EXIT (*ChannelExitParms*, *ChannelDefinition*)

Parameters

The MQ_CHANNEL_AUTO_DEF_EXIT call has the following parameters.

ChannelExitParms (MQCXP) - input/output

Channel exit parameter block.

This structure contains additional information relating to the invocation of the exit. The exit sets information in this structure to indicate how the MCA proceeds.

ChannelDefinition (MQCD) - input/output

Channel definition.

This structure contains parameters set by the administrator to control the behavior of channels which are created automatically. The exit sets information in this structure to modify the default behavior set by the administrator.

The MQCD fields listed must not be altered by the exit:

- *ChannelName*
- *ChannelType*
- *StrucLength*
- *Version*

If other fields are changed, the value set by the exit must be valid. If the value is not valid, an error message is written to the error log file or displayed on the console (as appropriate to the environment).

Attention: Auto-defined channels created by a channel automatic definition (CHAD) exit cannot set the certificate label, because the SSL or TLS handshake has occurred by the time the channel is created. Setting the certificate label in a CHAD exit for inbound channels has no effect.

C invocation

```
exitname (&ChannelExitParms, &ChannelDefinition);
```

The parameters passed to the exit are declared as follows:

```
MQCXP  ChannelExitParms;  /* Channel exit parameter block */
MQCD   ChannelDefinition; /* Channel definition */
```

COBOL invocation

```
CALL 'exitname' USING CHANNELEXITPARMS, CHANNELDEFINITION.
```

The parameters passed to the exit are declared as follows:

```
** Channel exit parameter block
01 CHANNELEXITPARMS.
   COPY CMQCXPV.
** Channel definition
01 CHANNELDEFINITION.
   COPY CMQCDV.
```

RPG invocation (ILE)

```
C*..1.....2.....3.....4.....5.....6.....7..
C                                CALLP      exitname(MQCXP : MQCD)
```

The prototype definition for the call is:

```
D*..1.....2.....3.....4.....5.....6.....7..
Dexitname          PR          EXTPROC('exitname')
D* Channel exit parameter block
D MQCXP                                160A
D* Channel definition
D MQCD                                1328A
```

System/390 assembler invocation

```
CALL EXITNAME, (CHANNELEXITPARMS, CHANNELDEFINITION)
```

The parameters passed to the exit are declared as follows:

```
CHANNELEXITPARMS  CMQCXPA  ,  Channel exit parameter block
CHANNELDEFINITION CMQCDA   ,  Channel definition
```

Usage notes

1. The function performed by the channel exit is defined by the provider of the exit. The exit, however, must conform to the rules defined here and in the associated control block, the MQCXP.
2. The *ChannelExitParms* parameter passed to the channel auto-definition exit is an MQCXP structure. The version of MQCXP passed depends on the environment in which the exit is running; see the description of the *Version* field in “MQCXP - Channel exit parameter” on page 1526 for details.
3. The *ChannelDefinition* parameter passed to the channel auto-definition exit is an MQCD structure. The version of MQCD passed depends on the environment in which the exit is running; see the description of the *Version* field in “MQCD - Channel definition” on page 1487 for details.

MQXWAIT - Wait in exit

The MQXWAIT call waits for an event to occur. It can be used only from a channel exit on z/OS.

The use of MQXWAIT helps to avoid performance problems that might otherwise occur if a channel exit does something that causes a wait. The event MQXWAIT is waiting on is signaled by an MVS ECB (event control block). The ECB is described in the MQXWD control block description.

 For more information about the use of MQXWAIT and writing channel-exit programs, see [Writing channel exit programs on z/OS](#)

Syntax

MQXWAIT (*Hconn*, *WaitDesc*, *CompCode*, *Reason*)

Parameters

The MQXWAIT call has the following parameters.

Hconn (MQHCONN) - input

Connection handle.

This handle represents the connection to the queue manager. The value of *Hconn* was returned by a previous MQCONN call issued in the same or earlier invocation of the exit.

WaitDesc (MQXWD) - input/output

Wait descriptor.

This parameter describes the event to wait for. See “MQXWD - Exit wait descriptor” on page 1540 for details of the fields in this structure.

CompCode (MQLONG) - output

Completion code.

It is one of the following codes:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

MQRC_ADAPTER_NOT_AVAILABLE

(2204, X'89C') Adapter not available.

MQRC_OPTIONS_ERROR

(2046, X'7FE') Options not valid or not consistent.

MQRC_XWAIT_CANCELED

(2107, X'83B') MQXWAIT call canceled.

MQRC_XWAIT_ERROR

(2108, X'83C') Invocation of MQXWAIT call not valid.

C invocation

```
MQXWAIT (Hconn, &WaitDesc, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONN  Hconn;      /* Connection handle */
MQXWD    WaitDesc;   /* Wait descriptor */
MQLONG   CompCode;   /* Completion code */
MQLONG   Reason;     /* Reason code qualifying CompCode */
```

System/390 assembler invocation

```
CALL MQXWAIT,(HCONN,WAITDESC,COMPCODE,REASON)
```

Declare the parameters as follows:

```
HCONN      DS      F      Connection handle
WAITDESC   CMQXWDA  ,      Wait descriptor
COMPCODE    DS      F      Completion code
REASON      DS      F      Reason code qualifying COMPCODE
```

MQCD - Channel definition

The MQCD structure contains the parameters which control execution of a channel. It is passed to each channel exit that is called from a Message Channel Agent (MCA).

For more information about channel exits, see [“MQ_CHANNEL_EXIT - Channel exit” on page 1480](#). The description in this topic relates both to message channels and to MQI channels.

Exit name fields

When an exit is called, the relevant field from *SecurityExit*, *MsgExit*, *SendExit*, *ReceiveExit*, and *MsgRetryExit* contains the name of the exit currently being invoked. The meaning of the name in these fields depends on the environment in which the MCA is running. Except where noted, the name is left-aligned within the field, with no embedded blanks; the name is padded with blanks to the length of the field. In the descriptions that follow, square brackets ([]) denote optional information:

UNIX systems

The exit name is the name of a dynamically loadable module or library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path:

```
[ path ] library ( function )
```

The name is limited to a maximum of 128 characters.

z/OS

The exit name is the name of a load module that is valid for specification on the EP parameter of the LINK or LOAD macro. The name is limited to a maximum of eight characters.

Windows

The exit name is the name of a dynamic-link library, suffixed with the name of a function residing in that library. The function name must be enclosed in parentheses. The library name can optionally be prefixed with a directory path and drive:

```
[d:][ path ] library ( function )
```

The name is limited to a maximum of 128 characters.

IBM i

The exit name is a 10 byte program name followed by a 10 byte library name. If the names are less than 10 bytes long, each name is padded with blanks to make it 10 bytes. The library name can be *LIBL except when calling a channel auto-definition exit, in which case a fully qualified name is required.

Changing MQCD fields in a channel exit

A channel exit can change fields in the MQCD. The changed value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance. The changed MQCD is also used by the MCA for its normal processing during the continuing lifetime of the channel.

The following MQCD fields must not be altered by the exit:

- ChannelName
- ChannelType
- StrucLength
- Version

[“Changing MQCD fields in a channel exit” on page 1523](#)

A channel exit can change fields in the MQCD. However, these changes are not typically acted on, except in the circumstances listed.

Fields

This topic lists all the fields in the MQCD structure and describes each field.

BatchDataLimit (MQLONG)

This field specifies the limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point.

A sync point is taken after the message that caused the limit to be reached has flowed across the channel.

The batch is terminated when one of the following conditions is met:

- **BatchSize** messages have been sent.

- **BatchDataLimit** bytes have been sent.
- The transmission queue is empty and **BatchInterval** is exceeded.

The value must be in the range 0 - 999999. The default value is 5000.

A value of zero in this attribute means that no data limit is applied to batches over this channel.

This parameter only applies to channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSRCVR, or MQCHT_CLUSSDR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_11.

BatchHeartbeat (MQLONG)

This field specifies the time interval that is used to trigger a batch heartbeat for the channel.

Batch heartbeating allows sender channels to determine whether the remote channel instance is still active before going indoubt. A batch heartbeat occurs if a sender channel has not communicated with the remote channel instance within the specified time interval.

The value is in the range 0 through 999 999; the units are milliseconds. A value of zero indicates that batch heartbeating is not enabled.

This field is relevant only for channels that have a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_7.

BatchInterval (MQLONG)

This field specifies the approximate time in milliseconds that a channel keeps a batch open, if fewer than *BatchSize* messages have been transmitted in the current batch.

If *BatchInterval* is greater than zero, the batch is terminated by whichever of the following events occur first:

- *BatchSize* messages have been sent, or
- *BatchInterval* milliseconds have elapsed since the start of the batch.

If *BatchInterval* is zero, the batch is terminated by whichever of the following events occur first:

- *BatchSize* messages have been sent, or
- the transmission queue becomes empty.

BatchInterval must be in the range zero through 999 999 999.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

This is an input field to the exit. The field is not present when *Version* is less than MQCD_VERSION_4.

BatchSize (MQLONG)

This field specifies the maximum number of messages that can be sent through a channel before synchronizing the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT_SVRCONN or MQCHT_CLNTCONN.

CertificateLabel (MQCHAR64)

This field gives details of the certificate label being used.

IBM MQ initializes the default value for the *CertificateLabel* field as blanks.

This is interpreted at runtime as the default value, and is backwards compatible.

For example, specifying a MQCD version less than 11, or using the default value of blanks for the *CertificateLabel* field, means that this field is ignored.

The length of this field is given by MQ_CERT_LABEL_LENGTH.

ChannelMonitoring (MQLONG)

This field specifies the current level of monitoring data collection for the channel.

This field is not relevant for channels with a ChannelType of MQCHT_CLNTCONN.

It is one of the following values:

- MQMON_OFF
- MQMON_LOW
- MQMON_MEDIUM
- MQMON_HIGH

This is an input field to the exit. It is not present if *Version* is less than MQCD_VERSION_8.

ChannelName (MQCHAR20)

This field specifies the channel definition name.

There must be a channel definition of the same name at the remote machine to be able to communicate.

The name must use only the characters:

- Uppercase A-Z
- Lowercase a-z
- Numerics 0-9
- Period (.)
- Forward slash (/)
- Underscore (_)
- Percent sign (%)

and be padded to the right with blanks. Leading or embedded blanks are not allowed.

The length of this field is given by MQ_CHANNEL_NAME_LENGTH.

ChannelStatistics (MQLONG)

This field specifies the current level of statistics data collection for the channel.

This field is not relevant for channels with a ChannelType of MQCHT_CLNTCONN or MQCHT_SVRCONN.

It is one of the following values:

- MQMON_OFF
- MQMON_LOW
- MQMON_MEDIUM
- MQMON_HIGH

This is an input field to the exit. It is not present if *Version* is less than MQCD_VERSION_8.

ChannelType (MQLONG)

This field specifies the type of channel.

It is one of the following values:

MQCHT_SENDER

Sender.

MQCHT_SERVER

Server.

MQCHT_RECEIVER

Receiver.

MQCHT_REQUESTER

Requester.

MQCHT_CLNTCONN

Client connection.

MQCHT_SVRCONN

Server-connection (for use by clients).

MQCHT_CLUSSDR

Cluster sender.

MQCHT_CLUSRCVR

Cluster receiver.

ClientChannelWeight (MQLONG)

This field specifies a weighting to influence which client-connection channel definition is used.

The ClientChannelWeight attribute is used so that client channel definitions can be selected at random based on their weighting when more than one suitable definition is available. When a client issues an MQCONN requesting connection to a queue manager group, by specifying a queue manager name starting with an asterisk, and more than one suitable channel definition is available in the client channel definition table (CCDT), the definition to use is randomly selected based on the weighting, with any applicable ClientChannelWeight(0) definitions selected first in alphabetical order.

Specify a value in the range 0 - 99. The default is 0.

A value of 0 indicates that no load balancing is performed and applicable definitions are selected in alphabetical order. To enable load balancing choose a value in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest. The distribution of messages between two or more channels with non-zero weightings is proportional to the ratio of those weightings. For example, three channels with ClientChannelWeight values of 2, 4, and 14 are selected approximately 10%, 20%, and 70% of the time. This distribution is not guaranteed.

This attribute is valid for the client-connection channel type only.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_9.

ClusterPtr (MQPTR)

This field specifies the address a list of cluster names.

If *ClustersDefined* is greater than zero, this address is the address of a list of cluster names. The channel belongs to each cluster listed.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLUSSDR or MQCHT_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_5.

ClustersDefined (MQLONG)

This field specifies the number of clusters to which the channel belongs.

This field is the number of cluster names pointed to by *ClusterPtr*. It is zero or greater.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLUSSDR or MQCHT_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_5.

CLWLChannelPriority (MQLONG)

This field specifies the cluster workload channel priority.

The workload manager choose algorithm selects a destination with the highest priority from the set of destinations selected based on rank. If there are two possible destination queue managers, this attribute can be used to make one queue manager failover onto the other queue manager. All the messages go to the queue manager with the highest priority until that ends, then the messages go to the queue manager with the next highest priority.

The value is in the range 0 through 9. The default is 0.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_8.

For further information, see [Configuring a queue manager cluster](#).

CLWLChannelRank (MQLONG)

This field specifies the cluster workload channel rank.

The workload manager choose algorithm selects a destination with the highest rank. When the final destination is a queue manager on a different cluster, you can set the rank of intermediate gateway queue managers (at the intersection of neighboring clusters) so the choose algorithm correctly chooses a destination queue manager nearer the final destination.

The value is in the range 0 through 9. The default is 0.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_8.

For further information, see [Configuring a queue manager cluster](#).

CLWLChannelWeight (MQLONG)

This field specifies the cluster workload channel weight.

Cluster workload channel weight.

The workload manager choose algorithm uses the "weight" attribute of the channel to skew the destination choice so that more messages can be sent to a particular machine. For example, you can give a channel on a large UNIX server a larger "weight" than another channel on small desktop PC, and the choose algorithm chooses the UNIX server more frequently than the PC.

The value is in the range 1 through 99. The default is 50.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_8.

For further information, see [Configuring a queue manager cluster](#).

ConnectionAffinity (MQLONG)

This field specifies whether client applications that connect multiple times using the same queue manager name, use the same client channel.

Use this attribute when multiple applicable channel definitions are available.

The value is one of the following:

MQCAFTY_PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the weighting with any applicable CLNTWGHT(0) definitions first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful definitions with CLNTWGHT values other than 0 are moved to the end of the list. CLNTWGHT(0) definitions remain at the start of the list and are selected first for each connection.

Each client process with the same host name always creates the same list.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET) the list is updated if the CCDT has been modified since the list was created.

This value is the default value.

MQCAFTY_NONE

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET) the list is updated if the CCDT has been modified since the list was created.

This attribute is valid for the client-connection channel type only.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_9.

ConnectionName (MQCHAR264)

This field specifies the connection name for the channel.

For cluster-receiver channels (when specified) CONNAME relates to the local queue manager, and for other channels it relates to the target queue manager. The value you specify depends on the transmission protocol (*TransportType*) to be used:

- For MQXPT_LU62, it is the fully-qualified name of the partner Logical Unit.
- For MQXPT_NETBIOS, it is the NetBIOS name defined on the remote machine.
- For MQXPT_TCP, it is either the host name, the network address of the remote machine specified in IPv4 dotted decimal or IPv6 hexadecimal format, or the local machine for cluster-receiver channels.
- For MQXPT_SPX, it is an SPX-style address comprising a 4 byte network address, a 6 byte node address, and a 2 byte socket number.

When defining a channel, this field is not relevant for channels with a *ChannelType* of MQCHT_SVRCONN or MQCHT_RECEIVER. However, when the channel definition is passed to an exit, this field contains the address of the partner, whatever the channel type.

The length of this field is given by MQ_CONN_NAME_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_2.

DataConversion (MQLONG)

This field specifies whether the sending message channel agent attempts conversion of the application message data if the receiving message channel agent is unable to perform this conversion.

This field applies only to messages that are not segments of logical messages; the MCA never attempts to convert messages which are segments.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR. It is one of the following:

MQCDC_SENDER_CONVERSION

Conversion by sender.

MQCDC_NO_SENDER_CONVERSION

No conversion by sender.

DefReconnect (MQLONG)

The DefReconnect channel attribute sets the default reconnection attribute value for a client connection channel.

The default automatic client reconnection option. You can configure a IBM MQ MQI client to automatically reconnect a client application. The IBM MQ MQI client tries to reconnect to a queue manager after a connection failure. It tries to reconnect without the application client issuing an MQCONN or MQCONNX MQI call.

Reconnection is an MQCONNX option. By using the DefReconnect channel attribute you can add reconnection behavior to existing applications that use MQCONN. You can also change the reconnection behavior of applications that use MQCONNX.

You can also set the DefRecon value from the mqclient.ini file to set or modify reconnection behavior. The DefRecon value from the mqclient.ini file takes precedence over the DefReconnect channel attribute.

Syntax

DefReconnect (MQRCN_NO | MQRCN_YES | MQRCN_Q_MGR |
MQRCN_DISABLED)

Parameters

MQRCN_NO

MQRCN_NO is the default value.

Unless overridden by MQCONNX, the client is not reconnected automatically.

MQRCN_YES

Unless overridden by MQCONNX, the client reconnects automatically.

MQRCN_Q_MGR

Unless overridden by MQCONNX, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO_RECONNECT_Q_MGR.

MQRCN_DISABLED

Reconnection is disabled, even if requested by the client program using the MQCONNX MQI call.

Automatic client reconnection is not supported by IBM MQ classes for Java.

Table 643. Automatic reconnection depends on the values set in the application and in the channel definition

DefReconnect	Reconnection options set in the application			
	MQCNO_RECONNE CT	MQCNO_RECONNE CT_Q_MGR	MQCNO_RECONNE CT_AS_DEF	MQCNO_RECONNE CT_DISABLED
MQRCN_NO	YES	QMGR	NO	NO
MQRCN_YES	YES	QMGR	YES	NO
MQRCN_Q_MGR	YES	QMGR	QMGR	NO
MQRCN_DISABLED	NO	NO	NO	NO

[Connection options](#)

Options that control the action of MQCONNX.

Desc (MQCHAR64)

This field can be used for descriptive commentary.

The content of the field is of no significance to Message Channel Agents. However, it must contain only characters that can be displayed. It cannot contain any null characters; if necessary, it is padded to the right with blanks. In a DBCS installation, the field can contain DBCS characters (subject to a maximum field length of 64 bytes).

Note: If this field contains characters that are not in the character set of the queue manager (as defined by the *CodedCharSetId* queue manager attribute), those characters might be translated incorrectly if this field is sent to another queue manager.

The length of this field is given by MQ_CHANNEL_DESC_LENGTH.

DiscInterval (MQLONG)

This field specifies the maximum time in seconds for which the channel waits for a message to arrive on the transmission queue, before terminating the channel.

In other words, it specifies the disconnect interval.

The A value of zero causes the MCA to wait indefinitely.

For server-connection channels using the TCP protocol, the interval represents the client inactivity disconnect value, specified in seconds. If a server-connection has received no communication from its partner client for this duration, it terminates the connection. The server-connection inactivity interval only applies between IBM MQ API calls from a client, so no client is disconnected during a long-running MQGET with wait call.

This attribute is not applicable for server-connection channels using protocols other than TCP.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, MQCHT_CLUSRCVR, or MQCHT_SVRCONN.

ExitDataLength (MQLONG)

This field specifies length in bytes of each of the user data items in the lists of exit user data items addressed by the *MsgUserDataPtr*, *SendUserDataPtr*, and *ReceiveUserDataPtr* fields.

This length is not necessarily the same as MQ_EXIT_DATA_LENGTH.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

ExitNameLength (MQLONG)

This field specifies the length in bytes of each of the names in the lists of exit names addressed by the *MsgExitPtr*, *SendExitPtr*, and *ReceiveExitPtr* fields.

This length is not necessarily the same as MQ_EXIT_NAME_LENGTH.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

HdrCompList [2] (MQLONG)

This field specifies the list of header data compression techniques which are supported by the channel.

The list contains one or more of the following values:

MQCOMPRESS_NONE

No header data compression is performed.

MQCOMPRESS_SYSTEM

Header data compression is performed.

MQCOMPRESS_NOT_AVAILABLE

Unused values in the list are set to this value.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_8.

HeartbeatInterval (MQLONG)

This field specifies the time in seconds between heartbeat flows.

The interpretation of this field depends on the channel type, as follows:

- For a channel type of MQCHT_SENDER, MQCHT_SERVER, MQCHT_RECEIVER, MQCHT_REQUESTER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR, this field is the time in seconds between heartbeat flows passed from the sending MCA when there are no messages on the transmission queue. This gives the receiving MCA the opportunity to quiesce the channel. To be useful, *HeartbeatInterval* must be less than *DiscInterval*.
- For a channel type of MQCHT_CLNTCONN or MQCHT_SVRCONN with the MQCD Sharing Conversations field set to zero, this field is the time in seconds between heartbeat flows passed from the server MCA when that MCA has issued an MQGET call with the MQGMO_WAIT option on behalf of a client application. This allows the server MCA to handle situations where the client connection fails during an MQGET with MQGMO_WAIT.
- For a channel type of MQCHT_CLNTCONN or MQCHT_SVRCONN with the MQCD Sharing Conversations field set to a non-zero value, this field is the time in seconds between heartbeat flow when there are no data flows sent or received. This allows the channel to be quiesced efficiently.

The value is in the range 0 through 999 999. The value that is used is the larger of the values specified at the sending side and receiving side unless a value of 0 is specified at either side, in which case no heartbeat exchange occurs.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

KeepAliveInterval (MQLONG)

This field specifies the value passed to the communications stack for keepalive timing for the channel.

The value is applicable for the TCP/IP and SPX communications protocols, though not all implementations support this parameter.

The value is in the range 0 through 99 999; the units are seconds. A value of zero indicates that channel keepalive is not enabled, although keepalive might still occur if TCP/IP keepalive (rather than channel keepalive) is enabled. The following special value is also valid:

MQKAI_AUTO

Automatic.

This value indicates that the keepalive interval is calculated from the negotiated heartbeat interval, as follows:

- If the negotiated heartbeat interval is greater than zero, the keepalive interval that is used is the heartbeat interval plus 60 seconds.
- If the negotiated heartbeat interval is zero, the keepalive interval that is used is zero.
- On z/OS, TCP/IP keepalive occurs when TCPKEEP(YES) is specified on the queue manager object.
- In other environments, TCP/IP keepalive occurs when the KEEPALIVE=YES parameter is specified in the TCP stanza in the distributed queuing configuration file.

This field is relevant only for channels that have a *TransportType* of MQXPT_TCP or MQXPT_SPX.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_7.

LocalAddress (MQCHAR48)

This field specifies the local TCP/IP address defined for the channel for outbound communications.

This field is blank if no specific address is defined for outbound communications. The address can optionally include a port number or range of port numbers. The format of this address is:

```
[ip-addr] [(low-port[,high-port])]
```

where square brackets ([]) denote optional information, ip-addr is specified in IPv4 dotted decimal, IPv6 hexadecimal, or alphanumeric form, and low-port and high-port are port numbers enclosed in parentheses. All are optional.

A specific IP address, port, or port range for outbound communications is useful in recovery scenarios where a channel is restarted on a different TCP/IP stack.

LocalAddress is similar in form to *ConnectionName*, but must not be confused with it. *LocalAddress* specifies the characteristics of the local communications, whereas *ConnectionName* specifies how to reach a remote queue manager.

This field is relevant only for channels with a *TransportType* of MQXPT_TCP, and a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_REQUESTER, MQCHT_CLNTCONN, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

The length of this field is given by MQ_LOCAL_ADDRESS_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_7.

LongMCAUserIdLength (MQLONG)

This field specifies the length in bytes of the full MCA user identifier pointed to by *LongMCAUserIdPtr*.

This field is not relevant for channels with a *ChannelType* of MQCHT_CLNTCONN.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCD_VERSION_6.

LongMCAUserIdPtr (MQPTR)

This field specifies the address of the long MCA user identifier.

If *LongMCAUserIdLength* is greater than zero, this field is the address of the full MCA user identifier. The length of the full identifier is given by *LongMCAUserIdLength*. The first 12 bytes of the MCA user identifier are also contained in the field *MCAUserIdentifier*.

See the description of the *MCAUserIdentifier* field for details of the MCA user identifier.

This field is not relevant for channels with a *ChannelType* of MQCHT_SDR, MQCHT_SVR, MQCHT_CLNTCONN, or MQCHT_CLUSSDR.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCD_VERSION_6.

LongRemoteUserIdLength (MQLONG)

This field specifies the length in bytes of the full remote user identifier pointed to by *LongRemoteUserIdPtr*.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLNTCONN or MQCHT_SVRCONN.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_6.

LongRemoteUserIdPtr (MQPTR)

This field specifies the address of the long remote user identifier.

If *LongRemoteUserIdLength* is greater than zero, this flag is the address of the full remote user identifier. The length of the full identifier is given by *LongRemoteUserIdLength*. The first 12 bytes of the remote user identifier are also contained in the field *RemoteUserIdentifier*.

See the description of the *RemoteUserIdentifier* field for details of the remote user identifier.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLNTCONN or MQCHT_SVRCONN.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_6.

LongRetryCount (MQLONG)

This field specifies the count used after the count specified by the *ShortRetryCount* has been exhausted.

It specifies the maximum number of further attempts that are made to connect to the remote machine, at intervals specified by *LongRetryInterval*, before logging an error to the operator.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

LongRetryInterval (MQLONG)

This field specifies the maximum number of seconds to wait before reattempting connection to the remote machine.

The interval between retries can be extended if the channel has to wait to become active.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

MaxInstances (MQLONG)

This field specifies the maximum number of simultaneous instances of an individual server-connection channel that can be started.

This field is used only on server-connection channels.

The field can have a value in the range 0 - 999 999 999. A value of zero prevents all client access.

The default value of this field is 999 999 999.

If the value of this field is reduced to a number that is less than the number of instances of the server-connection channel that are currently running, then those running instances are not affected. However, new instances cannot start until sufficient existing instances have ceased to run so that the number of currently running instances is less than the value of the field.

MaxInstancesPerClient (MQLONG)

This field specifies the maximum number of simultaneous instances of an individual server-connection channel that can be started from a single client.

In this context, connections that originate from the same remote network address are regarded as coming from the same client.

This field is used only on server-connection channels.

The field can have a value in the range 0 - 999 999 999. A value of zero prevents all client access.

The default value of this field is 999 999 999.

If the value of this field is reduced to a number that is less than the number of instances of the server-connection channel that are currently running from individual clients, then those running instances are not affected. However, new instances from any of those clients cannot start until sufficient existing instances have ceased to run such that the number of currently running instances, originating from the client attempting to start a new one, is less than the value of the field.

MaxMsgLength (MQLONG)

This field specifies the maximum message length that can be transmitted on the channel.

This is compared with the value for the remote channel and the actual maximum is the lower of the two values.

MCAName (MQCHAR20)

This field is a reserved field.

The value of this field is blank.

The length of this field is given by MQ_MCA_NAME_LENGTH.

MCASecurityId (MQBYTE40)

This field specifies the security identifier for the MCA.

This field is not relevant for channels with a *ChannelType* of MQCHT_CLNTCONN.

The following special value indicates that there is no security identifier:

MQSID_NONE

No security identifier specified.

The value is binary zero for the length of the field.

For the C programming language, the constant MQSID_NONE_ARRAY is also defined; this constant has the same value as MQSID_NONE, but is an array of characters instead of a string.

This is an input/output field to the exit. The length of this field is given by MQ_SECURITY_ID_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_6.

MCAType (MQLONG)

This field specifies the type of message channel agent program.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_REQUESTER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

The value is one of the following:

MQMCAT_PROCESS

Process.

The message channel agent runs as a separate process.

MQMCAT_THREAD

Thread (IBM i, UNIX, and Windows).

The message channel agent runs as a separate thread.

This field is not present when *Version* is less than MQCD_VERSION_2.

MCAUserIdentifier (MQCHAR12)

This field specifies the user identifier for the message channel agent (MCA).

This field uses the first 12 bytes of the MCA user identifier, and can be set by a security agent.

There are two fields that contain the MCA user identifier:

- *MCAUserIdentifier* contains the first 12 bytes of the MCA user identifier, and is padded with blanks if the identifier is shorter than 12 bytes. *MCAUserIdentifier* can be blank.
- *LongMCAUserIdPtr* points to the full MCA user identifier, which can be longer than 12 bytes. Its length is given by *LongMCAUserIdLength*. The full identifier contains no trailing blanks, and is not null-terminated. If the identifier is blank, *LongMCAUserIdLength* is zero, and the value of *LongMCAUserIdPtr* is undefined.

Note: *LongMCAUserIdPtr* is not present if *Version* is less than MQCD_VERSION_6.

If the MCA user identifier is nonblank, it specifies the user identifier to be used by the message channel agent for authorization to access IBM MQ resources. For channel types MQCHT_REQUESTER, MQCHT_RECEIVER, and MQCHT_CLUSRCVR, if PutAuthority is MQPA_DEFAULT this is the user identifier used for authorization checks for the put operation to destination queues.

If the MCA user identifier is blank, the message channel agent uses its default user identifier.

The MCA user identifier can be set by a security exit to indicate the user identifier that the message channel agent must use. The exit can change either *MCAUserIdentifier*, or the string pointed at by *LongMCAUserIdPtr*. If both are changed but differ from each other, the MCA uses *LongMCAUserIdPtr* in preference to *MCAUserIdentifier*. If the exit changes the length of the string addressed by *LongMCAUserIdPtr*, *LongMCAUserIdLength* must be set correspondingly. If the exit increases the length of the identifier, the exit must allocate storage of the required length, set that storage to the required identifier, and place the address of that storage in *LongMCAUserIdPtr*. The exit is responsible for freeing that storage when the exit is later invoked with the MQXR_TERM reason.

For channels with a *ChannelType* of MQCHT_SVRCONN, if *MCAUserIdentifier* in the channel definition is blank, any user identifier transferred from the client is copied into it. This user identifier (after any modification by the security exit at the server) is the one which the client application is assumed to be running under.

The MCA user identifier is not relevant for channels with a *ChannelType* of MQCHT_SDR, MQCHT_SVR, MQCHT_CLNTCONN, MQCHT_CLUSSDR.

This is an input/output field to the exit. The length of this field is given by MQ_USER_ID_LENGTH. This field is not present when *Version* is less than MQCD_VERSION_2.

ModeName (MQCHAR8)

This field specifies the LU 6.2 mode name.

This field is relevant only if the transmission protocol (*TransportType*) is MQXPT_LU62, and the *ChannelType* is not MQCHT_SVRCONN or MQCHT_RECEIVER.

This field is always blank. The information is contained in the communications Side Object instead.

The length of this field is given by MQ_MODE_NAME_LENGTH.

MsgCompList [16] (MQLONG)

This field specifies the list of message data compression techniques which are supported by the channel.

The list contains one or more of the following values:

MQCOMPRESS_NONE

No message data compression is performed.

MQCOMPRESS_RLE

Message data compression is performed using run-length encoding.

MQCOMPRESS_ZLIBFAST

Message data compression is performed using the zlib compression technique. A fast compression time is preferred.

MQCOMPRESS_ZLIBHIGH

Message data compression is performed using the zlib compression technique. A high level of compression is preferred.

MQCOMPRESS_ANY

Any compression technique supported by the queue manager can be used for message compression. MQCOMPRESS_ANY is only valid for receiver, requester, and server-connection channels.

MQCOMPRESS_NOT_AVAILABLE

Unused values in the list are set to this value.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_8.

MsgExit (MQCHARn)

This field specifies the channel message exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after a message has been retrieved from the transmission queue (sender or server), or immediately before a message is put to a destination queue (receiver or requester).

The exit is given the entire application message and transmission queue header for modification.

- At initialization and termination of the channel.

This field is not relevant for channels with a *ChannelType* of MQCHT_SVRCONN or MQCHT_CLNTCONN; a message exit is never invoked for such channels.

See “MQCD - Channel definition” on page 1487 for a description of the content of this field in various environments.

The length of this field is given by MQ_EXIT_NAME_LENGTH.

Note: The value of this constant is environment-specific.

MsgExitPtr (MQPTR)

This field specifies the address of the first *MsgExit* field.

If *MsgExitsDefined* is greater than zero, this address is the address of the list of names of each channel message exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message channel exit takes no explicit action - it does not change which exits are invoked.

If *MsgExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

MsgExitsDefined (MQLONG)

This field specifies the number of channel message exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

MsgRetryCount (MQLONG)

This field specifies the number of times MCA tries to put the message, after the first attempt has failed.

This field indicates the number of times that the MCA tries the open or put operation, if the first MQOPEN or MQPUT fails with completion code MQCC_FAILED. The effect of this attribute depends on whether *MsgRetryExit* is blank or nonblank:

- If *MsgRetryExit* is blank, the *MsgRetryCount* attribute controls whether the MCA attempts retries. If the attribute value is zero, no retries are attempted. If the attribute value is greater than zero, the retries are attempted at intervals given by the *MsgRetryInterval* attribute.

Retries are attempted only for the following reason codes:

- MQRC_PAGESET_FULL
- MQRC_PUT_INHIBITED
- MQRC_Q_FULL

For other reason codes, the MCA proceeds immediately to its normal failure processing, without retrying the failing message.

- If *MsgRetryExit* is nonblank, the *MsgRetryCount* attribute does not affect the MCA; instead it is the message-retry exit which determines how many times the retry is attempted, and at what intervals; the exit is invoked even if the *MsgRetryCount* attribute is zero.

The *MsgRetryCount* attribute is made available to the exit in the MQCD structure, but the exit is not required to honor it - retries continue indefinitely until the exit returns MQXCC_SUPPRESS_FUNCTION in the *ExitResponse* field of MQCXP.

This field is relevant only for channels with a *ChannelType* of MQCHT_REQUESTER, MQCHT_RECEIVER, or MQCHT_CLUSRCVR.

This field is not present when *Version* is less than MQCD_VERSION_3.

MsgRetryExit (MQCHARn)

This field specifies the channel message retry exit name.

The message retry exit is an exit that is invoked by the MCA when the MCA receives a completion code of MQCC_FAILED from an MQOPEN or MQPUT call. The purpose of the exit is to specify a time interval for which the MCA waits before trying the MQOPEN or MQPUT operation again. Alternatively, the exit can be set to not try the operation again.

The exit is invoked for all reason codes that have a completion code of MQCC_FAILED - the settings of the exit determine which reason codes it wants the MCA to try again, for how many attempts, and at what time intervals.

When the operation is not to be attempted any more, the MCA performs its normal failure processing; this processing includes generating an exception report message (if specified by the sender), and either placing the original message on the dead-letter queue or discarding the message (according to whether the sender specified MQRO_DEAD_LETTER_Q or MQRO_DISCARD_MSG). Failures involving the dead-letter queue (for example, dead-letter queue full) do not cause the message-retry exit to be invoked.

If the exit name is nonblank, the exit is called at the following times:

- Immediately before performing the wait before trying to deliver a message again
- At initialization and termination of the channel

See “MQCD - Channel definition” on page 1487 for a description of the content of this field in various environments.

This field is relevant only for channels with a *ChannelType* of MQCHT_REQUESTER, MQCHT_RECEIVER, or MQCHT_CLUSRCVR.

The length of this field is given by MQ_EXIT_NAME_LENGTH.

Note: The value of this constant is environment-specific.

This field is not present when *Version* is less than MQCD_VERSION_3.

MsgRetryInterval (MQLONG)

This field specifies the minimum interval in milliseconds after which the open or put operation is retried.

The effect of this attribute depends on whether *MsgRetryExit* is blank or nonblank:

- If *MsgRetryExit* is blank, the *MsgRetryInterval* attribute specifies the minimum period that the MCA waits before retrying a message, if the first MQOPEN or MQPUT fails with completion code MQCC_FAILED. A value of zero means that the retry will be performed as soon as possible after the previous attempt. Retries are performed only if *MsgRetryCount* is greater than zero.

This attribute is also used as the wait time if the message-retry exit returns an invalid value in the *MsgRetryInterval* field in MQCXP.

- If *MsgRetryExit* is not blank, the *MsgRetryInterval* attribute does not affect the MCA; instead it is the message-retry exit which determines how long the MCA waits. The *MsgRetryInterval* attribute is made available to the exit in the MQCD structure, but the exit is not required to honor it.

The value is in the range 0 through 999 999 999.

This field is relevant only for channels with a *ChannelType* of MQCHT_REQUESTER, MQCHT_RECEIVER, or MQCHT_CLUSRCVR.

This field is not present when *Version* is less than MQCD_VERSION_3.

The following fields in this structure are not present if *Version* is less than MQCD_VERSION_4.

MsgRetryUserData (MQCHAR32)

This field specifies the channel message retry exit user data.

This data is passed to the channel message-retry exit in the *ExitData* field of the *ChannelExitParms* parameter (see MQ_CHANNEL_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

This field is relevant only for channels with a *ChannelType* of MQCHT_REQUESTER, MQCHT_RECEIVER, or MQCHT_CLUSRCVR.

The length of this field is given by MQ_EXIT_DATA_LENGTH. This field is not present when *Version* is less than MQCD_VERSION_3.

This field is not relevant in IBM MQ for IBM i.

MsgUserData (MQCHAR32)

This field specifies channel message exit user data.

This data is passed to the channel message exit in the *ExitData* field of the *ChannelExitParms* parameter (see MQ_CHANNEL_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

This field is not relevant in IBM MQ for IBM i.

MsgUserDataPtr (MQPTR)

This field specifies the address of the first *MsgUserData* field.

If *MsgExitsDefined* is greater than zero, this address is the address of the list of user data items for each channel message exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *MsgExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

NetworkPriority (MQLONG)

This field specifies the priority of the network connection for the channel.

When multiple paths to a particular destination are available, the path with the highest priority is chosen. The value is in the range 0 through 9; 0 is the lowest priority.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLUSSDR or MQCHT_CLUSRCVR.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_5.

The following fields in this structure are not present if *Version* is less than MQCD_VERSION_6.

NonPersistentMsgSpeed (MQLONG)

This field specifies the speed at which nonpersistent messages travel through the channel.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_RECEIVER, MQCHT_REQUESTER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

The value is one of the following:

MQNPMS_NORMAL

Normal speed.

If a channel is defined to be MQNPMS_NORMAL, nonpersistent messages travel through the channel at normal speed. This has the advantage that these messages are not lost if there is a channel failure. Also, persistent and nonpersistent messages on the same transmission queue maintain their order relative to each other.

MQNPMS_FAST

Fast speed.

If a channel is defined to be MQNPMS_FAST, nonpersistent messages travel through the channel at fast speed. This improves the throughput of the channel, but means that nonpersistent messages are lost if there is a channel failure. Also, it is possible for nonpersistent messages to jump ahead of persistent messages waiting on the same transmission queue, that is, the order of nonpersistent messages is not maintained relative to persistent messages. However the order of nonpersistent messages relative to each other is maintained. Similarly, the order of persistent messages relative to each other is maintained.

Password (MQCHAR12)

This field specifies the password used by the message channel agent when attempting to initiate a secure SNA session with a remote message channel agent.

This field can be nonblank only on UNIX systems, and Windows, and is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_REQUESTER, or MQCHT_CLNTCONN. On z/OS, this field is not relevant.

The length of this field is given by MQ_PASSWORD_LENGTH. However, only the first 10 characters are used.

This field is not present if *Version* is less than MQCD_VERSION_2.

PropertyControl (MQLONG)

This field specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

The value can be any of the following values:

MQPROP_COMPATIBILITY

If the message contains a property with a prefix of **mcd.**, **jms.**, **usr.**, or **mqext.**, all message properties are delivered to the application in an MQRFH2 header. Otherwise all properties of the message, except those properties contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

This value is the default value; it allows applications, which expect JMS-related properties to be in an MQRFH2 header in the message data, to continue to work unmodified.

MQPROP_NONE

All properties of the message, except those properties in the message descriptor (or extension), are removed from the message before the message is sent to the remote queue manager.

MQPROP_ALL

All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

This attribute is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

[“MQIA_* \(Integer Attribute Selectors\)” on page 125](#)

[“MQPROP_* \(Queue and Channel Property Control Values and Maximum Properties Length\)” on page 165](#)

PutAuthority (MQLONG)

This field specifies whether the user identifier in the context information associated with a message is used to establish authority to put the message to the destination queue.

This field is relevant only for channels with a *ChannelType* of MQCHT_REQUESTER, MQCHT_RECEIVER, or MQCHT_CLUSRCVR. It is one of the following:

MQPA_DEFAULT

Default user identifier is used.

MQPA_CONTEXT

Context user identifier is used.

MQPA_ALTERNATE_OR_MCA

The user ID from the UserIdentifier field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

MQPA_ONLY_MCA

The default user ID is used. Any user ID received from the network is not used. This value is supported only on z/OS.

QMgrName (MQCHAR48)

This field specifies the name of the queue manager that an exit can connect to.

For channels with a *ChannelType* other than MQCHT_CLNTCONN, this field is the name of the queue manager that an exit can connect to, which on UNIX, Linux and Windows systems, is always nonblank.

The length of this field is given by MQ_Q_MGR_NAME_LENGTH.

ReceiveExit (MQCHARn)

This field specifies the channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.

The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

See [“MQCD - Channel definition” on page 1487](#) for a description of the content of this field in various environments.

The length of this field is given by MQ_EXIT_NAME_LENGTH.

Note: The value of this constant is environment-specific.

ReceiveExitPtr (MQPTR)

This field specifies the address of the first *ReceiveExit* field.

If *ReceiveExitsDefined* is greater than zero, this address is the address of the list of names of each channel receive exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *ReceiveExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message channel exit takes no explicit action - it does not change which exits are invoked.

If *ReceiveExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

ReceiveExitsDefined (MQLONG)

This field specifies the number of channel receive exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

ReceiveUserData (MQCHAR32)

This channel specifies channel receive exit user data.

This data is passed to the channel receive exit in the *ExitData* field of the *ChannelExitParms* parameter (see MQ_CHANNEL_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

This field is not relevant in IBM MQ for IBM i.

The following fields in this structure are not present if *Version* is less than MQCD_VERSION_2.

ReceiveUserDataPtr (MQPTR)

This field specifies the address of the first *ReceiveUserData* field.

If *ReceiveExitsDefined* is greater than zero, this address is the address of the list of user data item for each channel receive exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *ReceiveExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *ReceiveExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

The following fields in this structure are not present if *Version* is less than MQCD_VERSION_5.

RemotePassword (MQCHAR12)

This field specifies the password from a partner.

This field contains valid information only if *ChannelType* is MQCHT_CLNTCONN or MQCHT_SVRCONN.

- For a security exit at an MQCHT_CLNTCONN channel, this password is a password which has been obtained from the environment. The exit can choose to send it to the security exit at the server.
- For a security exit at an MQCHT_SVRCONN channel, this field might contain a password which has been obtained from the environment at the client, if there is no client security exit. The exit can use this password to validate the user identifier in *RemoteUserIdentifier*.

If there is a security exit at the client, then this information can be obtained in a security flow from the client.

The length of this field is given by MQ_PASSWORD_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_2.

RemoteSecurityId (MQBYTE40)

This field specifies the security identifier for the remote user.

This field is relevant only for channels with a *ChannelType* of MQCHT_CLNTCONN or MQCHT_SVRCONN.

The following special value indicates that there is no security identifier:

MQSID_NONE

No security identifier specified.

The value is binary zero for the length of the field.

For the C programming language, the constant MQSID_NONE_ARRAY is also defined; this constant has the same value as MQSID_NONE, but is an array of characters instead of a string.

This is an input field to the exit. The length of this field is given by MQ_SECURITY_ID_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_6.

The following fields in this structure are not present if *Version* is less than MQCD_VERSION_7.

RemoteUserIdentifier (MQCHAR12)

This field specifies the first 12 bytes of a user identifier from a partner.

There are two fields that contain the remote user identifier:

- *RemoteUserIdentifier* contains the first 12 bytes of the remote user identifier, and is padded with blanks if the identifier is shorter than 12 bytes. *RemoteUserIdentifier* can be blank.
- *LongRemoteUserIdPtr* points to the full remote user identifier, which can be longer than 12 bytes. Its length is given by *LongRemoteUserIdLength*. The full identifier contains no trailing blanks, and is not null-terminated. If the identifier is blank, *LongRemoteUserIdLength* is zero, and the value of *LongRemoteUserIdPtr* is undefined.

LongRemoteUserIdPtr is not present if *Version* is less than MQCD_VERSION_6.

The remote user identifier is relevant only for channels with a *ChannelType* of MQCHT_CLNTCONN or MQCHT_SVRCONN.

- For a security exit on an MQCHT_CLNTCONN channel, this value is a user identifier that has been obtained from the environment. The exit can choose to send it to the security exit at the server.
- For a security exit on an MQCHT_SVRCONN channel, this field might contain a user identifier which has been obtained from the environment at the client, if there is no client security exit. The exit might validate this user ID (possibly with the password in *RemotePassword*) and update the value in *MCAUserIdentifier*.

If there is a security exit at the client, then this information can be obtained in a security flow from the client.

The length of this field is given by MQ_USER_ID_LENGTH. This field is not present if *Version* is less than MQCD_VERSION_2.

SecurityExit (MQCHARn)

This field specifies the channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.

Before any messages are transferred, the exit is given the opportunity to instigate security flows to validate connection authorization.

- Upon receipt of a response to a security message flow.

Any security message flows received from the remote processor on the remote machine are given to the exit.

- At initialization and termination of the channel.

See [“MQCD - Channel definition” on page 1487](#) for a description of the content of this field in various environments.

The length of this field is given by MQ_EXIT_NAME_LENGTH.

Note: The value of this constant is environment-specific.

SecurityUserData (MQCHAR32)

This channel specifies the channel security exit user data.

This data is passed to the channel security exit in the *ExitData* field of the *ChannelExitParms* parameter (see MQ_CHANNEL_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not effect on the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

This field is not relevant in IBM MQ for IBM i.

SendExit (MQCHARn)

This field specifies the channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

See [“MQCD - Channel definition” on page 1487](#) for a description of the content of this field in various environments.

The length of this field is given by MQ_EXIT_NAME_LENGTH.

Note: The value of this constant is environment-specific.

SendExitPtr (MQPTR)

This field specifies the address of the first *SendExit* field.

If *SendExitsDefined* is greater than zero, this address is the address of the list of names of each channel send exit in the chain.

Each name is in a field of length *ExitNameLength*, padded to the right with blanks. There are *SendExitsDefined* fields adjoining one another - one for each exit.

Any changes made to these names by an exit are preserved, although the message send exit takes no explicit action - it does not change which exits are invoked.

If *SendExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

SendExitsDefined (MQLONG)

This field specifies the number of channel send exits defined in the chain.

It is greater than or equal to zero.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

SendUserData (MQCHAR32)

This field specifies the channel send exit user data.

This data is passed to the channel send exit in the *ExitData* field of the *ChannelExitParms* parameter (see MQ_CHANNEL_EXIT).

This field initially contains the data that was set in the channel definition. However, during the lifetime of this MCA instance, any changes made to the contents of this field by an exit of any type are preserved by the MCA, and made visible to subsequent invocations of exits (regardless of type) for this MCA instance. This applies to exits on different conversations. Such changes do not affect the channel definition used by other MCA instances. Any characters (including binary data) can be used.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

This field is not relevant in IBM MQ for IBM i.

SendUserDataPtr (MQPTR)

This field specifies the address of the *SendUserData* field.

If *SendExitsDefined* is greater than zero, this address is the address of the list of user data items for each channel message exit in the chain.

Each user data item is in a field of length *ExitDataLength*, padded to the right with blanks. There are *MsgExitsDefined* fields adjoining one another - one for each exit. If the number of user data items defined is less than the number of exit names, undefined user data items are set to blanks. Conversely, if the number of user data items defined is greater than the number of exit names, the excess user data items are ignored and not presented to the exit.

Any changes made to these values by an exit are preserved. This allows one exit to pass information to another exit. No validation is carried out on any changes so, for example, binary data can be written to these fields if required.

If *SendExitsDefined* is zero, this field is the null pointer.

On platforms where the programming language does not support the pointer data type, this field is declared as a byte string of the appropriate length.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_4.

SeqNumberWrap (MQLONG)

This field specifies the highest allowable message sequence number.

When this value is reached, sequence numbers wrap to start again at 1.

This value is non-negotiable and must match in both the local and remote channel definitions.

This field is not relevant for channels with a *ChannelType* of MQCHT_SVRCONN or MQCHT_CLNTCONN.

SharingConversations (MQLONG)

This field specifies the maximum number of conversations that can share a channel instance associated with this channel.

This field is used on client connection and server-connection channels.

A value of 0 means that the channel operates as it did in versions earlier than IBM WebSphere MQ 7.0 with respect to the following attributes:

- Conversation sharing
- Read ahead
- STOP CHANNEL(<channelname>) MODE(QUIESCE)
- Heartbeating
- Client asynchronous consumption

A value of 1 is the minimum value for IBM MQ V7.0 behavior. Although only one conversation is allowed on the channel instance, read ahead, asynchronous consumption, and the Version 7 behavior of CLNTCONN - SVRCONN heartbeating and quiescent channel stopping are available.

This is an input field to the exit. It is not present if *Version* is less than MQCD_VERSION_9.

The default value of this field is 10.

Note: *MaxInstances* and *MaxInstancesPerClient* limits applied to a channel restrict the number of channel instances, not the number of conversations that might be sharing those instances.

ShortConnectionName (MQCHAR20)

This field specifies the first 20 bytes of a connection name.

If the *Version* field is MQCD_VERSION_1, *ShortConnectionName* contains the full connection name.

If the *Version* field is MQCD_VERSION_2 or greater, *ShortConnectionName* contains the first 20 characters of the connection name. The full connection name is given by the *ConnectionName* field; *ShortConnectionName* and the first 20 characters of *ConnectionName* are identical.

See *ConnectionName* for details of the contents of this field.

Note: The name of this field was changed for MQCD_VERSION_2 and subsequent versions of MQCD; the field was previously called *ConnectionName*.

The length of this field is given by MQ_SHORT_CONN_NAME_LENGTH.

ShortRetryCount (MQLONG)

This field specifies the maximum number of attempts that are made to connect to a remote machine.

This field is the maximum number of attempts that are made to connect to the remote machine, at intervals specified by *ShortRetryInterval*, before the (normally longer) *LongRetryCount* and *LongRetryInterval* are used.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

ShortRetryInterval (MQLONG)

This field specifies the maximum number of seconds to wait before reattempting connection to the remote machine.

The interval between retries might be extended if the channel has to wait to become active.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_CLUSSDR, or MQCHT_CLUSRCVR.

SSLCipherSpec (MQCHAR32)

This field specifies the Cipher Spec that is in use when using SSL.

If SSLCipherSpec is blank, the channel is not using SSL. If it is not blank, this field contains a string specifying the CipherSpec in use.

This parameter is valid for all channel types. It is supported on AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS. It is valid only for channel types of a transport type (TRPTYPE) of TCP.

This is an input field to the exit. The length of this field is given by MQ_SSL_CIPHER_SPEC_LENGTH. The field is not present if *Version* is less than MQCD_VERSION_7.

SSLClientAuth (MQLONG)

This field specifies whether SSL client authentication is required.

This field is relevant only to SVRCONN channel definitions.

It is one of the following values:

MQSCA_REQUIRED

Client authentication required.

MQSCA_OPTIONAL

Client authentication optional.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_7.

SSLPeerNameLength (MQLONG)

This field specifies the length in bytes of the SSL peer name pointed to by *SSLPeerNamePtr*.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_7.

SSLPeerNamePtr (MQPTR)

This field specifies the address of the SSL peer name.

When a certificate is received during a successful SSL handshake, the Distinguished Name of the subject of the certificate is copied into the MQCD field accessed by *SSLPeerNamePtr* at the end of the channel which receives the certificate. It overwrites the *SSLPeerName* value for the channel if this value is present in the channel definition of the local user. If a security exit is specified at this end of the channel it receives the Distinguished Name from the peer certificate in the MQCD.

This is an input field to the exit. The field is not present if *Version* is less than MQCD_VERSION_7.

Note: Security exit applications constructed prior to the release of IBM MQ v7.1 may require updating. For more information see [Channel security exit programs](#).

StrucLength (MQLONG)

This field specifies the length in bytes of the MQCD structure.

The length does not include any of the strings addressed by pointer fields contained within the structure. The value is one of the following:

MQCD_LENGTH_4

Length of version-4 channel definition structure.

MQCD_LENGTH_5

Length of version-5 channel definition structure.

MQCD_LENGTH_6

Length of version-6 channel definition structure.

MQCD_LENGTH_7

Length of version-7 channel definition structure.

MQCD_LENGTH_8

Length of version-8 channel definition structure.

MQCD_LENGTH_9

Length of version-9 channel definition structure.

The following constant specifies the length of the current version:

MQCD_CURRENT_LENGTH

Length of current version of channel definition structure.

Note: These constants have values that are environment-specific.

The field is not present if *Version* is less than MQCD_VERSION_4.

TpName (MQCHAR64)

This field specifies the LU 6.2 transaction program name.

This field is relevant only if the transmission protocol (*TransportType*) is MQXPT_LU62, and the *ChannelType* is not MQCHT_SVRCONN or MQCHT_RECEIVER.

This field is always blank on platforms on which the information is contained in the communications Side Object instead.

The length of this field is given by MQ_TP_NAME_LENGTH.

TransportType (MQLONG)

This field specifies the transmission protocol to be used.

The value is not checked if the channel was initiated from the other end.

It is one of the following values:

MQXPT_LU62

LU 6.2 transport protocol.

MQXPT_TCP

TCP/IP transport protocol.

MQXPT_NETBIOS

NetBIOS transport protocol.

This value is supported in the following environments: Windows.

MQXPT_SPX

SPX transport protocol.

This value is supported in the following environments: Windows, plus IBM MQ clients connected to these systems.

UseDLQ (MQLONG)

This field specifies whether the dead-letter queue (or undelivered message queue) is used when messages cannot be delivered by channels.

It can contain one of the following values:

MQUSEDLQ_NO

Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the NPMSPPEED setting.

MQUSEDLQ_YES

When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

UserIdentifier (MQCHAR12)

This field specifies the user identifier used by the message channel agent when attempting to initiate a secure SNA session with a remote message channel agent.

This field can be nonblank only on UNIX systems and Windows, and is relevant only for channels with a *ChannelType* of MQCHT_SENDER, MQCHT_SERVER, MQCHT_REQUESTER, or MQCHT_CLNTCONN. On z/OS, this field is not relevant.

The length of this field is given by MQ_USER_ID_LENGTH. However, only the first 10 characters are used.

This field is not present when *Version* is less than MQCD_VERSION_2.

Version (MQLONG)

The *Version* field specifies the highest version number that you can set for the structure.

The value depends on the environment:

MQCD _VERSION_1

Version 1 channel definition structure.

MQCD _VERSION_2

Version 2 channel definition structure.

MQCD _VERSION_3

Version 3 channel definition structure.

MQCD _VERSION_4

Version 4 channel definition structure.

MQCD _VERSION_5

Version 5 channel definition structure.

MQCD _VERSION_6

Version 6 channel definition structure.

MQCD _VERSION_7

Version 7 channel definition structure.

MQCD _VERSION_8

Version 8 channel definition structure.

MQCD _VERSION_9

Version 9 channel definition structure.

Version 9 is the highest that you can set the field to on IBM WebSphere MQ 7.0 and IBM WebSphere MQ 7.0.1 on all platforms.

MQCD _VERSION_10

Version 10 channel definition structure.

Version 10 is the highest that you can set the field to on IBM WebSphere MQ 7.1 and IBM WebSphere MQ 7.5 on all platforms.

MQCD _VERSION_11

Version 11 channel definition structure.

Version 11 is the highest that you can set the field to on IBM MQ 8.0 on all platforms.

Fields that exist only in the more recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

MQCD_CURRENT_VERSION

The value set in MQCD_CURRENT_VERSION is the current version of the channel definition structure being used.

The value of MQCD_CURRENT_VERSION depends on the environment. It contains the highest value supported by the platform.

MQCD_CURRENT_VERSION is not used to initialize the default structures provided in the header, copy, and include files provided for different programming languages. The default initialization of Version depends on the platform and release.

For IBM WebSphere MQ 7.0 and later versions, the MQCD declarations in the header, copy, and include files are initialized to MQCD_VERSION_6. To use additional MQCD fields, applications must set the version number to MQCD_CURRENT_VERSION. If you are writing an application that is portable between several environments, you must choose a version that is supported in all the environments.

Tip: When a new version of the MQCD structure is introduced, the layout of the existing part is not changed. The exit must check the version number. It must be equal to or greater than the lowest version that contains the fields that the exit needs to use.

XmitQName (MQCHAR48)

This field specifies the name of the transmission queue from which messages are retrieved.

This field is relevant only for channels with a *ChannelType* of MQCHT_SENDER or MQCHT_SERVER.

The length of this field is given by MQ_Q_NAME_LENGTH.

C declaration

This declaration is the C declaration for the MQCD structure.

```
typedef struct tagMQCD MQCD;
typedef MQCD MQPOINTER PMQCD;
typedef PMQCD MQPOINTER PPMQCD;

struct tagMQCD {
    MQCHAR    ChannelName[20];          /* Channel definition name */
    MQLONG    Version;                  /* Structure version number */

Changing MQCD fields in a channel exit

A channel exit can change fields in the MQCD. However, these changes are not typically acted on, except in the circumstances listed.

If a channel exit program changes a field in the MQCD data structure, the new value is typically ignored by the IBM MQ channel process. However, the new value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance.

If SharingConversations is set to FALSE in the MQCXP structure, changes to certain fields can be acted on, depending on the type of exit program, the type of channel, and the exit reason code. The following table shows the fields that can be changed and affect the behavior of the channel, and in what circumstances. If an exit program changes one of these fields in any other circumstances, or any field not listed, the new value is ignored by the channel process. The new value remains in the MQCD and is passed to any remaining exits in an exit chain and to any conversation sharing the channel instance.

Any type of exit program when called for initialization (MQXR_INIT) can change the ChannelName field of any type of channel, as long as MQCXP SharingConversations is set to FALSE. Only a security exit can change the MCAUserIdentifier field, regardless of the value of MQCXP SharingConversations.

Field	Exit Reason Code	Exit Type	Channel Type

MQCXP - Channel exit parameter

The MQCXP structure is passed to each type of exit called by a Message Channel Agent (MCA), client-connection channel, or server-connection channel.

See MQ_CHANNEL_EXIT.

The fields described as "input to the exit" in the descriptions that follow are ignored by the channel when the exit returns control to the channel. Any input fields that the exit changes in the channel exit parameter block will not be preserved for its next invocation. Changes made to input/output fields (for example, the *ExitUserArea* field), are preserved for invocations of that instance of the exit only. Such changes cannot be used to pass data between different exits defined on the same channel, or between the same exit defined on different channels.

Fields

This topic lists all the fields in the MQCXP structure and describes each field.

StrucId (MQCHAR4)

This field specifies the structure identifier.

The value must be:

MQCXP_STRUC_ID

Identifier for channel exit parameter structure.

For the C programming language, the constant MQCXP_STRUC_ID_ARRAY is also defined; this constant has the same value as MQCXP_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the exit.

Version (MQLONG)

This field specifies the structure version number.

The value depends on the environment:

MQCXP_VERSION_1

Version-1 channel exit parameter structure.

MQCXP_VERSION_2

Version-2 channel exit parameter structure.

The field has this value in the HP Integrity NonStop Server environment.

MQCXP_VERSION_3

Version-3 channel exit parameter structure.

The field has this value in the following environments: UNIX systems not listed elsewhere.

MQCXP_VERSION_4

Version-4 channel exit parameter structure.

MQCXP_VERSION_5

Version-5 channel exit parameter structure.

MQCXP_VERSION_6

Version-6 channel exit parameter structure.

MQCXP_VERSION_8

Version-8 channel exit parameter structure.

The field has this value in the following environments: z/OS, AIX, HP-UX, Linux, IBM i, Solaris, Windows.

Fields that exist only in the more-recent versions of the structure are identified as such in the descriptions of the fields. The following constant specifies the version number of the current version:

MQCXP_CURRENT_VERSION

Current version of channel exit parameter structure.

The value depends on the environment.

Note: When a new version of the MQCXP structure is introduced, the layout of the existing part is not changed. The exit must therefore check that the version number is equal to or greater than the lowest version which contains the fields that the exit needs to use.

This is an input field to the exit.

ExitId (MQLONG)

This field specifies the type of exit being called and is set on entry to the exit routine.

The following values are possible:

MQXT_CHANNEL_SEC_EXIT

Channel security exit.

MQXT_CHANNEL_MSG_EXIT

Channel message exit.

MQXT_CHANNEL_SEND_EXIT

Channel send exit.

MQXT_CHANNEL_RCV_EXIT

Channel receive exit.

MQXT_CHANNEL_MSG_RETRY_EXIT

Channel message-retry exit.

MQXT_CHANNEL_AUTO_DEF_EXIT

Channel auto-definition exit.

On z/OS, this type of exit is supported only for channels of type MQCHT_CLUSSDR and MQCHT_CLUSRCVR.

This is an input field to the exit.

ExitReason (MQLONG)

This field specifies the reason why the exit is being called and is set on entry to the exit routine.

It is not used by the auto-definition exit. The following values are possible:

MQXR_INIT

Exit initialization.

This value indicates that the exit is being invoked for the first time. It allows the exit to acquire and initialize any resources that it needs (for example: memory).

MQXR_TERM

Exit termination.

This value indicates that the exit is about to be terminated. The exit should free any resources that it has acquired since it was initialized (for example: memory).

MQXR_MSG

Process a message.

This value indicates that the exit is being invoked to process a message. This value occurs for channel message exits only.

MQXR_XMIT

Process a transmission.

This value occurs for channel send and receive exits only.

MQXR_SEC_MSG

Security message received.

This value occurs for channel security exits only.

MQXR_INIT_SEC

Initiate security exchange.

This value occurs for channel security exits only.

The security exit of the receiver is always invoked with this reason immediately after being invoked with MQXR_INIT, to give it the opportunity to initiate a security exchange. If it declines the opportunity (by returning MQXCC_OK instead of MQXCC_SEND_SEC_MSG or MQXCC_SEND_AND_REQUEST_SEC_MSG), the security exit of the sender is invoked with MQXR_INIT_SEC.

If the security exit of the receiver does initiate a security exchange (by returning MQXCC_SEND_SEC_MSG or MQXCC_SEND_AND_REQUEST_SEC_MSG), the security exit of the sender is never invoked with MQXR_INIT_SEC; instead it is invoked with MQXR_SEC_MSG to process the message of the receiver. (In either case it is first invoked with MQXR_INIT.)

Unless one of the security exits requests termination of the channel (by setting *ExitResponse* to MQXCC_SUPPRESS_FUNCTION or MQXCC_CLOSE_CHANNEL), the security exchange must complete at the side that initiated the exchange. Therefore, if a security exit is invoked with MQXR_INIT_SEC and it does initiate an exchange, the next time the exit is invoked it will be with MQXR_SEC_MSG. This happens whether there is a security message for the exit to process or not. There is a security message if the partner returns MQXCC_SEND_SEC_MSG or MQXCC_SEND_AND_REQUEST_SEC_MSG, but not if the partner returns MQXCC_OK or there is no security exit at the partner. If there is no

security message to process, the security exit at the initiating end is re-invoked with a *DataLength* of zero.

MQXR_RETRY

Retry a message.

This value occurs for message-retry exits only.

MQXR_AUTO_CLUSSDR

Automatic definition of a cluster-sender channel.

This value occurs for channel auto-definition exits only.

MQXR_AUTO_RECEIVER

Automatic definition of a receiver channel.

This value occurs for channel auto-definition exits only.

MQXR_AUTO_SVRCONN

Automatic definition of a server-connection channel.

This value occurs for channel auto-definition exits only.

MQXR_AUTO_CLUSRCVR

Automatic definition of a cluster-receiver channel.

This value occurs for channel auto-definition exits only.

MQXR_SEC_PARMS

Security parameters

This value applies to security exits only and indicates that an MQCSP structure is being passed to the exit. For more information, see [“MQCSP - Security parameters” on page 320](#)

Note:

1. If you have more than one exit defined for a channel, they are each invoked with MQXR_INIT when the MCA is initialized. Also, they are each invoked with MQXR_TERM when the MCA is terminated.
2. For the channel auto-definition exit, *ExitReason* is not set if *Version* is less than MQCXP_VERSION_4. The value MQXR_AUTO_SVRCONN is implied in this case.

This is an input field to the exit.

ExitResponse (MQLONG)

This field specifies the response from the exit.

This field is set by the exit to communicate with the MCA. It must be one of the following values:

MQXCC_OK

Exit completed successfully.

- For the channel security exit, this value indicates that message transfer can now proceed normally.
- For the channel message retry exit, this value indicates that the MCA must wait for the time interval returned by the exit in the *MsgRetryInterval* field in MQCXP, and then try the message again.

The *ExitResponse2* field might contain additional information.

MQXCC_SUPPRESS_FUNCTION

Suppress function.

- For the channel security exit, this value indicates that the channel must be terminated.
- For the channel message exit, this value indicates that the message is not to proceed any further towards its destination. Instead the MCA generates an exception report message (if one was requested by the sender of the original message), and places the message contained in the original buffer on the dead-letter queue (if the sender specified MQRO_DEAD_LETTER_Q), or discards it (if the sender specified MQRO_DISCARD_MSG).

For persistent messages, if the sender specified MQRO_DEAD_LETTER_Q, but the put to the dead-letter queue fails, or there is no dead-letter queue, the original message is left on the transmission queue and the report message is not generated. The original message is also left on the transmission queue if the report message cannot be generated successfully.

The *Feedback* field in the MQDLH structure at the start of the message on the dead-letter queue indicates why the message was put on the dead-letter queue; this feedback code is also used in the message descriptor of the exception report message (if one was requested by the sender).

- For the channel message retry exit, this value indicates that the MCA does not wait and try the message again; instead, the MCA continues immediately with its normal failure processing (the message is placed on the dead-letter queue or discarded, as specified by the sender of the message).
- For the channel auto-definition exit, either MQXCC_OK or MQXCC_SUPPRESS_FUNCTION must be specified. If neither of these values is specified, MQXCC_SUPPRESS_FUNCTION is assumed by default and the auto-definition is abandoned.

This response is not supported for the channel send and receive exits.

MQXCC_SEND_SEC_MSG

Send security message.

This value can be set only by a channel security exit. It indicates that the exit has provided a security message which must be transmitted to the partner.

MQXCC_SEND_AND_REQUEST_SEC_MSG

Send security message that requires a reply.

This value can be set only by a channel security exit. It indicates

- that the exit has provided a security message which can be transmitted to the partner, and
- that the exit requires a response from the partner. If no response is received, the channel must be terminated, because the exit has not yet decided whether communications can proceed.

MQXCC_SUPPRESS_EXIT

Suppress exit.

- This value can be set by all types of channel exit other than a security exit or an auto-definition exit. It suppresses any further invocation of that exit (as if its name had been blank in the channel definition), until termination of the channel, when the exit is again invoked with an *ExitReason* of MQXR_TERM.
- If a message retry exit returns this value, message retries for subsequent messages are controlled by the *MsgRetryCount* and *MsgRetryInterval* channel attributes as normal. For the current message, the MCA performs the number of outstanding retries, at intervals given by the *MsgRetryInterval* channel attribute, but only if the reason code is one that the MCA would normally retry (see the *MsgRetryCount* field described in “MQCD - Channel definition” on page 1487). The number of outstanding retries is the value of the *MsgRetryCount* attribute, less the number of times the exit returned MQXCC_OK for the current message; if this number is negative, no further retries are performed by the MCA for the current message.

MQXCC_CLOSE_CHANNEL

Close channel.

This value can be set by any type of channel exit except an auto-definition exit.

If sharing conversations is not enabled, this value closes the channel.

If sharing conversations is enabled, this value ends the conversation. If this conversation is the only conversation on the channel, the channel also closes.

This field is an input/output field from the exit.

ExitResponse2 (MQLONG)

This field specifies the secondary response from the exit.

This field is set to zero on entry to the exit routine. It can be set by the exit to provide further information to the IBM MQ channel functions. It is not used by the auto-definition exit.

The exit can set one or more of the following values. If more than one is required, the values are added. Combinations that are not valid are noted; other combinations are allowed.

MQXR2_PUT_WITH_DEF_ACTION

Put with default action.

This value is set by the channel message exit of the receiver. It indicates that the message is to be put with the default action of the MCA, that is either the default user ID of the MCA, or the context *UserIdentifier* in the MQMD (message descriptor) of the message.

The value is zero, which corresponds to the initial value set when the exit is invoked. The constant is provided for documentation purposes.

MQXR2_PUT_WITH_DEF_USERID

Put with default user identifier.

This value can only be set by the channel message exit of the receiver. It indicates that the message is to be put with the default user identifier of the MCA.

MQXR2_PUT_WITH_MSG_USERID

Put with user identifier of the message.

This value can only be set by the channel message exit of the receiver. It indicates that the message is to be put with the context *UserIdentifier* in the MQMD (message descriptor) of the message (this might have been modified by the exit).

Only one of MQXR2_PUT_WITH_DEF_ACTION, MQXR2_PUT_WITH_DEF_USERID, and MQXR2_PUT_WITH_MSG_USERID should be set.

MQXR2_USE_AGENT_BUFFER

Use agent buffer.

This value indicates that any data to be passed on is in *AgentBuffer*, not *ExitBufferAddr*.

The value is zero, which corresponds to the initial value set when the exit is invoked. The constant is provided for documentation purposes.

MQXR2_USE_EXIT_BUFFER

Use exit buffer.

This value indicates that any data to be passed on is in *ExitBufferAddr*, not *AgentBuffer*.

Only one of MQXR2_USE_AGENT_BUFFER and MQXR2_USE_EXIT_BUFFER should be set.

MQXR2_DEFAULT_CONTINUATION

Default continuation.

Continuation with the next exit in the chain depends on the response from the last exit invoked:

- If MQXCC_SUPPRESS_FUNCTION or MQXCC_CLOSE_CHANNEL are returned, no further exits in the chain are called.
- Otherwise, the next exit in the chain is invoked.

MQXR2_CONTINUE_CHAIN

Continue with the next exit.

MQXR2_SUPPRESS_CHAIN

Skip remaining exits in chain.

This is an input/output field to the exit.

Feedback (MQLONG)

This field specifies the feedback code.

This field is set to MQFB_NONE on entry to the exit routine.

If a channel message exit sets the *ExitResponse* field to MQXCC_SUPPRESS_FUNCTION, the *Feedback* field specifies the feedback code that identifies why the message was put on the dead-letter (undelivered-message) queue, and is also used to send an exception report if one has been requested. In this case, if the *Feedback* field is MQFB_NONE, the following feedback code is used:

MQFB_STOPPED_BY_MSG_EXIT

Message stopped by channel message exit.

The value returned in this field by channel security, send, receive, and message-retry exits is not used by the MCA.

The value returned in this field by auto-definition exits is not used if *ExitResponse* is MQXCC_OK, but otherwise is used for the *AuxErrorDataInt1* parameter in the event message.

This is an input/output field from the exit.

MaxSegmentLength (MQLONG)

This field specifies the maximum length in bytes that can be sent in a single transmission.

It is not used by the auto-definition exit. It is of interest to a channel send exit, because this exit must ensure that it does not increase the size of a transmission segment to a value greater than *MaxSegmentLength*. The length includes the initial 8 bytes that the exit must not change. The value is negotiated between the IBM MQ channel functions when the channel is initiated. See [Writing channel-exit programs](#) for more information about segment lengths.

The value in this field is not meaningful if *ExitReason* is MQXR_INIT.

This is an input field to the exit.

ExitUserArea (MQBYTE16)

This field specifies the exit user area - a field available for the exit to use.

It is initialized to binary zero before the first invocation of the exit (which has an *ExitReason* set to MQXR_INIT), and thereafter any changes made to this field by the exit are preserved across invocations of the exit.

The following value is defined:

MQXUA_NONE

No user information.

The value is binary zero for the length of the field.

For the C programming language, the constant MQXUA_NONE_ARRAY is also defined; this constant has the same value as MQXUA_NONE, but is an array of characters instead of a string.

The length of this field is given by MQ_EXIT_USER_AREA_LENGTH. This is an input/output field to the exit.

ExitData (MQCHAR32)

This field specifies the exit data.

This field is set on entry to the exit routine to information that IBM MQ channel functions took from the channel definition. If no such information is available, this field is all blanks.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

This is an input field to the exit.

The following fields in this structure are not present if *Version* is less than MQCXP_VERSION_2.

MsgRetryCount (MQLONG)

This field specifies the number of times the message has been retried.

The first time the exit is invoked for a particular message, this field has the value zero (no retries yet attempted). On each subsequent invocation of the exit for that message, the value is incremented by one by the MCA.

This is an input field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR_INIT. The field is not present if *Version* is less than MQCXP_VERSION_2.

MsgRetryInterval (MQLONG)

This field specifies the minimum interval in milliseconds after which the put operation is retried.

The first time the exit is invoked for a particular message, this field contains the value of the *MsgRetryInterval* channel attribute. The exit can leave the value unchanged, or modify it to specify a different time interval in milliseconds. If the exit returns MQXCC_OK in *ExitResponse*, the MCA waits for at least this time interval before retrying the MQOPEN or MQPUT operation. The time interval specified must be zero or greater.

The second and subsequent times the exit is invoked for that message, this field contains the value returned by the previous invocation of the exit.

If the value returned in the *MsgRetryInterval* field is less than zero or greater than 999 999 999, and *ExitResponse* is MQXCC_OK, the MCA ignores the *MsgRetryInterval* field in MQCXP and waits instead for the interval specified by the *MsgRetryInterval* channel attribute.

This is an input/output field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR_INIT. The field is not present if *Version* is less than MQCXP_VERSION_2.

MsgRetryReason (MQLONG)

This field specifies the reason code from the previous attempt to put the message.

This field is the reason code from the previous attempt to put the message; it is one of the MQRC_* values.

This is an input field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR_INIT. The field is not present if *Version* is less than MQCXP_VERSION_2.

The following fields in this structure are not present if *Version* is less than MQCXP_VERSION_3.

HeaderLength (MQLONG)

This field specifies the length of header information.

This field is relevant only for a message exit and a message-retry exit. The value is the length of the routing header structures at the start of the message data; these are the MQXQH structure, the MQMDE (message description extension header), and (for a distribution-list message) the MQDH structure and arrays of MQOR and MQPMR records that follow the MQXQH structure.

The message exit can examine this header information, and modify it if necessary, but the data that the exit returns must still be in the correct format. The exit must not, for example, encrypt or compress the header data at the sending end, even if the message exit at the receiving end makes compensating changes.

If the message exit modifies the header information in such a way as to change its length (for example, by adding another destination to a distribution-list message), it must change the value of *HeaderLength* correspondingly before returning.

This is an input/output field to the exit. The value in this field is not meaningful if *ExitReason* is MQXR_INIT. The field is not present if *Version* is less than MQCXP_VERSION_3.

PartnerName (MQCHAR48)

This field specifies the name of the partner.

The name of the partner, as follows:

- For SVRCONN channels, it is the logged-on user ID at the client.

- For all other types of channel, it is the queue-manager name of the partner.

When the exit is initialized this field is blank because the queue manager does not know the name of the partner until after initial negotiation has taken place.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_3.

FAPLevel (MQLONG)

Negotiated Formats and Protocols level.

This is an input field to the exit. Changes to this field should only be made under the direction of IBM service. The field is not present if *Version* is less than MQCXP_VERSION_3.

CapabilityFlags (MQLONG)

This field specifies the capability flags.

The following are defined:

MQCF_NONE

No flags.

MQCF_DIST_LISTS

Distribution lists supported.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_3.

ExitNumber (MQLONG)

This field specifies the ordinal number of the exit.

The ordinal number of the exit, within the type defined in *ExitId*. For example, if the exit being invoked is the third message exit defined, this field contains the value 3. If the exit type is one for which a list of exits cannot be defined (for example, a security exit), this field has the value 1.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_3.

The following fields in this structure are not present if *Version* is less than MQCXP_VERSION_5.

ExitSpace (MQLONG)

This field specifies the number of bytes in the transmission buffer reserved for the exit to use.

This field is relevant only for a send exit. It specifies the amount of space in bytes that the IBM MQ channel functions reserve in the transmission buffer for the exit to use. This field allows the exit to add to the transmission buffer a small amount of data (typically not exceeding a few hundred bytes) for use by a complementary receive exit at the other end. The data added by the send exit must be removed by the receive exit.

The value is always zero on z/OS.

Note: This facility must not be used to send large amounts of data, as it might degrade performance, or even inhibit operation of the channel.

By setting *ExitSpace* the exit is guaranteed that there is always at least that number of bytes available in the transmission buffer for the exit to use. However, the exit can use less than the amount reserved, or more than the amount reserved if there is space available in the transmission buffer. The exit space in the buffer is provided following the existing data.

ExitSpace can be set by the exit only when *ExitReason* has the value MQXR_INIT; in all other cases the value returned by the exit is ignored. On input to the exit, *ExitSpace* is zero for the MQXR_INIT call, and is the value returned by the MQXR_INIT call in other cases.

If the value returned by the MQXR_INIT call is negative, or there are fewer than 1024 bytes available in the transmission buffer for message data after reserving the requested exit space for all the send exits in the chain, the MCA outputs an error message and closes the channel. Similarly, if during data transfer the exits in the send exit chain allocate more user space than they reserved such that fewer than 1024 bytes remain in the transmission buffer for message data, the MCA outputs an error message and closes

the channel. The limit of 1024 allows the control and administrative flows of the channel to be processed by the chain of send exits, without the need for the flows to be segmented.

This is an input/output field to the exit if *ExitReason* is MQXR_INIT, and an input field in all other cases. The field is not present if *Version* is less than MQCXP_VERSION_5.

SSLCertUserId (MQCHAR12)

This field specifies the UserId associated with the remote certificate.

It is blank on all platforms except z/OS

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6.

SSLRemCertIssNameLength (MQLONG)

This field specifies the length in bytes of the full Distinguished Name of the issuer of the remote certificate pointed to by SSLCertRemoteIssuerNamePtr.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6. The value is zero if it is not an SSL channel.

SSLRemCertIssNamePtr (PMQVOID)

This field specifies the address of the full Distinguished Name of the issuer of the remote certificate.

Its value is the null pointer if it is not an SSL channel.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6.

Note: The behavior of channel security exits in determining the Subject Distinguished Name and the Issuer Distinguished Name has altered in the release of IBM MQ v7.1. For more information see [Channel security exit programs](#).

SecurityParms (PMQCSP)

This field specifies the address of the MQCSP structure used to specify a user ID and password.

The initial value of this field is the null pointer.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6.

The value in this field that is returned by the exit must be usable by IBM MQ until MQXR_TERM.

CurHdrCompression (MQLONG)

This field specifies which technique is currently being used to compress the header data.

It is set to one of the following:

MQCOMPRESS_NONE

No header data compression is performed.

MQCOMPRESS_SYSTEM

Header data compression is performed.

The value can be altered by a sending channel's message exit to one of the negotiated supported values accessed from the HdrCompList field of the MQCD. This enables the technique used to compress the header data to be chosen for each message based on the content of the message. The altered value is used for the current message only. The channel ends if the attribute is altered to an unsupported value. The value is ignored if altered outside a sending channel's message exit.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6.

CurMsgCompression (MQLONG)

This field specifies which technique is currently being used to compress the message data.

It is set to one of the following:

MQCOMPRESS_NONE

No header data compression is performed.

MQCOMPRESS_RLE

Message data compression is performed using run-length encoding.

MQCOMPRESS_ZLIBFAST

Message data compression is performed using the zlib compression technique. A fast compression time is preferred.

MQCOMPRESS_ZLIBHIGH

Message data compression is performed using the zlib compression technique. A high level of compression is preferred.

The value can be altered by a sending channel's message exit to one of the negotiated supported values accessed from the `MsgCompList` field of the MQCD. This enables the technique used to compress the message data to be decided for each message based on the content of the message. The altered value is used for the current message only. The channel ends if the attribute is altered to an unsupported value. The value is ignored if altered outside a sending channel's message exit.

This is an input/output field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_6.

Hconn (MQHCONN)

This field specifies the connection handle that the exit uses if it needs to make any MQI calls within the exit.

This field is not relevant to exits running on client-connection channels, where it contains the value MQHC_UNUSABLE_HCONN (-1).

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_7.

SharingConversations (MQBOOL)

This field specifies whether the conversation is the only one that can currently be running on this channel instance, or whether more than one conversation can currently be running on this channel instance.

It also indicates whether the exit program is subject to the risk of the MQCD being altered by another exit program running at the same time.

This field is only relevant for exit programs running on client-connection or server-connection channels.

It is set to one of the following:

FALSE

The exit instance is the only exit instance that can currently be running on this channel instance. This allows the exit to safely update the MQCD fields without contention from other exits running on other channel instances. Whether changes to the MQCD fields are acted upon by the channel is defined by the table of MQCD fields in [“Changing MQCD fields in a channel exit” on page 1523](#).

TRUE

The exit instance is not the only exit instance that can currently be running on this channel instance. Any changes made to the MQCD are not acted upon by the channel, except for changes listed in the table of MQCD fields in [“Changing MQCD fields in a channel exit” on page 1523](#) for Exit Reasons other than MQXR_INIT. If this exit updates the MQCD fields, ensure there is no contention from other exits running on other conversations at the same time by providing serialization among the exits that run on this channel instance.

This is an input field to the exit. The field is not present if *Version* is less than MQCXP_VERSION_7.

MCAUserSource (MQLONG)

This field specifies the source of the provided MCA user ID.

It can contain one of the following values:

MQUSRC_MAP

The user ID is specified in the MCAUSER attribute.

MQUSRC_CHANNEL

The user ID is flowed from the inbound partner or specified in the MCAUSER field defined in the channel object.

This is an input field to the exit. The field is not present if Version is less than MQCXP_VERSION_8.

pEntryPoints (PMQIEP)

This field specifies the address of the interface entry point for the MQI or DCI call.

The field is not present if *Version* is less than MQCXP_VERSION_8.

RemoteProduct (MQCHAR4)

This field specifies the remote product name.

This field identifies the remote product of the client, for example, C or Java, as displayed in the **RPRODUCT** field of DISPLAY CHSATUS.

The field is not present if *Version* is less than MQCXP_VERSION_9.

RemoteVersion (MQCHAR8)

This field specifies the name of the remote version.

This field identifies the version of the client libraries, as displayed in the **RVERSION** field of DISPLAY CHSTATUS.

The field is not present if *Version* is less than MQCXP_VERSION_9.

C declaration

This declaration is the C declaration for the MQCXP structure.

```
typedef struct tagMQCXP MQCXP;
struct tagMQCXP {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */

MQXWD - Exit wait descriptor

The MQXWD structure is an input/output parameter on the MQXWAIT call.

This structure is supported only on z/OS.

Related reference

[“Fields” on page 1540](#)

This topic lists all the fields in the MQXWD structure and describes each field.

[“C declaration” on page 1541](#)

This declaration is the C declaration for the MQXWD structure.

[“System/390 assembler declaration” on page 1541](#)

This declaration is the System/390 assembler declaration for the MQXWD structure.

Fields

This topic lists all the fields in the MQXWD structure and describes each field.

StrucId (MQCHAR4)

This field specifies the structure identifier.

The value must be:

MQXWD_STRUC_ID

Identifier for exit wait descriptor structure.

For the C programming language, the constant MQXWD_STRUC_ID_ARRAY is also defined; this constant has the same value as MQXWD_STRUC_ID, but is an array of characters instead of a string.

The initial value of this field is MQXWD_STRUC_ID.

Version (MQLONG)

This field specifies the structure version number.

The value must be:

MQXWD_VERSION_1

Version number for exit wait descriptor structure.

The initial value of this field is MQXWD_VERSION_1.

Reserved1 (MQLONG)

This field is reserved. Its value must be zero.

This is an input field.

Reserved2 (MQLONG)

This field is reserved. Its value must be zero.

This is an input field.

Reserved3 (MQLONG)

This field is reserved. Its value must be zero.

This is an input field.

ECB (MQLONG)

This field specifies the event control block to wait on.

This field is the event control block (ECB) to wait on. It must be set to zero before the MQXWAIT call is issued; on successful completion it contains the post code.

This field is an input/output field.

C declaration

This declaration is the C declaration for the MQXWD structure.

```
typedef struct tagMQXWD MQXWD;
struct tagMQXWD {
    MQCHAR4  StrucId;    /* Structure identifier */
    MQLONG   Version;    /* Structure version number */
    MQLONG   Reserved1;  /* Reserved */
    MQLONG   Reserved2;  /* Reserved */
    MQLONG   Reserved3;  /* Reserved */
    MQLONG   ECB;        /* Event control block to wait on */
};
```

Cluster workload exit call and data structures

This section provides reference information for the cluster workload exit and the data structures. This is general-use programming interface information.

You can write cluster workload exits in the following programming languages:

- C
- System/390 assembler (IBM MQ for z/OS)

The call is described in:

- [“MQ_CLUSTER_WORKLOAD_EXIT - Call description” on page 1542](#)

The structure data types used by the exit are described in:

- [“MQXCLWLN - Navigate Cluster workload records” on page 1544](#)
- [“MQWXP - Cluster workload exit parameter structure” on page 1547](#)
- [“MQWDR - Cluster workload destination record structure” on page 1555](#)
- [“MQWQR - Cluster workload queue record structure” on page 1559](#)
- [“MQWCR - Cluster workload cluster record structure” on page 1564](#)
-  [Asynchronous behavior of CLUSTER commands on z/OS](#)

Throughout this section, queue-manager attributes and queue attributes are shown in full. The equivalent names that are used in the MQSC commands are shown below. For details of MQSC commands, see [MQSC commands](#).

Table 644. Queue-manager attributes	
Full name	Name used in MQSC
<i>ClusterWorkloadData</i>	CLWLDATA
<i>ClusterWorkloadExit</i>	CLWLEXIT
<i>ClusterWorkloadLength</i>	CLWLEN

Table 645. Queue attributes	
Full name	Name used in MQSC
<i>DefBind</i>	DEFBIND
<i>DefPersistence</i>	DEFPSIST
<i>DefPriority</i>	DEFPRTY
<i>InhibitPut</i>	PUT
<i>QDesc</i>	DESCR

[Writing and compiling cluster workload exits](#)

MQ_CLUSTER_WORKLOAD_EXIT - Call description

The cluster workload exit is called by the queue manager to route a message to an available queue manager.

Note: No entry point called MQ_CLUSTER_WORKLOAD_EXIT is provided by the queue manager. Instead, the name of the cluster workload exit is defined by the ClusterWorkloadExit queue-manager attribute.

The MQ_CLUSTER_WORKLOAD_EXIT exit is supported on all platforms.

Syntax

```
MQ_CLUSTER_WORKLOAD_EXIT (ExitParms)
```

Related reference

[MQXCLWLN - Navigate Cluster workload records](#)

The MQXCLWLN call is used to navigate through the chains of MQWDR, MQWQR, and MQWCR records stored in the cluster cache.

[MQWXP - Cluster workload exit parameter structure](#)

The following table summarizes the fields in the MQWXP - Cluster workload exit parameter structure.

[MQWDR - Cluster workload destination record structure](#)

The following table summarizes the fields in the MQWDR - Cluster workload destination record structure.

[MQWQR - Cluster workload queue record structure](#)

The following table summarizes the fields in the MQWQR - Cluster workload queue record structure.

[MQWCR - Cluster workload cluster record structure](#)

The following table summarizes the fields in the MQWCR cluster workload record structure.

Parameters for MQ_CLUSTER_WORKLOAD_EXIT

Description of the parameters in the MQ_CLUSTER_WORKLOAD_EXIT call.

ExitParms (MQWXP) - input/output

Exit parameter block.

- The exit sets information in MQWXP to indicate how to manage the workload.

Related reference

[Usage notes](#)

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

[Language invocations for MQ_CLUSTER_WORKLOAD_EXIT](#)

The MQ_CLUSTER_WORKLOAD_EXIT supports two languages, C and High Level Assembler.

Usage notes

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

No entry point called MQ_CLUSTER_WORKLOAD_EXIT is provided by the queue manager. However, a typedef is provided for the name MQ_CLUSTER_WORKLOAD_EXIT in the C programming language. Use the typedef to declare the user-written exit, to ensure that the parameters are correct.

Related reference

[Parameters for MQ_CLUSTER_WORKLOAD_EXIT](#)

Description of the parameters in the MQ_CLUSTER_WORKLOAD_EXIT call.

[Language invocations for MQ_CLUSTER_WORKLOAD_EXIT](#)

The MQ_CLUSTER_WORKLOAD_EXIT supports two languages, C and High Level Assembler.

Language invocations for MQ_CLUSTER_WORKLOAD_EXIT

The MQ_CLUSTER_WORKLOAD_EXIT supports two languages, C and High Level Assembler.

C invocation

```
MQ_CLUSTER_WORKLOAD_EXIT (&ExitParms);
```

Replace *MQ_CLUSTER_WORKLOAD_EXIT* with the name of your cluster workload exit function.

Declare the *MQ_CLUSTER_WORKLOAD_EXIT* parameters as follows:

```
MQWXP ExitParms; /* Exit parameter block */
```

High Level Assembler invocation

```
CALL EXITNAME, (EXITPARMS)
```

Declare the parameters as follows:

EXITPARMS	CMQWXP	Exit parameter block
-----------	--------	----------------------

Related reference

[Parameters for MQ_CLUSTER_WORKLOAD_EXIT](#)

Description of the parameters in the MQ_CLUSTER_WORKLOAD_EXIT call.

Usage notes

The function performed by the cluster workload exit is defined by the provider of the exit. The exit, however, must conform to the rules defined in the associated control block MQWXP.

MQXCLWLN - Navigate Cluster workload records

The MQXCLWLN call is used to navigate through the chains of MQWDR, MQWQR, and MQWCR records stored in the cluster cache.

The cluster cache is an area of main storage used to store information relating to the cluster.

If the cluster cache is static, it has a fixed size. If you set it to dynamic, the cluster cache can expand as required.

Set the type of cluster cache to STATIC or DYNAMIC using either a system parameter or macro.

- The system parameter ClusterCacheType on platforms other than z/OS
- The CLCACHE parameter in the CSQ6SYSP macro on z/OS.

Syntax

```
MQXCLWLN (ExitParms, CurrentRecord, NextOffset, NextRecord, Compcode, Reason)
```

[MQWCR - Cluster workload cluster record structure](#)

The following table summarizes the fields in the MQWCR cluster workload record structure.

Parameters for MQXCLWLN - Navigate Cluster workload records

Description of the parameters in the MQXCLWLN call.

ExitParms (MQWXP) - input/output

Exit parameter block.

This structure contains information relating to the invocation of the exit. The exit sets information in this structure to indicate how to manage the workload.

CurrentRecord (MQPTR) - input

Address of current record.

This structure contains information relating to the address of the record currently being examined by the exit. The record must be one of the following types:

- Cluster workload destination record (MQWDR)
- Cluster workload queue record (MQWQR)

- Cluster workload cluster record (MQWCR)

***NextOffset* (MQLONG) - input**

Offset of next record.

This structure contains information relating to the offset of the next record or structure. *NextOffset* is the value of the appropriate offset field in the current record, and must be one of the following fields:

- ChannelDefOffset field in MQWDR
- ClusterRecOffset field in MQWDR
- ClusterRecOffset field in MQWQR
- ClusterRecOffset field in MQWCR

***NextRecord* (MQPTR) - output**

Address of next record or structure.

This structure contains information relating to the address of the next record or structure.

If *CurrentRecord* is the address of an MQWDR, and *NextOffset* is the value of the ChannelDefOffset field, *NextRecord* is the address of the channel definition structure (MQCD).

If there is no next record or structure, the queue manager sets *NextRecord* to the null pointer, and the call returns completion code MQCC_WARNING and reason code MQRC_NO_RECORD_AVAILABLE.

***CompCode* (MQLONG) - output**

Completion code.

The completion code has one of the following values:

MQCC_OK

Successful completion.

MQCC_WARNING

Warning (partial completion).

MQCC_FAILED

Call failed.

***Reason* (MQLONG) - output**

Reason code qualifying CompCode

If CompCode is MQCC_OK:

MQRC_NONE

(0, X'0000')

No reason to report.

If CompCode is MQCC_WARNING:

MQRC_NO_RECORD_AVAILABLE

(2359, X'0937')

No record available. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The current record is the last record in the chain.

Corrective action: None.

If CompCode is MQCC_FAILED:

MQRC_CURRENT_RECORD_ERROR

(2357, X'0935')

CurrentRecord parameter not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The address specified by the *CurrentRecord* parameter is not the address of a valid record.

CurrentRecord must be the address of a destination record, MQWDR, queue record (MQWQR), or cluster record (MQWCR) residing within the cluster cache. Corrective action: Ensure that the cluster workload exit passes the address of a valid record residing in the cluster cache.

MQRC_ENVIRONMENT_ERROR
(2012, X'07DC')

Call not valid in environment. An MQXCLWLN call was issued, but not from a cluster workload exit.

MQRC_NEXT_OFFSET_ERROR
(2358, X'0936')

NextOffset parameter not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The offset specified by the *NextOffset* parameter is not valid. *NextOffset* must be the value of one of the following fields:

- ChannelDefOffset field in MQWDR
- ClusterRecOffset field in MQWDR
- ClusterRecOffset field in MQWQR
- ClusterRecOffset field in MQWCR

Corrective action: Ensure that the value specified for the *NextOffset* parameter is the value of one of the fields listed previously.

MQRC_NEXT_RECORD_ERROR
(2361, X'0939')

NextRecord parameter not valid.

MQRC_WXP_ERROR
(2356, X'0934')

Workload exit parameter structure not valid. An MQXCLWLN call was issued from a cluster workload exit to obtain the address of the next record in the chain. The workload exit parameter structure *ExitParms* is not valid, for one of the following reasons:

- The parameter pointer is not valid. It is not always possible to detect parameter pointers that are not valid; if not detected, unpredictable results occur.
- The StrucId field is not MQWXP_STRUC_ID.
- The Version field is not MQWXP_VERSION_2.
- The Context field does not contain the value passed to the exit by the queue manager.

Corrective action: Ensure that the parameter specified for *ExitParms* is the MQWXP structure that was passed to the exit when the exit was invoked.

[Usage notes for MQXCLWLN - Navigate Cluster workload records](#)

Use MQXCLWLN to navigate through cluster records, even if the cache is static.

[Language invocations of MQXCLWLN](#)

MQXCLWLN supports two languages, C and High Level Assembler.

Usage notes for MQXCLWLN - Navigate Cluster workload records

Use MQXCLWLN to navigate through cluster records, even if the cache is static.

If the cluster cache is dynamic, the MQXCLWLN call must be used to navigate through the records. The exit ends abnormally if simple pointer-and-offset arithmetic is used to navigate through the records.

If the cluster cache is static, MQXCLWLN need not be used to navigate through the records. Typically use MQXCLWLN even when the cache is static. You can then change the cluster cache to being dynamic without needing to change the workload exit.

MQXCLWLN supports two languages, C and High Level Assembler.

Language invocations of MQXCLWLN

MQXCLWLN supports two languages, C and High Level Assembler.

C invocation

```
MQXCLWLN (&ExitParms, CurrentRecord, NextOffset, &NextRecord, &CompCode, &Reason) ;
```

Declare the parameters as follows:

```
typedef struct tagMQXCLWLN {
MQWXP   ExitParms;      /* Exit parameter block */
MQPTR   CurrentRecord;  /* Address of current record*/
MQLONG  NextOffset;     /* Offset of next record */
MQPTR   NextRecord;     /* Address of next record or structure */
MQLONG  CompCode;       /* Completion code */
MQLONG  Reason;         /* Reason code qualifying CompCode */
}
```

High Level Assembler invocation

```
CALL MQXCLWLN, (CLWLEXITPARMS, CURRENTRECORD, NEXTOFFSET, NEXTRECORD, COMPCODE, REASON)
```

Declare the parameters as follows:

```
CLWLEXITPARMS CMQWXP, Cluster workload exit parameter block
CURRENTRECORD CMQWDRA, Current record
NEXTOFFSET     DS F      Next offset
NEXTRECORD     DS F      Next record
COMPCODE       DS F      Completion code
REASON         DS F      Reason code qualifying COMPCODE
```

MQWXP - Cluster workload exit parameter structure

The following table summarizes the fields in the MQWXP - Cluster workload exit parameter structure.

Table 646. Fields in MQWXP		
Field	Description	Page
<i>StrucId</i>	Structure identifier	StrucId
<i>Version</i>	Structure version number	Version
<i>ExitId</i>	Type of exit	ExitId
<i>ExitReason</i>	Reason for invoking exit	ExitReason
<i>ExitResponse</i>	Response from exit	ExitResponse
<i>ExitResponse2</i>	Secondary response from exit	ExitResponse2
<i>Feedback</i>	Feedback code	Feedback
<i>Flags</i>	Flags values. These bit flags are used to indicate information about the message being put	Flags
<i>ExitUserArea</i>	Exit user area	ExitUserArea

Table 646. Fields in MQWXP (continued)		
Field	Description	Page
<i>ExitData</i>	Exit data	ExitData
<i>MsgDescPtr</i>	Address of message descriptor (MQMD)	MsgDescPtr
<i>MsgBufferPtr</i>	Address of buffer containing some or all the message data	MsgBufferPtr
<i>MsgBufferLength</i>	Length of buffer containing message data	MsgBufferLength
<i>MsgLength</i>	Length of complete message	MsgLength
<i>QName</i>	Name of queue	QName
<i>QMgrName</i>	Name of local queue manager	QMgrName
<i>DestinationCount</i>	Number of possible destinations	DestinationCount
<i>DestinationChosen</i>	Destination chosen	DestinationChosen
<i>DestinationArrayPtr</i>	Address of an array of pointers to destination records (MQWDR)	DestinationArrayPtr
<i>QArrayPtr</i>	Address of an array of pointers to queue records (MQWQR)	QArrayPtr
Note: The remaining fields are ignored if Version is less than MQWXP_VERSION_2.		
<i>CacheContext</i>	Context information	CacheContext
<i>CacheType</i>	Type of cluster cache	CacheType
Note: The remaining fields are ignored if Version is less than MQWXP_VERSION_3.		
<i>CLWLMRUChannels</i>	Maximum number of allowed active outbound cluster channels	CLWLMRUChannels
Note: The remaining fields are ignored if Version is less than MQWXP_VERSION_4.		
<i>pEntryPoints</i>	Address of the MQIEP structure to allow MQI and DCI calls to be made	pEntryPoints

The cluster workload exit parameter structure describes the information that is passed to the cluster workload exit.

The cluster workload exit parameter structure is supported on all platforms

Additionally, the MQWXP1, MQWXP2 and MQWXP3 structures are available for backwards compatibility.

MQWCR - Cluster workload cluster record structure

The following table summarizes the fields in the MQWCR cluster workload record structure.

Fields in MQWXP - Cluster workload exit parameter structure

Description of the fields in the MQWXP - Cluster workload exit parameter structure

StrucId (MQCHAR4) - input

The structure identifier for the cluster workload exit parameter structure.

- The StrucId value is MQWXP_STRUC_ID.
- For the C programming language, the constant MQWXP_STRUC_ID_ARRAY is also defined. It has the same value as MQWXP_STRUC_ID. It is an array of characters instead of a string.

Version (MQLONG) - input

Indicates the structure version number. Version takes one of the following values:

MQWXP_VERSION_1

Version-1 cluster workload exit parameter structure.

MQWXP_VERSION_1 is supported in all environments.

MQWXP_VERSION_2

Version-2 cluster workload exit parameter structure.

MQWXP_VERSION_2 is supported in the following environments: AIX, HP-UX, Linux, IBM i, Solaris and Windows.

MQWXP_VERSION_3

Version-3 cluster workload exit parameter structure.

MQWXP_VERSION_3 is supported in the following environments: AIX, HP-UX, Linux, IBM i, Solaris and Windows.

MQWXP_VERSION_4

Version-4 cluster workload exit parameter structure.

MQWXP_VERSION_4 is supported in the following environments: AIX, HP-UX, Linux, IBM i, Solaris and Windows.

MQWXP_CURRENT_VERSION

Current version of cluster workload exit parameter structure.

ExitId (MQLONG) - input

Indicates the type of exit being called. The cluster workload exit is the only supported exit.

- The ExitId value must be MQXT_CLUSTER_WORKLOAD_EXIT

ExitReason (MQLONG) - input

Indicates the reason for invoking the cluster workload exit. ExitReason takes one of the following values:

MQXR_INIT

Indicates that the exit is being invoked for the first time.

Acquire and initialize any resources that the exit might need, such as main storage.

MQXR_TERM

Indicates that the exit is about to be terminated.

Free any resources that the exit might have acquired since it was initialized, such as main storage.

MQXR_CLWL_OPEN

Called by MQOPEN.

MQXR_CLWL_PUT

Called by MQPUT or MQPUT1.

MQXR_CLWL_MOVE

Called by MCA when the channel state has changed.

MQXR_CLWL_REPOS

Called by MQPUT or MQPUT1 for a repository-manager PCF message.

MQXR_CLWL_REPOS_MOVE

Called by MCA for a repository-manager PCF message if the channel state has changed.

ExitResponse (MQLONG) - output

Set ExitResponse to indicate whether processing of the message continues. It must be one of the following values:

MQXCC_OK

Continue processing the message normally.

- DestinationChosen identifies the destination to which the message is to be sent.

MQXCC_SUPPRESS_FUNCTION

Discontinue processing the message.

- The actions taken by the queue manager depend on the reason the exit was invoked:

Table 647. Actions taken by the queue manager.

There are two columns in this table. The first column lists the exit reasons and the second column describes the action taken for each exit reason.

ExitReason	Action taken
<ul style="list-style-type: none"> – MQXR_CLWL_OPEN – MQXR_CLWL_REPOS – MQXR_CLWL_PUT 	MQOPEN, MQPUT, or MQPUT1 call fail with completion code MQCC_FAILED and reason code MQRC_STOPPED_BY_CLUSTER_EXIT.
<ul style="list-style-type: none"> – MQXR_CLWL_MOVE – MQXR_CLWL_REPOS_MOVE 	The message is placed on the dead-letter queue.

MQXCC_SUPPRESS_EXIT

Continue processing the current message normally. Do not invoke the exit again until the queue manager shuts down.

The queue manager processes subsequent messages as if the ClusterWorkloadExit queue-manager attribute is blank. DestinationChosen identifies the destination to which the current message is sent.

Any other value

Process the message as if MQXCC_SUPPRESS_FUNCTION is specified.

ExitResponse2 (MQLONG) - input/output

Set ExitResponse2 to provide the queue manager with more information.

- MQXR2_STATIC_CACHE is the default value, and is set on entry to the exit.
- When ExitReason has the value MQXR_INIT, the exit can set one of the following values in ExitResponse2:

MQXR2_STATIC_CACHE

The exit requires a static cluster cache.

- If the cluster cache is static, the exit need not use the MQXCLWLN call to navigate the chains of records in the cluster cache.
- If the cluster cache is dynamic, the exit cannot navigate correctly through the records in the cache.

Note: The queue manager processes the return from the MQXR_INIT call as though the exit had returned MQXCC_SUPPRESS_EXIT in the ExitResponse field.

MQXR2_DYNAMIC_CACHE

The exit can operate with either a static or dynamic cache.

- If the exit returns this value, the exit must use the MQXCLWLN call to navigate the chains of records in the cluster cache.

Feedback (MQLONG) - input

A reserved field. The value is zero.

Flags (MQLONG) - input

Indicates information about the message being put.

- The value of Flags is MQWXP_PUT_BY_CLUSTER_CHL. The message originates from a cluster channel, rather than locally or from a non-cluster channel. In other words, the message has come from another cluster queue manager.

Reserved (MQLONG) - input

A reserved field. The value is zero.

ExitUserArea (MQBYTE16) - input/output

Set ExitUserArea to communicate between calls to the exit.

- ExitUserArea is initialized to binary zero before the first invocation of the exit. Any changes made to this field by the exit are preserved across the invocations of the exit that occur between the MQCONN call and the matching MQDISC call. The field is reset to binary zero when the MQDISC call occurs.
- The first invocation of the exit is indicated by the ExitReason field having the value MQXR_INIT.
- The following constants are defined:

MQXUA_NONE - string

MQXUA_NONE_ARRAY - character array

No user information. Both constants are binary zero for the length of the field.

MQ_EXIT_USER_AREA_LENGTH

The length of ExitUserArea.

ExitData (MQCHAR32) - input

The value of the ClusterWorkloadData queue-manager attribute. If no value has been defined for that attribute, this field is all blanks.

- The length of ExitData is given by MQ_EXIT_DATA_LENGTH.

MsgDescPtr (PMQMD) - input

The address of a copy of the message descriptor (MQMD) for the message being processed.

- Any changes made to the message descriptor by the exit are ignored by the queue manager.
- If ExitReason has one of the following values MsgDescPtr is set to the null pointer, and no message descriptor is passed to the exit:
 - MQXR_INIT
 - MQXR_TERM
 - MQXR_CLWL_OPEN

MsgBufferPtr (PMQVOID) - input

The address of a buffer containing a copy of the first MsgBufferLength bytes of the message data.

- Any changes made to the message data by the exit are ignored by the queue manager.
- No message data is passed to the exit when:
 - MsgDescPtr is the null pointer.
 - The message has no data.
 - The ClusterWorkloadLength queue-manager attribute is zero.

In these cases, MsgBufferPtr is the null pointer.

MsgBufferLength (MQLONG) - input

The length of the buffer containing the message data passed to the exit.

- The length is controlled by the ClusterWorkloadLength queue-manager attribute.
- The length might be less than the length of the complete message, see MsgLength.

MsgLength (MQLONG) - input

The length of the complete message passed to the exit.

- MsgBufferLength might be less than the length of the complete message.
- MsgLength is zero if ExitReason is MQXR_INIT, MQXR_TERM, or MQXR_CLWL_OPEN.

QName (MQCHAR48) - input

The name of the destination queue. The queue is a cluster queue.

- The length of QName is MQ_Q_NAME_LENGTH.

QMgrName (MQCHAR48) - input

The name of the local queue manager that has invoked the cluster workload exit.

- The length of QMgrName is MQ_Q_MGR_NAME_LENGTH.

DestinationCount (MQLONG) - input

The number of possible destinations. Destinations are instances of the destination queue and are described by destination records.

- A destination record is a MQWDR structure. There is one structure for each possible route to each instance of the queue.
- MQWDR structures are addressed by an array of pointers, see DestinationArrayPtr.

DestinationChosen (MQLONG) - input/output

The chosen destination.

- The number of the MQWDR structure that identifies the route and queue instance where the message is to be sent.
- The value is in the range 1 - DestinationCount.
- On input to the exit, DestinationChosen indicates the route and queue instance that the queue manager has selected. The exit can accept this choice, or choose a different route and queue instance.
- The value set by the exit must be in the range 1 - DestinationCount. If any other value is returned, the queue manager uses the value of DestinationChosen on input to the exit.

DestinationArrayPtr (PPMQWDR) - input

The address of an array of pointers to destination records (MQWDR).

- There are DestinationCount destination records.

QArrayPtr (PPMQWQR) - input

The address of an array of pointers to queue records (MQWQR).

- If queue records are available, there are DestinationCount of them.
- If no queue records are available, QArrayPtr is the null pointer.

Note: QArrayPtr can be the null pointer even when DestinationCount is greater than zero.

CacheContext (MQPTR) : Version 2 - input

The CacheContext field is reserved for use by the queue manager. The exit must not alter the value of this field.

CacheType (MQLONG) : Version 2 - input

The cluster cache has one of the following types:

MQCLCT_STATIC

The cache is static.

- The size of the cache is fixed, and cannot grow as the queue manager operates.
- You do not need to use the MQXCLWLN call to navigate the records in this type of cache.

MQCLCT_DYNAMIC

The cache is dynamic.

- The size of the cache can increase in order to accommodate the varying cluster information.
- You must use the MQXCLWLN call to navigate the records in this type of cache.

CLWLMRUChannels (MQLONG) : Version 3 - input

Indicates the maximum number of active outbound cluster channels, to be considered for use by the cluster workload choice algorithm.

- CLWLMRUChannels is a value 1 - 999 999 999.

pEntryPoints (PMQIEP) : Version 4

The address of an MQIEP structure through which MQI and DCI calls can be made.

[Description of the fields in the MQWXP - Cluster workload exit parameter structure](#)

MQWDR - Cluster workload destination record structure

The following table summarizes the fields in the MQWDR - Cluster workload destination record structure.

Table 649. Fields in MQWDR		
Field	Description	Page
<i>StrucId</i>	Structure identifier	StrucId
<i>Version</i>	Structure version number	Version
<i>StrucLength</i>	Length of MQWDR structure	StrucLength
<i>QMgrFlags</i>	Queue-manager flags	QMgrFlags
<i>QMgrIdentifier</i>	Queue-manager identifier	QMgrIdentifier
<i>QMgrName</i>	Queue-manager name	QMgrName
<i>ClusterRecOffset</i>	Logical offset of first cluster record (MQWCR)	ClusterRecOffset
<i>ChannelState</i>	Channel state	ChannelState
<i>ChannelDefOffset</i>	Logical offset of channel-definition structure (MQCD)	ChannelDefOffset
Note: The remaining fields are ignored if Version is less than MQWDR_VERSION_2.		
<i>DestSeqNumber</i>	Channel destination sequence number	DestSeqNumber
<i>DestSeqFactor</i>	Channel destination sequence factor for weighting	DestSeqFactor

The cluster workload destination record structure contains information relating to one of the possible destinations for the message. There is one cluster workload destination record structure for each instance of the destination queue.

The cluster workload destination record structure is supported in all environments.

Additionally, the MQWDR1 and MQWDR2 structures are available for backwards compatibility.

[MQ_CLUSTER_WORKLOAD_EXIT - Call description](#)

The cluster workload exit is called by the queue manager to route a message to an available queue manager.

MQXCLWLN - Navigate Cluster workload records

The MQXCLWLN call is used to navigate through the chains of MQWDR, MQWQR, and MQWCR records stored in the cluster cache.

MQWXP - Cluster workload exit parameter structure

The following table summarizes the fields in the MQWXP - Cluster workload exit parameter structure.

MQWQR - Cluster workload queue record structure

The following table summarizes the fields in the MQWQR - Cluster workload queue record structure.

MQWCR - Cluster workload cluster record structure

The following table summarizes the fields in the MQWCR cluster workload record structure.

Fields in MQWDR - Cluster workload destination record structure

Description of the parameters in the MQWDR - Cluster workload destination record structure.

StrucId (MQCHAR4) - input

The structure identifier for the cluster workload destination record structure.

- The StrucId value is MQWDR_STRUC_ID.
- For the C programming language, the constant MQWDR_STRUC_ID_ARRAY is also defined. It has the same value as MQWDR_STRUC_ID. It is an array of characters instead of a string.

Version (MQLONG) - input

The structure version number. Version takes one of the following values:

MQWDR_VERSION_1

Version-1 cluster workload destination record.

MQWDR_VERSION_2

Version-2 cluster workload destination record.

MQWDR_CURRENT_VERSION

Current version of cluster workload destination record.

StrucLength (MQLONG) - input

The length of MQWDR structure. StrucLength takes one of the following values:

MQWDR_LENGTH_1

Length of version-1 cluster workload destination record.

MQWDR_LENGTH_2

Length of version-2 cluster workload destination record.

MQWDR_CURRENT_LENGTH

Length of current version of cluster workload destination record.

QMgrFlags (MQLONG) - input

Queue manager flags indicating properties of the queue manager that hosts the instance of the destination queue described by the MQWDR structure. The following flags are defined:

MQQMF_REPOSITORY_Q_MGR

Destination is a full repository queue manager.

MQQMF_CLUSSDR_USER_DEFINED

Cluster-sender channel was defined manually.

MQQMF_CLUSSDR_AUTO_DEFINED

Cluster-sender channel was defined automatically.

MQQMF_AVAILABLE

Destination queue manager is available to receive messages.

Other values

Other flags in the field might be set by the queue manager for internal purposes.

QMgrIdentifier (MQCHAR48) - input

The queue manager identifier is a unique identifier for the queue manager that hosts the instance of the destination queue described by the MQWDR structure.

- The identifier is generated by the queue manager.
- The length of QMgrIdentifier is MQ_Q_MGR_IDENTIFIER_LENGTH.

QMgrName (MQCHAR48) - input

The name of the queue manager that hosts the instance of the destination queue described by the MQWDR structure.

- QMgrName can be the name of the local queue manager, as well another queue manager in the cluster.
- The length of QMgrName is MQ_Q_MGR_NAME_LENGTH.

ClusterRecOffset (MQLONG) - input

The logical offset of the first MQWCR structure that belongs to the MQWDR structure.

- For static caches, ClusterRecOffset is the offset of the first MQWCR structure that belongs to the MQWDR structure.
- The offset is measured in bytes from the start of the MQWDR structure.
- Do not use the logical offset for pointer arithmetic with dynamic caches. To obtain the address of the next record, the MQXCLWLN call must be used.

ChannelState (MQLONG) - input

The state of the channel that links the local queue manager to the queue manager identified by the MQWDR structure. The following values are possible:

MQCHS_BINDING

Channel is negotiating with the partner.

MQCHS_INACTIVE

Channel is not active.

MQCHS_INITIALIZING

Channel is initializing.

MQCHS_PAUSED

Channel has paused.

MQCHS_REQUESTING

Requester channel is requesting connection.

MQCHS_RETRYING

Channel is reattempting to establish connection.

MQCHS_RUNNING

Channel is transferring or waiting for messages.

MQCHS_STARTING

Channel is waiting to become active.

MQCHS_STOPPING

Channel is stopping.

MQCHS_STOPPED

Channel has stopped.

ChannelDefOffset (MQLONG) - input

The logical offset of the channel definition (MQCD) for the channel that links the local queue manager to the queue manager identified by the MQWDR structure.

- ChannelDefOffset is like ClusterRecOffset
- The logical offset cannot be used in pointer arithmetic. To obtain the address of the next record, the MQXCLWLN call must be used.

DestSeqFactor (MQLONG) - input

The destination sequence factor that allows a choice of the channel based on weight.

- DestSeqFactor is used before the queue manager changes it.
- The workload manager increases DestSeqFactor in a way that ensures messages are distributed down channels according to their weight.

DestSeqNumber (MQLONG) - input

The cluster channel destination value before the queue manager changes it.

- The workload manager increases DestSeqNumber every time a message is put down that channel.
- Workload exits can use DestSeqNumber to decide which channel to put a message down.

The following table summarizes the fields in the MQWCR cluster workload record structure.

Fields in MQWQR - Cluster workload queue record structure

Description of the fields in the MQWQR - Cluster workload queue record structure.

StrucId (MQCHAR4) - input

The structure identifier for the cluster workload queue record structure.

- The StrucId value is MQWQR_STRUC_ID.
- For the C programming language, the constant MQWQR_STRUC_ID_ARRAY is also defined. It has the same value as MQWQR_STRUC_ID. It is an array of characters instead of a string.

Version (MQLONG) - input

The structure version number. Version takes one of the following values:

MQWQR_VERSION_1

Version-1 cluster workload queue record.

MQWQR_VERSION_2

Version-2 cluster workload queue record.

MQWQR_VERSION_3

Version-3 cluster workload queue record.

MQWQR_CURRENT_VERSION

Current version of cluster workload queue record.

StrucLength (MQLONG) - input

The length of MQWQR structure. StrucLength takes one of the following values:

MQWQR_LENGTH_1

Length of version-1 cluster workload queue record.

MQWQR_LENGTH_2

Length of version-2 cluster workload queue record.

MQWQR_LENGTH_3

Length of version-3 cluster workload queue record.

MQWQR_CURRENT_LENGTH

Length of current version of cluster workload queue record.

QFlags (MQLONG) - input

The queue flags indicate properties of the queue. The following flags are defined:

MQQF_LOCAL_Q

Destination is a local queue.

MQQF_CLWL_USEQ_ANY

Allow use of local and remote queues in puts.

MQQF_CLWL_USEQ_LOCAL

Allow only local queue puts.

Other values

Other flags in the field might be set by the queue manager for internal purposes.

QName (MQCHAR48) - input

The name of the queue that is one of the possible destinations of the message.

- The length of QName is MQ_Q_NAME_LENGTH.

QMgrIdentifier (MQCHAR48) - input

The queue manager identifier is a unique identifier for the queue manager that hosts the instance of the queue described by the MQWQR structure.

- The identifier is generated by the queue manager.
- The length of QMgrIdentifier is MQ_Q_MGR_IDENTIFIER_LENGTH.

ClusterRecOffset (MQLONG) - input

The logical offset of the first MQWCR structure that belongs to the MQWQR structure.

- For static caches, ClusterRecOffset is the offset of the first MQWCR structure that belongs to the MQWQR structure.
- The offset is measured in bytes from the start of the MQWQR structure.
- Do not use the logical offset for pointer arithmetic with dynamic caches. To obtain the address of the next record, the MQXCLWLN call must be used.

QType (MQLONG) - input

The queue type of the destination queue. The following values are possible:

MQCQT_LOCAL_Q

Local queue.

MQCQT_ALIAS_Q

Alias queue.

MQCQT_REMOTE_Q

Remote queue.

MQCQT_Q_MGR_ALIAS

Queue-manager alias.

QDesc (MQCHAR64) - input

The queue description queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

- The length of QDesc is MQ_Q_DESC_LENGTH.

DefBind (MQLONG) - input

The default binding queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. Either MQBND_BIND_ON_OPEN or

MQBND_BIND_ON_GROUP must be specified when using groups with clusters. The following values are possible:

MQBND_BIND_ON_OPEN

Binding fixed by MQOPEN call.

MQBND_BIND_NOT_FIXED

Binding not fixed.

MQBND_BIND_ON_GROUP

Allows an application to request that a group of messages are all allocated to the same destination instance.

DefPersistence (MQLONG) - input

The default message persistence queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

MQPER_PERSISTENT

Message is persistent.

MQPER_NOT_PERSISTENT

Message is not persistent.

DefPriority (MQLONG) - input

The default message priority queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The priority range is 0 - MaxPriority.

- 0 is the lowest priority.
- MaxPriority is the queue manager attribute of the queue manager that hosts this instance of the destination queue.

InhibitPut (MQLONG) - input

The put inhibited queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

MQQA_PUT_INHIBITED

Put operations are inhibited.

MQQA_PUT_ALLOWED

Put operations are allowed.

CLWLQueuePriority (MQLONG) - input

The cluster workload queue priority attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

CLWLQueueRank (MQLONG) - input

The cluster workload queue rank defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure.

DefPutResponse (MQLONG) - input

The default put response queue attribute defined on the queue manager that hosts the instance of the destination queue described by the MQWQR structure. The following values are possible:

MQPRT_SYNC_RESPONSE

Synchronous response to MQPUT or MQPUT1 calls.

MQPRT_ASYNC_RESPONSE

Asynchronous response to MQPUT or MQPUT1 calls.

Description of the fields in the MQWQR - Cluster workload queue record structure.

MQWCR - Cluster workload cluster record structure

The following table summarizes the fields in the MQWCR cluster workload record structure.

Table 653. Fields in MQWCR.		
There are three columns in this table. The first column lists the field names, the second column provides a description of each field and the third column provides a link to further information about each field.		
Field	Description	Page
<i>ClusterName</i>	Name of cluster	ClusterName
<i>ClusterRecOffset</i>	Offset of next cluster record (MQWCR)	ClusterRecOffset
<i>ClusterFlags</i>	Cluster flags	ClusterFlags

The cluster workload cluster record structure contains information about a cluster. For each cluster the destination queue belongs to, there is one cluster workload cluster record structure.

The cluster workload cluster record structure is supported in all environments.

The following table summarizes the fields in the MQWQR - Cluster workload queue record structure.

Fields in the MQWCR - Cluster workload cluster record structure.

Description of the fields in the MQWCR - Cluster workload cluster record structure.

ClusterName (MQCHAR48) - input

The name of a cluster to which the instance of the destination queue that owns the MQWCR structure belongs. The destination queue instance is described by an MQWDR structure.

- The length of ClusterName is MQ_CLUSTER_NAME_LENGTH.

ClusterRecOffset (MQLONG) - input

The logical offset of the next MQWCR structure.

- If there are no more MQWCR structures, ClusterRecOffset is zero.
- The offset is measured in bytes from the start of the MQWCR structure.

ClusterFlags (MQLONG) - input

The cluster flags indicate properties of the queue manager identified by the MQWCR structure. The following flags are defined:

MQQMF_REPOSITORY_Q_MGR

Destination is a full repository queue manager.

MQQMF_CLUSSDR_USER_DEFINED

Cluster-sender channel was defined manually.

MQQMF_CLUSSDR_AUTO_DEFINED

Cluster-sender channel was defined automatically.

MQQMF_AVAILABLE

Destination queue manager is available to receive messages.

Other values

Other flags in the field might be set by the queue manager for internal purposes.

API exit reference

This section provides reference information mainly of interest to a programmer writing API exits.

General usage notes

notes:

1. All exit functions can issue the MQXEP call; this call is designed specifically for use from API exit functions.
2. The MQ_INIT_EXIT function cannot issue any MQ calls other than MQXEP.
3. You cannot issue the MQDISC call for the current connection.
4. If an exit function issues the MQCONN call, or the MQCONN call with the MQCNO_HANDLE_SHARE_NONE option, the call completes with reason code MQRC_ALREADY_CONNECTED, and the handle returned is the same as the one passed to the exit as a parameter.
5. In general when an API exit function issues an MQI call, API exits are not be called recursively. However, if an exit function issues the MQCONN call with the MQCNO_HANDLE_SHARE_BLOCK or MQCNO_HANDLE_SHARE_NO_BLOCK options, the call returns a new shared handle. This provides the exit suite with a connection handle of its own, and hence a unit of work that is independent of the application's unit of work. The exit suite can use this handle to put and get messages within its own unit of work, and commit or back out that unit of work; all of this can be done without affecting the application's unit of work in any way.

Because the exit function is using a connection handle that is different from the handle being used by the application, MQ calls issued by the exit function result in the relevant API exit functions being invoked. Exit functions can therefore be invoked recursively. Note that both the *ExitUserArea* field in MQAXP and the exit chain area have connection-handle scope. Consequently, an exit function cannot use those areas to signal to another instance of itself invoked recursively that it is already active.

6. Exit functions can also put and get messages within the application's unit of work. When the application commits or backs out the unit of work, all messages within the unit of work are committed or backed out together, regardless of who placed them in the unit of work (application or exit function). However, the exit can cause the application to exceed system limits sooner than would otherwise be the case (for example, by exceeding the maximum number of uncommitted messages in a unit of work).

When an exit function uses the application's unit of work in this way, the exit function should usually avoid issuing the MQCMIT call, as this commits the application's unit of work and might impair the correct functioning of the application. However, the exit function might sometimes need to issue the MQBACK call, if the exit function encounters a serious error that prevents the unit of work being committed (for example, an error putting a message as part of the application's unit of work). When

MQBACK is called, take care to ensure that the application unit of work boundaries are not changed. In this situation the exit function must set the appropriate values to ensure that completion code MQCC_WARNING and reason code MQRC_BACKED_OUT are returned to the application, so that the application can detect the fact that the unit of work has been backed out.

If an exit function uses the application's connection handle to issue MQ calls, those calls do not themselves result in further invocations of API exit functions.

7. If an MQXR_BEFORE exit function terminates abnormally, the queue manager might be able to recover from the failure. If it can, the queue manager continues processing as though the exit function had returned MQXCC_FAILED. If the queue manager cannot recover, the application is terminated.
8. If an MQXR_AFTER exit function terminates abnormally, the queue manager might be able to recover from the failure. If it can, the queue manager continues processing as though the exit function had returned MQXCC_FAILED. If the queue manager cannot recover, the application is terminated. Be aware that in the latter case, messages retrieved outside a unit of work are lost (this is the same situation as the application failing immediately after removing a message from the queue).
9. The MCA process performs a two phase commit.

If an API exit intercepts an MQCMIT from a prepared MCA process and attempts to perform an action within the unit of work, then the action will fail with reason code MQRC_UOW_NOT_AVAILABLE.
10. For a multi-installation environment, the only way to have an exit that works with both Websphere MQ Version 7.0 and Version 7.1 is to write the exit in a way which links at Version 7.0 with mqm.Lib and, for non-primary or relocated exits, to ensure that the application finds the correct mqm.Lib for the installation with which the queue manager is currently associated, prior to the application launch. (For example, run the **setmqenv -m QM** command before launching the application, even if the queue manager is owned by a Version 7.0 installation.)
11. Where multiple installations of IBM MQ are available, use the exits written for an earlier version of IBM MQ, as new functionality added in the later version might not work with earlier versions. For more information about changes between releases, see [What's changed in IBM MQ 8.0](#).

IBM MQ API exit parameter structure (MQAXP)

The MQAXP structure, an external control block, is used as an input or output parameter to the API exit. This topic also gives information about how queue managers process exit functions.

MQAXP has the following C declaration:

```
typedef struct tagMQAXP {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQLONG     ExitId;           /* Exit Identifier */
    MQLONG     ExitReason;       /* Exit invocation reason */
    MQLONG     ExitResponse;     /* Response code from exit */
    MQLONG     ExitResponse2;    /* Secondary response code from exit */
    MQLONG     Feedback;        /* Feedback code from exit */
    MQLONG     APICallerType;    /* MQSeries API caller type */
    MQBYTE16   ExitUserArea;     /* User area for use by exit */
    MQCHAR32   ExitData;        /* Exit data area */
    MQCHAR48   ExitInfoName;    /* Exit information name */
    MQBYTE48   ExitPDArea;      /* Problem determination area */
    MQCHAR48   QMgrName;        /* Name of local queue manager */
    PMQACH     ExitChainAreaPtr; /* Inter exit communication area */
    MQHCONFIG  Hconfig;         /* Configuration handle */
    MQLONG     Function;        /* Function Identifier */
    /* Ver:1 */
    MQHMSG     ExitMsgHandle     /* Exit message handle */
    /* Ver:2 */
};
```

The following parameter list is passed when functions in an API exit are invoked:

StrucId (MQCHAR4) - input

The exit parameter structure identifier, with a value of:

MQAXP_STRUC_ID.

The exit handler sets this field on entry to each exit function.

Version (MQLONG) - input

The structure version number, with a value of:

MQAXP_VERSION_1

Version 1 API exit parameter structure.

MQAXP_VERSION_2

Version 2 API exit parameter structure.

MQAXP_CURRENT_VERSION

Current version number for the API exit parameter structure.

The exit handler sets this field on entry to each exit function.

ExitId (MQLONG) - input

The exit identifier, set on entry to the exit routine, indicating the type of exit:

MQXT_API_EXIT

API exit.

ExitReason (MQLONG) - input

The reason for invoking the exit, set on entry to each exit function:

MQXR_CONNECTION

The exit is being invoked to initialize itself before an MQCONN or MQCONNEX call, or to end itself after an MQDISC call.

MQXR_BEFORE

The exit is being invoked before executing an API call, or before converting data on an MQGET.

MQXR_AFTER

The exit is being invoked after executing an API call.

ExitResponse (MQLONG) - output

The response from the exit, initialized on entry to each exit function to:

MQXCC_OK

Continue normally.

This field must be set by the exit function, to communicate to the queue manager the result of executing the exit function. The value must be one of the following:

MQXCC_OK

The exit function completed successfully. Continue normally.

This value can be set by all MQXR_* exit functions. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

MQXCC_FAILED

The exit function failed because of an error.

This value can be set by all MQXR_* exit functions. The queue manager sets CompCode to MQCC_FAILED, and Reason to:

- MQRC_API_EXIT_INIT_ERROR if the function is MQ_INIT_EXIT
- MQRC_API_EXIT_TERM_ERROR if the function is MQ_TERM_EXIT
- MQRC_API_EXIT_ERROR for all other exit functions

The values set can be altered by an exit function later in the chain.

ExitResponse2 is ignored; the queue manager continues processing as though MQXR2_SUPPRESS_CHAIN had been returned.

MQXCC_SUPPRESS_FUNCTION

Suppress IBM MQ API function.

This value can be set only by an MQXR_BEFORE exit function. It bypasses the API call. If it is returned by the MQ_DATA_CONV_ON_GET_EXIT, data conversion is bypassed. The queue manager sets CompCode to MQCC_FAILED, and Reason to MQRC_SUPPRESSED_BY_EXIT, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

If this value is set by an MQXR_AFTER or MQXR_CONNECTION exit function, the queue manager continues processing as though MQXCC_FAILED had been returned.

MQXCC_SKIP_FUNCTION

Skip IBM MQ API function.

This value can be set only by an MQXR_BEFORE exit function. It bypasses the API call. If it is returned by the MQ_DATA_CONV_ON_GET_EXIT, data conversion is bypassed. The exit function must set CompCode and Reason to the values to be returned to the application, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is used to decide whether to invoke exit functions later in the chain.

If this value is set by an MQXR_AFTER or MQXR_CONNECTION exit function, the queue manager continues processing as though MQXCC_FAILED had been returned.

MQXCC_SUPPRESS_EXIT

Suppress all exit functions belonging to the set of exits.

This value can be set only by the MQXR_BEFORE and MQXR_AFTER exit functions. It bypasses *all* subsequent invocations of exit functions belonging to this set of exits for this logical connection. This bypassing continues until the logical disconnect request occurs, when MQ_TERM_EXIT function is invoked with an ExitReason of MQXR_CONNECTION.

The exit function must set CompCode and Reason to the values to be returned to the application, but the values set can be altered by an exit function later in the chain. Other parameters for the call remain as the exit left them. ExitResponse2 is ignored.

If this value is set by an MQXR_CONNECTION exit function, the queue manager continues processing as though MQXCC_FAILED had been returned.

For information about the interaction between ExitResponse and ExitResponse2, and its effect on exit processing, see [“How queue managers process exit functions” on page 1571](#).

ExitResponse2 (MQLONG) - output

This is a secondary exit response code that qualifies the primary exit response code for MQXR_BEFORE exit functions. It is initialized to:

```
MQXR2_DEFAULT_CONTINUATION
```

on entry to an IBM MQ API call exit function. It can then be set to one of the values:

MQXR2_DEFAULT_CONTINUATION

Whether to continue with the next exit in the chain, depending on the value of ExitResponse.

If ExitResponse is MQXCC_SUPPRESS_FUNCTION or MQXCC_SKIP_FUNCTION, bypass exit functions later in the MQXR_BEFORE chain and the matching exit functions in the MQXR_AFTER chain. Invoke exit functions in the MQXR_AFTER chain that match exit functions earlier in the MQXR_BEFORE chain.

Otherwise, invoke the next exit in the chain.

MQXR2_SUPPRESS_CHAIN

Suppress the chain.

Bypass exit functions later in the MQXR_BEFORE chain and the matching exit functions in the MQXR_AFTER chain for this API call invocation. Invoke exit functions in the MQXR_AFTER chain that match exit functions earlier in the MQXR_BEFORE chain.

MQXR2_CONTINUE_CHAIN

Continue with the next exit in the chain.

For information about the interaction between ExitResponse and ExitResponse2, and its effect on exit processing, see [“How queue managers process exit functions” on page 1571](#).

Feedback (MQLONG) - input/output

Communicate feedback codes between exit function invocations. This is initialized to:

```
MQFB_NONE (0)
```

before invoking the first function of the first exit in a chain.

Exits can set this field to any value, including any valid MQFB_* or MQRC_* value. Exits can also set this field to a user-defined feedback value in the range MQFB_APPL_FIRST to MQFB_APPL_LAST.

APICallerType (MQLONG) - input

The API caller type, indicating whether the IBM MQ API caller is external or internal to the queue manager: MQXACT_EXTERNAL or MQXACT_INTERNAL.

ExitUserArea (MQBYTE16) - input/output

A user area, available to all the exits associated with a particular ExitInfoObject. It is initialized to MQXUA_NONE (binary zeros for the length of the ExitUserArea) before invoking the first exit function (MQ_INIT_EXIT) for the hconn. From then on, any changes made to this field by an exit function are preserved across invocations of functions of the same exit.

This field is aligned to a multiple of 4 MQLONGs.

Exits can also anchor any storage that they allocate from this area.

For each hconn, each exit in a chain of exits has a different ExitUserArea. The ExitUserArea cannot be shared by exits in a chain, and the contents of the ExitUserArea for one exit are not available to another exit in a chain.

For C programs, the constant MQXUA_NONE_ARRAY is also defined with the same value as MQXUA_NONE, but as an array of characters instead of a string.

The length of this field is given by MQ_EXIT_USER_AREA_LENGTH.

ExitData (MQCHAR32) - input

Exit data, set on input to each exit function to the 32 characters of exit-specific data that is provided in the exit. If you define no value in the exit this field is all blanks.

The length of this field is given by MQ_EXIT_DATA_LENGTH.

ExitInfoName (MQCHAR48) - input

The exit information name, set on input to each exit function to the ApiExit_name specified in the exit definitions in the stanzas.

ExitPDArea (MQBYTE48) - input/output

A problem determination area, initialized to MQXPDA_NONE (binary zeros for the length of the field) for each invocation of an exit function.

For C programs, the constant MQXPDA_NONE_ARRAY is also defined with the same value as MQXPDA_NONE, but as an array of characters instead of a string.

The exit handler always writes this area to the IBM MQ trace at the end of an exit, even when the function is successful.

The length of this field is given by MQ_EXIT_PD_AREA_LENGTH.

QMgrName (MQCHAR48) - input

The name of the queue manager the application is connected to, that has invoked an exit as a result of processing an IBM MQ API call.

If the name of a queue manager supplied on an MQCONN or MQCONNx calls is blank, this field is still set to the name of the queue manager to which the application is connected, whether the application is server or client.

The exit handler sets this field on entry to each exit function.

The length of this field is given by MQ_Q_MGR_NAME_LENGTH.

ExitChainAreaPtr (PMQACH) - input/output

This is used to communicate data across invocations of different exits in a chain. It is set to a NULL pointer before invoking the first function (MQ_INIT_EXIT with ExitReason MQXR_CONNECTION) of the first exit in a chain of exits. The value returned by the exit on one invocation is passed on to the next invocation.

Refer to [“The exit chain area and exit chain area header \(MQACH\)” on page 1575](#) for more details about how to use the exit chain area.

Hconfig (MQHCONFIG) - input

The configuration handle, representing the set of functions being initialized. This value is generated by the queue manager on the MQ_INIT_EXIT function, and is later passed to the API exit function. It is set on entry to each exit function.

You can use Hconfig as a pointer to the MQIEP structure to make MQI and DCI calls. You must check that the first 4 bytes of HConfig match the StrucId of the MQIEP structure before using the HConfig parameter as a pointer to the MQIEP structure.

Function (MQLONG) - input

The function identifier, valid values for which are the MQXF_* constants described in [“External constants” on page 1576](#).

The exit handler sets this field to the correct value, on entry to each exit function, depending on the IBM MQ API call that resulted in the exit being invoked.

ExitMsgHandle (MQHMSG) - input/output

When Function is MQXF_GET and ExitReason is MQXR_AFTER, a valid message handle is returned in this field allowing the API exit access to the message descriptor fields and any other properties matching the ExitProperties string specified in the MQXEPO structure when registering the API exit.

Any non-message descriptor properties that are returned in the ExitMsgHandle will not be available from the MsgHandle in the MQGMO structure if one was specified, or in the message data.

When Function is MQXF_GET and ExitReason is MQXR_BEFORE, if the exit program sets this field to MQHM_NONE then it will suppress the populating of the ExitMsgHandle properties.

This field is not set if Version is less than MQAXP_VERSION_2.

How queue managers process exit functions

The processing performed by the queue manager on return from an exit function depends on both ExitResponse and ExitResponse2.

[Table 655 on page 1572](#) summarizes the possible combinations and their effects for an MQXR_BEFORE exit function, showing:

- Who sets the CompCode and Reason parameters of the API call
- Whether the remaining exit functions in the MQXR_BEFORE chain and the matching exit functions in the MQXR_AFTER chain are invoked
- Whether the API call is invoked

For an MQXR_AFTER exit function:

- CompCode and Reason are set in the same way as MQXR_BEFORE
- ExitResponse2 is ignored (the remaining exit functions in the MQXR_AFTER chain are always invoked)
- MQXCC_SUPPRESS_FUNCTION and MQXCC_SKIP_FUNCTION are not valid

For an MQXR_CONNECTION exit function:

- CompCode and Reason are set in the same way as MQXR_BEFORE
- ExitResponse2 is ignored
- MQXCC_SUPPRESS_FUNCTION, MQXCC_SKIP_FUNCTION, MQXCC_SUPPRESS_EXIT are not valid

In all cases, where an exit or the queue manager sets `CompCode` and `Reason`, the values set can be changed by an exit invoked later, or by the API call (if the API call is invoked later).

Table 655. MQXR_BEFORE exit processing			
Value of ExitResponse	CompCode and Reason set by	Value of ExitResponse2 (default continuation) Chain	Value of ExitResponse2 (default continuation) API
MQXCC_OK	exit	Y	Y
MQXCC_SUPPRESS_EXIT	exit	Y	Y
MQXCC_SUPPRESS_FUNCTION	queue manager	N	N
MQXCC_SKIP_FUNCTION	exit	N	N
MQXCC_FAILED	queue manager	N	N

How clients process exit functions

In general, clients process exit functions in the same way that server applications do, and the *QMGrName* attribute in this structure applies whether the function is on a server or a client.

However, the client has no concept of the *mqs.ini* file, so the *ApiExitCommon* and *APIExitTemplate* stanzas do not apply. Only the *ApiExitLocal* stanza applies, and this stanza is configured in the *mqclient.ini* file.

IBM MQ API exit context structure (MQAXC)

The MQAXC structure, an external control block, is used as an input parameter to an API exit.

MQAXC has the following C declaration:

```
typedef struct tagMQAXC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQLONG     Environment;      /* Environment */
    MQCHAR12   UserId;           /* UserId associated with appl */
    MQBYTE40   SecurityId;       /* Extension to UserId running appl */
    MQCHAR264  ConnectionName;   /* Connection name */
    MQLONG     LongMCAUserIdLength; /* long MCA user identifier length */
    MQLONG     LongRemoteUserIdLength; /* long remote user identifier length */
    MQPTR      LongMCAUserIdPtr; /* long MCA user identifier address */
    MQPTR      LongRemoteUserIdPtr; /* long remote user identifier address */
    MQCHAR28   ApplName;         /* Application name */
    MQLONG     ApplType;         /* Application type */
    MQPID      ProcessId;        /* Process identifier */
    MQTID      ThreadId;         /* Thread identifier */

    /* Ver:1 */
    MQCHAR     ChannelName[20]   /* Channel Name */
    MQBYTE4    Reserved1;        /* Reserved */
    PMQCD      pChannelDefinition; /* Channel Definition pointer */
};
```

The parameters to MQAXC are:

StrucId (MQCHAR4) - input

The exit context structure identifier, with a value of `MQAXC_STRUC_ID`. For C programs, the constant `MQAXC_STRUC_ID_ARRAY` is also defined, with the same value as `MQAXC_STRUC_ID`, but as an array of characters instead of a string.

The exit handler sets this field on entry to each exit function.

Version (MQLONG) - input

The structure version number, with a value of:

MQAXC_VERSION_2

Version number for the exit context structure.

MQAXC_CURRENT_VERSION

Current version number for the exit context structure.

The exit handler sets this field on entry to each exit function.

Environment (MQLONG) - input

The environment from which an IBM MQ API call was issued that resulted in an exit function being driven. Valid values for this field are:

MQXE_OTHER

This value is consistent with invocations an API exit sees if the exit is called from a server application. This means that an API exit runs unchanged on a client and does not see anything different.

If the exit really needs to determine whether it is running on the client, the exit can do so by looking at the *ChannelName* and *ChannelDefinition* fields.

MQXE_MCA

Message channel agent

MQXE_MCA_SVRCONN

A message channel agent acting on behalf of a client

MQXE_COMMAND_SERVER

The command server

MQXE_MQSC

The runmqsc command interpreter

The exit handler sets this field on entry to each exit function.

UserId (MQCHAR12) - input

The user ID associated with the application. In particular, in the case of client connections, this field contains the user ID of the adopted user as opposed to the user ID under which the channel code is running. If a blank user ID flows from the client, then no change is made to the user ID already being used. That is, no new user ID is adopted.

The exit handler sets this field on entry to each exit function. The length of this field is given by MQ_USER_ID_LENGTH.

In the case of a client, this is the user ID sent from the client to the server. Note, that this might not be the effective user ID the client is running against in the queue manager, as there could be an MCAUser or CHLAUTH configuration which changes the user ID.

SecurityId (MQBYTE40) - input

An extension to the user ID running the application. Its length is given by MQ_SECURITY_ID_LENGTH.

In the case of a client, this is the user ID sent from the client to the server. Note, that this might not be the effective user ID the client is running against in the queue manager, as there could be an MCAUser or CHLAUTH configuration which changes the user ID.

ConnectionName (MQCHAR264) - input

The connection name field, set to the address of the client. For example, for TCP/IP, it would be the client IP address.

The length of this field is given by MQ_CONN_NAME_LENGTH.

In the case of a client, this is the partner address of the queue manager.

LongMCAUserIdLength (MQLONG) - input

The length of the long MCA user identifier.

When MCA connects to the queue manager this field is set to the length of the long MCA user identifier (or zero if there is no such identifier).

In the case of a client, this is the client long user identifier.

LongRemoteUserIdLength (MQLONG) - input

The length of the long remote user identifier.

When MCA connects to the queue manager this field is set to the length of the long remote user identifier. Otherwise this field will be set to zero

In the case of a client, set this field to zero.

LongMCAUserIdPtr (MQPTR) - input

Address of long MCA user identifier.

When MCA connects to the queue manager this field is set to the address of the long MCA user identifier (or to a null pointer if there is no such identifier).

In the case of a client, this is the client long user identifier.

LongRemoteUserIdPtr (MQPTR) - input

The address of the long remote user identifier.

When MCA connects to the queue manager this field is set to the address of the long remote user identifier (or to a null pointer if there is no such identifier).

In the case of a client, set this field to zero.

ApplName (MQCHAR28) - input

The name of the application or component that issued the IBM MQ API call.

The rules for generating the ApplName are the same as for generating the default name for an MQPUT.

The value of this field is found by querying the operating system for the program name. Its length is given by MQ_APPL_NAME_LENGTH.

ApplType (MQLONG) - input

The type of application or component that issued the IBM MQ API call.

The value is MQAT_DEFAULT for the platform on which the application is compiled, or it equates to one of the defined MQAT_* values.

The exit handler sets this field on entry to each exit function.

ProcessId (MQPID) - input

The operating system process identifier.

Where applicable, the exit handler sets this field on entry to each exit function.

ThreadId (MQTID) - input

The MQ thread identifier. This is the same identifier used in MQ trace and FFST dumps, but might be different from the operating system thread identifier.

Where applicable, the exit handler sets this field on entry to each exit function.

ChannelName (MQCHAR) - input

The name of the channel, padded with blanks, if applicable and known.

If not applicable, this field is set to NULL characters.

Reserved1 (MQBYTE4) - input

This field is reserved.

ChannelDefinition (PMQCD) - input

A pointer to the channel definition being used, if applicable and known.

If not applicable, this field is set to NULL characters.

Note that the pointer is only completed if the connection is processing on behalf of an IBM MQ channel and that channel definition has been read.

In particular, the channel definition is not given on the server when the first MQCONN call is made for the channel. Furthermore, if the pointer is filled, the structure (and any sub structures) pointed to by the pointer must be treated as read only; any updating of the structure would lead to unpredictable results and is not supported.

In the case of a client, fields other than those with a value specified for a client, contain values that are appropriate for a client application.

The exit chain area and exit chain area header (MQACH)

If required, an exit function can acquire storage for an exit chain area and set the ExitChainAreaPtr in MQAXP to point to this storage.

Exits (either the same or different exit functions) can acquire multiple exit chain areas and link them together. Exit chain areas must only be added or removed from this list while called from the exit handler. This ensures that there are no serialization issues caused by different threads adding or removing areas from the list at the same time.

An exit chain area must start with an MQACH header structure, the C declaration for which is:

```
typedef struct tagMQACH {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQLONG     StrucLength;      /* Length of the MQACH structure */
    MQLONG     ChainAreaLength; /* Exit chain area length */
    MQCHAR48   ExitInfoName;     /* Exit information name */
    PMQACH     NextChainAreaPtr; /* Pointer to next exit chain area */
};
```

The fields in the exit chain area header are:

StrucId (MQCHAR4) - input

The exit chain area structure identifier, with an initial value, defined by MQACH_DEFAULT, of MQACH_STRUC_ID.

For C programs, the constant MQACH_STRUC_ID_ARRAY is also defined; this has the same value as MQACH_STRUC_ID, but as an array of characters instead of a string.

Version (MQLONG) - input

The structure version number, as follows:

MQACH_VERSION_1

The version number for the exit parameter structure.

MQACH_CURRENT_VERSION

The current version number for the exit context structure.

The initial value of this field, defined by MQACH_DEFAULT, is MQACH_CURRENT_VERSION.

Note: If you introduce a new version of this structure, the layout of the existing part does not change. Exit functions must check that the version number is equal to or greater than the lowest version containing the fields that the exit function needs to use.

StrucLength (MQLONG) - input

The length of the MQACH structure. Exits can use this field to determine the start of the exit data, setting it to the length of the structure created by the exit.

The initial value of this field, defined by MQACH_DEFAULT, is MQACH_CURRENT_LENGTH.

ChainAreaLength (MQLONG) - input

The exit chain area length, set to the overall length of the current exit chain area, including the MQACH header.

The initial value of this field, defined by MQACH_DEFAULT, is zero.

ExitInfoName (MQCHAR48) - input

The exit information name.

When an exit creates an MQACH structure, it must initialize this field with its own ExitInfoName, so that later this MQACH structure can be found by either another instance of this exit, or by a cooperating exit.

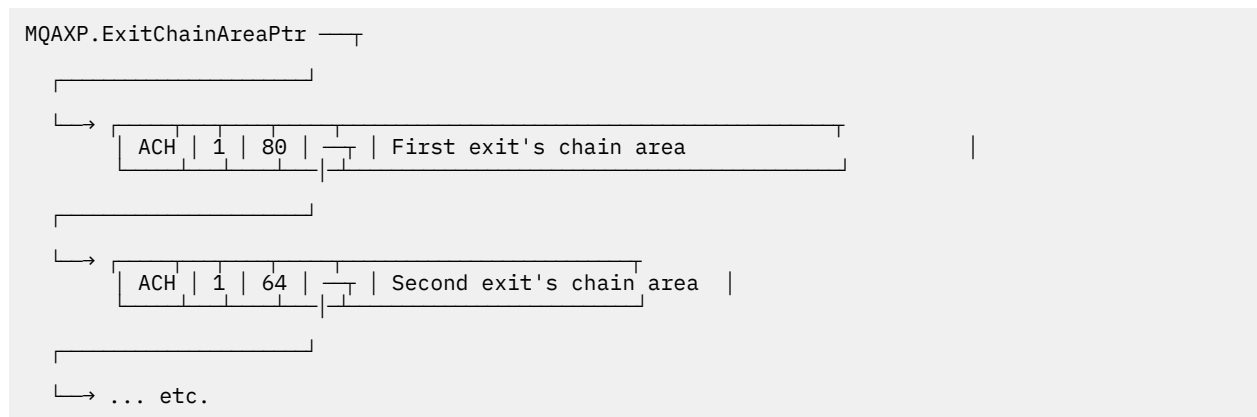

The initial value of this field, defined by MQACH_DEFAULT, is a zero length string ({}).

NextChainAreaPtr (PMQACH) - input

A pointer to the next exit chain area with an initial value, defined by MQACH_DEFAULT, of null pointer (NULL).

Exit functions must release the storage for any exit chain areas that they acquire, and manipulate the chain pointers to remove their exit chain areas from the list.

An exit chain area can be constructed as follows:

External constants

Use this topic as reference information for external constants available for API exits.

The following external constants are available for API exits:

MQXF_* (exit function identifiers)

MQXF_INIT	1	X'00000001'
MQXF_TERM	2	X'00000002'
MQXF_CONN	3	X'00000003'
MQXF_CONNX	4	X'00000004'
MQXF_DISC	5	X'00000005'
MQXF_OPEN	6	X'00000006'
MQXF_CLOSE	7	X'00000007'
MQXF_PUT1	8	X'00000008'
MQXF_PUT	9	X'00000009'
MQXF_GET	10	X'0000000A'
MQXF_DATA_CONV_ON_GET	11	X'0000000B'
MQXF_INQ	12	X'0000000C'
MQXF_SET	13	X'0000000D'

MQXCC_FAILED	-8
--------------	----

MQRC_* (reason codes)

MQRC_API_EXIT_ERROR 2374 X'00000946'

An exit function invocation has returned an invalid response code, or has failed in some way, and the queue manager cannot determine the next action to take.

Examine both the ExitResponse and ExitResponse2 fields of the MQAXP to determine the bad response code, and change the exit to return a valid response code.

MQRC_API_EXIT_INIT_ERROR 2375 X'00000947'

The queue manager encountered an error while initializing the execution environment for an API exit function.

MQRC_API_EXIT_TERM_ERROR 2376 X'00000948'

The queue manager encountered an error while closing the execution environment for an API exit function.

MQRC_EXIT_REASON_ERROR 2377 X'00000949'

The value of the ExitReason field supplied on an exit entry point registration call (MQXEP) call is in error.

Examine the value of the ExitReason field to determine and correct the bad exit reason value.

MQRC_RESERVED_VALUE_ERROR 2378 X'0000094A'

The value of the Reserved field is in error.

Examine the value of the Reserved field to determine and correct the Reserved value.

C language typedefs

This topic provides information about typedefs associated with API exits available in C language.

Here are the C language typedefs associated with the API exits:

```
typedef PMLONG      MQPOINTER PPMQLONG;
typedef PMQBYTE     MQPOINTER PPMQBYTE;
typedef PMQHOBJS    MQPOINTER PPMQHOBJS;
typedef PMQOD       MQPOINTER PPMQOD;
typedef PMQMD       MQPOINTER PPMQMD;
typedef PMQPMO      MQPOINTER PPMQPMO;
typedef PMQGM       MQPOINTER PPMQGM;
typedef PMQCNO      MQPOINTER PPMQCNO;
typedef PMQBO       MQPOINTER PPMQBO;

typedef MQAXP       MQPOINTER PMQAXP;
typedef MQACH       MQPOINTER PMQACH;
typedef MQAXC       MQPOINTER PMQAXC;

typedef MQCHAR      MQCHAR16[16];
typedef MQCHAR16    MQPOINTER PMQCHAR16;

typedef MQLONG      MQPID;
typedef MQLONG      MQTID;
```

The exit entry point registration call (MQXEP)

Use this information to learn about MQXEP, MQXEP C language invocation, and MQXEP C function prototype.

Use the MQXEP call to:

1. Register the before and after IBM MQ API exit invocation points at which to invoke exit functions
2. Specify the exit function entry points
3. Deregister the exit function entry points

You would typically code the MQXEP calls in the MQ_INIT_EXIT exit function, but you can specify them in any subsequent exit function.

If you use an MQXEP call to register an already registered exit function, the second MQXEP call completes successfully, replacing the registered exit function.

If you use an MQXEP call to register a NULL exit function, the MQXEP call completes successfully and the exit function is deregistered.

If MQXEP calls are used to register, deregister, and reregister a particular exit function during the life of a connection request, the previously registered exit function is reactivated. Any storage still allocated and associated with this exit function instance is available for use by the exit's functions. (This storage is typically released during the invocation of the termination exit function.)

The interface to MQXEP is:

```
MQXEP (Hconfig, ExitReason, Function, EntryPoint, &ExitOpts, &CompCode, &Reason)
```

where:

Hconfig (MQHCONFIG) - input

The configuration handle, representing the API exit that includes the set of functions being initialized. This value is generated by the queue manager immediately before invoking the MQ_INIT_EXIT function, and is passed in the MQAXP to each API exit function.

ExitReason (MQLONG) - input

The reason for which the entry point is being registered, from the following reasons:

- Connection level initialization or termination (MQXR_CONNECTION)
- Before an IBM MQ API call (MQXR_BEFORE)
- After an IBM MQ API call (MQXR_AFTER)

Function (MQLONG) - input

The function identifier, valid values for which are the MQXF_* constants (see [“External constants” on page 1576](#)).

EntryPoint (PMQFUNC) - input

The address of the entry point for the exit function to be registered. The value NULL indicates either that the exit function has not been provided, or that a previous registration of the exit function is being deregistered.

ExitOpts(MQXEPO)

API exits can specify options that control how API exits are registered. If a null pointer is specified for this field, the default values of the MQXEPO structure are assumed.

CompCode (MQLONG) - output

The completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

The reason code that qualifies the completion code.

If the completion code is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If the completion code is MQCC_FAILED:

MQRC_HCONFIG_ERROR

(2280, X'8E8') The supplied configuration handle is not valid. Use the configuration handle from the MQAXP.

MQRC_EXIT_REASON_ERROR

(2377, X'949') The supplied exit function invocation reason is either not valid or is not valid for the supplied exit function identifier.

Either use one of the valid exit function invocation reasons (MQXR_* value), or use a valid function identifier and exit reason combination. (See [Table 656 on page 1579](#).)

MQRC_FUNCTION_ERROR

(2281, X'8E9') The supplied function identifier is not valid for API exit reason. The following table shows valid combinations of function identifiers and ExitReasons.

Table 656. Valid combinations of function identifiers and ExitReasons	
Function	ExitReason
MQXF_INIT MQXF_TERM	MQXR_CONNECTION

Table 656. Valid combinations of function identifiers and ExitReasons (continued)

Function	ExitReason
MQXF_CONN MQXF_CONNX MQXF_DISC MQXF_OPEN MQXF_CLOSE MQXF_PUT1 MQXF_PUT MQXF_GET MQXF_INQ MQXF_SET MQXF_BEGIN MQXF_CMIT MQXF_BACK MQXF_STAT MQXF_CB MQXF_CTL MQXF_CALLBACK MQXF_SUB MQXF_SUBRQ	MQXR_BEFORE MQXR_AFTER
MQXF_DATA_CONV_ON_GET	MQXR_BEFORE

MQRC_RESOURCE_PROBLEM

(2102, X'836') An attempt to register or deregister an exit function has failed because of a resource problem.

MQRC_UNEXPECTED_ERROR

(2195, X'893') An attempt to register or deregister an exit function has failed unexpectedly.

MQRC_PROPERTY_NAME_ERROR

(2442, X'098A') Invalid ExitProperties name.

MQRC_XEPO_ERROR

(2507, X'09CB') Exit options structure not valid.

MQXEP C language invocation

```
MQXEP (Hconfig, ExitReason, Function, EntryPoint, &ExitOpts, &CompCode, &Reason);
```

Declaration for parameter list:

```

MQHCONFIG      Hconfig;          /* Configuration handle */
MQLONG         ExitReason;       /* Exit reason */
MQLONG         Function;         /* Function identifier */
PMQFUNC        EntryPoint;       /* Function entry point */
MQXEPO         ExitOpts;        /* Options that control the action of MQXEP */
MQLONG         CompCode;        /* Completion code */
MQLONG         Reason;          /* Reason code qualifying completion
                                code */

```

MQXEP C function prototype

```

void MQXEP (
MQHCONFIG      Hconfig,          /* Configuration handle */
MQLONG         ExitReason,       /* Exit reason */
MQLONG         Function,         /* Function identifier */
PMQFUNC        EntryPoint,       /* Function entry point */
PMQXEPO        pExitOpts;       /* Options that control the action of MQXEP */
PMQLONG        pCompCode,       /* Address of completion code */

```

```
PMQLONG      pReason);          /* Address of reason code qualifying completion
                                code */
```

Exit functions

This section provides some general information to help you when using the function calls and describes how to invoke the individual exit functions.

Use this information to understand the general rules for API exit routines, and setting up and cleaning up the exit execution environment.

General rules for API exit routines

The following general rules apply when invoking API exit routines:

- In all cases, API exit functions are driven before validating API call parameters, and before any security checks (in the case of MQCONN, MQCONNX, or MQOPEN).
- The values of fields entered into and output from an exit routine are:
 - On input to a *before* IBM MQ API exit function, the value of a field can be set by the application program, or by a previous exit function invocation.
 - On output from a *before* IBM MQ API exit function, the value of a field can be left unchanged, or set to some other value by the exit function.
 - On input to an *after* IBM MQ API exit function, the value of a field can be the value set by the queue manager after processing the IBM MQ API call, or can be set to a value by a previous exit function invocation in the chain of exit functions.
 - On output from an *after* IBM MQ API call exit function, the value of a field can be left unchanged, or set to some other value by the exit function.
- Exit functions must communicate with the queue manager by using the ExitResponse and ExitResponse2 fields.
- The CompCode and Reason code fields communicate back to the application. The queue manager and exit functions can set the CompCode and Reason code fields.
- The MQXEP call returns new reason codes to the exit functions that call MQXEP. However, exit functions can translate these new reason codes to any existing reasons codes that existing and new applications can understand.
- Each exit function prototype has similar parameters to the API function with an extra level of indirection except for the CompCode and Reason.
- API exits can issue MQI calls (except MQDISC), but these MQI calls do not themselves invoke API exits.

Note, that whether the application is on a server or a client, you cannot predict the sequencing of the API exit calls. An API exit BEFORE call might not be followed immediately by an AFTER call.

The BEFORE call can be followed by another BEFORE call. For example:

```
BEFORE MQCTL
BEFORE Callback
BEFORE MQPUT
AFTER MQPUT
AFTER Callback
AFTER MQCTL
```

or

```
BEFORE XAOPEN
BEFORE MQCONNX
AFTER MQCONNX
AFTER XAOPEN
```

On the client, there is an exit that can modify the behavior of the MQCONN or MQCONNEX call, called the PreConnect exit. The PreConnect exit can modify any of the parameters on the MQCONN or MQCONNEX call including the queue manager name. The client calls this exit first and then invokes the MQCONN or MQCONNEX call. Note that only the initial MQCONN or MQCONNEX call invokes the API exit; any subsequent reconnect calls have no effect.

The execution environment

In general, all errors from exit functions are communicated back to the exit handler using the ExitResponse and ExitResponse2 fields in MQAXP.

These errors in turn are converted into MQCC_* and MQRC_* values and communicated back to the application in the CompCode and Reason fields. However, any errors encountered in the exit handler logic are communicated back to the application as MQCC_* and MQRC_* values in the CompCode and Reason fields.

If an MQ_TERM_EXIT function returns an error:

- The MQDISC call has already taken place
- There is no other opportunity to drive the *after* MQ_TERM_EXIT exit function (and thus perform exit execution environment cleanup)
- Exit execution environment cleanup is *not* performed

The exit cannot be unloaded as it might still be in use. Also, other registered exits further down in the exit chain for which the *before* exit was successful, will be driven in the reverse order.

Setting up the exit execution environment

While processing an explicit MQCONN or MQCONNEX call, exit handling logic sets up the exit execution environment before invoking the exit initialization function (MQ_INIT_EXIT). Exit execution environment setup involves loading the exit, acquiring storage for, and initializing exit parameter structures. The exit configuration handle is also allocated.

If errors occur during this phase, the MQCONN or MQCONNEX call fails with CompCode MQCC_FAILED and one of the following reason codes:

MQRC_API_EXIT_LOAD_ERROR

An attempt to load an API exit module has failed.

MQRC_API_EXIT_NOT_FOUND

An API exit function could not be found in the API exit module.

MQRC_STORAGE_NOT_AVAILABLE

An attempt to initialize the execution environment for an API exit function failed because insufficient storage was available.

MQRC_API_EXIT_INIT_ERROR

An error was encountered while initializing the execution environment for an API exit function.

Cleaning up the exit execution environment

While processing an explicit MQDISC call, or an implicit disconnect request as a result of an application ending, exit handling logic might need to clean up the exit execution environment after invoking the exit termination function (MQ_TERM_EXIT), if registered.

Cleaning up the exit execution environment involves releasing storage for exit parameter structures, possibly deleting any modules previously loaded into memory.

If errors occur during this phase, an explicit MQDISC call fails with CompCode MQCC_FAILED and the following reason code (errors are not highlighted on implicit disconnect requests):

MQRC_API_EXIT_TERM_ERROR

An error was encountered while closing the execution environment for an API exit function. The exit should *not* return any failure from the MQDISC before or after the MQ_TERM* API exit function calls.

API exits on clients

A client uses the PreConnect exit to modify the behavior of the MQCONN and MQCONNX calls and does not support API exit properties.

PreConnect exit

On a client, the PreConnect exit can be used to look up the channel definition from a central repository, such as an LDAP server.

The PreConnect exit can also modify any parameter, or all the parameters, on an MQCONN or MQCONNX call itself, for example, the queue manager name.

In the case of client applications, the PreConnect exit must be called before the API exit because the MQCONN or MQCONNX API exit is called only once the name of the queue manager is known and this name can be changed by the PreConnect exit.

Note that only the initial MQCONN or MQCONNX call invokes the exit.

API exit properties

On a server, API exits can register an MQXEPO structure at initialization time. The MQXEPO structure contains the ExitProperties field which details the group of properties the exit is interested in. This has the effect of generating a separate message property handle which the exit can manipulate separately from any application message property handle.

On a client, API exit properties are not supported. If an attempt is made to register a property group name on a client, the function fails with a reason code of MQRC_EXIT_PROPS_NOT_SUPPORTED.

Backout - MQ_BACK_EXIT

MQ_BACK_EXIT provides a backout exit function to perform *before* and *after* backout processing. Use function identifier MQXF_BACK with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* backout call exit functions.

The interface to this function is:

```
MQ_BACK_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_BACK_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_BACK_EXIT (
PMQAXP    pExitParms,    /* Address of exit parameter structure */
PMQAXC    pExitContext,  /* Address of exit context structure */
PMQHCONN  pHconn,        /* Address of connection handle */
PMQLONG   pCompCode,     /* Address of completion code */
PMQLONG   pReason);      /* Address of reason code qualifying completion
                           code */
```

Begin - MQ_BEGIN_EXIT

MQ_BEGIN_EXIT provides a begin exit function to perform *before* and *after* MQBEGIN call processing. Use function identifier MQXF_BEGIN with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQBEGIN call exit functions.

The interface to this function is:

```
MQ_BEGIN_EXIT (&ExitParms, &ExitContext, &Hconn, &pBeginOptions, &CompCode,
               &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pBeginOptions (PMQBO)- input/output

Pointer to begin options.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
PMQBO    pBeginOptions;  /* Ptr to begin options */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_BEGIN_EXIT (&ExitParms, &ExitContext, &Hconn, &pBeginOptions, &CompCode,
               &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_BEGIN_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,          /* Address of connection handle */
PPMQBO    ppBeginOptions,  /* Address of ptr to begin options */
PMQLONG   pCompCode,       /* Address of completion code */
PMQLONG   pReason);        /* Address of reason code qualifying completion
                             code */
```

Callback - MQ_CALLBACK_EXIT

MQ_CALLBACK_EXIT provides an exit function to perform *before* and *after* callback processing. Use function identifier MQXF_CALLBACK with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* callback call exit functions.

The interface to this function is:

```
MQ_CALLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pMsgDesc, &pGetMsgOpts,
                  &pBuffer, &pMQCBContext)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure

ExitContext (MQAXC) - input/output

Exit context structure

Hconn (MQHCONN) - input/output

Connection handle

pMsgDesc

Message descriptor

pGetMsgOpts

Options that control the action of MQGET

pBuffer

Area to contain the message data

pMQCBContext

Context data for the callback

C language invocation

The queue manager logically defines the following variables:

```

MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
PMQMD    pMsgDesc;       /* Message descriptor */
PMQGM0   pGetMsgOpts;    /* Options that define the operation of the consumer */
PMQVOID  pBuffer;        /* Area to contain the message data */
PMQCBC   pContext;       /* Context data for the callback */

```

The queue manager then logically calls the exit as follows:

```

MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pMsgDesc, &pGetMsgOpts, &pBuffer,
               &pContext);

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_CALLBACK_EXIT (
PMQAXP    pExitParms;    /* Exit parameter structure */
PMQAXC    pExitContext;  /* Exit context structure */
PMQHCONN  pHconn;        /* Connection handle */
PPMQMD    ppMsgDesc;     /* Message descriptor */
PPMQGM0   ppGetMsgOpts;  /* Options that define the operation of the consumer */
PPMVOID   ppBuffer;      /* Area to contain the message data */
PPMCBC    ppContext;     /* Context data for the callback */
)

```

Usage notes

1. The Callback exit is invoked before the consumer is invoked and after the consumer's consumer function has completed. Although the MQMD and MQGMO structures are alterable, changing the values in the before exit does not redrive the retrieval of a message from the queue as the message has already been removed from the queue to be delivered to the consumer function

Manage callback functions - MQ_CB_EXIT

MQ_CB_EXIT provides an exit function to perform *before* and *after* the MQCB call. Use function identifier MQXF_CB with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQCB call exit functions.

The interface to this function is:

```

MQ_CB_EXIT (&ExitParms, &ExitContext, &Hconn, &Operation, &pCallbackDesc,
            &Hobj, &pMsgDesc, &pGetMsgOpts, &CompCode, &Reason)

```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure

ExitContext (MQAXC) - input/output

Exit context structure

Hconn (MQHCONN) - input/output

Connection handle

Operation (MQLONG) - input/output

Operation value

pCallbackDesc (PMQCBD) - input/output

Callback descriptor

Hobj (MQHOBJ) - input/output

Object handle

pMsgDesc (PMQMD) - input/output

Message descriptor

pGetMsgOpts (PMQGM0) - input/output

Options that control the action of MQCB

CompCode (MQLONG) - input/output

Completion code

Reason (MQLONG) - input/output

Reason code qualifying CompCode

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN   Hconn;         /* Connection handle */
MQLONG    Operation;     /* Operation value. */
MQCBD     pMsgDesc;      /* Callback descriptor. */
MQHOBJS   Hobj;         /* Object handle. */
PMQMD     pMsgDesc;      /* Message descriptor */
PMQGM0    pGetMsgOpts;   /* Options that define the operation of the consumer */
PMQLONG   CompCode;      /* Completion code. */
PMQLONG   Reason;        /* Reason code qualifying CompCode. */
```

The queue manager then logically calls the exit as follows:

```
MQ_CB_EXIT (&ExitParms, &ExitContext, &Hconn, &Operation, &Hobj, &pMsgDesc,
            &pGetMsgOpts, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CB_EXIT (
PMQAXP    pExitParms;    /* Exit parameter structure */
PMQAXC    pExitContext;  /* Exit context structure */
PMQHCONN   pHconn;       /* Connection handle */
MQLONG     pOperation;   /* Callback operation */
PMQHOBJS   pHobj;        /* Object handle */
PPMQMD     ppMsgDesc;    /* Message descriptor */
PPMQGM0    ppGetMsgOpts; /* Options that control the action of MQCB */
PMQLONG     pCompCode;   /* Completion code */
PMQLONG     pReason;     /* Reason code qualifying CompCode */
```

Close - MQ_CLOSE_EXIT

MQ_CLOSE_EXIT provides a close exit function to perform *before* and *after* MQCLOSE call processing. Use function identifier MQXF_CLOSE with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQCLOSE call exit functions.

The interface to this function is:

```
MQ_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHobj,
               &Options, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pHobj (PMQHOBJS) - input

Pointer to object handle.

Options (MQLONG)- input/output

Close options.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;          /* Connection handle */
PMQHOBj    pHobj;          /* Ptr to object handle */
MQLONG     Options;        /* Close options */
MQLONG     CompCode;       /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHobj, &Options,
               &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CLOSE_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQHCONN    pHconn,        /* Address of connection handle */
PPMHOBj     ppHobj,        /* Address of ptr to object handle */
PMQLONG     pOptions,      /* Address of close options */
PMQLONG     pCompCode,     /* Address of completion code */
PMQLONG     pReason);      /* Address of reason code qualifying
                             completion code */
```

Commit - MQ_CMtT_EXIT

MQ_CMtT_EXIT provides a commit exit function to perform *before* and *after* commit processing. Use function identifier MQXF_CMtT with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* commit call exit functions.

If a commit operation fails, and the transaction is backed out, the MQCMIT call fails with MQCC_WARNING and MQRC_BACKED_OUT. These return and reason codes are passed into any *after* MQCMIT exit functions to give the exit functions an indication that the unit of work has been backed out.

The interface to this function is:

```
MQ_CMtT_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;      /* Exit parameter structure */
MQAXC    ExitContext;    /* Exit context structure */
MQHCONN  Hconn;          /* Connection handle */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CMIT_EXIT (
PMQAXP    pExitParms,      /* Address of exit parameter structure */
PMQAXC    pExitContext,    /* Address of exit context structure */
PMQHCONN  pHconn,         /* Address of connection handle */
PMQLONG   pCompCode,       /* Address of completion code */
PMQLONG   pReason);        /* Address of reason code qualifying completion
                             code */
```

Usage notes

1. The MQ_GET_EXIT function interface described here is used for both the MQXF_GET exit function and the [“MQXF_DATA_CONV_ON_GET”](#) on page 1595 exit function.

Separate entry points are defined for these two exit functions, so to intercept *both* the MQXEP call must be used twice; for this call use function identifier MQXF_GET.

Because the MQ_GET_EXIT interface is the same for MQXF_GET and MQXF_DATA_CONV_ON_GET, a single exit function can be used for both; the *Function* field in the MQAXP structure indicates which exit function has been invoked. Alternatively, the MQXEP call can be used to register different exit functions for the two cases.

Connect and connect extension - MQ_CONNX_EXIT

MQ_CONNX_EXIT provides:

- Connection exit function to perform *before* and *after* MQCONN processing
- Connection extension exit function to perform *before* and *after* MQCONNX processing

The same interface, described here, is invoked for both MQCONN and MQCONNX call exit functions.

When the message channel agent (MCA) responds to an inbound client connection, the MCA can connect and make a number of IBM MQ API calls before the client state is fully known. These API calls call the

API exit functions with the MQAXC based on the MCA program itself (for example in the UserId and ConnectionName fields of the MQAXC).

When the MCA responds to subsequent inbound client API calls, the MQAXC structure is based on the inbound client, setting the UserId and ConnectionName fields appropriately.

The queue manager name set by the application on an MQCONN or MQCONNEX call is passed to the underlying connect call. Any attempt by a *before* MQ_CONNEX_EXIT to change the name of the queue manager has no effect.

Use function identifiers MQXF_CONN and MQXF_CONNEX with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQCONN and MQCONNEX call exit functions.

An MQ_CONNEX_EXIT exit called for reason MQXR_BEFORE *must not* issue any IBM MQ API calls, as the correct environment has not been set up at this time.

An MQ_CONNEX_EXIT cannot call MQDISC from an API exit call for the connection for which it is being called. This restriction is applicable to both client and server API exits.

The interface to MQCONN and MQCONNEX is identical:

```
MQ_CONNEX_EXIT (&ExitParms, &ExitContext, &pQMGrName, &pConnectOpts,  
&pHconn, &CompCode, &Reason);
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

pQMGrName (PMQCHAR) - input

Pointer to the queue manager name supplied on the MQCONNEX call. The exit must not change this name on the MQCONN or MQCONNEX call.

pConnectOpts (PMQCNO) - input/output

Pointer to the options that control the action of the MQCONNEX call.

See [“MQCNO - Connect options” on page 306](#) for details.

For exit function MQXF_CONN, pConnectOpts points to the default connect options structure (MQCNO_DEFAULT).

pHconn (PMQHCONN) - input

Pointer to the connection handle.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Warning (partial completion)

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
PMQCHAR    pQMgrName;     /* Ptr to Queue manager name */
PMQCNO     pConnectOpts;  /* Ptr to Connection options */
PMQHCONN   pHconn;        /* Ptr to Connection handle */
MQLONG     CompCode;       /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CONNX_EXIT (&ExitParms, &ExitContext, &pQMgrName, &pConnectOpts,
               &pHconn, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CONNX_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PPMQCHAR    ppQMgrName,   /* Address of ptr to queue manager name */
PPMCNO      ppConnectOpts, /* Address of ptr to connection options */
PPMHCONN    ppHconn,      /* Address of ptr to connection handle */
PMQLONG     pCompCode,    /* Address of completion code */
PMQLONG     pReason);     /* Address of reason code qualifying
                           completion code */
```

Usage notes

1. The MQ_CONNX_EXIT function interface described here is used for both the MQCONN call and the MQCONNX call. However, separate entry points are defined for these two calls. To intercept *both* calls, the MQXEP call must be used at least twice - once with function identifier MQXF_CONN, and again with MQXF_CONNX.

Because the MQ_CONNX_EXIT interface is the same for MQCONN and MQCONNX, a single exit function can be used for both calls; the *Function* field in the MQAXP structure indicates which call is in progress. Alternatively, the MQXEP call can be used to register different exit functions for the two calls.

2. When a message channel agent (MCA) responds to an inbound client connection, the MCA can issue a number of MQ calls before the client state is fully known. These MQ calls result in the API exit functions being invoked with the MQAXC structure containing data relating to the MCA, and not to the client (for example, user identifier and connection name). However, once the client state is fully known, subsequent MQ calls result in the API exit functions being invoked with the appropriate client data in the MQAXC structure.
3. All MQXR_BEFORE exit functions are invoked before any parameter validation is performed by the queue manager. The parameters might therefore be invalid (including invalid pointers for the addresses of parameters).

The MQ_CONNX_EXIT function is invoked before any authorization checks are performed by the queue manager.

4. The exit function must not change the name of the queue manager specified on the MQCONN or MQCONNX call. If the name is changed by the exit function, the results are undefined.
5. An MQXR_BEFORE exit function for the MQ_CONNX_EXIT cannot issue MQ calls other than MQXEP.

Control callback - MQ_CTL_EXIT

MQ_CTL_EXIT provides a subscription request exit function to perform *before* and *after* control callback processing. Use function identifier MQXF_CTL with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* control callback call exit functions.

The interface to this function is:

```
MQ_CTL_EXIT (&Hconn, &Operation, &ControlOpts, &CompCode, &Reason)
```

where the parameters are:

Hconn (MQHCONN) - input/output

Connection handle.

Operation (MQLONG) input/output

The operation being processed on the callback defined for the specified object handle

ControlOpts (MQCTLO) input/output

Options that control the action of MQCTL

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQHCONN  Hconn;          /* Connection handle */
MQLONG   Operation;      /* Operation being processed */
MQCTLO   ControlOpts;    /* Options that control the action of MQCTL */
MQLONG   CompCode;       /* Completion code */
MQLONG   Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_CTL_EXIT (&Hconn, &Operation, &ControlOpts, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_CTL_EXIT (
PMQHCONN pHconn;          /* Address of connection handle */
PMQLONG  pOperation;      /* Address of operation being processed */
PMQCTLO  pControlOpts;    /* Address of options that control the action of MQCTL */
PMQLONG  pCompCode;       /* Address of completion code */
PMQLONG  pReason;         /* Address of reason code qualifying completion code */
```

Disconnect - MQ_DISC_EXIT

MQ_DISC_EXIT provides a disconnect exit function to perform *before* and *after* MQDISC exit processing. Use function identifier MQXF_DISC with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQDISC call exit functions.

The interface to this function is

```
MQ_DISC_EXIT (&ExitParms, &ExitContext, &pHconn,
&CompCode, &Reason);
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

pHconn (PMQHCONN) - input

Pointer to the connection handle.

For the before MQDISC call, the value of this field is one of:

- The connection handle returned on the MQCONN or MQCONNEX call
- Zero, for environments where an environment-specific adapter has connected to the queue manager
- A value set by a previous exit function invocation

For the after MQDISC call, the value of this field is zero or a value set by a previous exit function invocation.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

MQAXP	ExitParms;	/* Exit parameter structure */
MQAXC	ExitContext;	/* Exit context structure */
PMQHCONN	pHconn;	/* Ptr to Connection handle */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code */

The queue manager then logically calls the exit as follows:

```
MQ_DISC_EXIT (&ExitParms, &ExitContext, &pHconn,
&CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_DISC_EXIT (
PMQAXP      pExitParms,      /* Address of exit parameter structure */
PMQAXC      pExitContext,    /* Address of exit context structure */
PPMQHCONN   ppHconn,         /* Address of ptr to connection handle */
PMQLONG     pCompCode,       /* Address of completion code */
```

```
PMQLONG      pReason);      /* Address of reason code qualifying
                             completion code */
```

Get - MQ_GET_EXIT

MQ_GET_EXIT provides a get exit function to perform *before* and *after* MQGET call processing.

There are two function identifiers:

1. Use MQXF_GET with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQGET call exit functions.
2. See “MQXF_DATA_CONV_ON_GET” on page 1595 for information on using the MQXF_DATA_CONV_ON_GET function identifier.

The interface to this function is:

```
MQ_GET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pGetMsgOpts, &BufferLength, &pBuffer, &pDataLength,
             &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

Hobj (MQHOBJ) - input/output

Object handle.

pMsgDesc (PMQMD) - input/output

Pointer to message descriptor.

pGetMsgOpts (PMQGMO) - input/output

Pointer to get message options.

BufferLength (MQLONG) - input/output

Message buffer length.

pBuffer (PMQBYTE) - input/output

Pointer to message buffer.

pDataLength (PMQLONG) - input/output

Pointer to data length field.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
MQHOBJ     Hobj;          /* Object handle */
PMQMD      pMsgDesc;       /* Ptr to message descriptor */
PMQPMO     pGetMsgOpts;    /* Ptr to get message options */
MQLONG     BufferLength;    /* Message buffer length */
PMQBYTE    pBuffer;        /* Ptr to message buffer */
PMQLONG    pDataLength;    /* Ptr to data length field */
MQLONG     CompCode;       /* Completion code */
MQLONG     Reason;         /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_GET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pGetMsgOpts, &BufferLength, &pBuffer, &pDataLength,
             &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_GET_EXIT (
    PMQAXP      pExitParms,      /* Address of exit parameter structure */
    PMQAXC      pExitContext,    /* Address of exit context structure */
    PMQHCONN    pHconn,         /* Address of connection handle */
    PMQHOBJ     pHobj,          /* Address of object handle */
    PPMQMD      ppMsgDesc,       /* Address of ptr to message descriptor */
    PPMQGMO     ppGetMsgOpts,    /* Address of ptr to get message options */
    PMQLONG     pBufferLength,   /* Address of message buffer length */
    PPMQBYTE    ppBuffer,        /* Address of ptr to message buffer */
    PPMQLONG    ppDataLength,    /* Address of ptr to data length field */
    PMQLONG     pCompCode,       /* Address of completion code */
    PMQLONG     pReason);        /* Address of reason code qualifying
                                completion code */
```

Usage notes

1. The MQ_GET_EXIT function interface described here is used for both the MQXF_GET exit function and the “MQXF_DATA_CONV_ON_GET” on page 1595 exit function.

Separate entry points are defined for these two exit functions, so to intercept *both* the MQXEP call must be used twice; for this call use function identifier MQXF_GET.

Because the MQ_GET_EXIT interface is the same for MQXF_GET and MQXF_DATA_CONV_ON_GET, a single exit function can be used for both; the *Function* field in the MQAXP structure indicates which exit function has been invoked. Alternatively, the MQXEP call can be used to register different exit functions for the two cases.

MQXF_DATA_CONV_ON_GET

See [MQ_GET_EXIT](#) for information about the interface to this call, and a sample C language declaration.

Usage notes

If registered, this entry point is called when messages arrive at the application but before any data conversion has occurred. This can be useful if the API exit needs to perform processing, such as decryption or decompression, before the message is passed to data conversion. The exit can, if necessary, cause data conversion to be bypassed by returning MQXCC_SUPPRESS_FUNCTION; for more information, see [MQAXP](#) structure.

Registering for this entry point on a client has the effect of causing the data conversion to be performed locally on the client machine. For correct operation it might, therefore, be necessary to install the application conversion exits on the client. Note that MQXF_DATA_CONV_ON_GET is also used for asynchronous consume.

When using the `MQ_GET_EXIT` call, use `MQXF_DATA_CONV_ON_GET`, with exit reason `MQXR_BEFORE`, to register a *before* MQGET data conversion exit function.

There is no `MQXR_AFTER` exit function for `MQXF_DATA_CONV_ON_GET`; the `MQXR_AFTER` exit function for `MQXF_GET` provides the required capability for exit processing after data conversion.

Separate entry points are defined for the `MQ_GET_EXIT` call, so to intercept *both* exit functions, the `MQXEP` call must be used twice; for this call use function identifier `MQXF_DATA_CONV_ON_GET`.

Because the `MQ_GET_EXIT` interface is the same for `MQXF_GET` and `MQXF_DATA_CONV_ON_GET`, a single exit function can be used for both; the *Function* field in the `MQAXP` structure indicates which exit function has been invoked. Alternatively, the `MQXEP` call can be used to register different exit functions for the two cases.

Initialization - MQ_INIT_EXIT

`MQ_INIT_EXIT` provides connection level initialization, indicated by setting `ExitReason` in `MQAXP` to `MQXR_CONNECTION`.

During the initialization, note the following:

- The `MQ_INIT_EXIT` function calls `MQXEP` to register the IBM MQ API verbs and the `ENTRY` and `EXIT` points in which it is interested.
- Exits do not need to intercept all the IBM MQ API verbs. Exit functions are invoked only if an interest has been registered.
- Storage that is to be used by the exit can be acquired while initializing it.
- If a call to this function fails, the `MQCONN` or `MQCONNEX` call that invoked it also fails with a `CompCode` and `Reason` that depend on the value of the `ExitResponse` field in `MQAXP`.
- An `MQ_INIT_EXIT` exit must not issue IBM MQ API calls, because the correct environment has not been set up at this time.
- If an `MQ_INIT_EXIT` fails with `MQXCC_FAILED`, the queue manager returns from the `MQCONN` or `MQCONNEX` call that called it with `MQCC_FAILED` and `MQRC_API_EXIT_ERROR`.
- If the queue manager encounters an error while initializing the API exit function execution environment before invoking the first `MQ_INIT_EXIT`, the queue manager returns from the `MQCONN` or `MQCONNEX` call that invoked `MQ_INIT_EXIT` with `MQCC_FAILED` and `MQRC_API_EXIT_INIT_ERROR`.

The interface to `MQ_INIT_EXIT` is:

```
MQ_INIT_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

CompCode (MQLONG) - input/output

Pointer to completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Pointer to reason code qualifying the completion code.

If the completion code is `MQCC_OK`, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

The CompCode and Reason returned to the application depend on the value of the ExitResponse field in MQAXP.

C language invocation

The queue manager logically defines the following variables:

MQAXP	ExitParms;	/* Exit parameter structure */
MQAXC	ExitContext;	/* Exit context structure */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code */

The queue manager then logically calls the exit as follows:

```
MQ_INIT_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_INIT_EXIT (
    PMQAXP      pExitParms,      /* Address of exit parameter structure */
    PMQAXC      pExitContext,    /* Address of exit context structure */
    PMQLONG     pCompCode,       /* Address of completion code */
    PMQLONG     pReason);        /* Address of reason code qualifying
                                completion code */
```

Usage notes

1. The MQ_INIT_EXIT function can issue the MQXEP call to register the addresses of the exit functions for the particular MQ calls to be intercepted. It is not necessary to intercept all MQ calls, or to intercept both MQXR_BEFORE and MQXR_AFTER calls. For example, an exit suite could choose to intercept only the MQXR_BEFORE call of MQPUT.
2. Storage that is to be used by exit functions in the exit suite can be acquired by the MQ_INIT_EXIT function. Alternatively, exit functions can acquire storage when they are invoked, as and when needed. However, all storage should be freed before the exit suite is terminated; the MQ_TERM_EXIT function can free the storage, or an exit function invoked earlier.
3. If MQ_INIT_EXIT returns MQXCC_FAILED in the *ExitResponse* field of MQAXP, or fails in some other way, the MQCONN or MQCONNX call that caused MQ_INIT_EXIT to be invoked also fails, with the *CompCode* and *Reason* parameters set to appropriate values.
4. An MQ_INIT_EXIT function cannot issue MQ calls other than MQXEP.

Inquire - MQ_INQ_EXIT

MQ_INQ_EXIT provides an inquire exit function to perform *before* and *after* MQINQ call processing. Use function identifier MQXF_INQ with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQINQ call exit functions.

The interface to this function is:

```
MQ_INQ_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttrs, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

Hobj (MQHOBJ) - input

Object handle.

SelectorCount (MQLONG) - input

Count of selectors

pSelectors (PMQLONG) - input/output

Pointer to array of selector values.

IntAttrCount (MQLONG) - input

Count of integer attributes.

pIntAttrs (PMQLONG) - input/output

Pointer to array of integer attribute values.

CharAttrLength (MQLONG) - input/output

Character attributes array length.

pCharAttrs (PMQCHAR) - input/output

Pointer to character attributes array.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;          /* Exit parameter structure */
MQAXC      ExitContext;        /* Exit context structure */
MQHCONN    Hconn;              /* Connection handle */
MQHOBJ     Hobj;               /* Object handle */
MQLONG     SelectorCount;      /* Count of selectors */
PMQLONG    pSelectors;         /* Ptr to array of attribute selectors */
MQLONG     IntAttrCount;       /* Count of integer attributes */
PMQLONG    pIntAttrs;          /* Ptr to array of integer attributes */
MQLONG     CharAttrLength;     /* Length of char attributes array */
PMQCHAR    pCharAttrs;         /* Ptr to character attributes */
MQLONG     CompCode;           /* Completion code */
MQLONG     Reason;             /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_INQ_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttrs, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_INQ_EXIT (
    PMQAXP    pExitParms,      /* Address of exit parameter structure */
    PMQAXC    pExitContext,    /* Address of exit context structure */
    PMQHCONN  pHconn,          /* Address of connection handle */
    PMQHOBJS  pHobj,           /* Address of object handle */
    PMQLONG   pSelectorCount,   /* Address of selector count */
    PPMQLONG  ppSelectors,      /* Address of ptr to array of selectors */
    PMQLONG   pIntAttrCount;    /* Address of count of integer attributes */
    PPMQLONG  ppIntAttrs,       /* Address of ptr to array of integer attributes */
    PMQLONG   pCharAttrLength,  /* Address of character attribute length */
    PPMQCHAR  ppCharAttrs,      /* Address of ptr to character attributes array */
    PMQLONG   pCompCode,        /* Address of completion code */
    PMQLONG   pReason;          /* Address of reason code qualifying completion
                                code */
)
```

Open - MQ_OPEN_EXIT

MQ_OPEN_EXIT provides an open exit function to perform *before* and *after* MQOPEN call processing. Use function identifier MQXF_OPEN with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQOPEN call exit functions.

The interface to this function is

```
MQ_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &Options,
              &pHobj, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pObjDesc (PMQOD) - input/output

Pointer to object descriptor.

Options (MQLONG) - input/output

Open options.

pHobj (PMQHOBJS) - input

Pointer to object handle.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;         /* Connection handle */
PMQOD      pObjDesc;      /* Ptr to object descriptor */
MQLONG     Options;       /* Open options */
MQHOBJ     pHobj;         /* Ptr to object handle */
MQLONG     CompCode;      /* Completion code */
MQLONG     Reason;        /* Reason code */
```

The queue manager then logically calls the exit as follows:

```
MQ_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &Options,
              &pHobj, &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_OPEN_EXIT (
PMQAXP      pExitParms,    /* Address of exit parameter structure */
PMQAXC      pExitContext,  /* Address of exit context structure */
PMQHCONN    pHconn,       /* Address of connection handle */
PPMQOD      ppObjDesc,    /* Address of ptr to object descriptor */
PMQLONG     pOptions,      /* Address of open options */
PPMQHOBJS   ppHobj,       /* Address of ptr to object handle */
PMQLONG     pCompCode,     /* Address of completion code */
PMQLONG     pReason);     /* Address of reason code qualifying
                           completion code */
```

Put - MQ_PUT_EXIT

MQ_PUT_EXIT provides a put exit function to perform *before* and *after* MQPUT call processing. Use function identifier MQXF_PUT with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQPUT call exit functions.

The interface to this function is:

```
MQ_PUT_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

Hobj (MQHOBJS) - input/output

Object handle.

pMsgDesc (PMQMD) - input/output

Pointer to message descriptor.

pPutMsgOpts (PMQPMO) - input/output

Pointer to put message options.

BufferLength (MQLONG) - input/output

Message buffer length.

pBuffer (PMQBYTE) - input/output

Pointer to message buffer.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

MQAXP	ExitParms;	/* Exit parameter structure */
MQAXC	ExitContext;	/* Exit context structure */
MQHCONN	Hconn;	/* Connection handle */
MQHOBJ	Hobj;	/* Object handle */
PMQMD	pMsgDesc;	/* Ptr to message descriptor */
PMQPMO	pPutMsgOpts;	/* Ptr to put message options */
MQLONG	BufferLength;	/* Message buffer length */
PMQBYTE	pBuffer;	/* Ptr to message data */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code */

The queue manager then logically calls the exit as follows:

```
MQ_PUT_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &pMsgDesc,
             &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_PUT_EXIT (
PMQAXP      pExitParms,      /* Address of exit parameter structure */
PMQAXC      pExitContext,    /* Address of exit context structure */
PMQHCONN    pHconn,         /* Address of connection handle */
PMQHOBJ     pHobj,          /* Address of object handle */
PPMQMD      ppMsgDesc,       /* Address of ptr to message descriptor */
PPMQPMO     ppPutMsgOpts,    /* Address of ptr to put message options */
PMQLONG     pBufferLength,   /* Address of message buffer length */
PPMQBYTE    ppBuffer,        /* Address of ptr to message buffer */
PMQLONG     pCompCode,       /* Address of completion code */
PMQLONG     pReason);        /* Address of reason code qualifying
                               completion code */
```

Usage notes

- Report messages generated by the queue manager skip the normal call processing. As a result, such messages cannot be intercepted by the MQ_PUT_EXIT function or the MQPUT1 function. However, report messages generated by the message channel agent are processed normally, and hence can be intercepted by the MQ_PUT_EXIT function or the MQ_PUT1_EXIT function. To be sure to intercepting all of the report messages generated by the MCA, both MQ_PUT_EXIT and MQ_PUT1_EXIT should be used.

Put1 - MQ_PUT1_EXIT

MQ_PUT1_EXIT provides a *put one message only* exit function to perform *before* and *after* MQPUT1 call processing. Use function identifier MQXF_PUT1 with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQPUT1 call exit functions.

The interface to this function is:

```
MQ_PUT1_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &pMsgDesc,  
&pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pObjDesc (PMQOD) - input/output

Pointer to object descriptor.

pMsgDesc (PMQMD) - input/output

Pointer to message descriptor.

pPutMsgOpts (PMQPMO) - input/output

Pointer to put message options.

BufferLength (MQLONG) - input/output

Message buffer length.

pBuffer (PMQBYTE) - input/output

Pointer to message buffer.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

MQAXP	ExitParms;	/* Exit parameter structure */
MQAXC	ExitContext;	/* Exit context structure */
MQHCONN	Hconn;	/* Connection handle */
PMQOD	pObjDesc;	/* Ptr to object descriptor */
PMQMD	pMsgDesc;	/* Ptr to message descriptor */
PMQPMO	pPutMsgOpts;	/* Ptr to put message options */
MQLONG	BufferLength;	/* Message buffer length */
PMQBYTE	pBuffer;	/* Ptr to message data */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code */

The queue manager then logically calls the exit as follows:

```
MQ_PUT1_EXIT (&ExitParms, &ExitContext, &Hconn, &pObjDesc, &pMsgDesc,
              &pPutMsgOpts, &BufferLength, &pBuffer, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_PUT1_EXIT (
    PMQAXP      pExitParms,      /* Address of exit parameter structure */
    PMQAXC      pExitContext,    /* Address of exit context structure */
    PMQHCONN    pHconn,         /* Address of connection handle */
    PPMQOD      ppObjDesc,       /* Address of ptr to object descriptor */
    PPMQMD      ppMsgDesc,       /* Address of ptr to message descriptor */
    PPMQPMO     ppPutMsgOpts,    /* Address of ptr to put message options */
    PMQLONG     pBufferLength,   /* Address of message buffer length */
    PMQBYTE     ppBuffer,        /* Address of ptr to message buffer */
    PMQLONG     pCompCode,       /* Address of completion code */
    PMQLONG     pReason);        /* Address of reason code qualifying
                                completion code */
```

Set - MQ_SET_EXIT

MQ_SET_EXIT provides a set exit function to perform *before* and *after* MQSET call processing. Use function identifier MQXF_SET with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQSET call exit functions.

The interface to this function is:

```
MQ_SET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttr, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

Hobj (MQHOBJ) - input

Object handle.

SelectorCount (MQLONG) - input

Count of selectors

pSelectors (PMQLONG) - input/output

Pointer to array of selector values.

IntAttrCount (MQLONG) - input

Count of integer attributes.

pIntAttrs (PMQLONG) - input/output

Pointer to array of integer attribute values.

CharAttrLength (MQLONG) - input/output

Character attributes array length.

pCharAttrs (PMQCHAR) - input/output

Pointer to character attribute values.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;          /* Exit parameter structure */
MQAXC      ExitContext;        /* Exit context structure */
MQHCONN    Hconn;             /* Connection handle */
MQHOBJ     Hobj;              /* Object handle */
MQLONG     SelectorCount;      /* Count of selectors */
PMQLONG    pSelectors;         /* Ptr to array of attribute selectors */
MQLONG     IntAttrCount;       /* Count of integer attributes */
PMQLONG    pIntAttrs;          /* Ptr to array of integer attributes */
MQLONG     CharAttrLength;     /* Length of char attributes array */
PMQCHAR    pCharAttrs;         /* Ptr to character attributes */
MQLONG     CompCode;           /* Completion code */
MQLONG     Reason;            /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_SET_EXIT (&ExitParms, &ExitContext, &Hconn, &Hobj, &SelectorCount,
             &pSelectors, &IntAttrCount, &pIntAttrs, &CharAttrLength,
             &pCharAttrs, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_SET_EXIT (
PMQAXP      pExitParms,        /* Address of exit parameter structure */
PMQAXC      pExitContext,      /* Address of exit context structure */
PMQHCONN    pHconn,           /* Address of connection handle */
PMQHOBJ     pHobj,            /* Address of object handle */
PMQLONG     pSelectorCount,    /* Address of selector count */
PPMQLONG    ppSelectors,       /* Address of ptr to array of selectors */
PMQLONG     pIntAttrCount;     /* Address of count of integer attributes */
PPMQLONG    ppIntAttrs,        /* Address of ptr to array of integer attributes */
PMQLONG     pCharAttrLength,   /* Address of character attribute length */
PPMQCHAR    ppCharAttrs,       /* Address of ptr to character attributes array */
PMQLONG     pCompCode,         /* Address of completion code */
PMQLONG     pReason);          /* Address of reason code qualifying completion
                                code */
```

Status - MQ_STAT_EXIT

MQ_STAT_EXIT provides a status exit function to perform *before* and *after* MQSTAT call processing. Use function identifier MQXF_STAT with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* MQSTAT call exit functions.

The interface to this function is:

```
MQ_STAT_EXIT (&ExitParms, &ExitContext, &Hconn, &Type, &pStatus
              &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

Type (MQLONG) - input

Type of status information to retrieve.

pStatus (PMQSTS) - output

Pointer to status buffer.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

Your exit must match the following C function prototype:

```
void MQENTRY MQ_STAT_EXIT (
    PMQAXP    pExitParms,      /* Address of exit parameter structure */
    PMQAXC    pExitContext,    /* Address of exit context structure */
    PMQHCONN  pHconn,         /* Address of connection handle */
    PMQLONG   pType,           /* Address of status type */
    PPMQSTS   ppStatus,        /* Address of status buffer */
    PMQLONG   pCompCode,       /* Address of completion code */
    PMQLONG   pReason);        /* Address of reason code qualifying completion
                                code */
```

Termination - MQ_TERM_EXIT

MQ_TERM_EXIT provides connection level termination, registered with a function identifier of MQXF_TERM and ExitReason MQXR_CONNECTION. If registered, MQ_TERM_EXIT is called once for every disconnect request.

As part of the termination, storage no longer required by the exit can be released, and any clean up required can be performed.

If an MQ_TERM_EXIT fails with MQXCC_FAILED, the queue manager returns from the MQDISC that called it with MQCC_FAILED and MQRC_API_EXIT_ERROR.

If the queue manager encounters an error while terminating the API exit function execution environment after invoking the last MQ_TERM_EXIT, the queue manager returns from the MQDISC call that invoked MQ_TERM_EXIT with MQCC_FAILED and MQRC_API_EXIT_TERM_ERROR

The interface to this function is:

```
MQ_TERM_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED, the exit function can set the reason code field to any valid MQRC_* value.

The CompCode and Reason returned to the application depend on the value of the ExitResponse field in MQAXP.

C language invocation

The queue manager logically defines the following variables:

MQAXP	ExitParms;	/* Exit parameter structure */
MQAXC	ExitContext;	/* Exit context structure */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code */

The queue manager then logically calls the exit as follows:

```
MQ_TERM_EXIT (&ExitParms, &ExitContext, &CompCode, &Reason)
```

Your exit must match the following C function prototype:

```
void MQENTRY MQ_TERM_EXIT (
PMQAXP      pExitParms,      /* Address of exit parameter structure */
PMQAXC      pExitContext,    /* Address of exit context structure */
PMQLONG     pCompCode,       /* Address of completion code */
PMQLONG     pReason);        /* Address of reason code qualifying
                               completion code */
```

Usage notes

1. The MQ_TERM_EXIT function is optional. It is not necessary for an exit suite to register a termination exit if there is no termination processing to be done.

If functions belonging to the exit suite acquire resources during the connection, an MQ_TERM_EXIT function is a convenient point at which to free those resources, for example, freeing storage obtained dynamically.
2. If an MQ_TERM_EXIT function is registered when the MQDISC call is issued, the exit function is invoked after all of the MQDISC exit functions have been invoked.
3. If MQ_TERM_EXIT returns MQXCC_FAILED in the *ExitResponse* field of MQAXP, or fails in some other way, the MQDISC call that caused MQ_TERM_EXIT to be invoked also fails, with the *CompCode* and *Reason* parameters set to appropriate values.

Register subscription - MQ_SUB_EXIT

MQ_SUB_EXIT provides an exit function to perform *before* and *after* subscription reregistration processing. Use function identifier MQXF_SUB with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* subscription registration call exit functions.

The interface to this function is:

```
MQ_SUB_EXIT (&ExitParms, &ExitContext, &Hconn, &pSubDesc, &pHobj, &pHsub, &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input/output

Connection handle.

pSubDesc - input/output

Array of attribute selectors.

pHobj - input/output

Object handle

pHsub (MQHOBJ) input/output

Subscription handle

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP      ExitParms;      /* Exit parameter structure */
MQAXC      ExitContext;    /* Exit context structure */
MQHCONN    Hconn;          /* Connection handle */
PMQSD      pSubDesc;       /* Subscription descriptor */
PMQHOBj    pHobj;          /* Object Handle */
PMQHOBj    pHsub;          /* Subscription handle */
MQLONG     CompCode;       /* Completion code */
MQLONG     Reason;         /* Reason code qualifying completion code */
```

The queue manager then logically calls the exit as follows:

```
MQ_SUB_EXIT (&ExitParms, &ExitContext, &Hconn, &pSubDesc, &pHobj, &pHsub,
             &CompCode, &Reason);
```

Your exit must match the following C function prototype:

```
PMQAXP    pExitParms;    /* Exit parameter structure */
PMQAXC    pExitContext;  /* Exit context structure */
PMQHCONN  pHconn;        /* Connection handle */
PPMQSD    ppSubDesc;     /* Subscription descriptor */
PPMQHOBJ  ppHobj;        /* Object Handle */
PPMQHOBJ  ppHsub;        /* Subscription handle */
PMQLONG    pCompCode;    /* Completion code */
PMQLONG    pReason;      /* Reason code qualifying completion code */
```

Subscription request - MQ_SUBRQ_EXIT

MQ_SUBRQ_EXIT provides a subscription request exit function to perform *before* and *after* subscription request processing. Use function identifier MQXF_SUBRQ with exit reasons MQXR_BEFORE and MQXR_AFTER to register *before* and *after* subscription request call exit functions.

The interface to this function is:

```
MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pHsub, &Action, &pSubRqOpts,
               &CompCode, &Reason)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input/output

Connection handle.

pHsub (MQHOBJ) input/output

Subscription handle

Action (MQLONG) input/output

Action

pSubRqOpts (MQSRO) input/output

CompCode (MQLONG) - input/output

Completion code, valid values for which are:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed

Reason (MQLONG) - input/output

Reason code qualifying the completion code.

If the completion code is MQCC_OK, the only valid value is:

MQRC_NONE

(0, x'000') No reason to report.

If the completion code is MQCC_FAILED or MQCC_WARNING, the exit function can set the reason code field to any valid MQRC_* value.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;    /* Exit parameter structure */
MQAXC    ExitContext;  /* Exit context structure */
MQHCONN  Hconn;        /* Connection handle */
PMQLONG  pHsub;        /* Subscription handle */
```

```

MQLONG    Action;           /* Action */
PMQSRO    pSubRqOpts;       /* Subscription Request Options */
MQLONG    CompCode;         /* Completion code */
MQLONG    Reason;           /* Reason code qualifying completion code */

```

The queue manager then logically calls the exit as follows:

```

MQ_SUBRQ_EXIT (&ExitParms, &ExitContext, &Hconn, &pHsub, &Action, &pSubRqOpts,
               &CompCode, &Reason);

```

Your exit must match the following C function prototype:

```

void MQENTRY MQ_SUBRQ_EXIT (
PMQAXP    pExitParms,       /* Address of exit parameter structure */
PMQAXC    pExitContext,     /* Address of exit context structure */
PMQHCONN  pHconn,          /* Address of connection handle */
PPMHOBJS  ppHsub;           /* Address of Subscription handle */
MQLONG    pAction;          /* Address of Action */
PMQSRO    ppSubRqOpts;      /* Address of Subscription Request Options */
MQLONG    pCompCode;        /* Address of completion code */
MQLONG    pReason;          /* Address of reason code qualifying completion
                             code */

```

xa_close - XA_CLOSE_EXIT

XA_CLOSE_EXIT provides an xa_close exit function to perform before and after xa_close processing. Use function identifier MQXF_XACLOSE with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_close call exit functions.

The interface to this function is:

```

XA_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode)

```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXa_info (PMQCHAR) - input/output

Instance-specific resource manager information.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```

MQAXP    ExitParms;         /* Exit parameter structure */
MQAXC    ExitContext;       /* Exit context structure */
MQHCONN  Hconn;             /* Connection handle */
PMQCHAR  pXa_info;          /* Instance-specific RM info */
MQLONG    Rmid;             /* Resource manager identifier */
MQLONG    Flags;            /* Resource manager options */
MQLONG    XARetCode;        /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```

XA_CLOSE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode);

```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_CLOSE_EXIT (
    PMQAXP    pExitParms,    /* Address of exit parameter structure */
    PMQAXC    pExitContext,  /* Address of exit context structure */
    PMQHCONN  pHconn,        /* Address of connection handle */
    PPMQCHAR  ppXa_info,     /* Address of instance-specific RM info */
    PMQLONG   pRmid,         /* Address of resource manager identifier */
    PMQLONG   pFlags,        /* Address of resource manager options */
    PMQLONG   pXARetCode);   /* Address of response from XA call */
```

xa_commit - XA_COMMIT_EXIT

XA_COMMIT_EXIT provides an xa_commit exit function to perform before and after xa_commit processing. Use function identifier MQXF_XACOMMIT with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_commit call exit functions.

The interface to this function is:

```
XA_COMMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms;    /* Exit parameter structure */
MQAXC    ExitContext;  /* Exit context structure */
MQHCONN  Hconn;        /* Connection handle */
MQPTR    pXID;         /* Transaction branch ID */
MQLONG   Rmid;         /* Resource manager identifier */
MQLONG   Flags;        /* Resource manager options */
MQLONG   XARetCode;    /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_COMMIT_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_COMMIT_EXIT (
    PMQAXP    pExitParms,    /* Address of exit parameter structure */
    PMQAXC    pExitContext,  /* Address of exit context structure */
    PMQHCONN  pHconn,        /* Address of connection handle */
    MQPTR     ppXID,         /* Address of transaction branch ID */
    PMQLONG   pRmid,        /* Address of resource manager identifier */
    PMQLONG   pFlags,        /* Address of resource manager options */
    PMQLONG   pXARetCode);   /* Address of response from XA call */
```

xa_complete - XA_COMPLETE_EXIT

XA_COMPLETE_EXIT provides an xa_complete exit function to perform before and after xa_complete processing. Use function identifier MQXF_XACOMPLETE with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_complete call exit functions.

The interface to this function is:

```
XA_COMPLETE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHandle, &pRetVal, &Rmid, &Flags,
&XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pHandle (PMQLONG) - input/output

Pointer to asynchronous operation.

pRetVal (PMQLONG) - input/output

Return value of asynchronous operation.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP   ExitParms;    /* Exit parameter structure */
MQAXC   ExitContext;  /* Exit context structure */
MQHCONN Hconn;        /* Connection handle */
PMQLONG pHandle;      /* Ptr to asynchronous op */
PMQLONG pRetVal;      /* Return value of async op */
MQLONG  Rmid;         /* Resource manager identifier */
MQLONG  Flags;        /* Resource manager options*/
MQLONG  XARetCode;    /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_COMPLETE_EXIT (&ExitParms, &ExitContext, &Hconn, &pHandle, &pRetVal, &Rmid, &Flags,
&XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_COMPLETE_EXIT (
    PMQAXP   pExitParms,    /* Address of exit parameter structure */
    PMQAXC   pExitContext,  /* Address of exit context structure */
    PMQHCONN pHconn,        /* Address of connection handle */
    PPMQLONG ppHandle,      /* Address of ptr to asynchronous op */
    PPMQLONG ppRetVal,      /* Address of return value of async op */
    PMQLONG  pRmid,         /* Address of resource manager identifier */
    PMQLONG  pFlags,        /* Address of resource manager options*/
    PMQLONG  pXARetCode);   /* Address of response from XA call */
```

xa_end - XA_END_EXIT

XA_END_EXIT provides an `xa_end` exit function to perform before and after `xa_end` processing. Use function identifier `MQXF_XAEND` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_end` call exit functions.

The interface to this function is:

```
XA_END_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP   ExitParms;    /* Exit parameter structure */
MQAXC   ExitContext;  /* Exit context structure */
MQHCONN Hconn;        /* Connection handle */
MQPTR   pXID;         /* Transaction branch ID */
MQLONG  Rmid;         /* Resource manager identifier */
MQLONG  Flags;        /* Resource manager options */
MQLONG  XARetCode;    /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_END_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_END_EXIT (
    PMQAXP pExitParms, /* Address of exit parameter structure */
    PMQAXC pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */
```

xa_forget - XA_FORGET_EXIT

XA_FORGET_EXIT provides an `xa_forget` exit function to perform before and after `xa_forget` processing. Use function identifier `MQXF_XAFORGET` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_forget` call exit functions.

The interface to this function is:

```
XA_FORGET_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext;  /* Exit context structure */
MQHCONN Hconn;       /* Connection handle */
MQPTR  pXID;         /* Transaction branch ID */
MQLONG Rmid;         /* Resource manager identifier */
MQLONG Flags;        /* Resource manager options */
MQLONG XARetCode;    /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_FORGET_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_FORGET_EXIT (
    PMQAXP  pExitParms,    /* Address of exit parameter structure */
    PMQAXC  pExitContext,  /* Address of exit context structure */
    PMQHCONN pHconn,       /* Address of connection handle */
    PMQPTR  ppXID,         /* Address of transaction branch ID */
    PMQLONG pRmid,         /* Address of resource manager identifier */
    PMQLONG pFlags,        /* Address of resource manager options */
    PMQLONG pXARetCode);   /* Address of response from XA call */

```

xa_open - XA_OPEN_EXIT

XA_OPEN_EXIT provides an `xa_open` exit function to perform before and after `xa_open` processing. Use function identifier `MQXF_XAOPEN` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_open` call exit functions.

The interface to this function is:

```
XA_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXa_info (PMQCHAR) - input/output

Instance-specific resource manager information.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn;      /* Connection handle */
PMQCHAR pXa_info;   /* Instance-specific RM info */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options */
MQLONG XARetCode;   /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_OPEN_EXIT (&ExitParms, &ExitContext, &Hconn, &pXa_info, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_OPEN_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PPMQCHAR ppXa_info, /* Address of instance-specific RM info */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */
```

xa_prepare - XA_PREPARE_EXIT

XA_PREPARE_EXIT provides an xa_prepare exit function to perform before and after xa_prepare processing. Use function identifier MQXF_XAPREPARE with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_prepare call exit functions.

The interface to this function is:

```
XA_PREPARE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR  pXID; /* Transaction branch ID */
MQLONG Rmid; /* Resource manager identifier */
MQLONG Flags; /* Resource manager options */
MQLONG XARetCode; /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_PREPARE_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_PREPARE_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */
```

xa_recover - XA_RECOVER_EXIT

XA_RECOVER_EXIT provides an `xa_recover` exit function to perform before and after `xa_recover` processing. Use function identifier `MQXF_XARECOVER` with exit reasons `MQXR_BEFORE` and `MQXR_AFTER` to register the before and after `xa_recover` call exit functions.

The interface to this function is:

```
XA_RECOVER_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Count, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Count (MQLONG) - input/output

Maximum XIDs in XID array

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR  pXID; /* Transaction branch ID */
```

```

MQLONG Count;      /* Max XIDs in XID array */
MQLONG Rmid;        /* Resource manager identifier */
MQLONG Flags;       /* Resource manager options*/
MQLONG XARetCode;   /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_RECOVER_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Count, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```

typedef void MQENTRY XA_RECOVER_EXIT (
    PMQAXP  pExitParms, /* Address of exit parameter structure */
    PMQAXC  pExitContext, /* Address of exit context structure */
    PMQHCONN pHconn, /* Address of connection handle */
    PMQPTR  ppXID, /* Address of transaction branch ID */
    PMQLONG pCount, /* Address of max XIDs in XID array */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options*/
    PMQLONG pXARetCode); /* Address of response from XA call */

```

xa_rollback - XA_ROLLBACK_EXIT

XA_ROLLBACK_EXIT provides an xa_rollback exit function to perform before and after xa_rollback processing. Use function identifier MQXF_XAROLLBACK with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_rollback call exit functions.

The interface to this function is:

```
XA_ROLLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```

MQAXP  ExitParms; /* Exit parameter structure */
MQAXC  ExitContext; /* Exit context structure */
MQHCONN Hconn; /* Connection handle */
MQPTR  pXID; /* Transaction branch ID */
MQLONG Rmid; /* Resource manager identifier */
MQLONG Flags; /* Resource manager options*/
MQLONG XARetCode; /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```
XA_ROLLBACK_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_ROLLBACK_EXIT (
    PMQAXP    pExitParms, /* Address of exit parameter structure */
    PMQAXC    pExitContext, /* Address of exit context structure */
    PMQHCONN  pHconn, /* Address of connection handle */
    PMQPTR    ppXID, /* Address of transaction branch ID */
    PMQLONG   pRmid, /* Address of resource manager identifier */
    PMQLONG   pFlags, /* Address of resource manager options */
    PMQLONG   pXARetCode); /* Address of response from XA call */
```

xa_start - XA_START_EXIT

XA_START_EXIT provides an xa_start exit function to perform before and after xa_start processing. Use function identifier MQXF_XASTART with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after xa_start call exit functions.

The interface to this function is:

```
XA_START_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP    ExitParms; /* Exit parameter structure */
MQAXC    ExitContext; /* Exit context structure */
MQHCONN  Hconn; /* Connection handle */
MQPTR    pXID; /* Transaction branch ID */
MQLONG   Rmid; /* Resource manager identifier */
MQLONG   Flags; /* Resource manager options */
MQLONG   XARetCode; /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
XA_START_EXIT (&ExitParms, &ExitContext, &Hconn, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY XA_START_EXIT (
    PMQAXP    pExitParms, /* Address of exit parameter structure */
    PMQAXC    pExitContext, /* Address of exit context structure */
    PMQHCONN  pHconn, /* Address of connection handle */
    PMQPTR    ppXID, /* Address of transaction branch ID */
    PMQLONG   pRmid, /* Address of resource manager identifier */
    PMQLONG   pFlags, /* Address of resource manager options */
    PMQLONG   pXARetCode); /* Address of response from XA call */
```

ax_reg - AX_REG_EXIT

AX_REG_EXIT provides an ax_reg exit function to perform before and after ax_reg processing. Use function identifier MQXF_AXREG with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after ax_reg call exit functions.

The interface to this function is:

```
AX_REG_EXIT (&ExitParms, &ExitContext, &pXID, &Rmid, &Flags, &XARetCode)
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Hconn (MQHCONN) - input

Connection handle.

pXID (MQPTR) - input/output

Transaction branch ID.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```
MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext;  /* Exit context structure */
MQPTR  pXID;         /* Transaction branch ID */
MQLONG Rmid;         /* Resource manager identifier */
MQLONG Flags;        /* Resource manager options */
MQLONG XARetCode;    /* Response from XA call */
```

The queue manager then logically calls the exit as follows:

```
AX_REG_EXIT (&ExitParms, &ExitContext, &pXID, &Rmid, &Flags, &XARetCode);
```

Your exit must match the following C function prototype:

```
typedef void MQENTRY AX_REG_EXIT (
    PMQAXP pExitParms, /* Address of exit parameter structure */
    PMQAXC pExitContext, /* Address of exit context structure */
    PMQPTR ppXID, /* Address of transaction branch ID */
    PMQLONG pRmid, /* Address of resource manager identifier */
    PMQLONG pFlags, /* Address of resource manager options */
    PMQLONG pXARetCode); /* Address of response from XA call */
```

ax_unreg - AX_UNREG_EXIT

AX_UNREG_EXIT provides an ax_unreg exit function to perform before and after ax_unreg processing. Use function identifier MQXF_AXUNREG with exit reasons MQXR_BEFORE and MQXR_AFTER to register the before and after ax_unreg call exit functions.

The interface to this function is:

```
AX_UNREG_EXIT (&ExitParms, &ExitContext, &Rmid, &Flags, &XARetCode);
```

where the parameters are:

ExitParms (MQAXP) - input/output

Exit parameter structure.

ExitContext (MQAXC) - input/output

Exit context structure.

Rmid (MQLONG) - input/output

Resource manager identifier.

Flags (MQLONG) - input/output

Resource manager options.

XARetCode (MQLONG) - input/output

Response from XA call.

C language invocation

The queue manager logically defines the following variables:

```

MQAXP  ExitParms;    /* Exit parameter structure */
MQAXC  ExitContext;  /* Exit context structure */
MQLONG Rmid;         /* Resource manager identifier */
MQLONG Flags;        /* Resource manager options*/
MQLONG XARetCode;    /* Response from XA call */

```

The queue manager then logically calls the exit as follows:

```

AX_UNREG_EXIT (&ExitParms, &ExitContext, &Rmid, &Flags, &XARetCode);

```

Your exit must match the following C function prototype:

```

typedef void MQENTRY AX_UNREG_EXIT (
    PMQAXP pExitParms,    /* Address of exit parameter structure */
    PMQAXC pExitContext,  /* Address of exit context structure */
    PMQLONG pRmid,        /* Address of resource manager identifier */
    PMQLONG pFlags,       /* Address of resource manager options*/
    PMQLONG pXARetCode);  /* Address of response from XA call */

```

General information on invoking exit functions

This topic provides some general guidance to help you to plan your exits, particularly related to handling errors and unexpected events.

Exit failure

If an exit function abnormally terminates after a destructive, out of syncpoint, MQGET call but before the message has been passed to the application, the exit handler can recover from the failure, and pass control to the application.

In this case, the message might be lost. This is like what happens when an application fails immediately after receiving a message from a queue.

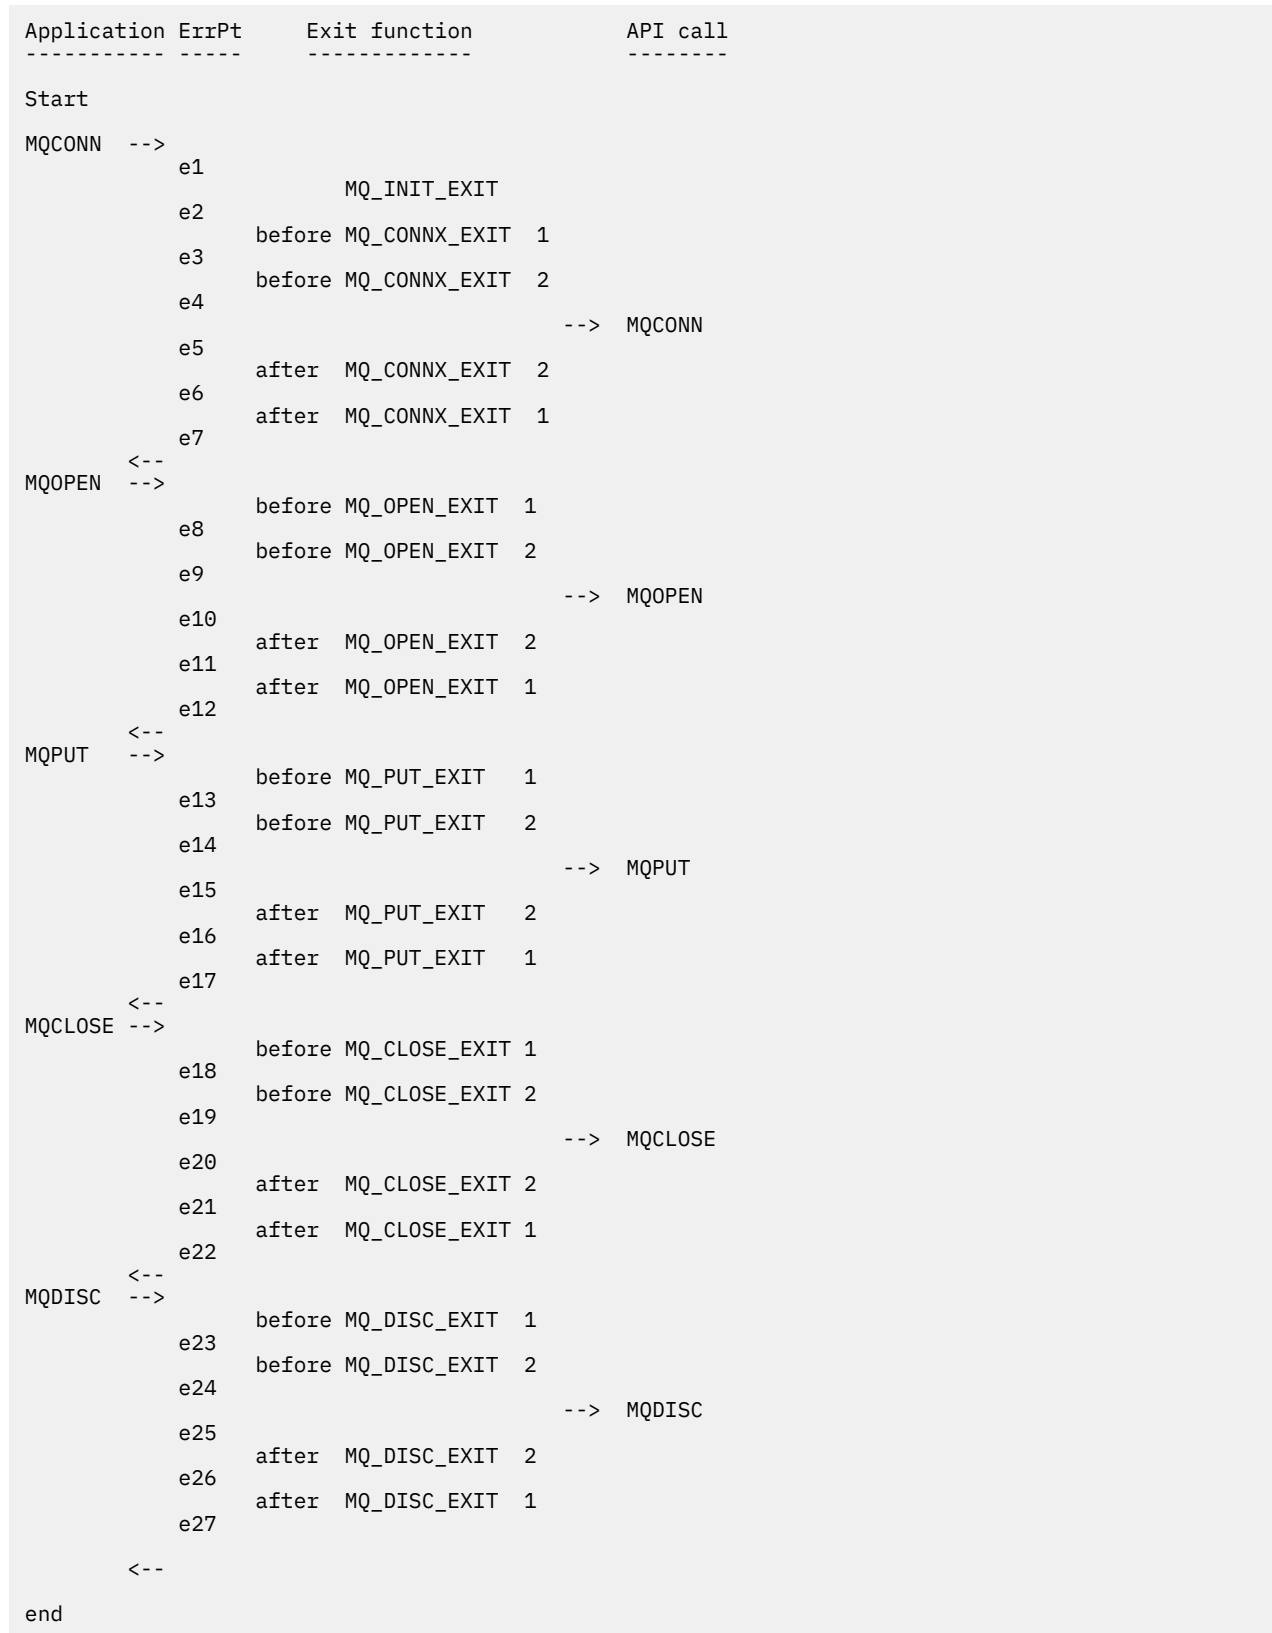

The MQGET call might complete with MQCC_FAILED and MQRC_API_EXIT_ERROR.

If a *before* API call exit function terminates abnormally, the exit handler can recover from the failure and pass control to the application without processing the API call. In this event, the exit function must recover any resources that it owns.

If chained exits are in use, the *after* API call exits for any *before* API call exits that had successfully been driven can themselves be driven. The API call might fail with MQCC_FAILED and MQRC_API_EXIT_ERROR.

Example error handling for exit functions

The following diagram shows the points (e N) at which errors can occur. It is only an example to show how exits behave and should be read together with the following table. In this example, two exit functions are invoked both before and after each API call to show the behavior with chained exits.

The following table lists the actions to be taken at each error point. Only a subset of the error points have been covered, as the rules shown here can apply to all others. It is the actions that specify the intended behavior in each case.

Table 657. API exit errors and appropriate actions to take		
Err Pt	Description	Actions
e1	Error while setting up environment setup.	<ol style="list-style-type: none"> 1. Undo environment setup as required 2. Drive no exit functions 3. Fail MQCONN with MQCC_FAILED, MQRC_API_EXIT_LOAD_ERROR
e2	MQ_INIT_EXIT function completes with: <ul style="list-style-type: none"> • MQXCC_FAILED • MQXCC_* 	<ul style="list-style-type: none"> • For MQXCC_FAILED: <ol style="list-style-type: none"> 1. Clean up environment 2. Fail MQCONN with MQCC_FAILED, MQRC_API_EXIT_INIT_ERROR • For MQXCC_* <ol style="list-style-type: none"> 1. Act as for the values of MQXCC_* and MQXR2_*¹ 2. Clean up environment
e3	<i>Before</i> MQ_CONNX_EXIT 1 function completes with: <ul style="list-style-type: none"> • MQXCC_FAILED • MQXCC_* 	<ul style="list-style-type: none"> • For MQXCC_FAILED: <ol style="list-style-type: none"> 1. Drive MQ_TERM_EXIT function 2. Clean up environment 3. Fail MQCONN call with MQCC_FAILED, MQRC_API_EXIT_ERROR • For MQXCC_* <ol style="list-style-type: none"> 1. Act as for the values of MQXCC_* and MQXR2_*¹ 2. Drive MQ_TERM_EXIT function if required 3. Clean up environment if required
e4	<i>Before</i> MQ_CONNX_EXIT 2 function completes with: <ul style="list-style-type: none"> • MQXCC_FAILED • MQXCC_* 	<ul style="list-style-type: none"> • For MQXCC_FAILED: <ol style="list-style-type: none"> 1. Drive <i>after</i> MQ_CONNX_EXIT 1 function 2. Drive MQ_TERM_EXIT function 3. Clean up environment 4. Fail MQCONN call with MQCC_FAILED, MQRC_API_EXIT_ERROR • For MQXCC_* <ol style="list-style-type: none"> 1. Act as for the values of MQXCC_* and MQXR2_*¹ 2. Drive <i>after</i> MQ_CONNX_EXIT 1 function if exit not suppressed 3. Drive MQ_TERM_EXIT function if required 4. Clean up environment if required

Table 657. API exit errors and appropriate actions to take (continued)

Err Pt	Description	Actions
e5	MQCONN call fails.	<ol style="list-style-type: none"> 1. Pass MQCONN CompCode and Reason 2. Drive <i>after</i> MQ_CONNX_EXIT 2 function if the <i>before</i> MQ_CONNX_EXIT 2 succeeded and the exit is not suppressed 3. e10	MQOPEN call fails	<ol style="list-style-type: none"> 1. Pass MQOPEN CompCode and Reason 2. Drive <i>after</i> MQ_OPEN_EXIT 2 function if exit not suppressed 3. Drive <i>after</i> MQ_OPEN_EXIT 1 function if exit not suppressed and if chained exits not suppressed

Table 657. API exit errors and appropriate actions to take (continued)		
Err Pt	Description	Actions
e1 1	<p>After MQ_OPEN_EXIT 2 function completes with:</p> <ul style="list-style-type: none"> • MQXCC_FAILED • MQXCC_* 	<ul style="list-style-type: none"> • For MQXCC_FAILED: <ol style="list-style-type: none"> 1. Drive <i>after</i> MQ_OPEN_EXIT 1 function 2. Complete MQOPEN call with MQCC_FAILED, MQRC_API_EXIT_ERROR • For MQXCC_* <ol style="list-style-type: none"> 1. Act as for the values of MQXCC_* and MQXR2_*¹ 2. Drive <i>after</i> MQ_OPEN_EXIT 1 function if exit not suppressed
e2 5	<p>After MQ_DISC_EXIT 2 function completes with:</p> <ul style="list-style-type: none"> • MQXCC_FAILED • MQXCC_* 	<ul style="list-style-type: none"> • For MQXCC_FAILED: <ol style="list-style-type: none"> 1. Drive <i>after</i> MQ_DISC_EXIT 1 function 2. Drive MQ_TERM_EXIT function 3. Clean up exit execution environment 4. Complete MQDISC call with MQCC_FAILED, MQRC_API_EXIT_ERROR • For MQXCC_* <ol style="list-style-type: none"> 1. Act as for the values of MQXCC_* and MQXR2_*¹ 2. Drive MQ_TERM_EXIT function 3. Clean up exit execution environment

Note:

1. The values of MQXCC_* and MQXR2_* and their corresponding actions are defined in [How queue managers process exit functions](#).

ExitResponse fields set incorrectly

This topic gives information about what would happen when the ExitResponse field is set to anything but the supported values.

If the ExitResponse field is set to a value other than one of the supported values, the following actions apply:

- For a *before* MQCONN or MQDISC API exit function:
 - The ExitResponse2 value is ignored.
 - No further *before* exit functions in the exit chain (if any) are invoked; the API call itself is not issued.
 - For any *before* exits that were successfully called, the *after* exits are called in reverse order.
 - If registered, the termination exit functions for those *before* MQCONN or MQDISC exit functions in the chain that were successfully invoked are driven to clean up after these exit functions.
 - The MQCONN or MQDISC call fails with MQRC_API_EXIT_ERROR.
- For a *before* IBM MQ API exit function other than MQCONN or MQDISC:
 - The ExitResponse2 value is ignored.
 - No further *before* or *after* data conversion functions in the exit chain (if any) are invoked.
 - For any *before* exits that were successfully called, the *after* exits are called in reverse order.
 - The IBM MQ API call itself is not issued.
 - The IBM MQ API call fails with MQRC_API_EXIT_ERROR.

- For an *after* MQCONN or MQDISC API exit function:
 - The ExitResponse2 value is ignored.
 - The remaining exit functions that were successfully called before the API call are called in reverse order.
 - If registered, the termination exit functions for those *before* or *after* MQCONN or MQDISC exit functions in the chain that were successfully invoked are driven to clean up after the exit.
 - A CompCode of the more severe of MQCC_WARNING and the CompCode returned by the exit is returned to the application.
 - A Reason of MQRC_API_EXIT_ERROR is returned to the application.
 - The IBM MQ API call is successfully issued.
- For an *after* IBM MQ API call exit function other than MQCONN or MQDISC:
 - The ExitResponse2 value is ignored.
 - The remaining exit functions that were successfully called before the API call are called in reverse order.
 - A CompCode of the more severe of MQCC_WARNING and the CompCode returned by the exit is returned to the application.
 - A Reason of MQRC_API_EXIT_ERROR is returned to the application.
 - The IBM MQ API call is successfully issued.
- For the *before* data conversion on get exit function:
 - The ExitResponse2 value is ignored.
 - The remaining exit functions that were successfully called before the API call are called in reverse order.
 - The message is not converted, and the unconverted message is returned to the application.
 - A CompCode of the more severe of MQCC_WARNING and the CompCode returned by the exit is returned to the application.
 - A Reason of MQRC_API_EXIT_ERROR is returned to the application.
 - The IBM MQ API call is successfully issued.

Note: As the error is with the exit, it is better to return MQRC_API_EXIT_ERROR than to return MQRC_NOT_CONVERTED.

If an exit function sets the ExitResponse2 field to a value other than one of the supported values, a value of MQXR2_DEFAULT_CONTINUATION is assumed instead.

Installable services interface reference information

This collection of topics provides reference information for the installable services.

The functions and data types are listed in alphabetical order within the group for each service type.

How the functions are shown

How the installable services functions are documented.

For each function there is a description, including the function identifier (for MQZEP).

The *parameters* are shown listed in the order they must occur. They must all be present.

Each parameter name is followed by its data type. These are the elementary data types described in the [“Elementary data types” on page 231](#).

The C language invocation is also given, after the description of the parameters.

MQZ_AUTHENTICATE_USER - Authenticate user

This function is provided by an MQZAS_VERSION_5 authorization service component, and is invoked by the queue manager to authenticate a user, or to set identity context fields. It is invoked when the IBM MQ user application context is established.

The application context is established during connect calls at the point where the application's user context is initialized, and at each point where the application's user context is changed. Each time a connect call is made, the application's user context information is reacquired in the *IdentityContext* field.

The function identifier for this function (for MQZEP) is MQZID_AUTHENTICATE_USER.

Syntax

MQZ_AUTHENTICATE_USER (*QMgrName* , *SecurityParms* , *ApplicationContext* , *IdentityContext* , *CorrelationPtr* , *ComponentData* , *Continuation* , *CompCode* , *Reason*)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

SecurityParms

Type: MQCSP - input

Security parameters. Data relating to the user ID, password, and authentication type. If the AuthenticationType attribute of the MQCSP structure is specified as MQCSP_AUTH_USER_ID_AND_PWD, both the user ID and password are compared against the equivalent fields in the IdentityContext (MQZIC) parameter to determine whether they match. For more information, see “MQCSP - Security parameters” on page 320.

During an MQCONN MQI call this parameter contains null, or default values.

ApplicationContext

Type: MQZAC - input

Application context. Data relating to the calling application. See [MQZAC - Application context](#) for details.

During every MQCONN or MQCONNX MQI call, the user context information in the MQZAC structure is reacquired.

IdentityContext

Type: MQZIC - input/output

Identity context. On input to the authenticate user function, this identifies the current identity context. The authenticate user function can change this, at which point the queue manager adopts the new identity context. See [MQZIC - Identity context](#) for more details on the MQZIC structure.

CorrelationPtr

Type: MQPTR - output

Correlation pointer. Specifies the address of any correlation data. This pointer is subsequently passed on to other OAM calls.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the `ComponentDataLength` parameter of the `MQZ_INIT_AUTHORITY` call.

Continuation

Type: `MLONG` - output

Continuation flag. You can specify the following values:

MQZCI_DEFAULT

Continuation dependent on other components.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: `MLONG` - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: `MLONG` - output

Reason code qualifying *CompCode*.

If *CompCode* is `MQCC_OK`:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is `MQCC_FAILED`:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
                      IdentityContext, &CorrelationPtr, ComponentData,  
                      &Continuation, &CompCode, &Reason);
```

Declare the parameters passed to the service as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCSP     SecurityParms;      /* Security parameters */  
MQZAC     ApplicationContext; /* Application context */  
MQZIC     IdentityContext;    /* Identity context */  
MQPTR     CorrelationPtr;     /* Correlation pointer */  
MQBYTE    ComponentData[n];   /* Component data */  
MLONG     Continuation;       /* Continuation indicator set by  
                               component */  
MLONG     CompCode;           /* Completion code */  
MLONG     Reason;            /* Reason code qualifying CompCode */
```

MQZ_CHECK_AUTHORITY - Check authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is started by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID_CHECK_AUTHORITY.

Syntax

MQZ_CHECK_AUTHORITY(*QMgrName* , *EntityName* , *EntityType* , *ObjectName* ,
ObjectType , *Authority* , *ComponentData* , *Continuation* , *CompCode* , *Reason*)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity whose authorization to the object is to be checked. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

It is not essential for this entity to be known to the underlying security service. If it is not known, the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by EntityName. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority

Type: MQLONG - input

Authority to be checked. If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO_* constants.

The following authorizations apply to use of the MQI calls:

MQZAO_CONNECT

Ability to use the MQCONN call.

MQZAO_BROWSE

Ability to use the MQGET call with a browse option.

This allows the MQGMO_BROWSE_FIRST, MQGMO_BROWSE_MSG_UNDER_CURSOR, or MQGMO_BROWSE_NEXT option to be specified on the MQGET call.

MQZAO_INPUT

Principal. Ability to use the MQGET call with an input option.

This allows the MQOO_INPUT_SHARED, MQOO_INPUT_EXCLUSIVE, or MQOO_INPUT_AS_Q_DEF option to be specified on the MQOPEN call.

MQZAO_OUTPUT

Ability to use the MQPUT call.

This allows the MQOO_OUTPUT option to be specified on the MQOPEN call.

MQZAO_INQUIRE

Ability to use the MQINQ call.

This allows the MQOO_INQUIRE option to be specified on the MQOPEN call.

MQZAO_SET

Ability to use the MQSET call.

This allows the MQOO_SET option to be specified on the MQOPEN call.

MQZAO_PASS_IDENTITY_CONTEXT

Ability to pass identity context.

This allows the MQOO_PASS_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_PASS_ALL_CONTEXT

Ability to pass all context.

This allows the MQOO_PASS_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_IDENTITY_CONTEXT

Ability to set identity context.

This allows the MQOO_SET_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_ALL_CONTEXT

Ability to set all context.

This allows the MQOO_SET_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_ALTERNATE_USER_AUTHORITY

Ability to use alternate user authority.

This allows the MQOO_ALTERNATE_USER_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO_ALTERNATE_USER_AUTHORITY option to be specified on the MQPUT1 call.

MQZAO_ALL_MQI

All of the MQI authorizations.

This enables all of the authorizations.

The following authorizations apply to administration of a queue manager:

MQZAO_CREATE

Ability to create objects of a specified type.

MQZAO_DELETE

Ability to delete a specified object.

MQZAO_DISPLAY

Ability to display the attributes of a specified object.

MQZAO_CHANGE

Ability to change the attributes of a specified object.

MQZAO_CLEAR

Ability to delete all messages from a specified queue.

MQZAO_AUTHORIZE

Ability to authorize other users for a specified object.

MQZAO_CONTROL

Ability to start or stop a listener, service, or non-client channel object, and the ability to ping a non-client channel object.

MQZAO_CONTROL_EXTENDED

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

MQZAO_ALL_ADMIN

Ability to set identity context.

All of the administration authorizations, other than MQZAO_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

MQZAO_ALL

All authorizations, other than MQZAO_CREATE.

MQZAO_NONE

No authorizations.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC_FAILED), and the *Continuation* parameter is MQZCI_DEFAULT or MQZCI_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI_DEFAULT before the call.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_CHECK_AUTHORITY (QMGrName, EntityName, EntityType, ObjectName,  
                    ObjectType, Authority, ComponentData,  
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```

MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;         /* Entity name */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority to be checked */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */

```

MQZ_CHECK_AUTHORITY_2 - Check authority (extended)

This function is provided by a MQZAS_VERSION_2 authorization service component, and is started by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID_CHECK_AUTHORITY.

MQZ_CHECK_AUTHORITY_2 is like MQZ_CHECK_AUTHORITY, but with the *EntityName* parameter replaced by the *EntityData* parameter.

Syntax

MQZ_CHECK_AUTHORITY_2(*QMgrName* , *EntityData* , *EntityType* , *ObjectName* , *ObjectType* , *Authority* , *ComponentData* , *Continuation* , *CompCode* , *Reason*)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity with authorization to the object that is to be checked. See [“MQZED - Entity descriptor” on page 1681](#) for details.

It is not essential for this entity to be known to the underlying security service. If it is not known, the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority to be checked. If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO_* constants.

The following authorizations apply to use of the MQI calls:

MQZAO_CONNECT

Ability to use the MQCONN call.

MQZAO_BROWSE

Ability to use the MQGET call with a browse option.

This allows the MQGMO_BROWSE_FIRST, MQGMO_BROWSE_MSG_UNDER_CURSOR, or MQGMO_BROWSE_NEXT option to be specified on the MQGET call.

MQZAO_INPUT

Principal. Ability to use the MQGET call with an input option.

This allows the MQOO_INPUT_SHARED, MQOO_INPUT_EXCLUSIVE, or MQOO_INPUT_AS_Q_DEF option to be specified on the MQOPEN call.

MQZAO_OUTPUT

Ability to use the MQPUT call.

This allows the MQOO_OUTPUT option to be specified on the MQOPEN call.

MQZAO_INQUIRE

Ability to use the MQINQ call.

This allows the MQOO_INQUIRE option to be specified on the MQOPEN call.

MQZAO_SET

Ability to use the MQSET call.

This allows the MQOO_SET option to be specified on the MQOPEN call.

MQZAO_PASS_IDENTITY_CONTEXT

Ability to pass identity context.

This allows the MQOO_PASS_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_PASS_ALL_CONTEXT

Ability to pass all context.

This allows the MQOO_PASS_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_IDENTITY_CONTEXT

Ability to set identity context.

This allows the MQOO_SET_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_ALL_CONTEXT

Ability to set all context.

This allows the MQOO_SET_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_ALTERNATE_USER_AUTHORITY

Ability to use alternate user authority.

This allows the MQOO_ALTERNATE_USER_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO_ALTERNATE_USER_AUTHORITY option to be specified on the MQPUT1 call.

MQZAO_ALL_MQI

All of the MQI authorizations.

This enables all of the authorizations.

The following authorizations apply to administration of a queue manager:

MQZAO_CREATE

Ability to create objects of a specified type.

MQZAO_DELETE

Ability to delete a specified object.

MQZAO_DISPLAY

Ability to display the attributes of a specified object.

MQZAO_CHANGE

Ability to change the attributes of a specified object.

MQZAO_CLEAR

Ability to delete all messages from a specified queue.

MQZAO_AUTHORIZE

Ability to authorize other users for a specified object.

MQZAO_CONTROL

Ability to start or stop a listener, service, or non-client channel object, and the ability to ping a non-client channel object.

MQZAO_CONTROL_EXTENDED

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

MQZAO_ALL_ADMIN

Ability to set identity context.

All of the administration authorizations, other than MQZAO_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

MQZAO_ALL

All authorizations, other than MQZAO_CREATE.

MQZAO_NONE

No authorizations.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_CHECK_AUTHORITY_2 (QMgrName, &EntityData, EntityType,  
                        ObjectName, ObjectType, Authority, ComponentData,  
                        &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZED     EntityData;         /* Entity data */  
MQLONG    EntityType;         /* Entity type */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQLONG    Authority;          /* Authority to be checked */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_CHECK_PRIVILEGED - Check if user is privileged

This function is provided by an MQZAS_VERSION_6 authorization service component, and is invoked by the queue manager to determine whether a specified user is a privileged user.

The function identifier for this function (for MQZEP) is MQZID_CHECK_PRIVILEGED.

Syntax

```
MQZ_CHECK_PRIVILEGED( QMgrName , EntityData , EntityType , ComponentData ,  
                     Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity that is to be checked. For more information, see [“MQZED - Entity descriptor”](#) on page 1681.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by EntityData. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC_FAILED), and the *Continuation* parameter is MQZCI_DEFAULT or MQZCI_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI_DEFAULT before the call.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_PRIVILEGED

(2584, X'A18') This user is not a privileged user ID.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_CHECK_PRIVILEGED (QMgrName, &EntityData, EntityType,  
                     ComponentData, &Continuation,  
                     &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZED     EntityData;         /* Entity name */  
MQLONG    EntityType;         /* Entity type */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_COPY_ALL_AUTHORITY - Copy all authority

This function is provided by an authorization service component. It is started by the queue manager to copy all of the authorizations that are currently in force for a reference object to another object.

The function identifier for this function (for MQZEP) is MQZID_COPY_ALL_AUTHORITY.

Syntax

```
MQZ_COPY_ALL_AUTHORITY( QMgrName , RefObjectName , ObjectName , ObjectType ,  
                        ComponentData , Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

RefObjectName

Type: MQCHAR48 - input

Reference object name. The name of the reference object, the authorizations for which are to be copied. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which accesses are to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *RefObjectName* and *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_REF_OBJECT

(2294, X'8F6') Reference object unknown.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_COPY_ALL_AUTHORITY (QMgrName, RefObjectName, ObjectName, ObjectType,  
                        ComponentData, &Continuation, &CompCode,  
                        &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR48  RefObjectName;      /* Reference object name */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_DELETE_AUTHORITY - Delete authority

This function is provided by an authorization service component, and is started by the queue manager to delete all of the authorizations associated with the specified object.

The function identifier for this function (for MQZEP) is MQZID_DELETE_AUTHORITY.

Syntax

```
MQZ_DELETE_AUTHORITY( QMgrName , ObjectName , ObjectType , ComponentData ,  
Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which accesses are to be deleted. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_DELETE_AUTHORITY (QMgrName, ObjectName, ObjectType, ComponentData,  
                      &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_ENUMERATE_AUTHORITY_DATA - Enumerate authority data

This function is provided by an MQZAS_VERSION_4 authorization service component, and is started repeatedly by the queue manager to retrieve all of the authority data that matches the selection criteria specified on the first invocation.

The function identifier for this function (for MQZEP) is MQZID_ENUMERATE_AUTHORITY_DATA.

Syntax

```
MQZ_ENUMERATE_AUTHORITY_DATA( QMgrName , StartEnumeration , Filter ,  
AuthorityBufferLength , AuthorityBuffer , AuthorityDataLength , ComponentData ,  
Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

StartEnumeration

Type: MQLONG - input

Flag indicating whether call can start enumeration. This indicates whether the call can start the enumeration of authority data, or continue the enumeration of authority data started by a previous call to MQZ_ENUMERATE_AUTHORITY_DATA. The value is one of the following values:

MQZSE_START

Start enumeration. The call is started with this value to start the enumeration of authority data. The *Filter* parameter specifies the selection criteria to be used to select the authority data returned by this and successive calls.

MQZSE_CONTINUE

Continue enumeration. The call is started with this value to continue the enumeration of authority data. The *Filter* parameter is ignored in this case, and can be specified as the null pointer (the selection criteria are determined by the *Filter* parameter specified by the call that had *StartEnumeration* set to MQZSE_START).

Filter

Type: MQZAD - input

Filter. If *StartEnumeration* is MQZSE_START, *Filter* specifies the selection criteria to be used to select the authority data to return. If *Filter* is the null pointer, no selection criteria are used, that is, all authority data is returned. See “MQZAD - Authority data” on page 1678 for details of the selection criteria that can be used.

If *StartEnumeration* is MQZSE_CONTINUE, *Filter* is ignored, and can be specified as the null pointer.

AuthorityBufferLength

Type: MQLONG - input

Length of *AuthorityBuffer*. This is the length in bytes of the *AuthorityBuffer* parameter. The authority buffer must be large enough to accommodate the data to be returned.

AuthorityBuffer

Type: MQZAD - output

Authority data. This is the buffer in which the authority data is returned. The buffer must be large enough to accommodate an MQZAD structure, an MQZED structure, plus the longest entity name and longest domain name defined.

Note: Note: This parameter is defined as an MQZAD, as the MQZAD always occurs at the start of the buffer. However, if the buffer is declared as an MQZAD, the buffer will be too small - it must be bigger than an MQZAD so that it can accommodate the MQZAD, MQZED, plus entity and domain names.

AuthorityDataLength

Type: MQLONG - output

Length of data returned in *AuthorityBuffer*. If the authority buffer is too small, *AuthorityDataLength* is set to the length of the buffer required, and the call returns completion code MQCC_FAILED and reason code MQRC_BUFFER_LENGTH_ERROR.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_ENUMERATE_AUTHORITY_DATA, this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_BUFFER_LENGTH_ERROR

(2005, X'7D5') Buffer length parameter not valid.

MQRC_NO_DATA_AVAILABLE

(2379, X'94B') No data available.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_ENUMERATE_AUTHORITY_DATA (QMgrName, StartEnumeration, &Filter,  
                               AuthorityBufferLength,  
                               &AuthorityBuffer,  
                               &AuthorityDataLength, ComponentData,  
                               &Continuation, &CompCode,  
                               &Reason);
```

The parameters passed to the service are declared as follows:

MQCHAR48	QMgrName;	/* Queue manager name */
MQLONG	StartEnumeration;	/* Flag indicating whether call should start enumeration */
MQZAD	Filter;	/* Filter */
MQLONG	AuthorityBufferLength;	/* Length of AuthorityBuffer */
MQZAD	AuthorityBuffer;	/* Authority data */
MQLONG	AuthorityDataLength;	/* Length of data returned in AuthorityBuffer */
MQBYTE	ComponentData[n];	/* Component data */
MQLONG	Continuation;	/* Continuation indicator set by component */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code qualifying CompCode */

MQZ_FREE_USER - Free user

This function is provided by a MQZAS_VERSION_5 authorization service component, and is started by the queue manager to free associated allocated resource.

It is started when an application has finished running under all user contexts, for example during an MQDISC MQI call.

The function identifier for this function (for MQZEP) is MQZID_FREE_USER.

Syntax

MQZ_FREE_USER(QMgrName , FreeParms , ComponentData , Continuation , CompCode , Reason)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

FreeParms

Type: MQZFP - input

Free parameters. A structure containing data relating to the resource to be freed. See [“MQZFP - Free parameters” on page 1684](#) for details.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation flag. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on other components.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
                        IdentityContext, CorrelationPtr, ComponentData,  
                        &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQZFP     FreeParms;          /* Resource to be freed */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_GET_AUTHORITY - Get authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object, including (if the entity is a principal) authorities possessed by the groups in which the principal is a member. Authorities from generic profiles are included in the returned authority set.

The function identifier for this function (for MQZEP) is MQZID_GET_AUTHORITY.

Syntax

```
MQZ_GET_AUTHORITY( QMgrName , EntityName , EntityType , ObjectName ,  
ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity whose access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which access is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_GET_AUTHORITY, this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_GET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                   ObjectType, &Authority, ComponentData,  
                   &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;         /* Entity name */  
MQLONG    EntityType;         /* Entity type */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQLONG    Authority;          /* Authority of entity */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_GET_AUTHORITY_2 - Get authority (extended)

This function is provided by a MQZAS_VERSION_2 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID_GET_AUTHORITY.

MQZ_GET_AUTHORITY_2 is like MQZ_GET_AUTHORITY, but with the *EntityName* parameter replaced by the *EntityData* parameter.

Syntax

```
MQZ_GET_AUTHORITY_2( QMgrName , EntityData , EntityType , ObjectName ,  
                    ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity for which authorization to the object is to be retrieved. See [“MQZED - Entity descriptor” on page 1681](#) for details.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

Syntax

MQZ_GET_AUTHORITY_2 (*QMgrName*, *EntityData*, *EntityType*, *ObjectName*, *ObjectType*, *Authority*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

C invocation

```
MQZ_GET_AUTHORITY_2 (QMgrName, &EntityData, EntityType, ObjectName,
                    ObjectType, &Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;         /* Entity data */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority of entity */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_GET_EXPLICIT_AUTHORITY - Get explicit authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is started by the queue manager to retrieve the authority that an entity has to access the specified object, including (if the entity is a principal) authorities possessed by the groups in which the principal is a member. Authorities from generic profiles are included in the returned authority set.

On UNIX platforms, for the built-in IBM MQ object authority manager (OAM), the returned authority is that possessed only by the principal's primary group.

The function identifier for this function (for MQZEP) is MQZID_GET_EXPLICIT_AUTHORITY.

Syntax

MQZ_GET_EXPLICIT_AUTHORITY(*QMgrName* , *EntityName* , *EntityType* , *ObjectName* , *ObjectType* , *Authority* , *ComponentData* , *Continuation* , *CompCode* , *Reason*)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity for which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_GET_AUTHORITY, this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_GET_EXPLICIT_AUTHORITY (QMgrName, EntityName, EntityType,
                             ObjectName, ObjectType, &Authority,
                             ComponentData, &Continuation,
                             &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;         /* Entity name */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority of entity */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_GET_EXPLICIT_AUTHORITY_2 - Get explicit authority (extended)

This function is provided by a MQZAS_VERSION_2 authorization service component, and is started by the queue manager to retrieve the authority that a named group has to access a specified object (but

without the additional authority of the **nobody** group), or the authority that the primary group of the named principal has to access a specified object.

The function identifier for this function (for MQZEP) is MQZID_GET_EXPLICIT_AUTHORITY.

MQZ_GET_EXPLICIT_AUTHORITY_2 is like MQZ_GET_EXPLICIT_AUTHORITY, but with the *EntityName* parameter replaced by the *EntityData* parameter.

Syntax

MQZ_GET_EXPLICIT_AUTHORITY_2(*QMgrName* , *EntityData* , *EntityType* , *ObjectName* , *ObjectType* , *Authority* , *ComponentData* , *Continuation* , *CompCode* , *Reason*)

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity whose authorization to the object is to be retrieved. See [“MQZED - Entity descriptor” on page 1681](#) for details.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object for which the entity authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_GET_EXPLICIT_AUTHORITY_2 (QMgrName, &EntityData, EntityType,
                               ObjectName, ObjectType, &Authority,
                               ComponentData, &Continuation,
                               &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;         /* Entity data */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority of entity */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_INIT_AUTHORITY - Initialize authorization service

This function is provided by an authorization service component, and is started by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID_INIT_AUTHORITY.

Syntax

```
MQZ_INIT_AUTHORITY( Hconfig , Options , QMgrName , ComponentDataLength ,
                    ComponentData , Version , CompCode , Reason )
```

Parameters***Hconfig***

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

Options

Type: MQLONG - input

Initialization options. It must be one of the following values:

MQZIO_PRIMARY

Primary initialization.

MQZIO_SECONDARY

Secondary initialization.

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ComponentDataLength

Type: MQLONG - input

Length of component data. Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This is initialized to all zeros before calling the component primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Version

Type: MQLONG - input/output

Version number. On input to the initialization function, this identifies the highest version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which it supports. If on return the queue manager does not support the version returned by the component, it calls the component MQZ_TERM_AUTHORITY function and makes no further use of this component.

The following values are supported:

MQZAS_VERSION_1

Version 1.

MQZAS_VERSION_2

Version 2.

MQZAS_VERSION_3

Version 3.

MQZAS_VERSION_4

Version 4.

MQZAS_VERSION_5

Version 5.

MQZAS_VERSION_6

Version 6.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_INITIALIZATION_FAILED

(2286, X'8EE') Initialization failed for an undefined reason.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_INIT_AUTHORITY (Hconfig, Options, QMgrName, ComponentDataLength,  
                    ComponentData, &Version, &CompCode,  
                    &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG    Hconfig;           /* Configuration handle */  
MQLONG       Options;           /* Initialization options */  
MQCHAR48     QMgrName;         /* Queue manager name */  
MQLONG       ComponentDataLength; /* Length of component data */  
MQBYTE       ComponentData[n]; /* Component data */  
MQLONG       Version;          /* Version number */  
MQLONG       CompCode;         /* Completion code */  
MQLONG       Reason;           /* Reason code qualifying CompCode */
```

MQZ_INQUIRE - Inquire authorization service

This function is provided by a MQZAS_VERSION_5 authorization service component, and is started by the queue manager to query the supported functionality.

Where multiple service components are used, service components are called in reverse order to the order they were installed in.

The function identifier for this function (for MQZEP) is MQZID_INQUIRE.

Syntax

```
MQZ_INQUIRE( QMgrName , SelectorCount , Selectors , IntAttrCount , IntAttrs ,  
             CharAttrLength , CharAttrs , SelectorReturned , ComponentData , Continuation ,  
             CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

SelectorCount

Type: MQLONG - input

Number of selectors. The number of selectors supplied in the *Selectors* parameter.

The value must be in the range 0 through 256.

Selectors

Type: MQLONGxSelectorCount - input

Array of selectors. Each selector identifies a required attribute and must be one of the following:

- MQIACF_INTERFACE_VERSION (integer)
- MQIACF_USER_ID_SUPPORT (integer)
- MQCACF_SERVICE_COMPONENT (character)

Selectors can be specified in any order. The number of selectors in the array is indicated by the *SelectorCount* parameter.

Integer attributes identified by selectors are returned in the *IntAttrs* parameter in the same order as they appear in *Selectors*.

Character attributes identified by selectors are returned in the *CharAttrs* parameter in the same order as they in appear *Selectors*.

IntAttrCount

Type: MQLONG - input

Number of integer attributes supplied in the *IntAttrs* parameter.

The value must be in the range 0 through 256.

IntAttrs

Type: MQLONG x *IntAttrCount* - output

Integer attributes. Array of integer attributes. The integer attributes are returned in the same order as the corresponding integer selectors in the *Selectors* array.

CharAttrCount

Type: MQLONG - input

Length of the character attributes buffer. The length in bytes of the *CharAttrs* parameter.

The value must be at least the sum of the lengths of the requested character attributes. If no character attributes are requested, zero is a valid value.

CharAttrs

Type: MQLONG x *CharAttrCount* - output

Character attributes buffer. Buffer containing character attributes, concatenated together. The character attributes are returned in the same order as the corresponding character selectors in the *Selectors* array.

The length of the buffer is given by the *CharAttrCount* parameter.

SelectorReturned

Type: MQLONG x *SelectorCount* - input

Selector returned. Array of values identifying which attributes have been returned from the set requested for by the selectors in the *Selectors* parameter. The number of values in this array is indicated by the *SelectorCount* parameter. Each value in the array relates to the selector from the corresponding position in the *Selectors* array. Each value is one of the following:

MQZSL_RETURNED

The attribute requested by the corresponding selector in the *Selectors* parameter has been returned.

MQZSL_NOT_RETURNED

The attribute requested by the corresponding selector in the *Selectors* parameter has not been returned.

The array is initialized with all values as *MQZSL_NOT_RETURNED*. When an authorization service component returns an attribute, it sets the appropriate value in the array to *MQZSL_NOT_RETURNED*. This allows any other authorization service components, to which the inquire call is made, to identify which attributes have already been returned.

ComponentData

Type: MQBYTE x *ComponentDataLength* - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_WARNING:

MQRC_CHAR_ATTRS_TOO_SHORT

Not enough space for character attributes.

MQRC_INT_COUNT_TOO_SMALL

Not enough space for integer attributes.

If *CompCode* is MQCC_FAILED:

MQRC_SELECTOR_COUNT_ERROR

Number of selectors is not valid.

MQRC_SELECTOR_ERROR

Attribute selector not valid.

MQRC_SELECTOR_LIMIT_EXCEEDED

Too many selectors specified.

MQRC_INT_ATTR_COUNT_ERROR

Number of integer attributes is not valid.

MQRC_INT_ATTRS_ARRAY_ERROR

Integer attributes array not valid.

MQRC_CHAR_ATTR_LENGTH_ERROR

Number of character attributes is not valid.

MQRC_CHAR_ATTRS_ERROR

Character attributes string is not valid.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_INQUIRE (QMgrName, SelectorCount, Selectors, IntAttrCount,
              &IntAttrs, CharAttrLength, &CharAttrs,
              SelectorReturned, ComponentData, &Continuation,
              &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48    QMgrName;           /* Queue manager name */
MQLONG       SelectorCount;      /* Selector count */
MQLONG       Selectors[n];       /* Selectors */
MQLONG       IntAttrCount;       /* IntAttrs count */
MQLONG       IntAttrs[n];        /* Integer attributes */
MQLONG       CharAttrCount;      /* CharAttrs count */
MQLONG       CharAttrs[n];       /* Character attributes */
MQLONG       SelectorReturned[n]; /* Selector returned */
MQBYTE       ComponentData[n];   /* Component data */
MQLONG       Continuation;       /* Continuation indicator set by
                                component */
MQLONG       CompCode;           /* Completion code */
MQLONG       Reason;            /* Reason code qualifying CompCode */
```

MQZ_REFRESH_CACHE - Refresh all authorizations

This function is provided by an MQZAS_VERSION_3 authorization service component, and is invoked by the queue manager to refresh the list of authorizations held internally by the component.

The function identifier for this function (for MQZEP) is MQZID_REFRESH_CACHE (8L).

Syntax

`MQZ_REFRESH_CACHE(QMgrName , ComponentData , Continuation , CompCode , Reason)`

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_WARNING:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

C invocation

```
MQZ_REFRESH_CACHE (QMgrName, ComponentData,
                  &Continuation, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG     Continuation;       /* Continuation indicator set by
                               component */
MQLONG     CompCode;           /* Completion code */
MQLONG     Reason;             /* Reason code qualifying CompCode */
```

MQZ_SET_AUTHORITY - Set authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is started by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID_SET_AUTHORITY.

Note: This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

Syntax

```
MQZ_SET_AUTHORITY( QMgrName , EntityName , EntityType , ObjectName ,
                  ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityName

Type: MQCHAR12 - input

Entity name. The name of the entity for which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityName*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If one authority is being set, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authority is being set, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_GET_AUTHORITY, this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_SET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                  ObjectType, Authority, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;         /* Entity name */  
MQLONG    EntityType;         /* Entity type */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQLONG    Authority;          /* Authority to be checked */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_SET_AUTHORITY_2 - Set authority (extended)

This function is provided by a MQZAS_VERSION_2 authorization service component, and is started by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID_SET_AUTHORITY.

Note: This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

MQZ_SET_AUTHORITY_2 is like MQZ_SET_AUTHORITY, but with the *EntityName* parameter replaced by the *EntityData* parameter.

Syntax

```
MQZ_SET_AUTHORITY_2( QMgrName , EntityData , EntityType , ObjectName ,  
                   ObjectType , Authority , ComponentData , Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity whose authorization to the object is to be set. See [“MQZED - Entity descriptor”](#) on page 1681 for details.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by *EntityData*. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName

Type: MQCHAR48 - input

Object name. The name of the object to which the entity authority is to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType

Type: MQLONG - input

Object type. The type of entity specified by *ObjectName*. It must be one of the following values:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

MQOT_TOPIC

Topic.

Authority

Type: MQLONG - input

Authority of entity. If one authority is being set, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authority is being set, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_SET_AUTHORITY_2 (QMgrName, &EntityData, EntityType, ObjectName,
                    ObjectType, Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;         /* Entity data */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority to be checked */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_TERM_AUTHORITY - Terminate authorization service

This function is provided by an authorization service component, and is started by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID_TERM_AUTHORITY.

Syntax

MQZ_TERM_AUTHORITY(Hconfig , Options , QMgrName , ComponentData , CompCode , Reason)

Parameters

Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being terminated. It is to be used by the component when calling the queue manager with the MQZEP function.

Options

Type: MQLONG - input

Termination options. It must be one of the following values:

MQZTO_PRIMARY

Primary termination.

MQZTO_SECONDARY

Secondary termination.

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter on the MQZ_INIT_AUTHORITY call.

When the MQZ_TERM_AUTHORITY call has completed, the queue manager discards this data.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_TERMINATION_FAILED

(2287, X'8FF') Termination failed for an undefined reason.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_TERM_AUTHORITY (Hconfig, Options, QMgrName, ComponentData,  
                    &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;          /* Termination options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;         /* Completion code */  
MQLONG     Reason;          /* Reason code qualifying CompCode */
```

MQZ_DELETE_NAME - Delete name

This function is provided by a name service component, and is started by the queue manager to delete an entry for the specified queue.

The function identifier for this function (for MQZEP) is MQZID_DELETE_NAME.

Syntax

```
MQZ_DELETE_NAME( QMgrName , QName , ComponentData , Continuation , CompCode ,  
Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

QName

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be deleted. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the ComponentDataLength parameter on the MQZ_INIT_NAME call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. It must be one of the following values:

MQZCI_DEFAULT

Continuation dependent on queue manager.

MQZCI_STOP

Do not continue with next component.

For the **MQZ_DELETE_NAME** command, the queue manager does not attempt to start another component, no matter what is returned in the **Continuation** parameter.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_WARNING

Warning (partial completion).

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_WARNING:

MQRC_UNKNOWN_NAME

(2288, X'8F0') Queue name not found.

Note: It might not be possible to return this code if the underlying service responds with success for this case.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_DELETE_NAME (QMgrName, QName, ComponentData, &Continuation,  
                 &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

MQCHAR48	QMgrName;	/* Queue manager name */
MQCHAR48	QName;	/* Queue name */
MQBYTE	ComponentData[n];	/* Component data */
MQLONG	Continuation;	/* Continuation indicator set by component */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code qualifying CompCode */

MQZ_INIT_NAME - Initialize name service

This function is provided by a name service component, and is started by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID_INIT_NAME.

Syntax

MQZ_INIT_NAME(*Hconfig* , *Options* , *QMgrName* , *ComponentDataLength* ,
ComponentData , *Version* , *CompCode* , *Reason*)

Parameters

Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

Options

Type: MQLONG - input

Initialization options. It must be one of the following values:

MQZIO_PRIMARY

Primary initialization.

MQZIO_SECONDARY

Secondary initialization.

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ComponentDataLength

Type: MQLONG - input

Length of component data. Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This is initialized to all zeros before calling the component primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Version

Type: MQLONG - input/output

Version number. On input to the initialization function, this identifies the highest version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which it supports. If on return the queue manager does not support the version returned by the component, it calls the component MQZ_TERM_NAME function and makes no further use of this component.

The following values are supported:

MQZAS_VERSION_1

Version 1.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_INITIALIZATION_FAILED

(2286, X'8EE') Initialization failed for an undefined reason.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_INIT_NAME (Hconfig, Options, QMgrName, ComponentDataLength,
               ComponentData, &Version, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */
MQLONG     Options;           /* Initialization options */
MQCHAR48   QMgrName;         /* Queue manager name */
MQLONG     ComponentDataLength; /* Length of component data */
MQBYTE     ComponentData[n];  /* Component data */
MQLONG     Version;           /* Version number */
MQLONG     CompCode;          /* Completion code */
MQLONG     Reason;            /* Reason code qualifying CompCode */
```

MQZ_INSERT_NAME - Insert name

This function is provided by a name service component, and is started by the queue manager to insert an entry for the specified queue, containing the name of the queue manager that owns the queue. If the queue is already defined in the service, the call fails.

The function identifier for this function (for MQZEP) is MQZID_INSERT_NAME.

Syntax

```
MQZ_INSERT_NAME( QMgrName , QName , ResolvedQMgrName , ComponentData ,
                 Continuation , CompCode , Reason )
```

Parameters**QMgrName**

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

QName

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be inserted. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

ResolvedQMgrName

Type: MQCHAR48 - input

Resolved queue manager name. The name of the queue manager to which the queue resolves. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_NAME call.

Continuation

Type: MQLONG - input/output

Continuation indicator set by component. For MQZ_INSERT_NAME, the queue manager does not attempt to start another component, whatever is returned in the *Continuation* parameter.

The following values are supported:

MQZCI_DEFAULT

Continuation dependent on queue manager.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_Q_ALREADY_EXISTS

(2290, X'8F2') Queue object already exists.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_INSERT_NAME (QMgrName, QName, ResolvedQMgrName, ComponentData,  
                &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR48  QName;             /* Queue name */  
MQCHAR48  ResolvedQMgrName;  /* Resolved queue manager name */  
MQBYTE    ComponentData[n];  /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;            /* Reason code qualifying CompCode */
```

MQZ_LOOKUP_NAME - Lookup name

This function is provided by a name service component, and is started by the queue manager to retrieve the name of the owning queue manager, for a specified queue.

The function identifier for this function (for MQZEP) is MQZID_LOOKUP_NAME.

Syntax

```
MQZ_LOOKUP_NAME( QMgrName , QName , ResolvedQMgrName , ComponentData ,  
Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

QName

Type: MQCHAR48 - input

Queue name. The name of the queue for which an entry is to be resolved. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

ResolvedQMgrName

Type: MQCHAR48 - output

Resolved queue manager name. If the function completes successfully, this is the name of the queue manager that owns the queue.

The name returned by the service component must be padded on the right with blanks to the full length of the parameter; the name must not be terminated by a null character, or contain leading or embedded blanks.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_NAME call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. For MQZ_LOOKUP_NAME, the queue manager specifies whether to start another name service component, as follows:

- If *CompCode* is MQCC_OK, no further components are started, whatever value is returned in *Continuation*.
- If *CompCode* is not MQCC_OK, a further component is started, unless *Continuation* is MQZCI_STOP.

The following values are supported:

MQZCI_DEFAULT

Continuation dependent on queue manager.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_Q_NAME

(2288, X'8F0') Queue name not found.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_LOOKUP_NAME (QMgrName, QName, ResolvedQMgrName, ComponentData,
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR48  QName;              /* Queue name */
MQCHAR48  ResolvedQMgrName;    /* Resolved queue manager name */
MQBYTE    ComponentData[n];    /* Component data */
MQLONG    Continuation;        /* Continuation indicator set by
                                component */
MQLONG    CompCode;            /* Completion code */
MQLONG    Reason;              /* Reason code qualifying CompCode */
```

MQZ_TERM_NAME - Terminate name service

This function is provided by a name service component, and is started by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID_TERM_NAME.

Syntax

MQZ_TERM_NAME(*Hconfig* , *Options* , *QMgrName* , *ComponentData* , *CompCode* , *Reason*)

Parameters

Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the particular component being terminated. It is used by the component when calling the queue manager with the MQZEP function.

Options

Type: MQLONG - input

Termination options. It must be one of the following values:

MQZTO_PRIMARY

Primary termination.

MQZTO_SECONDARY

Secondary termination.

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ComponentData

Type: MQBYTE x ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of these component functions is called.

Component data is in shared memory accessible to all processes.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_NAME call.

When the MQZ_TERM_NAME call has completed, the queue manager discards this data.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_TERMINATION_FAILED

(2287, X'8FF') Termination failed for an undefined reason.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_TERM_NAME (Hconfig, Options, QMgrName, ComponentData, &CompCode,  
               &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;           /* Termination options */  
MQCHAR48   QMgrName;          /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;          /* Completion code */  
MQLONG     Reason;            /* Reason code qualifying CompCode */
```

MQZAC - Application context

The MQZAC structure is used on the MQZ_AUTHENTICATE_USER call for the *ApplicationContext* parameter. This parameter specifies data related to the calling application.

[Table 1](#) summarizes the fields in the structure.

Table 658. Fields in MQZAC	
Field	Description
StrucId	Structure identifier
Version	Structure version number
ProcessId	Process identifier
ThreadId	Thread identifier
ApplName	Application name
UserID	User identifier
EffectiveUserID	Effective user identifier
Environment	Environment
CallerType	Caller type
AuthenticationType	Authentication type
BindType	Bind type

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQZAC_STRUC_ID

Identifier for application context structure.

For the C programming language, the constant MQZAC_STRUC_ID_ARRAY is also defined; this has the same value as MQZAC_STRUC_ID, but is an array of characters instead of a string.

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQZAC_VERSION_1

Version-1 application context structure. The constant MQZAC_CURRENT_VERSION specifies the version number of the current version.

ProcessId

Type: MQPID - input

Process identifier of the application.

ThreadId

Type: MQTID - input

Thread identifier of the application.

ApplName

Type: MQCHAR28 - input

Application name.

UserID

Type: MQCHAR12 - input

User identifier. On UNIX systems this field specifies the application's real user ID. On Windows this field specifies the application's user ID.

EffectiveUserID

Type: MQCHAR12 - input

Effective user identifier. On UNIX systems this field specifies the application's effective user ID. On Windows this field is blank.

Environment

Type: MQLONG - input

Environment. This field specifies the environment from which the call was made. The field is one of the following values:

MQXE_COMMAND_SERVER

Command server

MQXE_MQSC

runmqsc command interpreter

MQXE_MCA

Message channel agent MQXE_OTHER

MQXE_OTHER

Undefined environment

CallerType

Type: MQLONG - input

Caller Type. This field specifies the type of program that made the call. The field is one of the following values:

MQXACT_EXTERNAL

The call is external to the queue manager.

MQXACT_INTERNAL

The call is internal to the queue manager.

AuthenticationType

Type: MQLONG - input

Authentication Type. This field specifies the type of authentication being performed. The field is one of the following values:

MQZAT_INITIAL_CONTEXT

The authentication call is due to user context being initialized. This value is used during an MQCONN or MQCONNEX call.

MQZAT_CHANGE_CONTEXT

The authentication call is due to the user context being changed. This value is used when the MCA changes the user context. Parent topic: MQZAC -

BindType

Type: MQLONG - input

Bind Type. This field specifies the type of binding in use. The field is one of the following values:

MQCNO_FASTPATH_BINDING

Fastpath binding.

MQCNO_SHARED_BINDING

Shared binding.

MQCNO_ISOLATED_BINDING

Isolated binding.

C declaration

Declare the fields of the structure as follows:

```
typedef struct tagMQZAC MQZAC;
struct tagMQZAC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQPID      ProcessId;        /* Process identifier */
    MQTID      ThreadId;         /* Thread identifier */
    MQCHAR28   ApplName;         /* Application name */
    MQCHAR12   UserID;           /* User identifier */
    MQCHAR12   EffectiveUserID;   /* Effective user identifier */
    MQLONG     Environment;       /* Environment */
    MQLONG     CallerType;        /* Caller type */
    MQLONG     AuthenticationType; /* Authentication type */
    MQLONG     BindType;          /* Bind type */
};
```

MQZAD - Authority data

The MQZAD structure is used on the MQZ_ENUMERATE_AUTHORITY_DATA call for two parameters, one input and one output.

- MQZAD is used for the **Filter** parameter which is input to the call. This parameter specifies the selection criteria that are to be used to select the authority data returned by the call.
- MQZAD is also used for the **AuthorityBuffer** parameter which is output from the call. This parameter specifies the authorizations for one combination of profile name, object type, and entity.

Table 1. summarizes the fields in the structure.

Table 659. Fields in MQZAD	
Field	Description
<u>StrucId</u>	Structure identifier
<u>Version</u>	Structure version number

Table 659. Fields in MQZAD (continued)	
Field	Description
<u>ProfileName</u>	Profile name
<u>ObjectType</u>	Object type
<u>Authority</u>	Authority
<u>EntityDataPtr</u>	Pointer to entity data
<u>EntityType</u>	Entity type
<u>Options</u>	Options

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQZAD_STRUC_ID

Identifier for authority data structure.

For the C programming language, the constant MQZAD_STRUC_ID_ARRAY is also defined; this has the same value as MQZAD_STRUC_ID, but is an array of characters instead of a string.

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQZAD_VERSION_1

Version-1 application context structure. The constant MQZAD_CURRENT_VERSION specifies the version number of the current version.

The following constant specifies the version number of the current version:

MQZAD_CURRENT_VERSION

Current version of authority data structure.

ProfileName

Type: MQCHAR48 - input

Profile name.

For the **Filter** parameter, this field is the profile name for which authority data is required. If the name is entirely blank up to the end of the field or the first null character, authority data for all profile names is returned.

For the **AuthorityBuffer** parameter, this field is the name of a profile that matches the specified selection criteria.

ObjectType

Type: MQLONG - input

Object type.

For the **Filter** parameter, this field is the object type for which authority data is required. If the value is MQOT_ALL, authority data for all object types is returned.

For the **AuthorityBuffer** parameter, this field is the object type to which the profile identified by the **ProfileName** parameter applies.

The value is one of the following; for the **Filter** parameter, the value MQOT_ALL is also valid:

MQOT_AUTH_INFO

Authentication information

MQOT_CHANNEL

Channel

MQOT_CLNTCONN_CHANNEL

Client connection channel

MQOT_LISTENER

Listener

MQOT_NAMELIST

Namelist

MQOT_PROCESS

Process definition

MQOT_Q

Queue

MQOT_Q_MGR

Queue manager

MQOT_SERVICE

Service

Authority

Type: MQLONG - input

Authority.

For the **Filter** parameter, this field is ignored.

For the **AuthorityBuffer** parameter, this field represents the authorizations that the entity has to the objects identified by **ProfileName** and **ObjectType**. If the entity has only one authority, the field is equal to the appropriate authorization value (MQZAO_* constant). If the entity has more than one authority, the field is the bitwise OR of the corresponding MQZAO_* constants.

EntityDataPtr

Type: PMQZED - input

Address of MQZED structure identifying an entity.

For the **Filter** parameter, this field points to an MQZED structure that identifies the entity for which authority data is required. If **EntityDataPtr** is the null pointer, authority data for all entities is returned.

For the **AuthorityBuffer** parameter, this field points to an MQZED structure that identifies the entity for which authority data has been returned.

EntityType

Type: MQLONG - input

Entity type.

For the **Filter** parameter, this field specifies the entity type for which authority data is required. If the value is MQZAET_NONE, authority data for all entity types is returned.

For the **AuthorityBuffer** parameter, this field specifies the type of the entity identified by the MQZED structure pointed to by the **EntityDataPtr** parameter.

The value is one of the following; for the **Filter** parameter, the value MQZAET_NONE is also valid:

MQZAET_PRINCIPAL

Principal

MQZAET_GROUP

Group

Options

Type: MQAUTHOPT - input

Options. This field specifies options that give control over the profiles that are displayed. One of the following values must be specified:

MQAUTHOPT_NAME_ALL_MATCHING

Displays all profiles

MQAUTHOPT_NAME_EXPLICIT

Displays profiles that have exactly the same name as specified in the **ProfileName** field.

In addition, one of the following must also be specified:

MQAUTHOPT_ENTITY_SET

Display all profiles that are used to calculate the cumulative authority that the entity has to the object specified by the **ProfileName** parameter. The **ProfileName** parameter must not contain any wildcard characters.

- If the specified entity is a principal, for each member of the set {entity, groups} the most applicable profile that applies to the object is displayed.
- If the specified entity is a group, the most applicable profile from the group that applies to the object is displayed.
- If this value is specified, then the values of **ProfileName**, **ObjectType**, **EntityType**, and the entity name specified in the **EntityDataPtr** MQZED structure, must all be non-blank.

If you have specified MQAUTHOPT_NAME_ALL_MATCHING, you can also specify the following value:

MQAUTHOPT_ENTITY_EXPLICIT

Displays profiles that have exactly the same entity name as the entity name specified in the **EntityDataPtr** MQZED structure.

C declaration

```
typedef struct tagMQZAD MQZAD;  
struct tagMQZAD {  
    MQCHAR4    StrucId;        /* Structure identifier */  
    MQLONG     Version;        /* Structure version number */  
    MQCHAR48    ProfileName;    /* Profile name */  
    MQLONG     ObjectType;      /* Object type */  
    MQLONG     Authority;       /* Authority */  
    PMQZED     EntityDataPtr;   /* Address of MQZED structure identifying an  
                                entity */  
    MQLONG     EntityType;      /* Entity type */  
    MQAUTHOPT   Options;        /* Options */  
};
```

MQZED - Entity descriptor

The MQZED structure is used in a number of authorization service calls to specify the entity for which authorization is to be checked.

Table 1. summarizes the fields in the structure.

Table 660. Fields in MQZED	
Field	Description
StrucId	Structure identifier
Version	Version
EntityName Ptr	Entity name
EntityDomainPtr	Entity domain pointer
SecurityId	Security identifier

Table 660. Fields in MQZED (continued)	
Field	Description
<u>CorrelationPtr</u>	Correlation pointer

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQZED_STRUC_ID

Identifier for entity descriptor structure.

For the C programming language, the constant MQZED_STRUC_ID_ARRAY is also defined; this has the same value as MQZED_STRUC_ID, but is an array of characters instead of a string.

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQZED_VERSION_1

Version-1 entity descriptor structure.

The following constant specifies the version number of the current version:

MQZED_CURRENT_VERSION

Current version of entity descriptor structure.

EntityNamePtr

Type: PMQCHAR - input

Profile name.

Address of entity name. This is a pointer to the name of the entity whose authorization is to be checked.

EntityDomainPtr

Type: PMQCHAR - input

Address of entity domain name. This is a pointer to the name of the domain containing the definition of the entity whose authorization is to be checked.

SecurityId

Type: MQBYTE40 - input

Authority.

Security identifier. This is the security identifier whose authorization is to be checked.

CorrelationPtr

Type: MQPTR - input

Correlation pointer. This facilitates the passing of correlational data between the authenticate user function and other appropriate OAM functions.

C declaration

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    PMQCHAR    EntityNamePtr;    /* Address of entity name */
    PMQCHAR    EntityDomainPtr;  /* Address of entity domain name */
    MQBYTE40   SecurityId;       /* Security identifier */
    MQPTR      CorrelationPtr;   /* Address of correlation data */
}
```

Fields

MQZEP - Add component entry point

A service component starts this function, during initialization, to add an entry point to the entry point vector for that service component.

Syntax

MQZEP (*Hconfig*, *Function*, *EntryPoint*, *CompCode*, *Reason*)

Parameters

Hconfig

Type: MQHCONFIG - input

Configuration handle. This handle represents the component that is being configured for this particular installable service. It must be the same as the component passed to the component configuration function by the queue manager on the component initialization call.

Function

Type: MQLONG - input

Function identifier. Valid values for this are defined for each installable service.

If MQZEP is called more than once for the same function, the last call made provides the entry point that is used.

EntryPoint

Type: PMQFUNC - input

Function entry point. This is the address of the entry point provided by the component to perform the function.

The value NULL is valid, and indicates that the function is not provided by this component. NULL is assumed for entry points that are not defined using MQZEP.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_FUNCTION_ERROR

(2281, X'8E9') Function identifier not valid.

MQRC_HCONFIG_ERROR

(2280, X'8E8') Configuration handle not valid.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZEP (Hconfig, Function, EntryPoint, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONFIG  Hconfig;      /* Configuration handle */
MQLONG     Function;     /* Function identifier */
PMQFUNC    EntryPoint;   /* Function entry point */
MQLONG     CompCode;     /* Completion code */
MQLONG     Reason;       /* Reason code qualifying CompCode */
```

MQZFP - Free parameters

The MQZFP structure is used on the MQZ_FREE_USER call for the *FreeParms* parameter. This parameter specifies data related to resource to be freed.

Table 1. summarizes the fields in the structure.

Table 661. Fields in MQZFP	
Field	Description
<u>StrucId</u>	Structure identifier
<u>Version</u>	Version
<u>Reserved</u>	Reserved field
<u>CorrelationPtr</u>	Correlation pointer

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQZIC_STRUC_ID

Identifier for identity context structure. For the C programming language, the constant MQZIC_STRUC_ID_ARRAY is also defined; this has the same value as MQZIC_STRUC_ID, but is an array of characters instead of a string.

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQZFP_VERSION_1

Version-1 free parameters structure.

The following constant specifies the version number of the current version:

MQZFP_CURRENT_VERSION

Current version of free parameters structure.

Reserved

Type: MQBYTE8 - input

Reserved field. The initial value is null.

CorrelationPtr

Type: MQPTR - input

Correlation pointer. Address of correlation data relating to the resource to be freed.

C declaration

```
typedef struct tagMQZFP MQZFP;
struct tagMQZFP {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;          /* Structure version number */
    MQBYTE8    Reserved;         /* Reserved field */
    MQPTR      CorrelationPtr;   /* Address of correlation data */
};
```

Fields

MQZIC - Identity context

The MQZIC structure is used on the MQZ_AUTHENTICATE_USER call for the *IdentityContext* parameter.

The MQZIC structure contains identity context information, which identifies the user of the application that first put the message on a queue:

- The queue manager fills the *UserIdentifier* field with a name that identifies the user, the way that the queue manager can do this depends on the environment in which the application is running.
- The queue manager fills the *AccountingToken* field with a token or number that it determined from the application that put the message.
- Applications can use the *ApplIdentityData* field for any extra information that they want to include about the user (for example, an encrypted password).

Suitably authorized applications can set the identity context using the MQZ_AUTHENTICATE_USER function.

A Windows systems security identifier (SID) is stored in the *AccountingToken* field when a message is created under IBM MQ for Windows. The SID can be used to supplement the *UserIdentifier* field and to establish the credentials of a user.

Table 1. summarizes the fields in the structure.

Table 662. Fields in MQZIC	
Field	Description
StrucId	Structure identifier
Version	Version
UserIdentifier	User identifier
AccountingToken	Accounting token
ApplIdentityData	Application identity data

Fields

StrucId

Type: MQCHAR4 - input

Structure identifier. The value is as follows:

MQZIC_STRUC_ID

Identifier for identity context structure. For the C programming language, the constant MQZIC_STRUC_ID_ARRAY is also defined; this has the same value as MQZIC_STRUC_ID, but is an array of characters instead of a string.

Version

Type: MQLONG - input

Structure version number. The value is as follows:

MQZIC_VERSION_1

Version-1 identity context structure.

The following constant specifies the version number of the current version:

MQZIC_CURRENT_VERSION

Current version of identity context structure.

UserIdentifier

Type: MQCHAR12 - input

User identifier. This is part of the identity context of the message. *UserIdentifier* specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it. For more information on the *UserIdentifier* field, see [“UserIdentifier \(MQCHAR12\)” on page 441](#).

AccountingToken

Type: MQBYTE32 - input

Accounting token. This is part of the identity context of the message. *AccountingToken* allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content. For more information on the *AccountingToken* field, see [“AccountingToken \(MQBYTE32\)” on page 400](#).

ApplIdentityData

Type: MQCHAR32 - input

Application data relating to identity. This is part of the identity context of the message. *ApplIdentityData* is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted. For more information on the *ApplIdentityData* field, see [“ApplIdentityData \(MQCHAR32\)” on page 401](#).

C declaration

```
typedef struct tagMQZED MQZED;
struct tagMQZED {
    MQCHAR4    StrucId;          /* Structure identifier */
    MQLONG     Version;         /* Structure version number */
    MQCHAR12   UserIdentifier;   /* User identifier */
    MQBYTE32   AccountingToken; /* Accounting token */
    MQCHAR32   ApplIdentityData; /* Application data relating to identity */
};
```

Fields

Installable services interface reference information

Use this information to understand the reference information for the installable services.

For each function there is a description, including the function identifier (for MQZEP).

The *parameters* are shown listed in the order they must occur. They must all be present.

Each parameter name is followed by its data type in parentheses. These are the elementary data types described in [“Elementary data types” on page 959](#).

The C language invocation is also given, after the description of the parameters.

MQZEP - Add component entry point

This function is invoked by a service component, during initialization, to add an entry point to the entry point vector for that service component.

Syntax

```
MQZEP (Hconfig, Function, EntryPoint, CompCode, Reason)
```

Parameters

The MQZEP call has the following parameters.

Hconfig (MQHCONFIG) - input

Configuration handle.

This handle represents the component which is being configured for this particular installable service. It must be the same as the one passed to the component configuration function by the queue manager on the component initialization call.

Function (MQLONG) - input

Function identifier.

Valid values for this are defined for each installable service. If MQZEP is called more than once for the same function, the last call made provides the entry point which is used.

EntryPoint (PMQFUNC) - input

Function entry point.

This is the address of the entry point provided by the component to perform the function. The value NULL is valid, and indicates that the function is not provided by this component. NULL is assumed for entry points which are not defined using MQZEP.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_FUNCTION_ERROR

(2281, X'8E9') Function identifier not valid.

MQRC_HCONFIG_ERROR

(2280, X'8E8') Configuration handle not valid.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZEP (Hconfig, Function, EntryPoint, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQHCONFIG  Hconfig;      /* Configuration handle */
MQLONG     Function;     /* Function identifier */
PMQFUNC    EntryPoint;   /* Function entry point */
MQLONG     CompCode;     /* Completion code */
MQLONG     Reason;       /* Reason code qualifying CompCode */
```

MQHCONFIG - Configuration handle

The MQHCONFIG data type represents a configuration handle, that is, the component that is being configured for a particular installable service. A configuration handle must be aligned on its natural boundary.

Applications must test variables of this type for equality only.

C declaration

```
typedef void MQPOINTER MQHCONFIG;
```

PMQFUNC - Pointer to function

Pointer to a function.

C declaration

```
typedef void MQPOINTER PMQFUNC;
```

MQZ_AUTHENTICATE_USER - Authenticate user

This function is provided by a MQZAS_VERSION_5 authorization service component. It is invoked by the queue manager to authenticate a user, or to set identity context fields.

It is invoked when an IBM MQ user application context is established. This happens during connect calls at the point where the application's user context is initialized, and at each point where the application's user context is changed. Each time a connect call is made, the application's user context information is reacquired in the *IdentityContext* field.

The function identifier for this function (for MQZEP) is MQZID_AUTHENTICATE_USER.

Syntax

MQZ_AUTHENTICATE_USER (*QMgrName*, *SecurityParms*, *ApplicationContext*, *IdentityContext*, *CorrelationPtr*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_AUTHENTICATE_USER call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character. The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

SecurityParms (MQCSP) - input

Security parameters.

Data relating to the user ID, password, and authentication type.

During an MQCONN MQI call this parameter contains null, or default values.

ApplicationContext (MQZAC) - input

Application context.

Data relating to the calling application. See [“MQZAC - Application context”](#) on page 1717 for details. During every MQCONN or MQCONNX MQI call, the user context information in the MQZAC structure is reacquired.

IdentityContext (MQZIC) - input/output

Identity context.

On input to the authenticate user function, this identifies the current identity context. The authenticate user function can change this, at which point the queue manager adopts the new identity context. See [“MQZIC - Identity context”](#) on page 1724 for more details on the MQZIC structure.

CorrelationPtr (MQPTR) - output

Correlation pointer.

Specifies the address of any correlation data. This pointer is then passed on to other OAM calls.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this components functions is called. The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation flag.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on other components.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information about these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_AUTHENTICATE_USER (QMgrName, SecurityParms, ApplicationContext,  
                        IdentityContext, &CorrelationPtr, ComponentData,  
                        &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```

MQCHAR48  QMgrName;           /* Queue manager name */
MQCSP     SecurityParms;      /* Security parameters */
MQZAC     ApplicationContext; /* Application context */
MQZIC     IdentityContext;    /* Identity context */
MQPTR     CorrelationPtr;     /* Correlation pointer */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */

```

MQZ_CHECK_AUTHORITY - Check authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is invoked by the queue manager to check whether an entity has authority to perform a particular action, or actions, on a specified object.

The function identifier for this function (for MQZEP) is MQZID_CHECK_AUTHORITY.

Syntax

MQZ_CHECK_AUTHORITY (*QMgrName*, *EntityName*, *EntityType*,
ObjectName, *ObjectType*, *Authority*, *ComponentData*, *Continuation*, *CompCode*,
Reason)

Parameters

The MQZ_CHECK_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character. The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

EntityName (MQCHAR12) - input

Entity name.

The name of the entity whose authorization to the object is to be checked. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

It is not essential for this entity to be known to the underlying security service. If it is not known, then the authorizations of the special **nobody** group (to which all entities are assumed to belong) are used for the check. An all-blank name is valid and can be used in this way.

EntityType (MQLONG) - input

Entity type.

The type of entity specified by *EntityName*. It is one of the following:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName (MQCHAR48) - input

Object name.

The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType (MQLONG) - input

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority (MQLONG) - input

Authority to be checked.

If one authorization is being checked, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authorization is being checked, it is the bitwise OR of the corresponding MQZAO_* constants.

The following authorizations apply to use of the MQI calls:

MQZAO_CONNECT

Ability to use the MQCONN call.

MQZAO_BROWSE

Ability to use the MQGET call with a browse option.

This allows the MQGMO_BROWSE_FIRST, MQGMO_BROWSE_MSG_UNDER_CURSOR, or MQGMO_BROWSE_NEXT option to be specified on the MQGET call.

MQZAO_INPUT

Ability to use the MQGET call with an input option.

This allows the MQOO_INPUT_SHARED, MQOO_INPUT_EXCLUSIVE, or MQOO_INPUT_AS_Q_DEF option to be specified on the MQOPEN call.

MQZAO_OUTPUT

Ability to use the MQPUT call.

This allows the MQOO_OUTPUT option to be specified on the MQOPEN call.

MQZAO_INQUIRE

Ability to use the MQINQ call.

This allows the MQOO_INQUIRE option to be specified on the MQOPEN call.

MQZAO_SET

Ability to use the MQSET call.

This allows the MQOO_SET option to be specified on the MQOPEN call.

MQZAO_PASS_IDENTITY_CONTEXT

Ability to pass identity context.

This allows the MQOO_PASS_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_PASS_ALL_CONTEXT

Ability to pass all context.

This allows the MQOO_PASS_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_PASS_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_IDENTITY_CONTEXT

Ability to set identity context.

This allows the MQOO_SET_IDENTITY_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_IDENTITY_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_SET_ALL_CONTEXT

Ability to set all context.

This allows the MQOO_SET_ALL_CONTEXT option to be specified on the MQOPEN call, and the MQPMO_SET_ALL_CONTEXT option to be specified on the MQPUT and MQPUT1 calls.

MQZAO_ALTERNATE_USER_AUTHORITY

Ability to use alternate user authority.

This allows the MQOO_ALTERNATE_USER_AUTHORITY option to be specified on the MQOPEN call, and the MQPMO_ALTERNATE_USER_AUTHORITY option to be specified on the MQPUT1 call.

MQZAO_ALL_MQI

All of the MQI authorizations.

This enables all of the authorizations described previously.

The following authorizations apply to administration of a queue manager:

MQZAO_CREATE

Ability to create objects of a specified type.

MQZAO_DELETE

Ability to delete a specified object.

MQZAO_DISPLAY

Ability to display the attributes of a specified object.

MQZAO_CHANGE

Ability to change the attributes of a specified object.

MQZAO_CLEAR

Ability to delete all messages from a specified queue.

MQZAO_AUTHORIZE

Ability to authorize other users for a specified object.

MQZAO_CONTROL

Ability to start, stop, or ping a non-client channel object.

MQZAO_CONTROL_EXTENDED

Ability to reset a sequence number, or resolve an indoubt message on a non-client channel object.

MQZAO_ALL_ADMIN

All of the administration authorizations, other than MQZAO_CREATE.

The following authorizations apply to both use of the MQI and to administration of a queue manager:

MQZAO_ALL

All authorizations, other than MQZAO_CREATE.

MQZAO_NONE

No authorizations.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_CHECK_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,
                    ObjectType, Authority, ComponentData,
                    &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;         /* Entity name */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
```

```

MQLONG    ObjectType;          /* Object type */
MQLONG    Authority;          /* Authority to be checked */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */

```

MQZ_CHECK_PRIVILEGED - Check if user is privileged

This function is provided by an MQZAS_VERSION_6 authorization service component, and is invoked by the queue manager to determine whether a specified user is a privileged user.

The function identifier for this function (for MQZEP) is MQZID_CHECK_PRIVILEGED.

Syntax

```
MQZ_CHECK_PRIVILEGED( QMgrName , EntityData , EntityType , ComponentData ,
                     Continuation , CompCode , Reason )
```

Parameters

QMgrName

Type: MQCHAR48 - input

Queue manager name. The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

EntityData

Type: MQZED - input

Entity data. Data relating to the entity that is to be checked. For more information, see [“MQZED - Entity descriptor”](#) on page 1681.

EntityType

Type: MQLONG - input

Entity type. The type of entity specified by EntityData. It must be one of the following values:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ComponentData

Type: MQBYTE×ComponentDataLength - input/output

Component data. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of these component functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation

Type: MQLONG - output

Continuation indicator set by component. The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_CHECK_AUTHORITY, this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

If the call to a component fails (that is, *CompCode* returns MQCC_FAILED), and the *Continuation* parameter is MQZCI_DEFAULT or MQZCI_CONTINUE, the queue manager continues to call other components if there are any.

If the call succeeds (that is, *CompCode* returns MQCC_OK) no other components are called no matter what the setting of *Continuation* is.

If the call fails and the *Continuation* parameter is MQZCI_STOP then no other components are called and the error is returned to the queue manager. Components have no knowledge of previous calls, so the *Continuation* parameter is always set to MQZCI_DEFAULT before the call.

CompCode

Type: MQLONG - output

Completion code. It must be one of the following values:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason

Type: MQLONG - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_PRIVILEGED

(2584, X'A18') This user is not a privileged user ID.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information about these reason codes, see [API completion and reason codes](#).

C invocation

```
MQZ_CHECK_PRIVILEGED (QMgrName, &EntityData, EntityType,
                     ComponentData, &Continuation,
                     &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQZED     EntityData;         /* Entity name */
MQLONG    EntityType;         /* Entity type */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_COPY_ALL_AUTHORITY - Copy all authority

This function is provided by an authorization service component. It is invoked by the queue manager to copy all of the authorizations that are currently in force for a reference object to another object.

The function identifier for this function (for MQZEP) is MQZID_COPY_ALL_AUTHORITY.

Syntax

MQZ_COPY_ALL_AUTHORITY (*QMgrName, RefObjectName, ObjectName, ObjectType, ComponentData, Continuation, CompCode, Reason*)

Parameters

The MQZ_COPY_ALL_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

RefObjectName (MQCHAR48) - input

Reference object name.

The name of the reference object, the authorizations for which are to be copied. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

ObjectName (MQCHAR48) - input

Object name.

The name of the object for which accesses are to be set. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

ObjectType (MQLONG) - input

Object type.

The type of object specified by *RefObjectName* and *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_COPY_ALL_AUTHORITY this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_REF_OBJECT

(2294, X'8F6') Reference object unknown.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_COPY_ALL_AUTHORITY (QMgrName, RefObjectName, ObjectName, ObjectType,  
                        ComponentData, &Continuation, &CompCode,  
                        &Reason);
```

The parameters passed to the service are declared as follows:

```

MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR48  RefObjectName;      /* Reference object name */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */

```

MQZ_DELETE_AUTHORITY - Delete authority

This function is provided by an authorization service component, and is invoked by the queue manager to delete all of the authorizations associated with the specified object.

The function identifier for this function (for MQZEP) is MQZID_DELETE_AUTHORITY.

Syntax

MQZ_DELETE_AUTHORITY (*QMgrName*, *ObjectName*, *ObjectType*,
ComponentData, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_DELETE_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

ObjectName (MQCHAR48) - input

Object name.

The name of the object for which accesses are to be deleted. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType (MQLONG) - input

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_DELETE_AUTHORITY this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_DELETE_AUTHORITY (QMgrName, ObjectName, ObjectType, ComponentData,
                      &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48 QMgrName;           /* Queue manager name */
MQCHAR48 ObjectName;         /* Object name */
```

```

MQLONG    ObjectType;        /* Object type */
MQBYTE    ComponentData[n]; /* Component data */
MQLONG    Continuation;      /* Continuation indicator set by
                             component */
MQLONG    CompCode;          /* Completion code */
MQLONG    Reason;            /* Reason code qualifying CompCode */

```

MQZ_ENUMERATE_AUTHORITY_DATA - Enumerate authority data

This function is provided by an MQZAS_VERSION_4 authorization service component, and is invoked repeatedly by the queue manager to retrieve all of the authority data that matches the selection criteria specified on the first invocation.

The function identifier for this function (for MQZEP) is MQZID_ENUMERATE_AUTHORITY_DATA.

Syntax

MQZ_ENUMERATE_AUTHORITY_DATA (*QMgrName*, *StartEnumeration*, *Filter*, *AuthorityBufferLength*, *AuthorityBuffer*, *AuthorityDataLength*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_ENUMERATE_AUTHORITY_DATA call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

StartEnumeration (MQLONG) - input

Flag indicating whether call should start enumeration.

This indicates whether the call should start the enumeration of authority data, or continue the enumeration of authority data started by a previous call to MQZ_ENUMERATE_AUTHORITY_DATA. The value is one of the following:

MQZSE_START

Start enumeration.

The call is invoked with this value to start the enumeration of authority data. The *Filter* parameter specifies the selection criteria to be used to select the authority data returned by this and successive calls.

MQZSE_CONTINUE

Continue enumeration.

The call is invoked with this value to continue the enumeration of authority data. The *Filter* parameter is ignored in this case, and can be specified as the null pointer (the selection criteria are determined by the *Filter* parameter specified by the call that had *StartEnumeration* set to MQZSE_START).

Filter (MQZAD) - input

Filter.

If *StartEnumeration* is MQZSE_START, *Filter* specifies the selection criteria to be used to select the authority data to return. If *Filter* is the null pointer, no selection criteria are used, that is, all authority data is returned. See [“MQZAD \(Authority data\) on IBM i” on page 1719](#) for details of the selection criteria that can be used.

If *StartEnumeration* is MQZSE_CONTINUE, *Filter* is ignored, and can be specified as the null pointer.

AuthorityBufferLength (MQLONG) - input

Length of *AuthorityBuffer*.

This is the length in bytes of the *AuthorityBuffer* parameter. The authority buffer must be big enough to accommodate the data to be returned.

AuthorityBuffer (MQZAD) - output

Authority data.

This is the buffer in which the authority data is returned. The buffer must be big enough to accommodate an MQZAD structure, an MQZED structure, plus the longest entity name and longest domain name defined.

Note: This parameter is defined as an MQZAD, as the MQZAD always occurs at the start of the buffer. However, if the buffer is actually declared as an MQZAD, the buffer will be too small - it needs to be bigger than an MQZAD so that it can accommodate the MQZAD, MQZED, plus entity and domain names.

AuthorityDataLength (MQLONG) - output

Length of data returned in *AuthorityBuffer*.

This is the length of the data returned in *AuthorityBuffer*. If the authority buffer is too small, *AuthorityDataLength* is set to the length of the buffer required, and the call returns completion code MQCC_FAILED and reason code MQRC_BUFFER_LENGTH_ERROR.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_ENUMERATE_AUTHORITY_DATA this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_BUFFER_LENGTH_ERROR

(2005, X'7D5') Buffer length parameter not valid.

MQRC_NO_DATA_AVAILABLE

(2379, X'94B') No data available.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_ENUMERATE_AUTHORITY_DATA (QMgrName, StartEnumeration, &Filter,  
                               AuthorityBufferLength,  
                               &AuthorityBuffer,  
                               &AuthorityDataLength, ComponentData,  
                               &Continuation, &CompCode,  
                               &Reason);
```

The parameters passed to the service are declared as follows:

MQCHAR48	QMgrName;	/* Queue manager name */
MQLONG	StartEnumeration;	/* Flag indicating whether call should start enumeration */
MQZAD	Filter;	/* Filter */
MQLONG	AuthorityBufferLength;	/* Length of AuthorityBuffer */
MQZAD	AuthorityBuffer;	/* Authority data */
MQLONG	AuthorityDataLength;	/* Length of data returned in AuthorityBuffer */
MQBYTE	ComponentData[n];	/* Component data */
MQLONG	Continuation;	/* Continuation indicator set by component */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code qualifying CompCode */

MQZ_FREE_USER - Free user

This function is provided by a MQZAS_VERSION_5 authorization service component, and is invoked by the queue manager to free associated allocated resource. It is invoked when an application has finished running under all user contexts, for example during an MQDISC MQI call.

The function identifier for this function (for MQZEP) is MQZID_FREE_USER.

MQZ_GET_AUTHORITY - Get authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is invoked by the queue manager to retrieve the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID_GET_AUTHORITY.

Syntax

MQZ_GET_AUTHORITY (*QMgrName, EntityName, EntityType, ObjectName,*
ObjectType, Authority, ComponentData, Continuation, CompCode, Reason)

Parameters

The MQZ_GET_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

EntityName (MQCHAR12) - input

Entity name.

The name of the entity whose access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType (MQLONG) - input

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName (MQCHAR48) - input

Object name.

The name of the object for which the entity's authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType (MQLONG) - input

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority (MQLONG) - output

Authority of entity.

If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_GET_AUTHORITY this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_GET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,  
                  ObjectType, &Authority, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;         /* Entity name */  
MQLONG    EntityType;         /* Entity type */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */
```

MQLONG	Authority;	/* Authority of entity */
MQBYTE	ComponentData[n];	/* Component data */
MQLONG	Continuation;	/* Continuation indicator set by component */
MQLONG	CompCode;	/* Completion code */
MQLONG	Reason;	/* Reason code qualifying CompCode */

MQZ_GET_EXPLICIT_AUTHORITY - Get explicit authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is invoked by the queue manager to retrieve the authority that a named group has to access a specified object (but without the additional authority of the **nobody** group), or the authority that the primary group of the named principal has to access a specified object.

The function identifier for this function (for MQZEP) is MQZID_GET_EXPLICIT_AUTHORITY.

Syntax

MQZ_GET_EXPLICIT_AUTHORITY (*QMgrName*, *EntityName*, *EntityType*, *ObjectName*, *ObjectType*, *Authority*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_GET_EXPLICIT_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

EntityName (MQCHAR12) - input

Entity name.

The name of the entity from which access to the object is to be retrieved. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType (MQLONG) - input

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName (MQCHAR48) - input

Object name.

The name of the object for which the entity's authority is to be retrieved. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType (MQLONG) - input

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority (MQLONG) - output

Authority of entity.

If the entity has one authority, this field is equal to the appropriate authorization operation (MQZAO_* constant). If it has more than one authority, this field is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_GET_EXPLICIT_AUTHORITY this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_GET_EXPLICIT_AUTHORITY (QMgrName, EntityName, EntityType,  
                             ObjectName, ObjectType, &Authority,  
                             ComponentData, &Continuation,  
                             &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQCHAR12  EntityName;         /* Entity name */  
MQLONG    EntityType;         /* Entity type */  
MQCHAR48  ObjectName;         /* Object name */  
MQLONG    ObjectType;         /* Object type */  
MQLONG    Authority;          /* Authority of entity */  
MQBYTE    ComponentData[n];   /* Component data */  
MQLONG    Continuation;       /* Continuation indicator set by  
                               component */  
MQLONG    CompCode;           /* Completion code */  
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_INIT_AUTHORITY - Initialize authorization service

This function is provided by an authorization service component, and is invoked by the queue manager during configuration of the component. It is expected to call MQZEP in order to provide information to the queue manager.

The function identifier for this function (for MQZEP) is MQZID_INIT_AUTHORITY.

Syntax

MQZ_INIT_AUTHORITY (*Hconfig*, *Options*, *QMgrName*, *ComponentDataLength*,
ComponentData, *Version*, *CompCode*, *Reason*)

Parameters

The MQZ_INIT_AUTHORITY call has the following parameters.

Hconfig (MQHCONFIG) - input

Configuration handle.

This handle represents the particular component being initialized. It is to be used by the component when calling the queue manager with the MQZEP function.

Options (MQLONG) - input

Initialization options.

It is one of the following:

MQZIO_PRIMARY

Primary initialization.

MQZIO_SECONDARY

Secondary initialization.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

ComponentDataLength (MQLONG) - input

Length of component data.

Length in bytes of the *ComponentData* area. This length is defined in the component configuration data.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This is initialized to all zeros before calling the component's primary initialization function. This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions (including the initialization function) provided by this component are preserved, and presented the next time one of this component's functions is called.

Version (MQLONG) - input/output

Version number.

On input to the initialization function, this identifies the *highest* version number that the queue manager supports. The initialization function must change this, if necessary, to the version of the interface which *it* supports. If on return the queue manager does not support the version returned by the component, it calls the component's MQZ_TERM_AUTHORITY function and makes no further use of this component.

The following values are supported:

MQZAS_VERSION_1

Version 1.

MQZAS_VERSION_2

Version 2.

MQZAS_VERSION_3

Version 3.

MQZAS_VERSION_4

Version 4.

MQZAS_VERSION_5

Version 5.

MQZAS_VERSION_6

Version 6.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_INITIALIZATION_FAILED

(2286, X'8EE') Initialization failed for an undefined reason.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_INIT_AUTHORITY (Hconfig, Options, QMgrName, ComponentDataLength,  
                    ComponentData, &Version, &CompCode,  
                    &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;           /* Configuration handle */  
MQLONG     Options;           /* Initialization options */  
MQCHAR48   QMgrName;         /* Queue manager name */  
MQLONG     ComponentDataLength; /* Length of component data */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     Version;          /* Version number */  
MQLONG     CompCode;         /* Completion code */  
MQLONG     Reason;           /* Reason code qualifying CompCode */
```

MQZ_INQUIRE - Inquire authorization service

This function is provided by a MQZAS_VERSION_5 authorization service component, and is invoked by the queue manager to query the supported functionality. Where multiple service components are used, service components are called in reverse order to the order they were installed in.

The function identifier for this function (for MQZEP) is MQZID_INQUIRE.

Syntax

MQZ_INQUIRE

(*QMgrName*, *SelectorCount*, *Selectors*, *IntAttrCount*, *IntAttrs*, *CharAttrLength*,
CharAttrs, *SelectorReturned*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_INQUIRE call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

SelectorCount (MQLONG) - input

Number of selectors.

The number of selectors supplied in the Selectors parameter.

The value must be between zero and 256.

Selectors (MQLONG x SelectorCount) - input

Selectors.

Array of selectors. Each selector identifies a required attribute and must be of one of the following types:

- MQIACF_* (integer)
- MQCACF_* (character)

Selectors can be specified in any order. The number of selectors in the array is indicated by the SelectorCount parameter.

Integer attributes identified by selectors are returned in the IntAttrs parameter in the same order as they appear in Selectors.

Character attributes identified by selectors are returned in the CharAttrs parameter in the same order as they appear in Selectors.

IntAttrCount (MQLONG) - input

Number of integer attributes.

The number of integer attributes supplied in the IntAttrs parameter.

The value must be in the range 0 through 256.

IntAttrs (MQLONG x IntAttrCount) - output

Integer attributes.

Array of integer attributes. The integer attributes are returned in the same order as the corresponding integer selectors in the Selectors array.

CharAttrCount (MQLONG) - input

Length of the character attributes buffer.

The length in bytes of the CharAttrs parameter.

The value must at least sum of the lengths of the requested character attributes. If no character attributes are requested, zero is a valid value.

CharAttrs (MQLONG x CharAttrCount) - output

Character attributes buffer.

Buffer containing character attributes, concatenated together. The character attributes are returned in the same order as the corresponding character selectors in the Selectors array.

The length of the buffer is given by the CharAttrCount parameter.

SelectorReturned (MQLONGxSelectorCount) - input

Selector returned.

Array of values identifying which attributes have been returned from the set requested for by the selectors in the Selectors parameter. The number of values in this array is indicated by the SelectorCount parameter. Each value in the array relates to the selector from the corresponding position in the Selectors array. Each value is one of the following:

MQZSL_RETURNED

The attribute requested by the corresponding selector in the Selectors parameter has been returned.

MQZSL_NOT_RETURNED

The attribute requested by the corresponding selector in the Selectors parameter has not been returned.

The array is initialized with all values as *MQZSL_NOT_RETURNED*. When an authorization service component returns an attribute, it sets the appropriate value in the array to *MQZSL_RETURNED*. This

allows any other authorization service components, to which the inquire call is made, to identify which attributes have already been returned.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation flag.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on other components.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_WARNING

Partial completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_WARNING:

MQRC_CHAR_ATTRS_TOO_SHORT

Not enough space for character attributes.

MQRC_INT_COUNT_TOO_SMALL

Not enough space for integer attributes.

If *CompCode* is MQCC_FAILED:

MQRC_SELECTOR_COUNT_ERROR

Number of selectors is not valid.

MQRC_SELECTOR_ERROR

Attribute selector not valid.

MQRC_SELECTOR_LIMIT_EXCEEDED

Too many selectors specified.

MQRC_INT_ATTR_COUNT_ERROR

Number of integer attributes is not valid.

MQRC_INT_ATTRS_ARRAY_ERROR

Integer attributes array not valid.

MQRC_CHAR_ATTR_LENGTH_ERROR

Number of character attributes is not valid.

MQRC_CHAR_ATTRS_ERROR

Character attributes string is not valid.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

C invocation

```
MQZ_INQUIRE (QMgrName, SelectorCount, Selectors, IntAttrCount,
              &IntAttrs, CharAttrLength, &CharAttrs,
              SelectorReturned, ComponentData, &Continuation,
              &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQLONG    SelectorCount;      /* Selector count */
MQLONG    Selectors[n];       /* Selectors */
MQLONG    IntAttrCount;       /* IntAttrs count */
MQLONG    IntAttrs[n];        /* Integer attributes */
MQLONG    CharAttrCount;      /* CharAttrs count */
MQLONG    CharAttrs[n];       /* Character attributes */
MQLONG    SelectorReturned[n]; /* Selector returned */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_REFRESH_CACHE - Refresh all authorizations

This function is provided by an MQZAS_VERSION_3 authorization service component. It is invoked by the queue manager to refresh the list of authorizations held internally by the component.

The function identifier for this function (for MQZEP) is MQZID_REFRESH_CACHE (8L).

Syntax

MQZ_REFRESH_CACHE

(QMgrName, ComponentData, Continuation, CompCode, Reason)

Parameters

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to use it in any defined manner.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component. Any changes made to it by any of the functions provided by this component are preserved, and presented the next time a function of the component is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_REFRESH_CACHE, this has the same effect as MQZCI_CONTINUE.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

C invocation

```
MQZ_REFRESH_CACHE (QMgrName, ComponentData,  
                  &Continuation, &CompCode, &Reason);
```

Declare the parameters as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */  
MQBYTE    ComponentData[n];  /* Component data */  
MQLONG    Continuation;      /* Continuation indicator set by  
                             component */  
MQLONG    CompCode;          /* Completion code */  
MQLONG    Reason;            /* Reason code qualifying CompCode */
```

MQZ_SET_AUTHORITY - Set authority

This function is provided by a MQZAS_VERSION_1 authorization service component, and is invoked by the queue manager to set the authority that an entity has to access the specified object.

The function identifier for this function (for MQZEP) is MQZID_SET_AUTHORITY.

Note: This function overrides any existing authorities. To preserve any existing authorities you must set them again with this function.

Syntax

MQZ_SET_AUTHORITY (*QMgrName*, *EntityName*, *EntityType*, *ObjectName*,
ObjectType, *Authority*, *ComponentData*, *Continuation*, *CompCode*, *Reason*)

Parameters

The MQZ_SET_AUTHORITY call has the following parameters.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

EntityName (MQCHAR12) - input

Entity name.

The name of the entity for which access to the object is to be set. The maximum length of the string is 12 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

EntityType (MQLONG) - input

Entity type.

The type of entity specified by *EntityName*. The following value can be specified:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

ObjectName (MQCHAR48) - input

Object name.

The name of the object to which access is required. The maximum length of the string is 48 characters; if it is shorter than that it is padded to the right with blanks. The name is not terminated by a null character.

If *ObjectType* is MQOT_Q_MGR, this name is the same as *QMgrName*.

ObjectType (MQLONG) - input

Object type.

The type of entity specified by *ObjectName*. It is one of the following:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority (MQLONG) - input

Authority to be checked.

If one authorization is being set, this field is equal to the appropriate authorization operation (MQZAO_* constant). If more than one authorization is being set, it is the bitwise OR of the corresponding MQZAO_* constants.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter of the MQZ_INIT_AUTHORITY call.

Continuation (MQLONG) - output

Continuation indicator set by component.

The following values can be specified:

MQZCI_DEFAULT

Continuation dependent on queue manager.

For MQZ_SET_AUTHORITY this has the same effect as MQZCI_STOP.

MQZCI_CONTINUE

Continue with next component.

MQZCI_STOP

Do not continue with next component.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_NOT_AUTHORIZED

(2035, X'7F3') Not authorized for access.

MQRC_SERVICE_ERROR

(2289, X'8F1') Unexpected error occurred accessing service.

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_UNKNOWN_ENTITY

(2292, X'8F4') Entity unknown to service.

C invocation

```
MQZ_SET_AUTHORITY (QMgrName, EntityName, EntityType, ObjectName,
                  ObjectType, Authority, ComponentData,
                  &Continuation, &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQCHAR48  QMgrName;           /* Queue manager name */
MQCHAR12  EntityName;         /* Entity name */
MQLONG    EntityType;         /* Entity type */
MQCHAR48  ObjectName;         /* Object name */
MQLONG    ObjectType;         /* Object type */
MQLONG    Authority;          /* Authority to be checked */
MQBYTE    ComponentData[n];   /* Component data */
MQLONG    Continuation;       /* Continuation indicator set by
                               component */
MQLONG    CompCode;           /* Completion code */
MQLONG    Reason;             /* Reason code qualifying CompCode */
```

MQZ_TERM_AUTHORITY - Terminate authorization service

This function is provided by an authorization service component, and is invoked by the queue manager when it no longer requires the services of this component. The function must perform any cleanup required by the component.

The function identifier for this function (for MQZEP) is MQZID_TERM_AUTHORITY.

Syntax

MQZ_TERM_AUTHORITY (*Hconfig, Options, QMgrName, ComponentData, CompCode, Reason*)

Parameters

The MQZ_TERM_AUTHORITY call has the following parameters.

Hconfig (MQHCONFIG) - input

Configuration handle.

This handle represents the particular component being terminated.

Options (MQLONG) - input

Termination options.

It is one of the following:

MQZTO_PRIMARY

Primary termination.

MQZTO_SECONDARY

Secondary termination.

QMgrName (MQCHAR48) - input

Queue manager name.

The name of the queue manager calling the component. This name is padded with blanks to the full length of the parameter; the name is not terminated by a null character.

The queue-manager name is passed to the component for information; the authorization service interface does not require the component to make use of it in any defined manner.

ComponentData (MQBYTE x ComponentDataLength) - input/output

Component data.

This data is kept by the queue manager on behalf of this particular component; any changes made to it by any of the functions provided by this component are preserved, and presented the next time one of this component's functions is called.

The length of this data area is passed by the queue manager in the *ComponentDataLength* parameter on the MQZ_INIT_AUTHORITY call.

When the MQZ_TERM_AUTHORITY call has completed, the queue manager discards this data.

CompCode (MQLONG) - output

Completion code.

It is one of the following:

MQCC_OK

Successful completion.

MQCC_FAILED

Call failed.

Reason (MQLONG) - output

Reason code qualifying *CompCode*.

If *CompCode* is MQCC_OK:

MQRC_NONE

(0, X'000') No reason to report.

If *CompCode* is MQCC_FAILED:

MQRC_SERVICE_NOT_AVAILABLE

(2285, X'8ED') Underlying service not available.

MQRC_TERMINATION_FAILED

(2287, X'8FF') Termination failed for an undefined reason.

For more information on these reason codes, see [Messages and reason codes](#).

C invocation

```
MQZ_TERM_AUTHORITY (Hconfig, Options, QMgrName, ComponentData,  
                    &CompCode, &Reason);
```

The parameters passed to the service are declared as follows:

```
MQHCONFIG  Hconfig;          /* Configuration handle */  
MQLONG     Options;          /* Termination options */  
MQCHAR48   QMgrName;        /* Queue manager name */  
MQBYTE     ComponentData[n]; /* Component data */  
MQLONG     CompCode;         /* Completion code */  
MQLONG     Reason;           /* Reason code qualifying CompCode */
```

MQZAC - Application context

This parameter specifies data related to the calling application.

The MQZAC structure is used on the MQZ_AUTHENTICATE_USER call for the *ApplicationContext* parameter.

Fields

StrucId (MQCHAR4)

Structure identifier.

The value is:

MQZAC_STRUC_ID

Identifier for application context structure.

For the C programming language, the constant MQZAC_STRUC_ID_ARRAY is also defined; this has the same value as MQZAC_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the service.

Version (MQLONG)

Structure version number.

The value is:

MQZAC_VERSION_1

Version-1 application context structure.

The following constant specifies the version number of the current version:

MQZAC_CURRENT_VERSION

Current version of application context structure.

This is an input field to the service.

ProcessId (MQPID)

Process identifier.

The process identifier of the application.

ThreadId (MQTID)

Thread identifier.

The thread identifier of the application.

ApplName (MQCHAR28)

Application name.

The application name.

UserID (MQCHAR12)

User identifier.

For IBM i systems the user profile that the application job was created under. (IBM i: when a profile swap is done with the QWTSETP API in the application job the current user profile is returned).

EffectiveUserID (MQCHAR12)

Effective user identifier.

For IBM i systems the application job's current user profile.

Environment (MQLONG)

Environment.

This field specifies the environment from which the call was made.

This can have one of the following values:

MQXE_COMMAND_SERVER

Command server.

MQXE_MQSC

runmqsc command interpreter.

MQXE_MCA

Message channel agent

MQXE_OTHER

Undefined environment

CallerType (MQLONG)

Caller Type.

This field specifies the type of program that made the call.

This can have one of the following values:

MQXACT_EXTERNAL

The call is external to the queue manager.

MQXACT_INTERNAL

The call is internal to the queue manager.

AuthenticationType (MQLONG)

Authentication Type.

This field specifies the type of authentication being performed.

This can have one of the following values:

MQZAT_INITIAL_CONTEXT

The authentication call is due to user context being initialized. This value is used during an MQCONN or MQCONNEX call.

MQZAT_CHANGE_CONTEXT

The authentication call is due to the user context being changed. This value is used when the MCA changes the user context.

v

BindType (MQLONG)

Bind Type.

This field specifies the type of binding in use.

This can have one of the following values:

MQCNO_FASTPATH_BINDING

Fastpath binding.

MQCNO_SHARED_BINDING

Shared binding.

MQCNO_ISOLATED_BINDING

Isolated binding.

C declaration

```
typedef struct tagMQZAC MQZAC;
struct tagMQZAC {
    MQCHAR4    StrucId;           /* Structure identifier */
    MQLONG     Version;           /* Structure version number */
    MQPID      ProcessId;         /* Process identifier */
    MQTID      ThreadId;          /* Thread identifier */
    MQCHAR28   ApplName;          /* Application name */
    MQCHAR12   UserID;            /* User identifier */
    MQCHAR12   EffectiveUserID;    /* Effective user identifier */
    MQLONG     Environment;        /* Environment */
    MQLONG     CallerType;         /* Caller type */
    MQLONG     AuthenticationType; /* Authentication type */
    MQLONG     BindType;           /* Bind type */
};
```

IBM i MQZAD (Authority data) on IBM i

The MQZAD structure is used on the MQZ_ENUMERATE_AUTHORITY_DATA call for two parameters.

The two parameters are:

- MQZAD is used for the **Filter** parameter which is input to the call. This parameter specifies the selection criteria that are to be used to select the authority data returned by the call.
- MQZAD is also used for the **AuthorityBuffer** parameter which is output from the call. This parameter specifies the authorizations for one combination of profile name, object type, and entity.

Fields

StrucId (MQCHAR4)

Structure identifier.

The value is:

MQZAD_STRUC_ID

Identifier for authority data structure.

For the C programming language, the constant MQZAD_STRUC_ID_ARRAY is also defined; this has the same value as MQZAD_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the service.

Version (MQLONG)

Structure version number.

The value is:

MQZAD_VERSION_1

Version-1 authority data structure.

The following constant specifies the version number of the current version:

MQZAD_CURRENT_VERSION

Current version of authority data structure.

This is an input field to the service.

ProfileName (MQCHAR48)

Profile name.

For the **Filter** parameter, this field is the profile name from which authority data is required. If the name is entirely blank up to the end of the field or the first null character, authority data for all profile names is returned.

For the **AuthorityBuffer** parameter, this field is the name of a profile that matches the specified selection criteria.

ObjectType (MQLONG)

Object type.

For the **Filter** parameter, this field is the object type for which authority data is required. If the value is MQOT_ALL, authority data for all object types is returned.

For the **AuthorityBuffer** parameter, this field is the object type to which the profile identified by **ProfileName** applies.

The value is one of the following; for the **Filter** parameter, the value MQOT_ALL is also valid:

MQOT_AUTH_INFO

Authentication information.

MQOT_CHANNEL

Channel.

MQOT_CLNTCONN_CHANNEL

Client connection channel.

MQOT_LISTENER

Listener.

MQOT_NAMELIST

Namelist.

MQOT_PROCESS

Process definition.

MQOT_Q

Queue.

MQOT_Q_MGR

Queue manager.

MQOT_SERVICE

Service.

Authority (MQLONG)

Authority.

For the **Filter** parameter, this field is ignored.

For the **AuthorityBuffer** parameter, this field represents the authorizations that the entity has to the objects identified by **ProfileName** and **ObjectType**. If the entity has only one authority, the field is equal to the appropriate authorization value (MQZAO_* constant). If the entity has more than one authority, the field is the bitwise OR of the corresponding MQZAO_* constants.

EntityDataPtr (PMQZED)

Address of MQZED structure identifying an entity.

For the **Filter** parameter, this field points to an MQZED structure that identifies the entity from which authority data is required. If **EntityDataPtr** is the null pointer, authority data for all entities is returned.

For the **AuthorityBuffer** parameter, this field points to an MQZED structure that identifies the entity that the returned authority data came from.

EntityType (MQLONG)

Entity type.

For the **Filter** parameter, this field specifies the entity type for which authority data is required. If the value is MQZAET_NONE, authority data for all entity types is returned.

For the **AuthorityBuffer** parameter, this field specifies the type of the entity identified by the MQZED structure pointed to by **EntityDataPtr**.

The value is one of the following; for the **Filter** parameter, the value MQZAET_NONE is also valid:

MQZAET_PRINCIPAL

Principal.

MQZAET_GROUP

Group.

Options (MQAUTHOPT)

Options.

This field specifies options that give control over the profiles that are displayed.

One of the following must be specified:

MQAUTHOPT_NAME_ALL_MATCHING

Displays all profiles

MQAUTHOPT_NAME_EXPLICIT

Displays profiles that have exactly the same name as specified in the **ProfileName** field.

In addition, one of the following must also be specified:

MQAUTHOPT_ENTITY_SET

Display all profiles used to calculate the cumulative authority that the entity has to the object specified by **ProfileName**. The **ProfileName** field must not contain any wildcard characters.

- If the specified entity is a principal, for each member of the set {entity, groups} the most applicable profile that applies to the object is displayed.
- If the specified entity is a group, the most applicable profile from the group that applies to the object is displayed.
- If this value is specified, then the values of **ProfileName**, **ObjectType**, **EntityType**, and the entity name specified in the **EntityDataPtr** MQZED structure, must all be non-blank.

If you have specified *MQAUTHOPT_NAME_ALL_MATCHING*, you can also specify the following:

MQAUTHOPT_ENTITY_EXPLICIT

Displays profiles that have exactly the same entity name as the entity name specified in the **EntityDataPtr** MQZED structure.

C declaration

```
typedef struct tagMQZAD MQZAD;  
struct tagMQZAD {  
    MQCHAR4    StrucId;           /* Structure identifier */  
    MQLONG     Version;          /* Structure version number */  
    MQCHAR48    ProfileName;     /* Profile name */  
    MQLONG     ObjectType;       /* Object type */  
    MQLONG     Authority;        /* Authority */  
    PMQZED     EntityDataPtr;    /* Address of MQZED structure identifying an  
                                entity */  
    MQLONG     EntityType;       /* Entity type */  
    MQAUTHOPT  Options;         /* Options */  
};
```

MQZED - Entity descriptor

The MQZED structure is used in a number of authorization service calls to specify the entity for which authorization is to be checked.

Fields

StrucId (MQCHAR4)

Structure identifier.

The value is:

MQZED_STRUC_ID

Identifier for entity descriptor structure.

For the C programming language, the constant MQZED_STRUC_ID_ARRAY is also defined; this has the same value as MQZED_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the service.

Version (MQLONG)

Structure version number.

The value is:

MQZED_VERSION_1

Version-1 entity descriptor structure.

The following constant specifies the version number of the current version:

MQZED_CURRENT_VERSION

Current version of entity descriptor structure.

This is an input field to the service.

EntityNamePtr (PMQCHAR)

Address of entity name.

This is a pointer to the name of the entity whose authorization is to be checked.

EntityDomainPtr (PMQCHAR)

Address of entity domain name.

This is a pointer to the name of the domain containing the definition of the entity whose authorization is to be checked.

SecurityId (MQBYTE40)

Security identifier.

This is the security identifier whose authorization is to be checked.

CorrelationPtr (MQPTR)

Correlation pointer.

This facilitates the passing of correlational data between the authenticate user function and other appropriate OAM functions.

C declaration

```
typedef struct tagMQZED MQZED;  
struct tagMQZED {  
    MQCHAR4    StrucId;           /* Structure identifier */  
    MQLONG     Version;          /* Structure version number */  
    PMQCHAR    EntityNamePtr;    /* Address of entity name */  
    PMQCHAR    EntityDomainPtr;  /* Address of entity domain name */  
    MQBYTE40   SecurityId;       /* Security identifier */  
    MQPTR      CorrelationPtr;   /* Address of correlation data */  
};
```

MQZFP - Free parameters

This parameter specifies data related to resource to be freed.

The MQZFP structure is used on the MQZ_FREE_USER call for the *FreeParms* parameter.

Fields

StrucId (MQCHAR4)

Structure identifier.

The value is:

MQZFP_STRUC_ID

Identifier for free parameters structure.

For the C programming language, the constant MQZFP_STRUC_ID_ARRAY is also defined; this has the same value as MQZFP_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the service.

Version (MQLONG)

Structure version number.

The value is:

MQZFP_VERSION_1

Version-1 free parameters structure.

The following constant specifies the version number of the current version:

MQZFP_CURRENT_VERSION

Current version of free parameters structure.

This is an input field to the service.

Reserved (MQBYTE8)

Reserved field.

The initial value is null.

CorrelationPtr (MQPTR)

Correlation pointer.

Address of correlation data relating to the resource to be freed.

C declaration

```
typedef struct tagMQZFP MQZFP;  
struct tagMQZFP {  
    MQCHAR4    StrucId;           /* Structure identifier */  
    MQLONG     Version;          /* Structure version number */  
    MQBYTE8    Reserved;         /* Reserved field */  
};
```

```
MQPTR    CorrelationPtr;    /* Address of correlation data */
};
```

MQZIC - Identity context

The MQZIC structure is used on the MQZ_AUTHENTICATE_USER call for the *IdentityContext* parameter.

The MQZIC structure contains identity context information, that identifies the user of the application that first put the message on a queue:

- The queue manager fills the *UserIdentifier* field with a name that identifies the user, the way that the queue manager can do this depends on the environment in which the application is running.
- The queue manager fills the *AccountingToken* field with a token or number that it determined from the application that put the message.
- Applications can use the *ApplIdentityData* field for any extra information that they want to include about the user (for example, an encrypted password).

Suitably authorized applications may set the identity context using the MQZ_AUTHENTICATE_USER function.

A Windows systems security identifier (SID) is stored in the *AccountingToken* field when a message is created under IBM MQ for Windows. The SID can be used to supplement the *UserIdentifier* field and to establish the credentials of a user.

Fields

StrucId (MQCHAR4)

Structure identifier.

The value is:

MQZIC_STRUC_ID

Identifier for identity context structure.

For the C programming language, the constant MQZIC_STRUC_ID_ARRAY is also defined; this has the same value as MQZIC_STRUC_ID, but is an array of characters instead of a string.

This is an input field to the service.

Version (MQLONG)

Structure version number.

The value is:

MQZIC_VERSION_1

Version-1 identity context structure.

The following constant specifies the version number of the current version:

MQZIC_CURRENT_VERSION

Current version of identity context structure.

This is an input field to the service.

UserIdentifier (MQCHAR12)

User identifier.

This is part of the **identity context** of the message.

UserIdentifier specifies the user identifier of the application that originated the message. The queue manager treats this information as character data, but does not define the format of it. For more information on the *UserIdentifier* field, see [“UserIdentifier \(MQCHAR12\)” on page 441](#).

AccountingToken (MQBYTE32)

Accounting token.

This is part of the **identity context** of the message.

AccountingToken allows an application to cause work done as a result of the message to be appropriately charged. The queue manager treats this information as a string of bits and does not check its content. For more information on the *AccountingToken* field, see “*AccountingToken* (MQBYTE32)” on page 400.

ApplIdentityData (MQCHAR32)

Application data relating to identity.

This is part of the **identity context** of the message.

ApplIdentityData is information that is defined by the application suite that can be used to provide additional information about the origin of the message. For example, it could be set by applications running with suitable user authority to indicate whether the identity data is trusted. For more information on the *ApplIdentityData* field, see “*ApplIdentityData* (MQCHAR32)” on page 401.

C declaration

```
typedef struct tagMQZED MQZED;  
struct tagMQZED {  
    MQCHAR4    StrucId;           /* Structure identifier */  
    MQLONG     Version;          /* Structure version number */  
    MQCHAR12   UserIdentifier;    /* User identifier */  
    MQBYTE32   AccountingToken;  /* Accounting token */  
    MQCHAR32   ApplIdentityData; /* Application data relating to identity */  
};
```

Reference material for IBM MQ bridge for HTTP

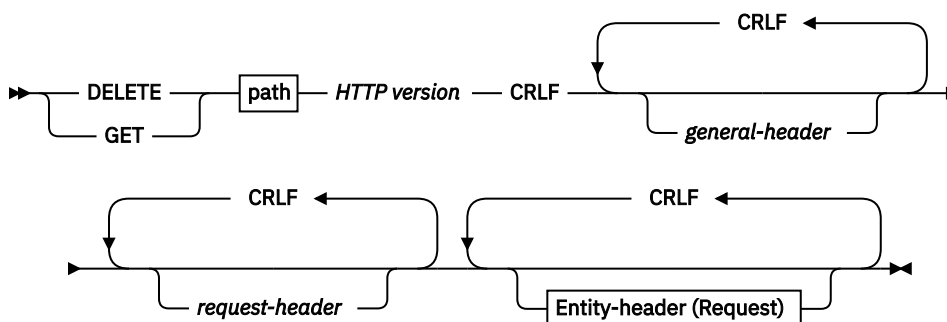

Reference topics for IBM MQ bridge for HTTP, arranged alphabetically

HTTP DELETE: IBM MQ bridge for HTTP command

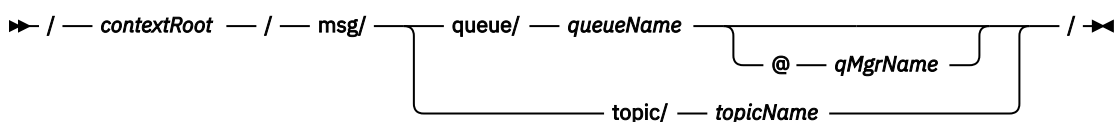

The HTTP **DELETE** operation gets a message from an IBM MQ queue, or retrieves a publication from a topic. The message is removed from the queue. If the publication is retained, it is not removed. A response message is sent back to the client including information about the message.

Syntax

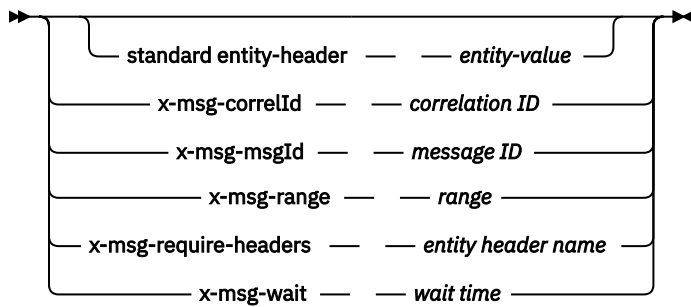

Request

Path

entity-header (Request)

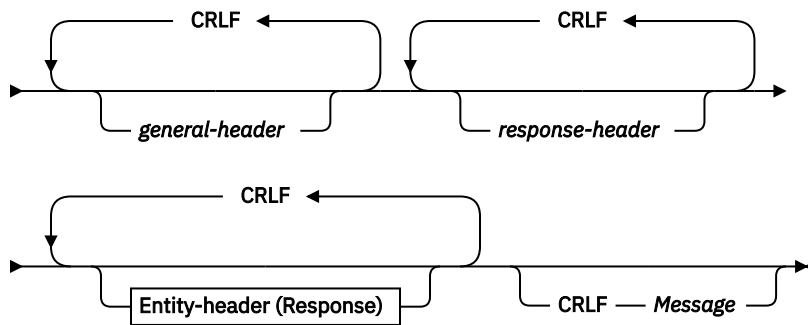

Note:

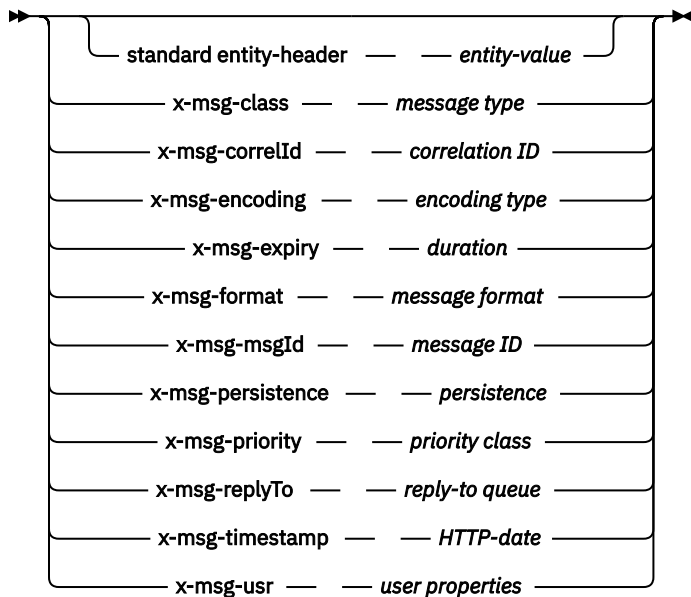

1. If a question mark (?) is used it must be substituted with %3f. For example, orange?topic should be specified as orange%3ftopic.
2. @ qMgrName is only valid on an HTTP **POST**

Response

➡ HTTP version — HTTP Status-Code — HTTP Reason-Phrase — CRLF ➡

entity-header (Response)

Request parameters

Path

See [“URI Format”](#) on page 1759.

HTTP version

HTTP version; for example, HTTP/1.1

general-header

See [HTTP/1.1 - 4.5 General Header Fields](#).

request-header

See [HTTP/1.1 - 5.3 Request Header Fields](#). The Host field is mandatory on an HTTP/1.1 request. It is often automatically inserted by the tool you use to create a client request.

entity-header (Request)

See [HTTP/1.1 - 7.1 Entity Header Fields](#). One of the entity headers listed in the Request syntax diagram.

Response parameters**Path**

See [“URI Format” on page 1759](#).

HTTP version

HTTP version; for example, HTTP/1.1

general-header

See [HTTP/1.1 - 4.5 General Header Fields](#).

response-header

See [HTTP/1.1 - 6.2 Response Header Fields](#).

entity-header (Response)

See [HTTP/1.1 - 7.1 Entity Header Fields](#). One of the entity or response headers listed in the Response syntax diagram. The Content-Length is always present in a response. It is set to zero if there is no message body.

Message

Message body.

Description

If the HTTP **DELETE** request is successful, the response message contains the data retrieved from the IBM MQ queue. The number of bytes in the body of the message is returned in the HTTP Content-Length header. The status code for the HTTP response is set to 200 OK. If x-msg-range is specified as 0, or 0-0, then the status code of the HTTP response is 204 No Content.

If the HTTP **DELETE** request is unsuccessful, the response includes an IBM MQ bridge for HTTP error message and an HTTP status code.

HTTP DELETE example

HTTP **DELETE** gets a message from a queue and deletes the message, or retrieves and deletes a publication. The **HTTPDELETE** Java sample is an example an HTTP **DELETE** request reading a message from a queue. Instead of using Java, you could create an HTTP **DELETE** request using a browser form, or an AJAX toolkit instead.

The following figure shows an HTTP request to delete the next message on queue called myQueue. In response, the message body is returned to the client. In IBM MQ terms, HTTP **DELETE** is a destructive get.

The request contains the HTTP request header x-msg-wait, which instructs IBM MQ bridge for HTTP how long to wait for a message to arrive on the queue. The request also contains the x-msg-require-headers request header, which specifies that the client is to receive the message correlation ID in the response.

```
DELETE /msg/queue/myQueue/ HTTP/1.1
Host: www.example.org
x-msg-wait: 10
x-msg-require-headers: correlID
```

Figure 37. Example of an HTTP **DELETE** request

The following figure shows the response returned to the client. The correlation ID is returned to the client, as requested in x-msg-require-headers of the request.

```
HTTP/1.1 200 OK
Date: Wed, 2 Jan 2007 22:38:34 GMT
Server: Apache-Coyote/1.1 WMQ-HTTP/1.1 JEE-Bridge/1.1
Content-Length: 50
Content-Type: text/plain; charset=utf-8
x-msg-correlId: 1234567890
```

Here is my message body that is retrieved from the queue.

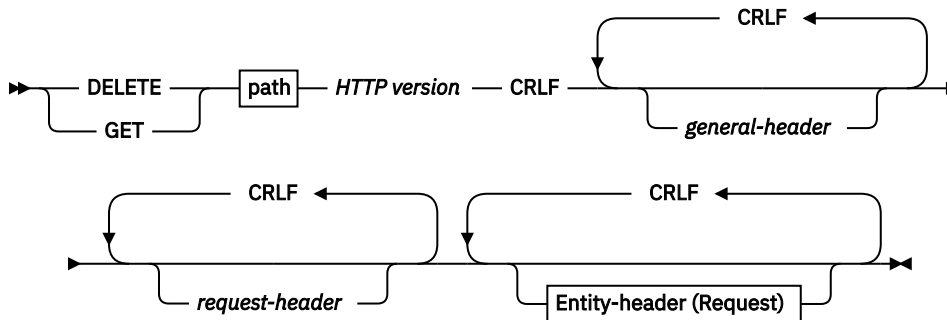

Figure 38. Example of an HTTP **DELETE** response

HTTP GET: IBM MQ bridge for HTTP command

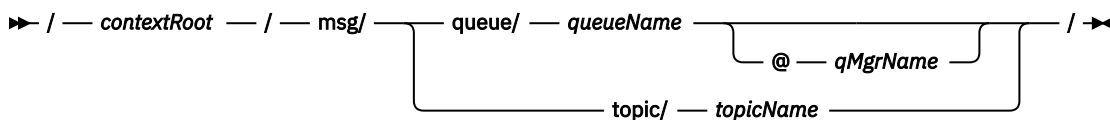

The HTTP **GET** operation gets a message from an IBM MQ queue. The message remains on the queue. The HTTP **GET** operation is equivalent to browsing an IBM MQ queue.

Syntax

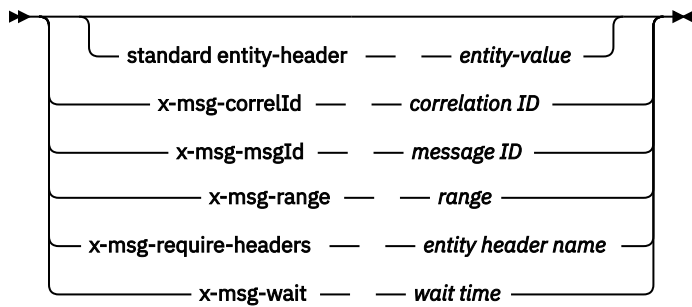

Request

Path

entity-header (Request)

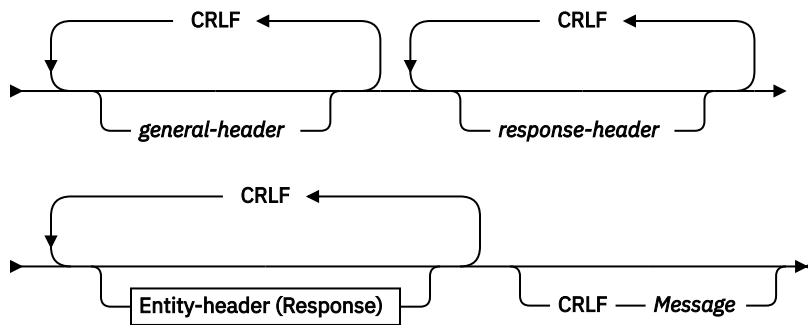

Note:

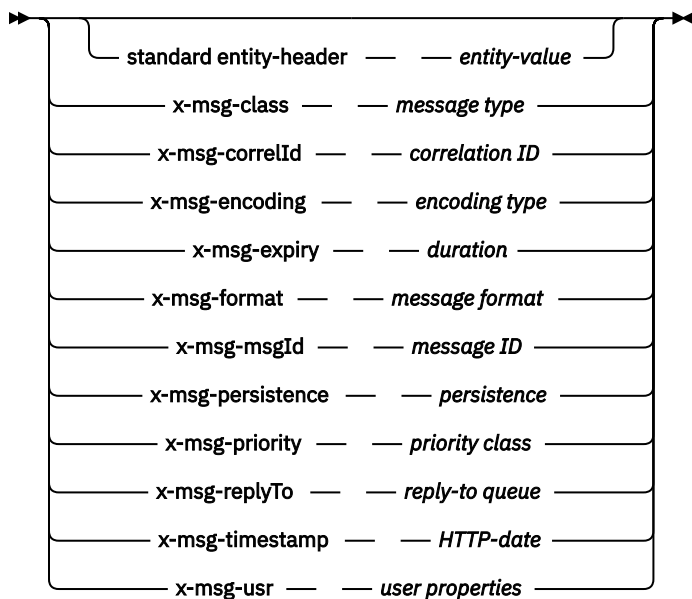

1. If a question mark (?) is used it must be substituted with %3f. For example, orange?topic should be specified as orange%3ftopic.
2. @ qMgrName is only valid on an HTTP **POST**

Response

➡ HTTP version — HTTP Status-Code — HTTP Reason-Phrase — CRLF ➡

HTTP version

HTTP version; for example, HTTP/1.1

general-header

See [HTTP/1.1 - 4.5 General Header Fields](#).

response-header

See [HTTP/1.1 - 6.2 Response Header Fields](#).

entity-header (Response)

See [HTTP/1.1 - 7.1 Entity Header Fields](#). One of the entity or response headers listed in the Response syntax diagram. The Content-Length is always present in a response. It is set to zero if there is no message body.

Message

Message body.

Description

If the HTTP **GET** request is successful, the response message contains the data retrieved from the IBM MQ queue. The number of bytes in the body of the message is returned in the HTTP Content-Length header. The status code for the HTTP response is set to 200 OK. If x-msg-range is specified as 0, or 0-0, then the status code of the HTTP response is 204 No Content.

If the HTTP **GET** request is unsuccessful, the response includes an IBM MQ bridge for HTTP error message and an HTTP status code.

HTTP GET example

HTTP **GET** gets a message from a queue. The message remains on the queue. In IBM MQ terms, HTTP **GET** is a browse request. You could create an HTTP **GET** request using a Java client, a browser form, or an AJAX toolkit.

The following figure shows an HTTP request to browse the next message on queue called myQueue.

The request contains the HTTP request header x-msg-wait, which instructs IBM MQ bridge for HTTP how long to wait for a message to arrive on the queue. The request also contains the x-msg-require-headers request header, which specifies that the client is to receive the message correlation ID in the response.

```
GET /msg/queue/myQueue/ HTTP/1.1
Host: www.example.org
x-msg-wait: 10
x-msg-require-headers: correlID
```

Figure 39. Example of an HTTP **GET** request

The following figure shows the response returned to the client. The correlation ID is returned to the client, as requested in `x-msg-require-headers` of the request.

```
HTTP/1.1 200 OK
Date: Wed, 2 Jan 2007 22:38:34 GMT
Server: Apache-Coyote/1.1 WMQ-HTTP/1.1 JEE-Bridge/1.1
Content-Length: 50
Content-Type: text/plain; charset=utf-8
x-msg-correlId: 1234567890
```

Here is my message body that appears on the queue.

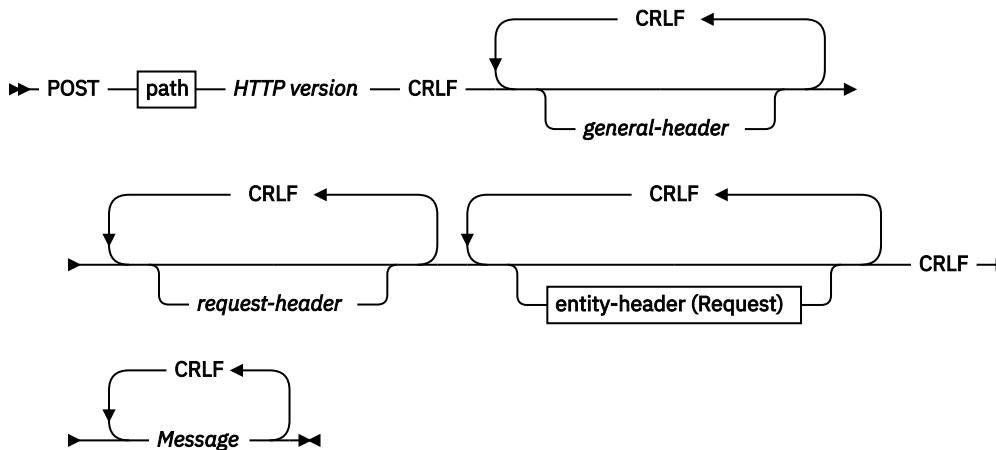

Figure 40. Example of an HTTP **GET** response

HTTP POST: IBM MQ bridge for HTTP command

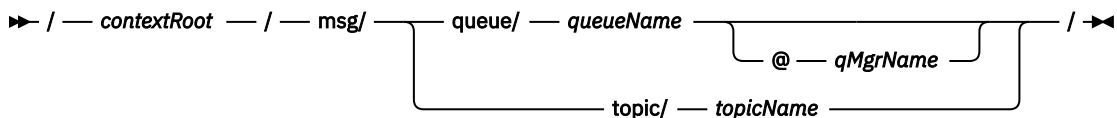

The HTTP **POST** operation puts a message on an IBM MQ queue, or publishes a message to a topic.

Syntax

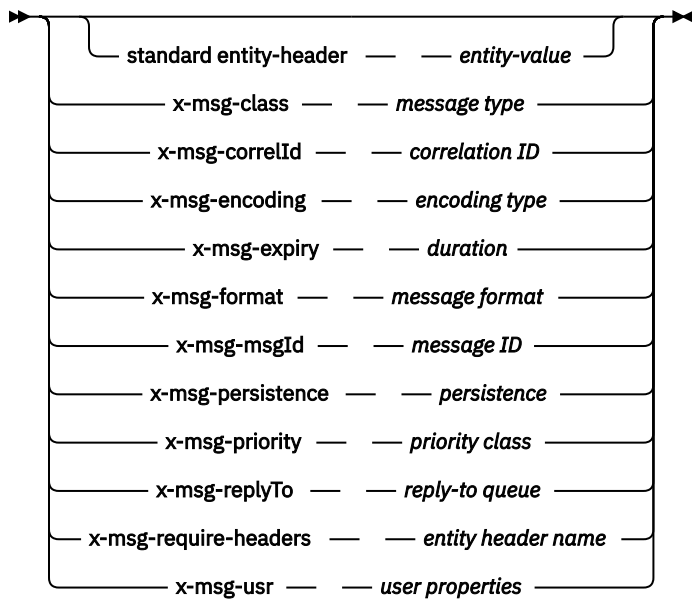

Request

Path

entity-header (Request)

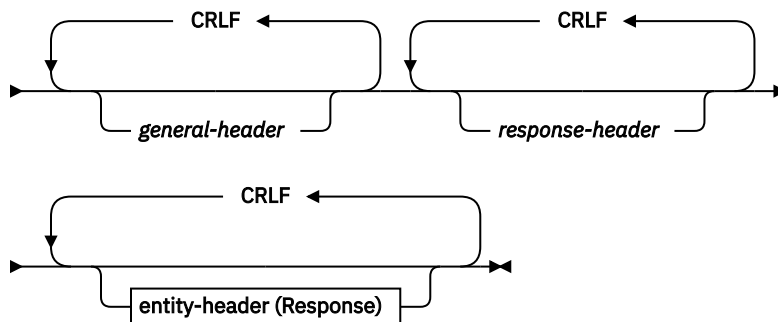

Note:

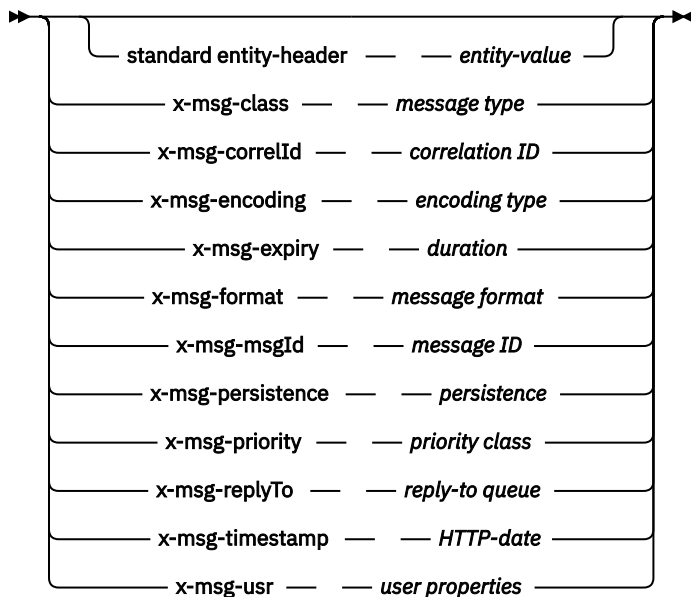

1. If a question mark (?) is used it must be substituted with %3f. For example, orange?topic should be specified as orange%3ftopic.
2. @ *qMgrName* is only valid on an HTTP **POST**

Response

➡ HTTP version — HTTP Status-Code — HTTP Reason-Phrase — CRLF ➡

entity-header (Response)

Request parameters

Path

See [“URI Format” on page 1759](#).

HTTP version

HTTP version; for example, HTTP/1.1

general-header

See [HTTP/1.1 - 4.5 General Header Fields](#).

request-header

See [HTTP/1.1 - 5.3 Request Header Fields](#). The Host field is mandatory on an HTTP/1.1 request. It is often automatically inserted by the tool you use to create a client request.

entity-header (Request)

See [HTTP/1.1 - 7.1 Entity Header Fields](#). One of the entity headers listed in the Request syntax diagram. The Content-Length and Content-Type should be inserted in a request, and are often inserted automatically by the tool you use to create a client request. The Content-Type must match the type defined in the x-msg-class custom entity-header, if it is specified.

Message

Message to put onto the queue, or publication to post to a topic.

Response parameters

Path

See [“URI Format” on page 1759](#).

HTTP version

HTTP version; for example, HTTP/1.1

general-header

See [HTTP/1.1 - 4.5 General Header Fields](#).

response-header

See [HTTP/1.1 - 6.2 Response Header Fields](#).

entity-header (Response)

See [HTTP/1.1 - 7.1 Entity Header Fields](#). One of the entity or response headers listed in the Response syntax diagram. The Content-Length is always present in a response. It is set to zero if there is no message body.

Description

If no `x-msg-usr` header is included, and message class is BYTES or TEXT, the message put on the queue does not have an MQRFH2.

Use HTTP entity and request headers in the HTTP **POST** request to set the properties of the message that is put onto the queue. You can also use `x-msg-require-headers` to request which headers are returned in the response message.

If the HTTP **POST** request is successful, the entity of the response message is empty and its Content-Length is zero. The HTTP status code is 200 OK.

If the HTTP **POST** request is unsuccessful, the response includes an IBM MQ bridge for HTTP error message and an HTTP status code. The IBM MQ message is not put on the queue or topic.

HTTP POST example

HTTP **POST** puts a message to a queue, or a publication to a topic. The **HTTPPOST** Java sample is an example an HTTP **POST** request of a message to a queue. Instead of using Java, you could create an HTTP **POST** request using a browser form, or an AJAX toolkit instead.

The following figure shows an HTTP request to put a message on a queue called myQueue. This request contains the HTTP header `x-msg-correlID` to set the correlation ID of the IBM MQ message.

```
POST /msg/queue/myQueue/ HTTP/1.1
Host: www.example.org
Content-Type: text/plain
x-msg-correlID: 1234567890
Content-Length: 50

Here is my message body that is posted on the queue.
```

*Figure 41. Example of an HTTP **POST** request to a queue*

The following figure shows the response sent back to the client. There is no response content.

```
HTTP/1.1 200 OK
Date: Wed, 2 Jan 2007 22:38:34 GMT
Server: Apache-Coyote/1.1 WMQ-HTTP/1.1 JEE-Bridge/1.1
Content-Length: 0
```

*Figure 42. Example of an HTTP **POST** response*

HTTP headers

The IBM MQ bridge for HTTP supports custom request HTTP headers, custom entity HTTP headers, and a subset of standard HTTP headers.

HTTP practice is to prefix all custom headers with `x-`, so the IBM MQ Bridge for HTTP headers are prefixed with `x-msg-`. For example, to set the priority header use `x-msg-priority`.

Note:

- Most header values are case sensitive. For example, when using the `msgId` header, `NONE` is a keyword, whereas `none` is a `msgID`.
- Misspelled headers are ignored.

Custom entity HTTP headers

The custom entity HTTP headers contain information about IBM MQ messages. Using entity headers, you can set values in the message descriptor (MQMD), or query values in the MQMD. An additional entity header, `x-msg-usr`, sets and returns any user property information you want to associate with a request.

You can use entity headers in different HTTP request contexts:

DELETE

You can only use the `x-msg-correlId`, or `x-msg-msgId`, or both, entity headers with a **DELETE** HTTP request. The effect of the headers is to select a particular message by `MsgId` and `CorrelId` in an `MQGET`, and to delete the message from its queue.

GET

You can only use the `x-msg-correlId`, or `x-msg-msgId`, or both, entity headers with a **GET** HTTP request. The effect of the headers is to select a particular message by `MsgId` and `CorrelId` in an `MQGET` for browse.

POST

You can use any entity header in a **POST** HTTP request, except `x-msg-timestamp`.

x-msg-require-headers

On any **GET**, **POST** or **DELETE** HTTP request, you can add multiple entity headers inside the `x-msg-require-headers` request header, separated by commas. The effect is to return the specified entity headers in the HTTP response message, containing the value of the associated message property.

The description of each header lists in which contexts the header is processed by IBM MQ bridge for HTTP. For example, in the header **POST**, `x-msg-require-headers`, the header is processed by IBM MQ bridge for HTTP in an HTTP **POST** request, or in the `x-msg-require-headers` request header in either an HTTP **POST**, **GET**, or **DELETE** request. If the header is included in a context it is not allowed in, the header is ignored. No error is reported.

You can put any standard HTTP headers into requests to be processed by the Web server, or other request handlers. Similarly, the response might contain other standard HTTP headers inserted by the Web server or other response handlers.

Custom request HTTP headers

The three custom request HTTP headers, `x-msg-range`, `x-msg-require-headers`, and `x-msg-wait`, pass additional information about the HTTP request to the server. They act as request modifiers. With `x-msg-range`, you can restrict the amount of message data returned in a response. With `x-msg-require-headers`, you can request the response to contain information about the result of the request. With `x-msg-wait`, you can modify the time the client waits for an HTTP response.

Standard HTTP headers

The `Host` standard HTTP request-header must be specified in an HTTP/1.1 request.

The `Content-Length` and `Content-Type` standard HTTP entity headers can be specified in a request.

The `Content-Length`, `Content-Location`, `Content-Range`, `Content-Type`, and `Server` standard HTTP entity headers can be returned in response to a request. Specify one or more of the standard HTTP headers in the `x-msg-request-header` header in the request message.

Alphabetic list of HTTP headers

class: HTTP x-msg-class entity-header

Set or return the message type.

Type	Description
HTTP header name	<code>x-msg-class</code>

Type	Description
HTTP header type	Entity-header
Valid in HTTP request message	POST, x-msg-require-headers
Allowed values	BYTES MAP STREAM TEXT
Default value	BYTES

Description

- In an HTTP **POST** request, sets the type of the message created.
- Specifying the class header on a **GET** or **DELETE** returns a 400 Bad Request with entity body of MQHTTP40007.
- Specified in x-msg-require-headers, sets x-msg-class in the HTTP response message to the type of a message.
- If an invalid value is specified for this header a MQHTTP40005 message is returned.
- If the x-msg-class header is not specified and the content-type of the message is application/x-www-form-urlencoded, the data is assumed to be a JMS map object.

Content-Length: HTTP entity-header

Set or return the length, in bytes, of the body of the message.

Type	Description
HTTP header name	Content-Length
HTTP header type	Entity-header
Valid in HTTP request message	x-msg-require-headers
Allowed and returned value	Integer value Length in bytes of the message body.

Description

- The Content-Length is optional in an HTTP request. For a **GET** or **DELETE** the length must be zero. For **POST**, if Content-Length is specified and it does not match the length of the message-line, the message is either truncated, or padded with nulls to the specified length.
- The Content-Length is always returned in the HTTP response even when there is no content, in which case the value is zero.

Content-Location: HTTP entity-header

Returns the queue or topic referenced in the request, in the standard Content-Location header in the HTTP response message.

Type	Description
HTTP header name	Content-Location
HTTP header type	Entity-header

Type	Description
Valid in HTTP request message	x-msg-require-headers
Returned value	URI in the format, <div>/msg/queue/queuename</div> or <div>/msg/topic/topicname</div>

Description

- When requested in x-msg-require-headers, the Content-Location entity-header returns the queue or topic referenced in the HTTP request.

Content-Range: HTTP entity-header

Return the range of bytes selected from an IBM MQ message in the Content-Range header in an HTTP response.

Type	Description
HTTP header name	Content-Range
HTTP header type	Entity-header
Valid in HTTP request message	x-msg-require-headers
Returned value	String Returns the lower limit, <i>m</i> and upper limit, <i>n</i> of the returned substring, and <i>length</i> of the whole message. For example, <div><i>m</i> - <i>n</i>/<i>length</i></div>

Description

-
- The Content-Range is only returned in the HTTP response when Content-Range is specified in a **GET** or **DELETE** request that contains an x-msg-range request header.
- If x-msg-range is specified on a **GET** or **DELETE** request, the range of bytes specified in the Content-Range header are returned in the response. For example, if x-msg-range: 0-60 is used in a request for a message containing 100 bytes, the content-range header holds the string 0-60/100
- An x-msg-range request also returns the content range in the x-msg-range header in the HTTP response.

Content-Type: HTTP entity-header

Set or return the class of the JMS message in an IBM MQ message according the to HTTP content-type.

Type	Description
HTTP header name	Content-Type
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers

Type	Description
Allowed or returned value	media-type For media-types that are supported see Table 663 on page 1738 .

Table 663. Mapping between x-msg-class and HTTP Content-Type

x-msg-class	HTTP Content-Type
BYTES	application/octet-stream application/xml
TEXT	text/*
MAP	application/x-www-form-urlencoded application/xml (optional)
STREAM	application/xml (optional)

Description

- On an HTTP **POST** request, specify either the Content-Type or the x-msg-class. If you specify both, they must be consistent or an HTTP Bad Request exception, Status code 400 is returned. If you omit both, the Content-Type and the x-msg-class, a Content-Type of text/* is assumed.
- The Content-Type is always set in the response to an HTTP **GET** or **DELETE** that has a message body. The Content-Type is set according to the rules in [Table 664 on page 1738](#).

Table 664. Mapping message types to x-msg-class and Content-Type

Message format	JMS Message type	x-msg-class	Content-Type
Anything except MQFMT_STRING	None	BYTES	application/octet-stream
MQFMT_STRING	None	TEXT	text/plain
MQFMT_NONE	jms_bytes	BYTES	application/octet-stream
MQFMT_NONE	jms_text	TEXT	text/plain
MQFMT_NONE	jms_map	MAP	application/xml
MQFMT_NONE	jms_stream	STREAM	application/xml

correlId: HTTP x-msg-correlId entity-header

Set or return the correlation identifier.

Type	Description
HTTP header name	x-msg-correlId
HTTP header type	Entity-header
Valid in HTTP request message	DELETE, GET, POST , x-msg-require-headers

Type	Description
Allowed values	<p>String value For example:</p> <pre>x-msg-correlId: mycorrelationid</pre> <p>Strings enclosed in quotation marks are permitted; for example:</p> <pre>x-msg-correlId: "my id"</pre> <p>Hex value A hex value prefixed with 0x : ; for example:</p> <pre>x-msg-correlId: 0x:43c1d23a</pre> <p>The hex value following 0x: is limited to 48 characters representing 24 bytes. Additional data is ignored.</p>
Default value	Not applicable

Description

- On an HTTP **POST** request, sets the correlation ID of the message created.
- On an HTTP **GET** or **DELETE** request, selects the message from the queue or topic. If no message exists with the specified correlation ID, an HTTP 504 Gateway Timeout response is returned. `x-msg-correlId` can be used with `x-msg-msgID` to select a message from a queue or topic that matches both selectors.
- Specified in `x-msg-require-headers`, sets `x-msg-coreId` in the HTTP response message to the correlation ID of a message.
- Horizontal white space is allowed after the `0x :` prefix.

Note:

- Specifying `x-msg-correlId` without a value on an HTTP **GET** or **DELETE** request; for example, `"x-msg-correlId: "`, returns the next message on the queue or topic regardless of its correlation ID.
- If you specify a selector of 24 characters or fewer, or `0x:` followed by 48 characters or fewer, IBM MQ bridge for HTTP uses an optimized selector for improved performance.
- A JMS message selector containing `JMSCorrelationID` is used when selecting messages from the queue. This selector behaves as described in [Selection behavior](#).

encoding: HTTP x-msg-encoding entity-header

Set or return the message encoding.

Type	Description
HTTP header name	<code>x-msg-encoding</code>
HTTP header type	Entity-header
Valid in HTTP request message	POST , <code>x-msg-require-headers</code>
Allowed values	<p>A comma-separated list of the following values:</p> <p>DECIMAL_NORMAL</p> <p>DECIMAL_REVERSED</p> <p>FLOAT_IEEE_NORMAL</p> <p>FLOAT_IEEE_REVERSED</p>

Type	Description
	FLOAT_S390 INTEGER_NORMAL INTEGER_REVERSED For example, <pre>x-msg-encoding: INTEGER_NORMAL,DECIMAL_NORMAL,FLOAT_IEEE_NORMAL</pre> Note: The value is case-sensitive
Default value	DECIMAL_NORMAL, FLOAT_IEEE_NORMAL, INTEGER_NORMAL

Description

- On an HTTP **POST** request, specifies the encoding of the message created.
- On an HTTP **GET** or **DELETE** request, the x-msg-encoding header is ignored.
- Specified in x-msg-require-headers, sets x-msg-encoding in the HTTP response message to the encoding property of a message.

expiry: HTTP x-msg-expiry entity-header

Set or return the message expiry duration.

Type	Description
HTTP header name	x-msg-expiry
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	UNLIMITED For example; <pre>x-msg-expiry: UNLIMITED</pre> Integer value Milliseconds before expiry. For example; <pre>x-msg-expiry: 10000</pre>
Default value	UNLIMITED

Description

- When set on an HTTP **POST** request, the request message expires in the time specified.
- On an HTTP **GET** or **DELETE** request, the x-msg-expiry header is ignored.
- Specified in x-msg-require-headers, sets x-msg-expiry in the HTTP response message to the expiry time of a message.
- UNLIMITED specifies that the message never expires.
- The expiry of a message starts from the time the message arrives on the queue, as a result network latency is ignored.
- The maximum value is limited by IBM MQ to 214748364700 milliseconds. If a value greater than this is specified then the maximum possible expiry time is assumed.

format: HTTP x-msg-format entity-header

Set or return the IBM MQ message format.

Type	Description
HTTP header name	x-msg-format
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	NONE For example, <pre>x-msg-format: NONE</pre> String value Any user-defined value of up to eight characters. For example, <pre>x-msg-format: myformat</pre>
Default value	None

Description

- When set on an HTTP **POST** request, set the request message format.
- On an HTTP **GET** or **DELETE** request, the x-msg-format header is ignored.
- Specified in x-msg-require-headers, sets x-msg-format in the HTTP response message to the format of a message.
- NONE is case sensitive, and indicates that the message format is blank.
- The value of x-msg-format is used, even if it contradicts the media-type of the HTTP request. See [Table 665 on page 1741](#).

Table 665. Mapping content-type and x-msg-class to message format		
x-msg-class	Content-type	Message format on queue/topic
BYTES	<ul style="list-style-type: none">• application/octet-stream• application/xml	IBM MQ message: MQFMT set to MQC.MQFMT_NONE
TEXT	<ul style="list-style-type: none">• text/*	IBM MQ message: MQFMT set to MQC.MQFMT_STRING
MAP	<ul style="list-style-type: none">• application/x-www-form-urlencoded• application/xml (optional)	JMSMap
STREAM	<ul style="list-style-type: none">• application/xml (optional)	JMSStream

msgId: HTTP x-msg-msgId entity-header

Set or return the message identifier.

Type	Description
HTTP header name	x-msg-msgId

Type	Description
HTTP header type	Entity-header
Valid in HTTP request message	DELETE, GET, POST , x-msg-require-headers
Allowed values	<p>String value For example,</p> <pre>x-msg-msgId: mymsgid</pre> <p>Strings enclosed in quotation marks for example, x-msg-msgId: "my id"</p> <p>Hex value A hex value prefixed with 0x : ; for example,</p> <pre>x-msg-msgId: 0x:43c1d23a</pre>
Default value	Not applicable

Description

- On an HTTP **POST** request, sets the message ID of the message created.
- On an HTTP **GET** or **DELETE** request, selects the message from the queue or topic. If no message exists with the specified message ID, an HTTP 504 Gateway Timeout response is returned. x-msg-msgId can be used with x-msg-correlID to select a message from a queue or topic that matches both selectors.
- Specified in x-msg-require-headers, returns x-msg-msgId in the HTTP response to the message ID of a message.
- Horizontal white space is allowed after the 0x : prefix.

Note: Specifying x-msg-msgId without a value on an HTTP **GET** or **DELETE** request; for example, "x-msg-msgId: ", returns the next message on the queue or topic regardless of its message ID.

A JMS message selector containing JMSMessageID is used when selecting messages from the queue. This selector behaves as described in [Selection behavior](#).

persistency: HTTP x-msg-persistence entity-header

Set or return the message persistence.

Type	Description
HTTP header name	x-msg-persistence
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	<p>NON_PERSISTENT The message does not survive system failures or queue manager restarts. For example,</p> <pre>x-msg-persistence: NON_PERSISTENT</pre> <p>PERSISTENT The message survives system failures and restarts of the queue manager.</p>

Type	Description
	<p>For example,</p> <pre>x-msg-persistence: PERSISTENT</pre> <p>AS_DESTINATION Applies to POST only. Use the default persistence of the destination as determined by the message provider.</p> <p>Note: Case sensitive</p>
Default value	NON_PERSISTENT

Description

- When set on an HTTP **POST** request, set the request message persistence.
- On an HTTP **GET** or **DELETE** request, the x-msg-persistence header is ignored.
- Specified in x-msg-require-headers, sets x-msg-persistence in the HTTP response message to the persistence of a message.

priority: HTTP x-msg-priority entity-header

Set or return the message priority.

Type	Description
HTTP header name	x-msg-priority
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	<p>LOW For example,</p> <pre>x-msg-priority: LOW</pre> <p>MEDIUM This priority is equal to an IBM MQ priority level of 4. For example,</p> <pre>x-msg-priority: MEDIUM</pre> <p>HIGH For example,</p> <pre>x-msg-priority: HIGH</pre> <p>Integer value A string representation of an integer in the range 0 through 9; for example,</p> <pre>x-msg-priority: 3</pre> <p>AS_DESTINATION Applies to POST only. Use the default priority of the destination as determined by the message provider.</p> <p>Note: Case sensitive</p>

Type	Description
Default value	MEDIUM

Description

- When set on an HTTP **POST** request, set the request message priority.
- On an HTTP **GET** or **DELETE** request, the x-msg-priority header is ignored.
- Specified in x-msg-require-headers, sets x-msg-priority in the HTTP response message to the priority of a message.

priority: HTTP x-msg-priority entity-header

Set or return the message priority.

Type	Description
HTTP header name	x-msg-priority
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	<p>LOW For example,</p> <pre>x-msg-priority: LOW</pre> <p>MEDIUM This priority is equal to an IBM MQ priority level of 4. For example,</p> <pre>x-msg-priority: MEDIUM</pre> <p>HIGH For example,</p> <pre>x-msg-priority: HIGH</pre> <p>Integer value A string representation of an integer in the range 0 through 9; for example,</p> <pre>x-msg-priority: 3</pre> <p>AS_DESTINATION Applies to POST only. Use the default priority of the destination as determined by the message provider.</p> <p>Note: Case sensitive</p>
Default value	MEDIUM

Description

- When set on an HTTP **POST** request, set the request message priority.
- On an HTTP **GET** or **DELETE** request, the x-msg-priority header is ignored.
- Specified in x-msg-require-headers, sets x-msg-priority in the HTTP response message to the priority of a message.

replyTo: HTTP x-msg-replyTo entity-header

Set or return the message reply-to queue and queue manager name.

Type	Description
HTTP header name	x-msg-replyTo
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	URI A point-to-point URI; for example, <pre>x-msg-replyTo: /msg/queue/myReplyQueue x-msg-replyTo: /msg/queue/myReplyQueue@myReplyQueueManager</pre> Note: Case sensitive
Default value	MEDIUM

Description

- When set on an HTTP **POST** request, set the request message replyTo destination.
- On an HTTP **GET** or **DELETE** request, the x-msg-replyTo header is ignored.
- Specified in x-msg-require-headers, sets x-msg-replyTo in the HTTP response message to the reply-to queue and queue manager name of a message.

Note: The URI in the HTTP response can include the name of the queue manager to which the IBM MQ bridge for HTTP is connected.

Server: HTTP response-header

Returns information about the server and protocol the client is connected to.

Type	Description
HTTP header name	Server
HTTP header type	Response-header
Valid in HTTP request message	x-msg-require-headers
Returned value	<pre>WMQ-HTTP/1.1 JEE-Bridge/1.1</pre> or <pre>Server: Product-token WMQ-HTTP/1.1 JEE-Bridge/1.1</pre>

Description

- If IBM MQ Bridge for HTTP is deployed to an application server, the IBM MQ bridge for HTTP details is appended to the server response header. For example, the IBM MQ bridge for HTTP deployed to WebSphere Application Server Community Edition, called Apache-Coyote, gives the response:

```
Server: Apache-Coyote/1.1 WMQ-HTTP/1.1 JEE-Bridge/1.1
```

require-headers: HTTP x-msg-require-headers request-header

Set which headers to return in the HTTP response message.

Type	Description
HTTP header name	x-msg-require-headers
HTTP header type	Request-header
Valid in HTTP request message	POST, GET, DELETE
Allowed values	<p>A comma-separated list of the entity header names:</p> <p>ALL</p> <p>ALL-USR</p> <p>class</p> <p>content-location</p> <p>correlId</p> <p>encoding</p> <p>expiry</p> <p>format</p> <p>msgId</p> <p>NO_require-headers</p> <p>persistence</p> <p>priority</p> <p>replyTo</p> <p>server</p> <p>timestamp</p> <p>usr- <i>property name</i></p> <p>For example,</p> <pre>x-msg-require-headers: msgId</pre> <p>or,</p> <pre>x-msg-require-headers: expiry,correlId,timestamp</pre> <p>To request a specific property:</p> <pre>x-msg-require-headers: usr-myCustomProperty</pre> <p>To request all properties:</p> <pre>x-msg-require-headers: ALL-USR, ALL</pre>
Default value	NO_require-headers

Description

- The value of x-msg-require-headers is not case-sensitive, except in the cases of the ALL, NO_require-headers, and ALL-USR constants, and the *property-name* variable.

timestamp: HTTP x-msg-timestamp entity-header

Return the message time stamp.

Type	Description
HTTP header name	x-msg-timestamp
HTTP header type	Entity-header
Valid in HTTP request message	x-msg-require-headers
Returned value	HTTP-date A date in the format; day, date month year time time-zone; for example, <pre>Sun, 06 Nov 1994 08:49:37 GMT</pre> Defined by RFC 822, and updated in RFC 1123.
Default value	Not applicable

Description

- On an HTTP **POST**, **GET** or **DELETE** request, the x-msg-timestamp header is ignored.
- Specified in x-msg-require-headers, sets x-msg-timestamp in the HTTP response message to the timestamp of a message.

usr: HTTP x-msg-usr entity-header

Set or return the user properties.

Type	Description
HTTP header name	x-msg-usr
HTTP header type	Entity-header
Valid in HTTP request message	POST , x-msg-require-headers
Allowed values	See “Syntax” on page 1748 ; for example, <pre>x-msg-usr: myProp1;5;i1, x-msg-usr: myProp2;"My String";string</pre>
Default value	Not applicable

Description

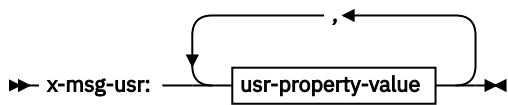

- When set on an HTTP **POST** request, set the request message user properties.
- On an HTTP **GET** or **DELETE** request, the x-msg-usr header is ignored.
- Specified in x-msg-require-headers, sets x-msg-usr in the HTTP response message to user properties of a message.
- Multiple properties can be set on a message. Specify multiple comma-separated properties in a single x-msg-usr header, or by using two or more separate instances of the x-msg-usr header.
- You can request a specific property to be returned in the response to a **GET** or **DELETE** request. Specify the name of the property in the x-msg-require-headers header of the request, using the prefix **usr-**. For example,

```
x-msg-require-headers: usr-myProp1
```

- To request that all user properties are returned in a response, use the ALL-USR constant. For example,

```
x-msg-require-headers: ALL-USR
```

Syntax

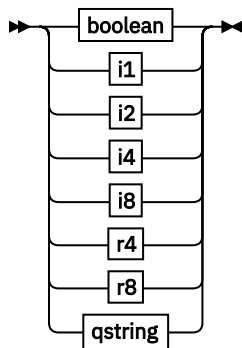

usr-property-value

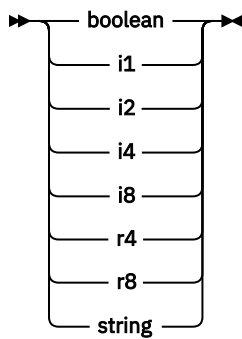

property-name

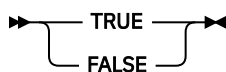

usr-value

usr-type

wait: HTTP x-msg-wait request-header

Set the period of time to wait for a message to arrive, before returning an HTTP 504 Gateway Timeout response message.

Type	Description
HTTP header name	x-msg-wait
HTTP header type	Request-header
Valid in HTTP request message	GET, DELETE
Allowed value	NO_WAIT For example, <pre>x-msg-wait: NO_WAIT</pre> Integer value The number of milliseconds that the IBM MQ bridge for HTTP waits for a message to arrive; for example, <pre>x-msg-wait: 8</pre>
Default value	NO_WAIT

Description

- On an HTTP **POST** request, the x-msg-wait header is ignored.
- On an HTTP **GET** or **DELETE** request, x-msg-wait specifies time to wait for a message to arrive before returning an HTTP 504 Gateway Timeout response.
- NO_WAIT is case-sensitive.
- The default maximum wait time is 35000. You can change the default by setting the maximum_wait_time parameter of the servlet. See the [Installing, configuring, and verifying IBM MQ bridge for HTTP](#) section for more information.
- If you set a value greater than maximum_wait_time, maximum_wait_time is used instead.

HTTP return codes

List of return codes from the IBM MQ bridge for HTTP

The IBM MQ bridge for HTTP returns four types of error:

Servlet errors

MQHTTP0001 and MQHTTP0002 are servlet errors. They are logged, but not returned to the HTTP client.

Successful operations

An HTTP status code in the range 200 - 299 indicates a successful operation.

Client errors

An HTTP status code in the range 400 - 499 indicates a client error. IBM MQ Bridge for HTTP return codes in the range MQHTTP40001 - MQHTTP49999 correspond to client errors.

Server errors

An HTTP status code in the range 500 - 599 indicates a client error. IBM MQ Bridge for HTTP return codes in the range MQHTTP50001 - MQHTTP59999 correspond to server errors.

If a server error occurs, a complete stack trace is output to the application server error log. The stack trace is also returned to the HTTP client in the HTTP response. Handle the stack trace in the client application or refer it to the application server administrator to resolve the problem.

If the stack trace contains resource adapter errors, refer to the documentation for your resource adapter.

Alphabetic list of return codes

HTTP 200: OK

This class of status code indicates that the request was successfully received, understood and accepted.

HTTP status code

200 OK

HTTP 204: No content

Sent following a successful HTTP **GET** or **DELETE** and x-msg-range: 0 was sent in the request.

HTTP status code

204 No Content

MQHTTP0001: No connection factory specified in the Servlet context

Servlet error

Explanation

Servlet error

HTTP status code

None

Programmer response

Where these errors are logged is specific to your application server. Refer to the documentation for your application server.

MQHTTP0002: Could not get connection manager for *queueOrTopic* using the JNDI name of *jndiNameTried*

Servlet error

Explanation

Servlet error

HTTP status code

None

Programmer response

Where these errors are logged is specific to your application server. Refer to the documentation for your application server.

MQHTTP40001: Reserved

Reserved

HTTP status code

400 Bad Request

MQHTTP40002: URI is not valid for IBM MQ transport for HTTP

The URI specified in the HTTP request is not valid.

Explanation

The URI specified in the HTTP request is not valid.

HTTP status code

400 Bad Request

Programmer response

Confirm that the format and syntax of the specified URI are correct.

MQHTTP40003: URI is not valid. @qmgr is only valid on POST

The @qmgr URI option has been specified in a URI for an HTTP request that is not a **POST** request.

Explanation

The @qmgr URI option has been specified in a URI for an HTTP request that is not a **POST** request.

HTTP status code

400 Bad Request

Programmer response

If you are attempting to put a message by using the **POST** verb, change the HTTP request to a **POST** request. If you are attempting to get a message by using the **DELETE** or **GET** verbs, remove @qmgr from the URI.

MQHTTP40004: Invalid Content-Type specified

The Content-Type header field specified on a **POST** request is not compatible with the x-msg-class header value.

Explanation

The Content-Type header field specified on a **POST** request is not compatible with the x-msg-class header value.

HTTP status code

400 Bad Request

Programmer response

Change the Content-Type header field to one that is supported. The Content-Type header must be compatible with the specified x-msg-class header field.

MQHTTP40005: Bad message header value

A supported header field has been specified with a value that is not valid for the specified request.

Explanation

A supported header field has been specified with a value that is not valid for the specified request.

HTTP status code

400 Bad Request

Programmer response

Change the value specified for the given header field to a value which is valid. Check the case of the value specified, as some header fields have case-sensitive values.

MQHTTP40006: *Header_name* is not a valid request header

A header that is valid only in an HTTP response message has been specified in an HTTP request message.

Explanation

A header which is valid only in an HTTP response message has been specified in an HTTP request message.

HTTP status code

400 Bad Request

Programmer response

Remove any headers from the HTTP request which are only valid in an HTTP response; for example, x-msg-timestamp.

MQHTTP40007: *Header_name* is only valid on ...

A header has been specified in an HTTP request, but the header field is not valid for the given request verb.

Explanation

A header has been specified in an HTTP request, but the header field is not valid for the given request verb.

HTTP status code

400 Bad Request

Programmer response

Remove any headers from the HTTP request which are not valid for the given request verb. For example, x-msg-encoding is valid for HTTP **POST** requests, but not valid for HTTP **GET** or HTTP **DELETE** requests.

MQHTTP40008: *Header_name* maximum length is ...

The maximum length for the given header field has been exceeded.

Explanation

The maximum length for the given header field has been exceeded.

HTTP status code

400 Bad Request

Programmer response

Change the value of the header field to a value which is within the range permitted for the header field.

MQHTTP40009: Header field *header_field* is not valid for ...

A header field specified in an HTTP request is not supported by the messaging provider to which the IBM MQ bridge for HTTP is connected.

Explanation

A header field specified in an HTTP request is not supported by the messaging provider to which the IBM MQ bridge for HTTP is connected. The error occurs if a messaging provider is used that cannot support all the features of the IBM MQ bridge for HTTP.

HTTP status code

400 Bad Request

Programmer response

Remove the unsupported header from the HTTP request.

MQHTTP40010: Message with Content-Type *content_type* could not be parsed

The content of the HTTP request is not compatible with the Content-Type of the request.

Explanation

The content of the HTTP request is not compatible with the Content-Type of the request. A common cause is badly formed application/x-www-form-urlencoded or application/xml data.

HTTP status code

400 Bad Request

Programmer response

Correct the content of the HTTP request so that it is in the correct format for the Content-Type of the request.

MQHTTP40301: You are forbidden from accessing ...

The IBM MQ bridge for HTTP has been unable to authenticate itself for the specified destination.

Explanation

The IBM MQ bridge for HTTP has been unable to authenticate itself for the specified destination.

HTTP status code

403 Forbidden

Programmer response

Change the authentication properties of the destination so that the IBM MQ Bridge for HTTP is authorized to connect to it. Alternatively, specify a destination to which the IBM MQ bridge for HTTP is authorized to connect.

MQHTTP40302: You are forbidden from ...

The IBM MQ bridge for HTTP has been unable to connect to the queue manager.

Explanation

The IBM MQ bridge for HTTP has been unable to connect to the queue manager. The IBM MQ bridge for HTTP security configuration is incorrect.

HTTP status code

403 Forbidden

Programmer response

Change the authentication configuration of the queue manager so that the IBM MQ Bridge for HTTP is authorized to connect to it. Alternatively, configure the IBM MQ bridge for HTTP to connect to a queue manager to which it is authorized to connect.

MQHTTP40401: The destination *destination_name* could not be found

The destination specified in the HTTP request URI cannot be found by the IBM MQ bridge for HTTP.

Explanation

The destination specified in the HTTP request URI cannot be found by the IBM MQ bridge for HTTP.

HTTP status code

404 Not found

Programmer response

Check that the destination specified in the HTTP request URI exists, or specify an alternative destination.

MQHTTP40501: Method *method_name* not allowed

The method specified in the HTTP request is not supported by the IBM MQ bridge for HTTP.

Explanation

The method specified in the HTTP request is not supported by the IBM MQ bridge for HTTP.

HTTP status code

405 Method not allowed

Programmer response

Change the method specified in the HTTP request to one which is supported by the IBM MQ bridge for HTTP.

MQHTTP41301: The message being posted was too large for the destination

The destination specified in the HTTP POST request URI cannot accept messages that are as long as the message specified in the HTTP request.

Explanation

The destination specified in the HTTP POST request URI cannot accept messages that are as long as the message specified in the HTTP request.

HTTP status code

413 Request entity too large

Programmer response

Reduce the size of the message specified in the HTTP request. Alternatively, specify a destination which can support messages of the wanted length.

MQHTTP41501: The media type character set is unsupported

The character set specified in the Content-Type header field is not supported by the IBM MQ bridge for HTTP.

Explanation

The character set specified in the Content-Type header field is not supported by the IBM MQ bridge for HTTP.

HTTP status code

415 Unsupported media type

Programmer response

Change the character set of the Content-Type header field to one that is supported by the IBM MQ bridge for HTTP.

MQHTTP41502: Media-type *media-type* is not supported ...

The media-type specified in the HTTP request is not supported by the IBM MQ bridge for HTTP for the specified HTTP verb.

Explanation

The media-type specified in the HTTP request is not supported by the IBM MQ bridge for HTTP for the specified HTTP verb.

HTTP status code

415 Unsupported media type

Programmer response

Change the media-type specified in the HTTP request to one that is supported by the IBM MQ Bridge for HTTP for the specified HTTP verb.

MQHTTP41503: Media-type *media-type* is not supported ...

The media-type specified in the HTTP request is not supported by the IBM MQ bridge for HTTP for the specified x-msg-class header field.

Explanation

The media-type specified in the HTTP request is not supported by the IBM MQ bridge for HTTP for the specified x-msg-class header field.

HTTP status code

415 Unsupported media type

Programmer response

Change the media-type specified in the HTTP request to one that is supported by the IBM MQ Bridge for HTTP for the specified x-msg-class header field.

MQHTTP41701: The HTTP header Expect is not supported

The IBM MQ bridge for HTTP does not support the Expect header field.

Explanation

The Expect header has been specified in an HTTP request. The IBM MQ bridge for HTTP does not support the Expect header field.

HTTP status code

417 Expectation failed

Programmer response

Remove the Expect header from the HTTP request.

MQHTTP50001: There has been an unexpected problem ...

An error has occurred in the IBM MQ bridge for HTTP.

Explanation

An error has occurred in the IBM MQ bridge for HTTP.

HTTP status code

500 Internal server error

Programmer response

Contact the system administrator of the IBM MQ Bridge for HTTP.

MQHTTP50201: An error has occurred between the IBM MQ bridge for HTTP and the queue manager

An error has occurred between the IBM MQ bridge for HTTP and the queue manager

Explanation

An error has occurred between the IBM MQ bridge for HTTP and the queue manager

HTTP status code

502 Bad Gateway

Programmer response

Contact the system administrator of the IBM MQ Bridge for HTTP.

MQHTTP50401: Message retrieval timed out

No message matching the specified request parameters in an HTTP **GET** or HTTP **DELETE** was returned in the timeout period.

Explanation

No message matching the specified request parameters in an HTTP **GET** or HTTP **DELETE** was returned in the timeout period. The return code indicates that no suitable message was available at any time during the life of the HTTP request.

HTTP status code

504 Gateway timeout

Programmer response

If a message was expected, check the header fields of the HTTP request such as `x-msg-correlId` and `x-msg-msgid`. Check that the destination specified in the HTTP request URI is correct. Try extending the wait time of the HTTP request using the `x-msg-wait` header field.

MQHTTP50501: HTTP 1.1 and upwards ...

The HTTP protocol used in the HTTP request is not supported by the IBM MQ bridge for HTTP.

Explanation

The HTTP protocol used in the HTTP request is not supported by the IBM MQ bridge for HTTP.

HTTP status code

505 HTTP version not supported

Programmer response

Change the HTTP request to use HTTP protocol V1.1 or higher.

Message types and message mappings for WebSphere Bridge for HTTP

IBM MQ bridge for HTTP supports four message classes, TEXT, BYTES, STREAM and MAP. The message classes are mapped to JMS message types and HTTP Content-Type.

HTTP POST

The message type that arrives at the destination depends on the value of the `x-msg-class` header or the Content-Type of the HTTP request. [Table 666 on page 1757](#) shows the HTTP Content-Type type that corresponds to each `x-msg-class`. Either field can be used to set the message type and message format. If both fields are set, and are set inconsistently, then a `Bad Request` exception is returned (HTTP 400, MQHTTP20004).

Table 666. Mapping between <i>x-msg-class</i> and HTTP Content-Type	
x-msg-class	HTTP Content-Type
BYTES	application/octet-stream application/xml
TEXT	text/*
MAP	application/x-www-form-urlencoded application/xml (optional)
STREAM	application/xml (optional)

If the JMS message type is set in the MQRFH2 header, it is mapped according to [Table 667 on page 1757](#).

Table 667. Mapping between <i>x-msg-class</i> and JMS message types.	
x-msg-class	JMS message type
BYTES	jms_bytes
TEXT	jms_text
MAP	jms_map

Table 667. Mapping between <i>x-msg-class</i> and JMS message types. (continued)	
x-msg-class	JMS message type
STREAM	jms_stream

The JMS message type is always set for a message class of MAP or STREAM. It is not always set for a message class of BYTES or TEXT. If a MQRFH2 is to be created for the request, the JMS message type is always set. Otherwise, if no MQRFH2 is created, no JMS message type is set. An MQRFH2 is created if user properties are set in the request, using the `x-msg-user` header.

If the JMS message type is set, then the message format is set to MQFMT_NONE, see [Table 669 on page 1758](#):

Table 668. Mapping between <i>x-msg-class</i> and IBM MQ message format		
x-msg-class	Message format with MQRFH2 present in message	Message format with no MQRFH2 present in message
BYTES	MQFMT_NONE	MQFMT_NONE
TEXT	MQFMT_NONE	MQFMT_STRING
MAP	MQFMT_NONE	Not possible
STREAM	MQFMT_NONE	Not possible

HTTP GET or DELETE

The message type or format retrieved determines the value of the `x-msg-class` header and the Content-Type of the HTTP response. The `x-msg-class` header is returned only if requested in a `x-msg-headers` request.

[Table 669 on page 1758](#) describes the mappings between `x-msg-class` and Content-Type, and the message type retrieved from the queue or topic.

Table 669. Mapping message types to <i>x-msg-class</i> and Content-Type			
Message format	JMS Message type	x-msg-class	Content-Type
Anything except MQFMT_STRING	None	BYTES	application/octet-stream
MQFMT_STRING	None	TEXT	text/plain
MQFMT_NONE	jms_bytes	BYTES	application/octet-stream
MQFMT_NONE	jms_text	TEXT	text/plain
MQFMT_NONE	jms_map	MAP	application/xml
MQFMT_NONE	jms_stream	STREAM	application/xml

MAP and STREAM message class serialization

MAP and STREAM message classes are serialized back to the client in the HTTP response in the same way as a message is serialized to a queue.

For MAP, the XML name, type, and value triplets are encoded as:

```
<map>
  <elt name="elementname1" dt="datatype1">value1</elt>
  <elt name="elementname2" dt="datatype2">value2</elt>
```

```
</map>
```

STREAM is like MAP, but it does not have element names:

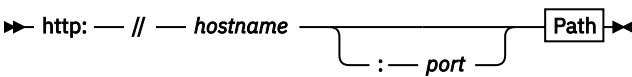

```
<stream>
  <elt dt="datatype1">value1</elt>
  <elt dt="datatype2">value2</elt>
  ...
</stream>
```

Note: datatype is one of the data types defined for defining user-defined properties and listed in [“usr: HTTP x-msg-usr entity-header” on page 1747](#). The attribute dt="string" is omitted for string elements because the default data type is string.

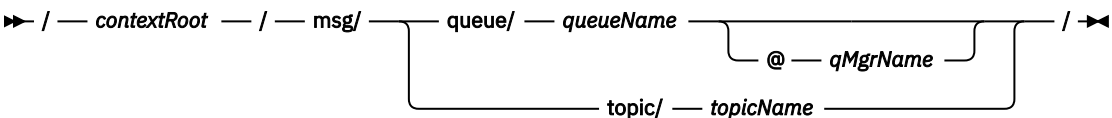

URI Format

URIs intercepted by IBM MQ bridge for HTTP.

Syntax

Path

Note:

1. If a question mark (?) is used it must be substituted with %3f. For example, orange?topic should be specified as orange%3ftopic.
2. @qMgrName is only valid on an HTTP **POST**

Description

Deploy the IBM MQ bridge for HTTP servlet to your JEE application server with a context root of *contextRoot*. Requests to

```
http://hostname: port/context_root/msg/queue/queueName @ qMgrName
```

and

```
http://hostname: port/context_root/msg/topic/topicString
```

are intercepted by IBM MQ bridge for HTTP.

The IBM MQ .NET classes and interfaces

IBM MQ .NET classes and interfaces are listed alphabetically. The properties, methods and constructors are described.

MQAsyncStatus.NET class

Use MQAsyncStatus to inquire on the status of previous MQI activity; for example inquiring on the success of previous asynchronous put operations. MQAsyncStatus encapsulates features of the MQSTS data structure.

Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQAsyncStatus
```

`public class IBM.WMQ.MQAsyncStatus extends IBM.WMQ.MQBaseObject;`

- [“Properties” on page 1760](#)
- [“Constructors” on page 1761](#)

Properties

Test for MQException being thrown when getting properties.

public static int CompCode {get;}

The completion code from the first error or warning.

public static int Reason {get;}

The reason code from the first error or warning.

public static int PutSuccessCount {get;}

The number of successful asynchronous MQI put calls.

public static int PutWarningCount {get;}

The number of asynchronous MQI put calls that succeeded with a warning.

public static int PutFailureCount {get;}

The number of failed asynchronous MQI put calls.

public static int ObjectType {get;}

The object type for the first error. The following values are possible:

- MQC.MQOT_ALIAS_Q
- MQC.MQOT_LOCAL_Q
- MQC.MQOT_MODEL_Q
- MQC.MQOT_Q
- MQC.MQOT_REMOTE_Q
- MQC.MQOT_TOPIC
- 0, meaning that no object is returned

public static string ObjectName {get;}

The object name.

public static string ObjectQMgrName {get;}

The object queue manager name.

public static string ResolvedObjectName {get;}

The resolved object name.

public static string ResolvedObjectQMgrName {get;}

The resolved object queue manager name.

Constructors

public MQAsyncStatus() throws MQException;

Constructor method, constructs an object with fields initialized to zero or blank as appropriate.

MQAuthenticationInformationRecord.NET class

Use `MQAuthenticationInformationRecord` to specify information about an authenticator that is to be used in an IBM MQ SSL client connection. `MQAuthenticationInformationRecord` encapsulates an authentication information record, MQAIR.

Class

```
System.Object
└─ IBM.WMQ.MQAuthenticationInformationRecord
```

public class IBM.WMQ.MQAuthenticationInformationRecord extends System.Object;

- [“Properties” on page 1761](#)
- [“Constructors” on page 1762](#)

Properties

Test for `MQException` being thrown when getting properties.

public long Version {get; set;}

Structure version number.

public long AuthInfoType {get; set;}

The type of authentication information. This attribute must be set to one of the following values:

- OCSP - Certificate revocation status checking is done using OCSP.
- CRLLDAP - Certificate revocation status checking is done using Certificate Revocation Lists on LDAP servers.

public string AuthInfoConnName {get; set;}

The DNS name or IP address of the host on which the LDAP server is running, with an optional port number. This keyword is required.

public string LDAPPassword {get; set;}

The password associated with the distinguished name of the user who is accessing the LDAP server. This property applies only when **AuthInfoType** is set to CRLLDAP.

```
public string LDAPUserName {get; set;}
```

The distinguished name of the user who is accessing the LDAP server. When you set this property, LDAPUserNameLength and LDAPUserNamePtr are automatically set correctly. This property applies only when AuthInfoType is set to CRLLDAP.

```
public string OCSPResponderURL {get; set;}
```

The URL at which the OCSP responder can be contacted. This property applies only when AuthInfoType is set to OCSP

This field is case sensitive. It must start with the string http:// in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation.

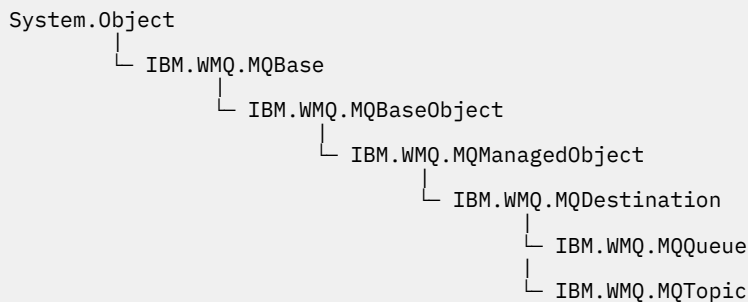

Constructors

```
MQAuthenticationInformationRecord();
```

MQDestination.NET class

Use MQDestination to access methods that are common to MQQueue and MQTopic. MQDestination is an abstract base class and cannot be instantiated.

Class

```
public class IBM.WMQ.MQDestination extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1762](#)
- [“Methods” on page 1763](#)
- [“Constructors” on page 1764](#)

Properties

Test for MQException being thrown when getting properties.

```
public DateTime CreationDateTime {get;}
```

The date and time that the queue or topic was created. Originally contained within MQQueue, this property has been moved into the base MQDestination class.

There is no default value.

```
public int DestinationType {get;}
```

Integer value describing the type of destination being used. Initialized from the sub classes constructor, MQQueue or MQTopic, this value can take one of these values:

- MQOT_Q
- MQOT_TOPIC

There is no default value.

Methods

```
public void Get(MQMessage message);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int  
MaxMsgSize);
```

Throws MQException.

Gets a message from a queue if the destination is an MQQueue object or from a topic if the destination is an MQTopic object, using a default instance of MQGetMessageOptions to do the get.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC_BACKED_OUT after successful reconnection, for messages received under MQGM_SYNCPOINT.

getMessageOptions

Options controlling the action of the get.

Using option MQC.MQGM_CONVERT might result in an exception with reason code MQC.MQRC_CONVERTED_STRING_TOO_BIG when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If *getMessageOptions* is not specified, the message option used is MQGM_NOWAIT.

If you use the MQGM_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

MaxMsgSize

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the MQGM_ACCEPT_TRUNCATED_MSG flag is set in the MQGetMessageOptions object, the message is filled with as much of the message data as possible. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_ACCEPTED reason code.
- If the MQGM_ACCEPT_TRUNCATED_MSG flag is not set, the message remains on the queue. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_FAILED reason code.

If *MaxMsgSize* is not specified, the whole message is retrieved.

```
public void Put(MQMessage message);  
public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);
```

Throws MQException.

Puts a message to a queue if the destination is an MQQueue object or publishes a message to a topic if the destination is an MQTopic object.

Modifications to the MQMessage object after the Put call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

Put updates the MessageId and CorrelationId properties of the MQMessage object and does not clear message data. Further Put or Get calls refer to the updated information in the MQMessage object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");
q.Put(msg,pmo);
msg.WriteString("b");
q.Put(msg,pmo);
```

message

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC_CALL_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- MQRC_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

Note: For simplicity and performance, if you want to put a single message to a queue, use MQQueueManager.Put object. You should have an MQQueue object for this.

Constructors

MQDestination is an abstract base class and cannot be instantiated. Access destinations using MQQueue and MQTopic constructors, or using MQQueueManager.AccessQueue and MQQueueManager.AccessTopic methods.

MQEnvironment.NET class

Use MQEnvironment to control how the MQQueueManager constructor is called and to select an IBM MQ MQI client connection. The MQEnvironment class contains properties that control the behavior of the IBM MQ.

Class

```
System.Object
└─ IBM.WMQ.MQEnvironment
```

```
public class IBM.WMQ.MQEnvironment extends System.Object;
```

- [“Properties - client only” on page 1764](#)
- [“Properties” on page 1765](#)
- [“Constructors” on page 1766](#)

Properties - client only

Test for MQException being thrown when getting properties.

public static int CertificateValPolicy {get; set;}

Set which SSL/TLS certificate validation policy is used to validate digital certificates received from remote partner systems. Valid values are:

- MQC.CERTIFICATE_VALIDATION_POLICY_ANY
- MQC.CERTIFICATE_VALIDATION_POLICY_RFC5280

public static ArrayList EncryptionPolicySuiteB {get; set;}

Set the level of Suite B compliant cryptography. Valid values are:

- MQC.MQ_SUITE_B_NONE - This is the default value.
- MQC.MQ_SUITE_B_128_BIT
- MQC.MQ_SUITE_B_192_BIT

public static string Channel {get; set;}

The name of the channel to connect to the target queue manager. You *must* set the channel property before instantiating an MQQueueManager instance in client mode.

public static int FipsRequired {get; set;}

Specify MQC.MQSSL_FIPS_YES to use only FIPS-certified algorithms if cryptography is carried out in IBM MQ. The default is MQC.MQSSL_FIPS_NO.

If cryptographic hardware is configured, the cryptographic modules used are those provided by the hardware product. Depending on the hardware in use, these might not be FIPS-certified to a particular level.

public static string Hostname {get; set;}

The TCP/IP host name of the computer on which the IBM MQ server resides. If the host name is not set, and no overriding properties are set, server bindings mode is used to connect to the local queue manager.

public static int Port {get; set;}

The port to connect to. This is the port on which the IBM MQ server is listening for incoming connection requests. The default value is 1414.

public static string SSLCipherSpec {get; set;}

Set SSLCipherSpec to the value of the CipherSpec set on the SVRCONN channel to enable SSL for the connection. The default is Null, and SSL is not enabled for the connection.

public static string sslPeerName {get; set;}

A distinguished name pattern. If sslCipherSpec is set, this variable can be used to ensure that the correct queue manager is used. If set to null (default), the DN of the queue manager is not performed. sslPeerName is ignored if sslCipherSpec is null.

Properties

Test for MQException being thrown when getting properties.

public static ArrayList HdrCompList {get; set;}

Header Data Compression List

public static int KeyResetCount {get; set;}

Indicates the number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated.

public static ArrayList MQAIRArray {get; set;}

An array of MQAuthenticationInformationRecord objects.

public static ArrayList MsgCompList {get; set;}

Message Data Compression List

public static string Password {get; set;}

The password to be authenticated. The password referenced from the MQCSP structure gets populated by setting this Password property.

public static string ReceiveExit {get; set;}

A receive exit allows you to examine and alter data received from a queue manager. It is normally used with a corresponding send exit at the queue manager. If ReceiveExit is set to null, no receive exit is called.

public static string ReceiveUserData {get; set;}

The user data associated with a receive exit. Limited to 32 characters.

public static string SecurityExit {get; set;}

A security exit allows you to customize the security flows that occur when an attempt is made to connect to a queue manager. If SecurityExit is set to null, no security exit is called.

public static string SecurityUserData {get; set;}

The user data associated with a security exit. Limited to 32 characters.

public static string SendExit {get; set;}

A send exit allows you to examine or alter the data sent to a queue manager. It is normally used with a corresponding receive exit at the queue manager. If SendExit is set to null, no send exit is called.

public static string SendUserData {get; set;}

The user data associated with a send exit. Limited to 32 characters.

public static string SharingConversations {get; set;}

The SharingConversations field is used on connections from .NET applications, when these applications are not using a client channel definition table (CCDT).

SharingConversations determines the maximum number of conversations that can be shared on a socket associated with this connection.

A value of 0 means that the channel operates as it did before IBM WebSphere MQ 7.0, with regard to conversation sharing, read ahead, and heartbeat.

The field is passed in the hash table of properties as a SHARING_CONVERSATIONS_PROPERTY, when instantiating an IBM MQ queue manager.

If you do not specify SharingConversations, a default value of 10 is used.

public static string SSLCryptoHardware {get; set;}

Sets the name of the parameter string required to configure the cryptographic hardware present on the system. SSLCryptoHardware is ignored if sslCipherSpec is null.

public static string SSLKeyRepository {get; set;}

Set the fully qualified file name of the key repository.

If SSLKeyRepository is set to null (default), the certificate MQSSLKEYR environment variable is used to locate the key repository. SSLCryptoHardware is ignored if sslCipherSpec is null.

Note: The .kdb extension is a mandatory part of the file name, but is not included as part of the value of the parameter. The directory you specify must exist. IBM MQ creates the file the first time it accesses the new key repository, unless the file already exists.

public static string UserId {get; set;}

The user ID to be authenticated. The user ID referenced from the MQCSP structure gets populated by setting UserId. Authenticate UserId using an API or Security exit.

Constructors

public MQEnvironment()

MQException.NET class

Use MQException to find out the completion and reason code of a failed IBM MQ function. An MQException is thrown whenever an IBM MQ error occurs.

Class

```
System.Object
├── System.Exception
│   └── System.ApplicationException
│       └── IBM.WMQ.MQException
```

```
public class IBM.WMQ.MQException extends System.ApplicationException;
```

- [“Properties” on page 1767](#)
- [“Constructors” on page 1767](#)

Properties

public int CompletionCode {get; set;}

The IBM MQ completion code associated with the error. The possible values are:

- MQException.MQCC_OK
- MQException.MQCC_WARNING
- MQException.MQCC_FAILED

public int ReasonCode {get; set;}

IBM MQ reason code describing the error.

Constructors

public MQException(int *completionCode*, int *reasonCode*)

completionCode

The IBM MQ completion code.

reasonCode

The IBM MQ completion code.

MQGetMessageOptions.NET class

Use MQGetMessageOptions to specify how messages are retrieved. It modifies the behavior of MQDestination.Get.

Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQGetMessageOptions
```

```
public class IBM.WMQ.MQGetMessageOptions extends IBM.WMQ.MQBaseObject;
```

- [“Properties” on page 1768](#)
- [“Constructors” on page 1770](#)

Properties

Note: The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with an asterisk *.

Test for MQException being thrown when getting properties.

public int GroupStatus {get;}*

GroupStatus indicates whether the retrieved message is in a group and if it is the last in the group. Possible values are:

MQC.MQGS_LAST_MSG_IN_GROUP

Message is the last or only message in the group.

MQC.MQGS_MSG_IN_GROUP

Message is in a group, but is not the last in the group.

MQC.MQGS_NOT_IN_GROUP

Message is not in a group.

public int MatchOptions {get; set;}*

MatchOptions determines how a message is selected. The following match options can be set:

MQC.MQMO_MATCH_CORREL_ID

Correlation ID to be matched.

MQC.MQMO_MATCH_GROUP_ID

Group ID to be matched.

MQC.MQMO_MATCH_MSG_ID

Message ID to be matched.

MQC.MQMO_MATCH_MSG_SEQ_NUMBER

Match message sequence number.

MQC.MQMO_NONE

No matching required.

public int Options {get; set;}

Options control the action of MQQueue.get. Any of the following values can be specified. If more than one option is required, the values can be added, or combined using the bitwise OR operator.

MQC.MQGMO_ACCEPT_TRUNCATED_MSG

Allow truncation of message data.

MQC.MQGMO_ALL_MSGS_AVAILABLE*

Retrieve messages from a group only when all the messages in the group are available.

MQC.MQGMO_ALL_SEGMENTS_AVAILABLE*

Retrieve the segments of a logical message only when all the segments in the group are available.

MQC.MQGMO_BROWSE_FIRST

Browse from start of queue.

MQC.MQGMO_BROWSE_MSG_UNDER_CURSOR*

Browse message under browse cursor.

MQC.MQGMO_BROWSE_NEXT

Browse from the current position in the queue.

MQC.MQGMO_COMPLETE_MSG*

Retrieve only complete logical messages.

MQC.MQGMO_CONVERT

Request the application data to be converted, to conform to the CharSet and Encoding attributes of the MQMessage, before the data is copied into the message buffer. Because data conversion is also applied when the data is retrieved from the message buffer, applications do not set this option.

Using this option can cause problems when converting from single-byte character sets to double-byte character sets. Instead, do the conversion using the `readString`, `readLine`, and `writeString` methods after the message has been delivered.

MQC.MQGMO_FAIL_IF_QUIESCING

Fail if the queue manager is quiescing.

MQC.MQGMO_LOCK*

Lock the message that is browsed.

MQC.MQGMO_LOGICAL_ORDER*

Return messages in groups, and segments of logical messages, in logical order.

If you use the `MQGMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned to the application.

MQC.MQGMO_MARK_SKIP_BACKOUT*

Allow a unit of work to be backed out without reinstating the message on the queue.

MQC.MQGMO_MSG_UNDER_CURSOR

Get message under browse cursor.

MQC.MQGMO_NONE

No other options have been specified; all options assume their default values.

MQC.MQGMO_NO_PROPERTIES

No properties of the message, except properties contained in the message descriptor (or extension) are retrieved.

MQC.MQGMO_NO_SYNCPOINT

Get message without sync point control.

MQC.MQGMO_NO_WAIT

Return immediately if there is no suitable message.

MQC.MQGMO_PROPERTIES_AS_Q_DEF

Retrieve message properties as defined by the `PropertyControl` attribute of `MQQueue`. Access to the message properties in the message descriptor, or extension, are not affected by the `PropertyControl` attribute.

MQC.MQGMO_PROPERTIES_COMPATIBILITY

Retrieve message properties with a prefix of `mcd`, `jms`, `usr`, or `mqext`, in `MQRFH2` headers. Other properties of the message, except properties contained in the message descriptor, or extension, are discarded.

MQC.MQGMO_PROPERTIES_FORCE_MQRFH2

Retrieve message properties, except properties contained in the message descriptor, or extension, in `MQRFH2` headers. Use `MQC.MQGMO_PROPERTIES_FORCE_MQRFH2` in applications that are expecting to retrieve properties but cannot be changed to use message handles.

MQC.MQGMO_PROPERTIES_IN_HANDLE

Retrieve message properties using a `MsgHandle`.

MQC.MQGMO_SYNCPOINT

Get the message under sync point control. The message is marked as being unavailable to other applications, but it is deleted from the queue only when the unit of work is committed. The message is made available again if the unit of work is backed out.

MQC.MQGMO_SYNCPOINT_IF_PERSISTENT*

Get message with sync point control if message is persistent.

MQC.MQGMO_UNLOCK*

Unlock a previously locked message.

MQC.MQGMO_WAIT

Wait for a message to arrive.

public string ResolvedQueueName {get;}

The queue manager sets ResolvedQueueName to the local name of the queue from which the message was retrieved. ResolvedQueueName is different from the name used to open the queue if an alias queue or model queue was opened.

public char Segmentation {get;}*

Segmentation indicates whether you can allow segmentation for the retrieved message. Possible values are:

MQC.MQSEG_INHIBITED

Do not allow segmentation.

MQC.MQSEG_ALLOWED

Allow segmentation

public byte SegmentStatus {get;}*

SegmentStatus is an output field that indicates whether the retrieved message is a segment of a logical message. If the message is a segment, the flag indicates whether it is the last segment. Possible values are:

MQC.MQSS_LAST_SEGMENT

Message is the last or only segment of the logical message.

MQC.MQSS_NOT_A_SEGMENT

Message is not a segment.

MQC.MQSS_SEGMENT

Message is a segment, but is not the last segment of the logical message.

public int WaitInterval {get; set;}

WaitInterval is the maximum time in milliseconds that an MQQueue.get call waits for a suitable message to arrive. Use WaitInterval with MQC.MQGMO_WAIT. Set a value of MQC.MQWI_UNLIMITED to wait an unlimited time for a message.

Constructors

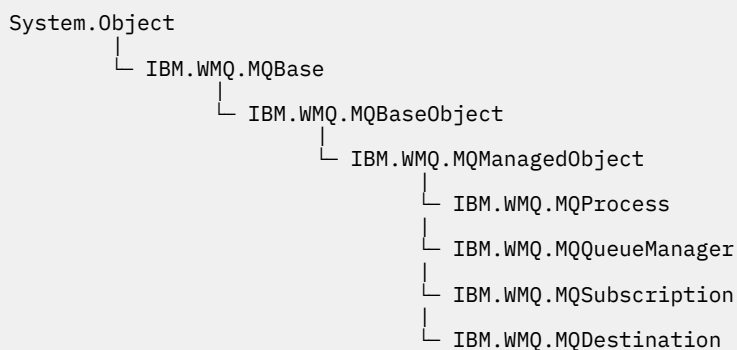

public MQGetMessageOptions()

Construct a new MQGetMessageOptions object with Options set to MQC.MQGMO_NO_WAIT, WaitInterval set to zero, and ResolvedQueueName set to blank.

MQManagedObject.NET class

Use MQManagedObject to inquire and set attributes of MQDestination, MQProcess, MQQueueManager, and MQSubscription. MQManagedObject is a superclass of these classes.

Classes

public class IBM.WMQ.MQManagedObject extends IBM.WMQ.MQBaseObject;

- [“Properties” on page 1771](#)

- [“Methods” on page 1771](#)
- [“Constructors” on page 1773](#)

Properties

Test for `MQException` being thrown when getting properties.

public string AlternateUserId {get; set;}

The alternate user ID, if any, set when the resource was opened. `AlternateUserId.set` is ignored when issued for an object that is opened. `AlternateUserId` is not valid for subscriptions.

public int CloseOptions {get; set;}

Set this attribute to control the way the resource is closed. The default value is `MQC.MQCO_NONE`. `MQC.MQCO_NONE` is the only permissible value for all resources other than permanent dynamic queues, temporary dynamic queues, subscriptions, and topics that are being accessed by the objects that created them.

For queues and topics, the following additional values are permissible:

MQC.MQCO_DELETE

Delete the queue if there are no messages.

MQC.MQCO_DELETE_PURGE

Delete the queue, purging any messages on it.

MQC.MQCO_QUIESCE

Request the queue be closed, receiving a warning if any messages remain (allowing them to be retrieved before final closing).

For subscriptions, the following additional values are permissible:

MQC.MQCO_KEEP_SUB

The subscription is not deleted. This option is valid only if the original subscription is durable. `MQC.MQCO_KEEP_SUB` is the default value for a durable topic.

MQC.MQCO_REMOVE_SUB

The subscription is deleted. `MQC.MQCO_REMOVE_SUB` is the default value for a non-durable, unmanaged topic.

MQC.MQCO_PURGE_SUB

The subscription is deleted. `MQC.MQCO_PURGE_SUB` is the default value for a non-durable, managed topic.

public MQQueueManager ConnectionReference {get;}

The queue manager to which this resource belongs.

public string MQDescription {get;}

The description of the resource as held by the queue manager. `MQDescription` returns an empty string for subscriptions and topics.

public boolean IsOpen {get;}

Indicates whether the resource is currently open.

public string Name {get;}

The name of the resource. The name is either the supplied on the access method, or the allocated by the queue manager for a dynamic queue.

public int OpenOptions {get; set;}

`OpenOptions` are set when an IBM MQ object is opened. The `OpenOptions.set` method is ignored and does not cause an error. Subscriptions have no `OpenOptions`.

Methods

public virtual void Close();

Throws `MQException`.

Closes the object. No further operations against this resource are permitted after calling Close. To change the behavior of the Close method, set the `closeOptions` attribute.

public string GetAttributeString(int *selector*, int *length*);

Throws MQException.

Gets an attribute string.

selector

Integer indicating which attribute is being queried.

length

Integer indicating the length of the string required.

public void Inquire(int[] *selectors*, int[] *intAttrs*, byte[] *charAttrs*);

Throws MQException.

Returns an array of integers and a set of character strings containing the attributes of a queue, process, or queue manager. The attributes to be queried are specified in the *selectors* array.

Note: Many of the more common attributes can be queried using the Get methods defined in MQManagedObject, MQQueue and MQQueueManager.

selectors

Integer array identifying the attributes with values to be inquired on.

intAttrs

The array in which the integer attribute values are returned. Integer attribute values are returned in the same order as the integer attribute selectors in the *selectors* array.

charAttrs

The buffer in which the character attributes are returned, concatenated. Character attributes are returned in the same order as the character attribute selectors in the *selectors* array. The length of each attribute string is fixed for each attribute.

public void Set(int[] *selectors*, int[] *intAttrs*, byte[] *charAttrs*);

Throws MQException.

Sets the attributes defined in the vector of selectors. The attributes to be set are specified in the *selectors* array.

selectors

Integer array identifying the attributes with values to be set.

intAttrs

The array of integer attribute values to be set. These values must be in the same order as the integer attribute selectors in the *selectors* array.

charAttrs

The buffer in which the character attributes to be set are concatenated. These values must be in the same order as the character attribute selectors in the *selectors* array. The length of each character attribute is fixed.

public void SetAttributeString(int *selector*, string *value*, int *length*);

Throws MQException.

Sets an attribute string.

selector

Integer indicating which attribute is being set.

value

The string to set as the attribute value.

length

Integer indicating the length of the string required.

Constructors

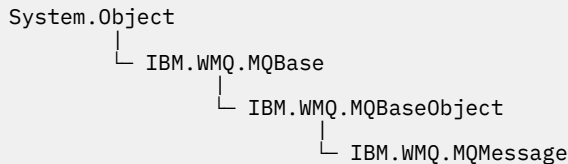

protected MQManagedObject()

Constructor method. This object is an abstract base class which cannot be instantiated by itself.

MQMessage.NET class

Use MQMessage to access the message descriptor and data for an IBM MQ message. MQMessage encapsulates an IBM MQ message.

Class

```
public class IBM.WMQ.MQMessage extends IBM.WMQ.MQBaseObject;
```

Create an MQMessage object and then use the Read and Write methods to transfer data between the message and other objects in your application. Send and receive MQMessage objects using the Put and Get methods of the MQDestination, MQQueue and MQTopic classes.

Get and set the properties of the message descriptor using the properties of MQMessage. Set and Get extended message properties using the SetProperty and GetProperty methods.

- [“Properties” on page 1773](#)
- [“Read and Write message methods” on page 1779](#)
- [“Buffer methods” on page 1781](#)
- [“Property methods” on page 1782](#)
- [“Constructors” on page 1784](#)

Properties

Test for MQException being thrown when getting properties.

public string AccountingToken {get; set;}

Part of the identity context of the message; it helps an application to charge for work done as a result of the message. The default value is MQC.MQACT_NONE.

public string ApplicationIdData {get; set;}

Part of the identity context of the message. ApplicationIdData is information that is defined by the application suite, and can be used to provide additional information about the message or its originator. The default value is "".

public string ApplicationOriginData {get; set;}

Information defined by the application that can be used to provide additional information about the origin of the message. The default value is "".

public int BackoutCount {get;}

A count of the number of times the message has previously been returned and backed out by an MQQueue.Get call as part of a unit of work. The default value is zero.

public int CharacterSet {get; set;}

The coded character set identifier of character data in the message.

Set CharacterSet to identify the character set of character data in the message. Get CharacterSet to find out in what character set has been used to encode character data in the message.

.NET applications always run in Unicode, whereas in other environments applications run in the same character set as the queue manager is running under.

The `ReadString` and `ReadLine` methods convert the character data in the message to Unicode for you.

The `WriteString` method converts from Unicode to the character set encoded in `CharacterSet`. If `CharacterSet` is set to its default value, `MQC.MQCCSI_Q_MGR`, which is 0, no conversion takes place and `CharacterSet` is set to 1200. If you set `CharacterSet` to some other value, `WriteString` converts from Unicode to the alternate value.

Note: Other read and write methods do not use `CharacterSet`.

- `ReadChar` and `WriteChar` read and write a Unicode character to and from the message buffer without conversion.
- `ReadUTF` and `WriteUTF` convert between a Unicode string in the application, and a UTF-8 string, prefixed by a 2-byte length field, in the message buffer.
- Byte methods transfer bytes between the application and the message buffer without alteration.

public byte[] CorrelationId {get; set;}

- For an `MQQueue.Get` call, the correlation identifier of the message to be retrieved. The queue manager returns the first message with a message identifier and a correlation identifier that match the message descriptor fields. The default value, `MQC.MQCI_NONE`, helps any correlation identifier to match.
- For an `MQQueue.Put` call, the correlation identifier to set.

public int DataLength {get;}

The number of bytes of message data remaining to be read.

public int DataOffset {get; set;}

The current cursor position within the message data. Reads and writes take effect at the current position.

public int Encoding {get; set;}

The representation used for numeric values in the application message data. Encoding applies to binary, packed decimal, and floating point data. The behavior of the read and write methods for these numeric formats is altered accordingly. Construct a value for the encoding field by adding one value from each of these three sections. Alternatively, construct the value combining the values from each of the three sections using the bitwise OR operator.

1. Binary integer

MQC.MQENC_INTEGER_NORMAL

Big-endian integers.

MQC.MQENC_INTEGER_REVERSED

Little-endian integers, as used in Intel architecture.

2. Packed-decimal

MQC.MQENC_DECIMAL_NORMAL

Big-endian packed-decimal, as used by z/OS.

MQC.MQENC_DECIMAL_REVERSED

Little-endian packed-decimal.

3. Floating-point

MQC.MQENC_FLOAT_IEEE_NORMAL

Big-endian IEEE floats.

MQC.MQENC_FLOAT_IEEE_REVERSED

Little-endian IEEE floats, as used Intel architecture.

MQC.MQENC_FLOAT_S390

z/OS format floating points.

The default value is:

```
MQC.MQENC_INTEGER_REVERSED |  
MQC.MQENC_DECIMAL_REVERSED |  
MQC.MQENC_FLOAT_IEEE_REVERSED
```

The default setting causes `WriteInt` to write a little-endian integer, and `ReadInt` to read a little-endian integer. If you set the flag `MQC.MQENC_INTEGER_NORMAL` flag instead, `WriteInt` writes a big-endian integer, and `ReadInt` reads a big-endian integer.

Note: A loss in precision can occur when converting from IEEE format floating points to zSeries format floating points.

public int Expiry {get; set;}

An expiry time expressed in tenths of a second, set by the application that puts the message. After the expiry time of a message has elapsed, it is eligible to be discarded by the queue manager. If the message specified one of the `MQC.MQRO_EXPIRATION` flags, a report is generated when the message is discarded. The default value is `MQC.MQEI_UNLIMITED`, meaning that the message never expires.

public int Feedback {get; set;}

Use `Feedback` with a message of type `MQC.MQMT_REPORT` to indicate the nature of the report. The following feedback codes are defined by the system:

- `MQC.MQFB_EXPIRATION`
- `MQC.MQFB_COA`
- `MQC.MQFB_COD`
- `MQC.MQFB_QUIT`
- `MQC.MQFB_PAN`
- `MQC.MQFB_NAN`
- `MQC.MQFB_DATA_LENGTH_ZERO`
- `MQC.MQFB_DATA_LENGTH_NEGATIVE`
- `MQC.MQFB_DATA_LENGTH_TOO_BIG`
- `MQC.MQFB_BUFFER_OVERFLOW`
- `MQC.MQFB_LENGTH_OFF_BY_ONE`
- `MQC.MQFB_IIH_ERROR`

Application-defined feedback values in the range `MQC.MQFB_APPL_FIRST` to `MQC.MQFB_APPL_LAST` can also be used. The default value of this field is `MQC.MQFB_NONE`, indicating that no feedback is provided.

public string Format {get; set;}

A format name used by the sender of the message to indicate the nature of the data in the message to the receiver. You can use your own format names, but names beginning with the letters `MQ` have meanings that are defined by the queue manager. The queue manager built-in formats are:

MQC.MQFMT_ADMIN

Command server request/reply message.

MQC.MQFMT_COMMAND_1

Type 1 command reply message.

MQC.MQFMT_COMMAND_2

Type 2 command reply message.

MQC.MQFMT_DEAD_LETTER_HEADER

Dead-letter header.

MQC.MQFMT_EVENT

Event message.

MQC.MQFMT_NONE

No format name.

MQC.MQFMT_PCF

User-defined message in programmable command format.

MQC.MQFMT_STRING

Message consisting entirely of characters.

MQC.MQFMT_TRIGGER

Trigger message

MQC.MQFMT_XMIT_Q_HEADER

Transmission queue header.

The default value is MQC.MQFMT_NONE.

public byte[] GroupId {get; set;}

A byte string that identifies the message group to which the physical message belongs. The default value is MQC.MQGI_NONE.

public int MessageFlags {get; set;}

Flags controlling the segmentation and status of a message.

public byte[] MessageId {get; set;}

For an MQQueue.Get call, this field specifies the message identifier of the message to be retrieved. Normally, the queue manager returns the first message with a message identifier and correlation identifier that match the message descriptor fields. Allow any message identifier to match using the special value MQC.MQMI_NONE.

For an MQQueue.Put call, this field specifies the message identifier to use. If MQC.MQMI_NONE is specified, the queue manager generates a unique message identifier when the message is put. The value of this member variable is updated after the put, to indicate the message identifier that was used. The default value is MQC.MQMI_NONE.

public int MessageLength {get;}

The number of bytes of message data in the MQMessage object.

public int MessageSequenceNumber {get; set;}

The sequence number of a logical message within a group.

public int MessageType {get; set;}

Indicates the type of the message. The following values are currently defined by the system:

- MQC.MQMT_DATAGRAM
- MQC.MQMT_REPLY
- MQC.MQMT_REPORT
- MQC.MQMT_REQUEST

Application-defined values can also be used, in the range MQC.MQMT_APPL_FIRST to MQC.MQMT_APPL_LAST. The default value of this field is MQC.MQMT_DATAGRAM.

public int Offset {get; set;}

In a segmented message, the offset of data in a physical message from the start of a logical message.

public int OriginalLength {get; set;}

The original length of a segmented message.

public int Persistence {get; set;}

Message persistence. The following values are defined:

- MQC.MQPER_NOT_PERSISTENT

If you set this option in a reconnectable client, the MQRC_NONE reason code is returned to the application when the connection is successful.

- MQC.MQPER_PERSISTENT

If you set this option in a reconnectable client, the MQRC_CALL_INTERRUPTED reason code is returned to the application after the connection is successful.

- MQC.MQPER_PERSISTENCE_AS_Q_DEF

The default value is MQC.MQPER_PERSISTENCE_AS_Q_DEF, which takes the persistence for the message from the default persistence attribute of the destination queue.

public int Priority {get; set;}

The message priority. The special value MQC.MQPRI_PRIORITY_AS_Q_DEF can also be set in outbound message. The priority for the message is then taken from the default priority attribute of the destination queue. The default value is MQC.MQPRI_PRIORITY_AS_Q_DEF.

public int PropertyValidation {get; set;}

Specifies whether validation of properties takes place when a property of the message is set. Possible values are:

- MQCMHO_DEFAULT_VALIDATION
- MQCMHO_VALIDATE
- MQCMHO_NO_VALIDATION

The default value is MQCMHO_DEFAULT_VALIDATION.

public string PutApplicationName {get; set;}

The name of the application that put the message. The default value is "".

public int PutApplicationType {get; set;}

The type of application that put the message. PutApplicationType can be a system-defined or user-defined value. The following values are defined by the system:

- MQC.MQAT_AIX
- MQC.MQAT_CICS
- MQC.MQAT_DOS
- MQC.MQAT_IMS
- MQC.MQAT_MVS
- MQC.MQAT_OS2
- MQC.MQAT_OS400
- MQC.MQAT_QMGR
- MQC.MQAT_UNIX
- MQC.MQAT_WINDOWS
- MQC.MQAT_JAVA

The default value is MQC.MQAT_NO_CONTEXT, which indicates that no context information is present in the message.

public DateTime PutDateTime {get; set;}

The time and date that the message was put.

public string ReplyToQueueManagerName {get; set;}

The name of the queue manager to send reply or report messages. The default value is "", and the queue manager provides the ReplyToQueueManagerName.

public string ReplyToQueueName {get; set;}

The name of the message queue to which the application that issued the get request for the message sends MQC.MQMT_REPLY and MQC.MQMT_REPORT messages. The default ReplyToQueueName is "".

public int Report {get; set;}

Use Report to specify options about report and reply messages:

- Whether reports are required.
- Whether the application message data is to be included in the reports.
- How to set the message and correlation identifiers in the report or reply.

Any combination of the four report types can be requested:

- Specify any combination of the four report types. Selecting any of the three options for each report type, depending on whether the application message data is to be included in the report message.

1. Confirm on arrival

- MQC.MQRO_COA
- MQC.MQRO_COA_WITH_DATA
- MQC.MQRO_COA_WITH_FULL_DATA **

2. Confirm on delivery

- MQC.MQRO_COD
- MQC.MQRO_COD_WITH_DATA
- MQC.MQRO_COD_WITH_FULL_DATA **

3. Exception

- MQC.MQRO_EXCEPTION
- MQC.MQRO_EXCEPTION_WITH_DATA
- MQC.MQRO_EXCEPTION_WITH_FULL_DATA **

4. Expiration

- MQC.MQRO_EXPIRATION
- MQC.MQRO_EXPIRATION_WITH_DATA
- MQC.MQRO_EXPIRATION_WITH_FULL_DATA **

Note: Values marked with ** in the list are not supported by z/OS queue managers. Do not use them if your application is likely to access a z/OS queue manager, regardless of the platform on which the application is running.

- Specify one of the following to control how the message ID is generated for the report or reply message:

- MQC.MQRO_NEW_MSG_ID
- MQC.MQRO_PASS_MSG_ID

- Specify one of the following to control how the correlation ID of the report or reply message is to be set:

- MQC.MQRO_COPY_MSG_ID_TO_CORREL_ID
- MQC.MQRO_PASS_CORREL_ID

- Specify one of the following to control the disposition of the original message when it cannot be delivered to the destination queue:

- MQC.MQRO_DEAD_LETTER_Q
- MQC.MQRO_DISCARD_MSG **

- If no report options are specified, the default is:

```
MQC.MQRO_NEW_MSG_ID |
MQC.MQRO_COPY_MSG_ID_TO_CORREL_ID |
MQC.MQRO_DEAD_LETTER_Q
```

- You can specify one or both of the following to request that the receiving application sends a positive action or negative action report message.

- MQC.MQRO_PAN
- MQC.MQRO_NAN

public int TotalMessageLength {get;}

The total number of bytes in the message as stored on the message queue from which this message was received.

public string UserId {get; set;}

UserId is part of the identity context of the message. The queue manager generally provides the value. You can override the value if you have authority to set the identity context.

public int Version {get; set;}

The version of the MQMD structure in use.

Read and Write message methods

The Read and Write methods perform the same functions as the members of the `BinaryReader` and `BinaryWriter` classes in the `.NET System.IO` namespace. See MSDN for the full language syntax and usage examples. The methods read or write from the current position in the message buffer. They move the current position forward by the number of bytes read or written.

Note: If the message data contains an MQRFH or MQRFH2 header, you must use the `ReadBytes` method to read the data.

- All the methods throw `IOException`.
- The `ReadFully` methods automatically resize the target byte or sbyte array to fit the message exactly. A null array is also resized.
- Read methods throw `EndOfStreamException`.
- `WriteDecimal` methods throw `MQException`.
- `ReadString`, `ReadLine` and `WriteString` methods convert between Unicode and the character set of the message; see [CharacterSet](#).
- The `Decimal` methods read and write packed decimal numbers encoded either in big-endian, `MQC.MQENC_DECIMAL_NORMAL`, or little-endian `MQC.MQENC_DECIMAL_REVERSE` format, according to the value of `Encoding`. Decimal ranges and corresponding .NET types are as follows:

Decimal2/short

-999 to 999

Decimal4/int

-9999999 to 9999999

Decimal8/long

-999999999999999 to 999999999999999

- The `Double` and `Float` methods read and write floating values encoded in IEEE big-endian and little-endian formats, `MQC.MQENC_FLOAT_IEEE_NORMAL` and `MQC.MQENC_FLOAT_IEEE_REVERSED`, or in S/390 format, `MQC.MQENC_FLOAT_S390`, according to the value of `Encoding`.
- The `Int` methods read and write integer values encoded in big-endian, `MQC.MQENC_INTEGER_NORMAL`, or little-endian, `MQC.MQENC_INTEGER_REVERSED`, format, according to the value of `Encoding`. The integers are all signed, except for the addition of an unsigned 2-byte integer type. The integer sizes, and .NET and IBM MQ types are as follows:

2 byte

short, Int2, ushort, UInt2

4 byte

int, Int4

8 byte

long, Int8

- `WriteObject` transfers the class of an object, the values of its non-transient and non-static fields, and the fields of its supertypes, to the message buffer.
- `ReadObject` creates an object from the class of the object, the signature of the class, and the values of its non-transient and non-static fields, and the fields of its supertypes.

Table 670. Read and Write message methods

Target type	Method signatures
Boolean	<pre>public bool ReadBoolean();</pre> <pre>public void WriteBoolean(bool value);</pre>
Byte	<pre>public byte ReadByte()</pre> <pre>public byte ReadUnsignedByte()</pre> <pre>public void Write(int value)</pre> <pre>public void WriteByte(int value)</pre> <pre>public void WriteByte(byte value)</pre> <pre>public void WriteByte(sbyte value)</pre>
Bytes	<pre>public byte[] ReadBytes(int count)</pre> <pre>public void ReadFully(ref byte[] value)</pre> <pre>public void ReadFully(ref sbyte[] value)</pre> <pre>public void ReadFully(ref byte[] value, int offset, int length)</pre> <pre>public void ReadFully(ref sbyte[] value, int offset, int length)</pre> <pre>public void Write(byte[] value)</pre> <pre>public void Write(sbyte[] value)</pre> <pre>public void Write(byte[] value, int offset, int length)</pre> <pre>public void Write(sbyte[] value, int offset, int length)</pre> <pre>public void WriteBytes(string value)</pre>
Decimal2	<pre>public void WriteDecimal2(short value)</pre>
Decimal4	<pre>public void WriteDecimal4(short value)</pre>
Decimal8	<pre>public void WriteDecimal8(short value)</pre>
Double	<pre>public double ReadDouble()</pre> <pre>public void WriteDouble(double value)</pre>
Float	<pre>public float ReadFloat()</pre> <pre>public void WriteFloat(float value)</pre>
Int2	<pre>public void WriteInt2(int value)</pre>
Int4	<pre>public int readDecimal4()</pre> <pre>public int ReadInt()</pre> <pre>public int ReadInt4()</pre> <pre>public void WriteInt(int value)</pre> <pre>public void WriteInt4(int value)</pre>
Int8	<pre>public void WriteInt8(long value)</pre>

Table 670. Read and Write message methods (continued)

Target type	Method signatures
Long	<pre>public long ReadDecimal8() public long ReadLong() public long ReadInt8() public void WriteLong(long value)</pre>
Object	<pre>public Object ReadObject() public void WriteObject(Object object)</pre>
Short	<pre>public short ReadShort() public short ReadDecimal2() public short ReadInt2() public void WriteShort(int value)</pre>
string	<pre>public string ReadString(int length) public void WriteString(string string)</pre>
Unsigned Short	<pre>public ushort ReadUnsignedShort() public ushort ReadUInt2()</pre>
Unicode	<pre>public string ReadLine() public char ReadChar() public void WriteChar(int value) public void WriteChars(string string)</pre>
UTF	<pre>public string ReadUTF() public void WriteUTF(string string)</pre>

Buffer methods

public void ClearMessage();

Throws IOException.

Discards any data in the message buffer and sets the data offset back to zero.

public void ResizeBuffer(int size)

Throws IOException.

A hint to the MQMessage object about the size of buffer that might be required for subsequent get operations. If the message currently contains message data, and the new size is less than the current size, the message data is truncated.

public void Seek(int pos)

Throws IOException, ArgumentOutOfRangeException, ArgumentException.

Moves the cursor to the absolute position in the message buffer given by *pos*. Subsequent reads and writes act at this position in the buffer.

public int SkipBytes(int i)

Throws IOException, EndOfStreamException.

Moves forward *n* bytes in the message buffer and returns *n*, the number of bytes skipped.

SkipBytes method blocks until one of the following events occurs:

- All the bytes are skipped
- The end of message buffer is detected
- An exception is thrown

Property methods

public void DeleteProperty(string name);

Throws MQException.

Deletes a property with the specified name from the message.

name

The name of the property to delete.

public System.Collections.IEnumerator GetPropertyNames(string name)

Throws MQException.

Returns an IEnumerator of all the property names matching the specified name. The percent sign '%' can be used at the end of the name as a wildcard character to filter the properties of the message, matching on zero, or more characters, including the period.

name

The name of the property to match on.

SetProperty and GetProperty methods

All the SetProperty and GetProperty methods throw MQException.

The SetProperty method of MQMessage .NET class adds a new property if a property does not exist already. However, if the property already exists, then the supplied property value is added to the end of the list. When multiple values are set to a property name using SetProperty, calling GetProperty for that name returns those values sequentially in the order that those values were set.

The behavior is same for all the Set*Property and Get*Property typed methods such as GetLongProperty, SetLongProperty, GetBooleanProperty, SetBooleanProperty, GetStringProperty, and SetStringProperty.

Table 671. SetProperty and GetProperty methods	
Type	Method signatures
Boolean	<pre>public boolean GetBooleanProperty(string name); public boolean GetBooleanProperty(string name, MQPropertyDescriptor pd);</pre>
	<pre>public void SetBooleanProperty(string name, boolean value); public void SetBooleanProperty(string name, MQPropertyDescriptor pd, boolean value);</pre>
Byte	<pre>public sbyte GetByteProperty(string name); public sbyte GetByteProperty(string name, MQPropertyDescriptor pd);</pre>
	<pre>public void SetByteProperty(string name, sbyte value); public void SetByteProperty(string name, MQPropertyDescriptor pd, sbyte value);</pre>

Table 671. *SetProperty* and *GetProperty* methods (continued)

Type	Method signatures
Bytes	<pre>public sbyte[] GetBytesProperty(string name); public sbyte[] GetBytesProperty(string name, MQPropertyDescriptor pd); public void SetBytesProperty(string name, sbyte[] value); public void SetBytesProperty(string name, MQPropertyDescriptor pd, sbyte[] value);</pre>
Double	<pre>public double GetDoubleProperty(string name); public double GetDoubleProperty(string name, MQPropertyDescriptor pd); public void SetDoubleProperty(string name, double value); public void SetDoubleProperty(string name, MQPropertyDescriptor pd, double value);</pre>
Float	<pre>public float GetFloatProperty(string name); public float GetFloatProperty(string name, MQPropertyDescriptor pd); public void SetFloatProperty(string name, float value); public void SetFloatProperty(string name, MQPropertyDescriptor pd, float value);</pre>
Int2	<pre>public short GetInt2Property(string name); public short GetInt2Property(string name, MQPropertyDescriptor pd); public void SetInt2Property(string name, short value); public void SetInt2Property(string name, MQPropertyDescriptor pd, short value);</pre>
Int4	<pre>public int GetInt4Property(string name); public int GetInt4Property(string name, MQPropertyDescriptor pd); public void SetInt4Property(string name, int value); public void SetInt4Property(string name, MQPropertyDescriptor pd, int value);</pre>
Int8	<pre>public long GetInt8Property(string name); public long GetInt8Property(string name, MQPropertyDescriptor pd); public void SetInt8Property(string name, long value); public void SetInt8Property(string name, MQPropertyDescriptor pd, long value);</pre>
Long	<pre>public long GetLongProperty(string name); public long GetLongProperty(string name, MQPropertyDescriptor pd); public void SetLongProperty(string name, long value); public void SetLongProperty(string name, MQPropertyDescriptor pd, long value);</pre>
Object	<pre>public Object GetObjectProperty(string name); public Object GetObjectProperty(string name, MQPropertyDescriptor pd); public void SetObjectProperty(string name, Object value); public void SetObjectProperty(string name, MQPropertyDescriptor pd, Object value);</pre>

Table 671. *SetProperty* and *GetProperty* methods (continued)

Type	Method signatures
Short	<pre>public short GetShortProperty(string name); public short GetShortProperty(string name, MQPropertyDescriptor pd); public void SetShortProperty(string name, short value); public void SetShortProperty(string name, MQPropertyDescriptor pd, short value);</pre>
string	<pre>public string GetStringProperty(string name); public string GetStringProperty(string name, MQPropertyDescriptor pd); public void SetStringProperty(string name, string value); public void SetStringProperty(string name, MQPropertyDescriptor pd, string value);</pre>

Constructors

public MQMessage();

Creates an MQMessage object with default message descriptor information and an empty message buffer.

MQProcess.NET class

Use MQProcess to query the attributes of an IBM MQ process. Create an MQProcess object using a constructor, or an MQQueueManager AccessProcess method.

Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQManagedObject
│           └── IBM.WMQ.MQProcess
```

```
public class IBM.WMQ.MQProcess extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1784](#)
- [“Constructors” on page 1785](#)

Properties

Test for MQException being thrown when getting properties.

public string ApplicationId {get;}

Gets the character string that identifies the application to be started. ApplicationId is used by a trigger monitor application. ApplicationId is sent to the initiation queue as part of the trigger message.

The default value is null.

public int ApplicationType {get;}

Identifies the type of the process to be started by a trigger monitor application. Standard types are defined, but others can be used:

- MQAT_AIX

- MQAT_CICS
- MQAT_IMS
- MQAT_MVS
- MQAT_NATIVE
- MQAT_OS400
- MQAT_UNIX
- MQAT_WINDOWS
- MQAT_JAVA
- MQAT_USER_FIRST
- MQAT_USER_LAST

The default value is MQAT_NATIVE.

public string EnvironmentData {get;}

Gets information about the environment of the application that is to be started.

The default value is null.

public string UserData {get;}

Gets information the user has provided about the application to be started.

The default value is null.

Constructors

public MQProcess(MQQueueManager queueManager, string processName, int openOptions);
public MQProcess(MQQueueManager qMgr, string processName, int openOptions, string queueManagerName, string alternateUserId);

Throws MQException.

Access an IBM MQ process on queue manager *qMgr* to inquire on process attributes.

qMgr

Queue manager to access.

processName

The name of the process to open.

openOptions

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- MQC.MQ00_FAIL_IF QUIESCING
- MQC.MQ00_INQUIRE
- MQC.MQ00_SET
- MQC.MQ00_ALTERNATE_USER_AUTHORITY

queueManagerName

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

alternateUserId

If MQC.MQ00_ALTERNATE_USER_AUTHORITY is specified in the *openOptions* parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If MQ00_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if MQC.MQ00_ALTERNATE_USER_AUTHORITY is not specified.

```
public MQProcess MQQueueManager.AccessProcess(string processName, int  
openOptions);  
public MQProcess MQQueueManager.AccessProcess(string processName, int  
openOptions, string queueManagerName, string alternateUserId);
```

Throws MQException.

Access an IBM MQ process on this queue manager to inquire on process attributes.

processName

The name of the process to open.

openOptions

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- MQC.MQ00_FAIL_IF QUIESCING
- MQC.MQ00_INQUIRE
- MQC.MQ00_SET
- MQC.MQ00_ALTERNATE_USER_AUTHORITY

queueManagerName

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

alternateUserId

If MQC.MQ00_ALTERNATE_USER_AUTHORITY is specified in the *openOptions* parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If MQ00_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if MQC.MQ00_ALTERNATE_USER_AUTHORITY is not specified.

MQPropertyDescriptor.NET class

Use MQPropertyDescriptor as a parameter to MQMessage GetProperty and SetProperty methods. MQPropertyDescriptor describes an MQMessage property.

Class

```
System.Object  
└─ IBM.WMQ.MQPropertyDescriptor
```

```
public class IBM.WMQ.MQPropertyDescriptor extends System.Object;
```

- [“Properties” on page 1786](#)
- [“Constructors” on page 1788](#)

Properties

Test for MQException being thrown when getting properties.

```
public int Context {get; set;}
```

The message context the property belongs to. Possible values are:

MQC.MQPD_NO_CONTEXT

The property is not associated with a message context.

MQC.MQPD_USER_CONTEXT

The property is associated with the user context.

If the user is authorized, a property associated with the user context is saved when a message is retrieved. A subsequent Put method referencing the saved context, can pass the property into the new message.

public int CopyOptions {get; set;}

CopyOptions describes which type of message the property can be copied into.

When a queue manager receives a message containing an IBM MQ defined property that the queue manager recognizes as being incorrect, the queue manager corrects the value of the CopyOptions field.

Any combination of the following options can be specified. Combine the options by adding the values, or using bitwise OR.

MQC.MQCOPY_ALL

The property is copied into all types of subsequent messages.

MQC.MQCOPY_FORWARD

The property is copied into a message being forwarded.

MQC.MQCOPY_PUBLISH

The property is copied into the message received by a subscriber when a message is being published.

MQC.MQCOPY_REPLY

The property is copied into a reply message.

MQC.MQCOPY_REPORT

The property is copied into a report message.

MQC.MQCOPY_DEFAULT

The value indicated no other copy options have been specified. No relationship exists between the property and subsequent messages. MQC.MQCOPY_DEFAULT is always returned for message descriptor properties.

MQC.MQCOPY_NONE

The same as MQC.MQCOPY_DEFAULT

public int Options { set; }

Options defaults to CMQC.MQPD_NONE. You cannot set any other value.

public int Support { get; set; }

Set Support to specify the level of support required for IBM MQ-defined message properties. Support for all other properties is optional. Any or none of the following values can be specified

MQC.MQPD_SUPPORT_OPTIONAL

The property is accepted by a queue manager even if it is not supported. The property can be discarded in order for the message to flow to a queue manager that does not support message properties. This value is also assigned to properties that are not IBM MQ defined.

MQC.MQPD_SUPPORT_REQUIRED

Support for the property is required. If you put the message to a queue manager that does not support the IBM MQ-defined property, the method fails. It returns completion code MQC.MQCC_FAILED and reason code MQC.MQRC_UNSUPPORTED_PROPERTY.

MQC.MQPD_SUPPORT_REQUIRED_IF_LOCAL

Support for the property is required, if the message is destined for a local queue. If you put the message to a local queue on a queue manager that does not support the IBM MQ-defined property, the method fails. It returns completion code MQC.MQCC_FAILED and reason code MQC.MQRC_UNSUPPORTED_PROPERTY.

No check is made if the message is put to a remote queue manager.

Constructors

PropertyDescriptor();

Create a property descriptor.

MQPutMessageOptions.NET class

Use MQPutMessageOptions to specify how messages are sent. It modifies the behavior of MQDestination.Put.

Class

```
System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQPutMessageOptions
```

```
public class IBM.WMQ.MQPutMessageOptions extends IBM.WMQ.MQBaseObject;
```

- [“Properties” on page 1788](#) [“Constructors” on page 1790](#)

Properties

Test for MQException being thrown when getting properties.

Note: The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with an asterisk, *.

public MQQueue ContextReference {get; set;}

If the options field includes MQC.MQPMO_PASS_IDENTITY_CONTEXT or MQC.MQPMO_PASS_ALL_CONTEXT, set this field to refer to the MQQueue from which to take the context information.

The initial value of this field is null.

public int InvalidDestCount {get;} *

Generally, used for distribution lists, InvalidDestCount indicates the number of messages that could not be sent to queues in a distribution list. The count includes queues that failed to open and also the queues that were opened successfully, but for which the put operation had failed.

.NET does not support distribution lists, but InvalidDestCount is set when opening a single queue.

public int KnownDestCount {get;} *

Generally used for distribution lists, KnownDestCount indicates the number of messages that the current call has sent successfully to queues that resolve to local queues.

.NET does not support distribution lists, but InvalidDestCount is set when opening a single queue.

public int Options {get; set;}

Options that control the action of MQDestination.put and MQQueueManager.put. Any or none of the following values can be specified. If more than one option is required, the values can be added or combined using the bitwise OR operator.

MQC.MQPMO_ASYNC_RESPONSE

This option causes the MQDestination.put call to be made asynchronously, with some response data.

MQC.MQPMO_DEFAULT_CONTEXT

Associate default context with the message.

MQC.MQPMO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQPMO_LOGICAL_ORDER *

Put logical messages and segments in message groups into their logical order.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned to the application.

MQC.MQPMO_NEW_CORREL_ID *

Generate a new correlation ID for each sent message.

MQC.MQPMO_NEW_MSG_ID *

Generate a new message ID for each sent message.

MQC.MQPMO_NONE

No options specified. Do not use with other options.

MQC.MQPMO_NO_CONTEXT

No context is to be associated with the message.

MQC.MQPMO_NO_SYNCPOINT

Put a message without sync point control. If the sync point control option is not specified, a default of no sync point is assumed.

MQC.MQPMO_PASS_ALL_CONTEXT

Pass all context from an input queue handle.

MQC.MQPMO_PASS_IDENTITY_CONTEXT

Pass identity context from an input queue handle.

MQC.MQPMO_RESPONSE_AS_Q_DEF

For an MQDestination.put call, this option takes the put response type from DEFPRESP attribute of the queue.

For an MQQueueManager.put call, this option causes the call to be made synchronously.

MQC.MQPMO_RESPONSE_AS_TOPIC_DEF

MQC.MQPMO_RESPONSE_AS_TOPIC_DEF is a synonym for MQC.MQPMO_RESPONSE_AS_Q_DEF for use with topic objects.

MQC.MQPMO_RETAIN

The publication being sent is to be retained by the queue manager. If this option is used and the publication cannot be retained, the message is not published and the call fails with MQC.MQRC_PUT_NOT_RETAINED.

Request a copy of this publication after the time it was published, by calling the MQSubscription.RequestPublicationUpdate method. The saved publication is sent to applications that create a subscription without setting the MQC.MQSO_NEW_PUBLICATIONS_ONLY option. Check the MQIsRetained message property of a publication, when it is received, to find out if it was the retained publication.

When retained publications are requested by a subscriber, the subscription used might contain a wildcard in the topic string. If there are multiple retained publications in the topic tree that match the subscription, they are all sent.

MQC.MQPMO_SET_ALL_CONTEXT

Set all context from the application.

MQC.MQPMO_SET_IDENTITY_CONTEXT

Set identity context from the application.

MQC.MQPMO_SYNC_RESPONSE

This option causes the MQDestination.put or MQQueueManager.put call to be made synchronously, with full response data.

MQC.MQPMO_SUPPRESS_REPLYTO

Any information filled into the ReplyToQueueName and ReplyToQueueManagerName fields of the publication is not passed on to subscribers. If this option is used in combination with a report option that requires a ReplyToQueueName, the call fails with MQC.MQRC_MISSING_REPLY_TO_Q.

MQC.MQPMO_SYNCPOINT

Put a message with sync point control. The message is not visible outside the unit of work until the unit of work is committed. If the unit of work is backed out, the message is deleted.

public int RecordFields {get; set;} *

Information about distribution lists. Distribution lists are not supporting in .NET.

public string ResolvedQueueManagerName {get;}

An output field set by the queue manager to the name of the queue manager that owns the queue specified by the remote queue name. ResolvedQueueManagerName might be different from the name of the queue manager from which the queue was accessed if the queue is a remote queue.

A nonblank value is returned only if the object is a single queue. If the object is a distribution list or a topic, the value returned is undefined.

public string ResolvedQueueName {get;}

An output field that is set by the queue manager to the name of the queue on which the message is placed. ResolvedQueueName might be different from the name used to open the queue if the opened queue was an alias or model queue.

A non-blank value is returned only if the object is a single queue. If the object is a distribution list or a topic, the value returned is undefined.

public int UnknownDestCount {get;} *

Generally used for distribution lists, UnknownDestCount is an output field set by the queue manager. It reports the number of messages that the current call has sent successfully to queues that resolve to remote queues.

.NET does not support distribution lists, but InvalidDestCount is set when opening a single queue.

Constructors

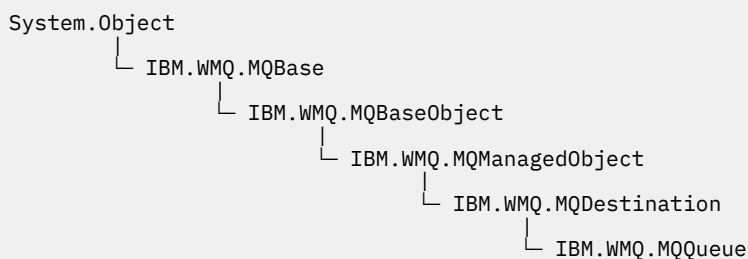

public MQPutMessageOptions();

Construct a new MQPutMessageOptions object with no options set, and a blank ResolvedQueueName and ResolvedQueueManagerName.

MQueue.NET class

Use MQueue to send and receive messages, and query attributes of an IBM MQ queue. Create an MQueue object using a constructor, or an MQueueManager.AccessProcess method.

Class

```
public class IBM.WMQ.MQQueue extends IBM.WMQ.MQDestination;
```

- [“Properties” on page 1791](#)
- [“Methods” on page 1793](#)
- [“Constructors” on page 1795](#)

Properties

Test for MQException being thrown when getting properties.

public int ClusterWorkLoadPriority {get;}

Specifies the priority of the queue. This parameter is valid only for local, remote, and alias queues.

public int ClusterWorkLoadRank {get;}

Specifies the rank of the queue. This parameter is valid only for local, remote, and alias queues.

public int ClusterWorkLoadUseQ {get;}

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. This parameter does not apply if the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

public DateTime CreationDateTime {get;}

The date and time that this queue was created.

public int CurrentDepth {get;}

Gets the number of messages currently on the queue. This value is incremented during a put call, and during backout of a get call. It is decremented during a non-browse get and during backout of a put call.

public int DefinitionType {get;}

How the queue was defined. The possible values are:

- MQC.MQQDT_PREDEFINED
- MQC.MQQDT_PERMANENT_DYNAMIC
- MQC.MQQDT_TEMPORARY_DYNAMIC

public int InhibitGet {get; set;}

Controls whether you can get messages on this queue or for this topic. The possible values are:

- MQC.MQQA_GET_INHIBITED
- MQC.MQQA_GET_ALLOWED

public int InhibitPut {get; set;}

Controls whether you can put messages on this queue or for this topic. The possible values are:

- MQQA_PUT_INHIBITED
- MQQA_PUT_ALLOWED

public int MaximumDepth {get;}

The maximum number of messages that can exist on the queue at any one time. An attempt to put a message to a queue that already contains this many messages fails with reason code MQC.MQRC_Q_FULL.

public int MaximumMessageLength {get;}

The maximum length of the application data that can exist in each message on this queue. An attempt to put a message larger than this value fails with reason code MQC.MQRC_MSG_TOO_BIG_FOR_Q.

public int NonPersistentMessageClass {get;}

The level of reliability for non-persistent messages put to this queue.

public int OpenInputCount {get;}

The number of handles that are currently valid for removing messages from the queue. OpenInputCount is the total number of valid input handles known to the local queue manager, not just handles created by the application.

public int OpenOutputCount {get;}

The number of handles that are currently valid for adding messages to the queue. OpenOutputCount is the total number of valid output handles known to the local queue manager, not just handles created by the application.

public int QueueAccounting {get;}

Specifies whether you can enable the collection of accounting information for the queue.

public int QueueMonitoring {get;}

Specifies whether you can enable the monitoring for the queue.

public int QueueStatistics {get;}

Specifies whether you can enable the collection of statistics for the queue.

public int QueueType {get;}

The type of this queue with one of the following values:

- MQC.MQQT_ALIAS
- MQC.MQQT_LOCAL
- MQC.MQQT_REMOTE
- MQC.MQQT_CLUSTER

public int Shareability {get;}

Whether the queue can be opened for input multiple times. The possible values are:

- MQC.MQQA_SHAREABLE
- MQC.MQQA_NOT_SHAREABLE

public string TPIPE {get;}

The TPIPE name used for communication with OTMA using the IBM MQ IMS bridge.

public int TriggerControl {get; set;}

Whether trigger messages are written to an initiation queue, to start an application to service the queue. The possible values are:

- MQC.MQTC_OFF
- MQC.MQTC_ON

public string TriggerData {get; set;}

The free-format data that the queue manager inserts into the trigger message. It inserts TriggerData when a message arriving on this queue causes a trigger message to be written to the initiation queue. The maximum permissible length of the string is given by MQC.MQ_TRIGGER_DATA_LENGTH.

public int TriggerDepth {get; set;}

The number of messages that must be on the queue before a trigger message is written when trigger type is set to MQC.MQTT_DEPTH.

public int TriggerMessagePriority {get; set;}

The message priority under which messages do not contribute to the generation of trigger messages. That is, the queue manager ignores these messages when deciding whether to generate a trigger. A value of zero causes all messages to contribute to the generation of trigger messages.

public int TriggerType {get; set;}

The conditions under which trigger messages are written as a result of messages arriving on this queue. The possible values are:

- MQC.MQTT_NONE
- MQC.MQTT_FIRST
- MQC.MQTT EVERY
- MQC.MQTT_DEPTH

Methods

```
public void Get(MQMessage message);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int  
MaxMsgSize);
```

Throws MQException.

Gets a message from a queue.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC_BACKED_OUT after successful reconnection, for messages received under MQGM_SYNCPOINT.

getMessageOptions

Options controlling the action of the get.

Using option MQC.MQGM_CONVERT might result in an exception with reason code MQC.MQRC_CONVERTED_STRING_TOO_BIG when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If *getMessageOptions* is not specified, the message option used is MQGM_NOWAIT.

If you use the MQGM_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

MaxMsgSize

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the MQGM_ACCEPT_TRUNCATED_MSG flag is set in the MQGetMessageOptions object, the message is filled with as much of the message data as possible. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_ACCEPTED reason code.
- If the MQGM_ACCEPT_TRUNCATED_MSG flag is not set, the message remains on the queue. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_FAILED reason code.

If *MaxMsgSize* is not specified, the whole message is retrieved.

```
public void Put(MQMessage message);  
public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);
```

Throws MQException.

Puts a message to a queue.

Modifications to the MQMessage object after the Put call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

Put updates the `MessageId` and `CorrelationId` properties of the `MQMessage` object and does not clear message data. Further Put or Get calls refer to the updated information in the `MQMessage` object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");
q.Put(msg,pmo);
msg.WriteString("b");
q.Put(msg,pmo);
```

message

An `MQMessage` object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- `MQRC_CALL_INTERRUPTED` if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- `MQRC_NONE` if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of `MQPutMessageOptions` is used.

If you use the `MQPMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned.

Note: For simplicity and performance, if you want to put a single message to a queue, use `MQQueueManager.Put` object. You should have an `MQQueue` object for this.

```
public void PutForwardMessage(MQMessage message);  
public void PutForwardMessage(MQMessage message, MQPutMessageOptions  
putMessageOptions);
```

Throws `MQException`

Put a message being forwarded onto the queue, where *message* is the original message.

message

An `MQMessage` object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- `MQRC_CALL_INTERRUPTED` if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- `MQRC_NONE` if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of `MQPutMessageOptions` is used.

If you use the `MQPMO_LOGICAL_ORDER` option in a reconnectable client, the `MQRC_RECONNECT_INCOMPATIBLE` reason code is returned.

```
public void PutReplyMessage(MQMessage message)  
public void PutReplyMessage(MQMessage message, MQPutMessageOptions  
putMessageOptions)
```

Throws `MQException`.

Put a reply message onto the queue, where *message* is the original message.

message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC_BACKED_OUT after successful reconnection, for messages received under MQGM_SYNCPOINT.

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

```
public void PutReportMessage(MQMessage message)  
public void PutReportMessage(MQMessage message, MQPutMessageOptions  
putMessageOptions)
```

Throws MQException.

Put a report message onto the queue, where *message* is the original message.

message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC_BACKED_OUT after successful reconnection, for messages received under MQGM_SYNCPOINT.

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

Constructors

```
public MQQueue MQQueueManager.AccessQueue(string queueName, int openOptions);  
public MQQueue MQQueueManager.AccessQueue(string queueName, int openOptions,  
string queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on this queue manager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

queueName

Name of queue to open.

openOptions

Options that control the opening of the queue.

MQC.MQOO_ALTERNATE_USER_AUTHORITY

Validate with the specified user identifier.

MQC.MQOO_BIND_AS_QDEF

Use default binding for queue.

MQC.MQOO_BIND_NOT_FIXED

Do not bind to a specific destination.

MQC.MQOO_BIND_ON_OPEN

Bind handle to destination when queue is opened.

MQC.MQOO_BROWSE

Open to browse message.

MQC.MQOO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQOO_INPUT_AS_Q_DEF

Open to get messages using queue-defined default.

MQC.MQOO_INPUT_SHARED

Open to get messages with shared access.

MQC.MQOO_INPUT_EXCLUSIVE

Open to get messages with exclusive access.

MQC.MQOO_INQUIRE

Open for inquiry - required if you want to query properties.

MQC.MQOO_OUTPUT

Open to put messages.

MQC.MQOO_PASS_ALL_CONTEXT

Allow all context to be passed.

MQC.MQOO_PASS_IDENTITY_CONTEXT

Allow identity context to be passed.

MQC.MQOO_SAVE_ALL_CONTEXT

Save context when message retrieved.

MQC.MQOO_SET

Open to set attributes - required if you want to set properties.

MQC.MQOO_SET_ALL_CONTEXT

Allows all context to be set.

MQC.MQOO_SET_IDENTITY_CONTEXT

Allows identity context to be set.

queueManagerName

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

dynamicQueueName

dynamicQueueName is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last nonblank character in the name is an asterisk, *, the queue manager replaces the asterisk with a string of characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

alternateUserId

If MQC.MQOO_ALTERNATE_USER_AUTHORITY is specified in the *openOptions* parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQOO_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

```
public MQQueue(MQQueueManager queueManager, string queueName, int openOptions,  
string queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on queueManager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

queueManager

Queue manager to access queue on.

queueName

Name of queue to open.

openOptions

Options that control the opening of the queue.

MQC.MQOO_ALTERNATE_USER_AUTHORITY

Validate with the specified user identifier.

MQC.MQOO_BIND_AS_QDEF

Use default binding for queue.

MQC.MQOO_BIND_NOT_FIXED

Do not bind to a specific destination.

MQC.MQOO_BIND_ON_OPEN

Bind handle to destination when queue is opened.

MQC.MQOO_BROWSE

Open to browse message.

MQC.MQOO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQOO_INPUT_AS_Q_DEF

Open to get messages using queue-defined default.

MQC.MQOO_INPUT_SHARED

Open to get messages with shared access.

MQC.MQOO_INPUT_EXCLUSIVE

Open to get messages with exclusive access.

MQC.MQOO_INQUIRE

Open for inquiry - required if you want to query properties.

MQC.MQOO_OUTPUT

Open to put messages.

MQC.MQOO_PASS_ALL_CONTEXT

Allow all context to be passed.

MQC.MQOO_PASS_IDENTITY_CONTEXT

Allow identity context to be passed.

MQC.MQOO_SAVE_ALL_CONTEXT

Save context when message retrieved.

MQC.MQOO_SET

Open to set attributes - required if you want to set properties.

MQC.MQOO_SET_ALL_CONTEXT

Allows all context to be set.

MQC.MQOO_SET_IDENTITY_CONTEXT

Allows identity context to be set.

queueManagerName

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

dynamicQueueName

dynamicQueueName is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last nonblank character in the name is an asterisk, *, the queue manager replaces the asterisk with a string of characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

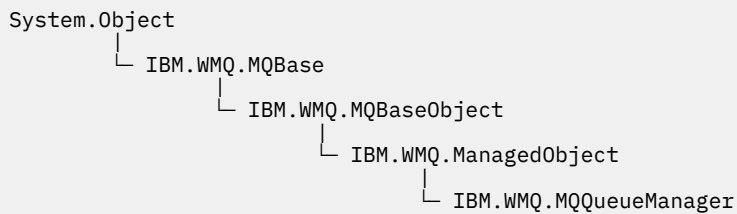

alternateUserId

If MQC.MQ00_ALTERNATE_USER_AUTHORITY is specified in the openOptions parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQ00_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

MQQueueManager.NET class

Use MQQueueManager to connect to a queue manager and access queue manager objects. It also controls transactions. The MQQueueManager constructor creates either a client or server connection.

Class

```
public class IBM.WMQ.MQQueueManager extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1798](#)
- [“Methods” on page 1801](#)
- [“Constructors” on page 1807](#)

Properties

Test for MQException being thrown when getting properties.

public int AccountingConnOverride {get;}

Whether applications can override the setting of the MQI accounting and queue accounting values.

public int AccountingInterval {get;}

How long before intermediate accounting records are written (in seconds).

public int ActivityRecording {get;}

Controls the generation of activity reports.

public int AdoptNewMCACheck {get;}

Specifies which elements are checked to determine whether the MCA is adopted when a new inbound channel is detected. To be adopted, the MCA name must match the name of an active MCA.

public int AdoptNewMCAInterval {get;}

The amount of time, in seconds, that the new channel waits for the orphaned channel to end.

public int AdoptNewMCAType {get;}

Whether an orphaned MCA instance is to be adopted (restarted) when a new inbound channel request is detected matching the AdoptNewMCACheck value.

public int BridgeEvent {get;}

Whether IMS bridge events are generated.

public int ChannelEvent {get;}

Whether channel events are generated.

public int ChannelInitiatorControl {get;}

Whether the channel initiator starts automatically when the queue manager starts.

public int ChannelInitiatorAdapters {get;}

The number of adapter subtasks to process IBM MQ calls.

public int ChannelInitiatorDispatchers {get;}

The number of dispatchers to use for the channel initiator.

public int ChannelInitiatorTraceAutoStart {get;}

Specifies whether the channel initiator trace starts automatically.

public int ChannelInitiatorTraceTableSize {get;}

The size, in megabytes, of the trace data space of a channel initiator.

public int ChannelMonitoring {get;}

Whether channel monitoring is used.

public int ChannelStatistics {get;}

Controls the collection of statistics data for channels.

public int CharacterSet {get;}

Returns the coded character set identifier (CCSID) of the queue manager. CharacterSet is used by the queue manager for all character string fields in the application programming interface.

public int ClusterSenderMonitoring {get;}

Controls the collection of online monitoring data for automatically defined cluster sender channels.

public int ClusterSenderStatistics {get;}

Controls the collection of statistics data for automatically defined cluster sender channels.

public int ClusterWorkLoadMRU {get;}

The maximum number of outbound cluster channels.

public int ClusterWorkLoadUseQ {get;}

The default value of the MQQueue property, ClusterWorkLoadUseQ, if it specifies a value of QMGR.

public int CommandEvent {get;}

Specifies whether command events are generated.

public string CommandInputQueueName {get;}

Returns the name of the command input queue defined on the queue manager. Applications can send commands to this queue, if authorized to do so.

public int CommandLevel {get;}

Indicates the function level of the queue manager. The set of functions that correspond to a particular function level depends on the platform. On a particular platform, you can rely on every queue manager supporting the functions at the lowest functional level common to all the queue managers.

public int CommandLevel {get;}

Whether the command server starts automatically when the queue manager starts.

public string DNSGroup {get;}

No longer used.

public int DNSWLM {get;}

No longer used.

public int IPAddressVersion {get;}

Which IP protocol (IPv4 or IPv6) to use for a channel connection.

public boolean IsConnected {get;}

Returns the value of the isConnected.

If true, a connection to the queue manager has been made, and is not known to be broken. Any calls to IsConnected do not actively attempt to reach the queue manager, so it is possible that physical connectivity can break, but IsConnected can still return true. The IsConnected state is only updated when activity, for example, putting a message, getting a message, is performed on the queue manager.

If false, a connection to the queue manager has not been made, or has been broken, or has been disconnected.

public int KeepAlive {get;}

Specifies whether the TCP KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

public int ListenerTimer {get;}

The time interval, in seconds, between attempts by IBM MQ to restart the listener after an APPC or TCP/IP failure.

public int LoggerEvent {get;}

Whether logger events are generated.

public string LU62ARMSuffix {get;}

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC=xx is issued.

public string LUGroupName {get; z/os}

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue-sharing group.

public string LUName {get;}

The name of the LU to use for outbound LU 6.2 transmissions.

public int MaximumActiveChannels {get;}

The maximum number of channels that can be active at any time.

public int MaximumCurrentChannels {get;}

The maximum number of channels that can be current at any time (including server-connection channels with connected clients).

public int MaximumLU62Channels {get;}

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol.

public int MaximumMessageLength {get;}

Returns the maximum length of a message (in bytes) that can be handled by the queue manager. No queue can be defined with a maximum message length greater than MaximumMessageLength.

public int MaximumPriority {get;}

Returns the maximum message priority supported by the queue manager. Priorities range from zero (lowest) to this value. Throws MQException if you call this method after disconnecting from the queue manager.

public int MaximumTCPChannels {get;}

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol.

public int MQIAccounting {get;}

Controls the collection of accounting information for MQI data.

public int MQIStatistics {get;}

Controls the collection of statistics monitoring information for the queue manager.

public int OutboundPortMax {get;}

The maximum value in the range of port numbers to be used when binding outgoing channels.

public int OutboundPortMin {get;}

The minimum value in the range of port numbers to be used when binding outgoing channels.

public int QueueAccounting {get;}

Whether class 3 accounting (thread-level and queue-level accounting) data is to be used for all queues.

public int QueueMonitoring {get;}

Controls the collection of online monitoring data for queues.

public int QueueStatistics {get;}

Controls the collection of statistics data for queues.

public int ReceiveTimeout {get;}

The length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to the inactive state.

public int ReceiveTimeoutMin {get;}

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

public int ReceiveTimeoutType {get;}

The qualifier to apply to the value in ReceiveTimeout.

public int SharedQueueQueueManagerName {get;}

Specifies how to deliver messages to a shared queue. If the put specifies a different queue manager from the same queue sharing group as the target queue manager, the message is delivered in two ways:

MQC.MQSQQM_USE

Messages are delivered to the object queue manager before being put on the shared queue.

MQCMQSQQM_IGNORE

Messages are put directly on the shared queue.

public int SSLEvent {get;}

Whether SSL events are generated.

public int SSLFips {get;}

Whether only FIPS-certified algorithms are to be used if cryptography is performed in IBM MQ, rather than cryptographic hardware.

public int SSLKeyResetCount {get;}

Indicates the number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated.

public int ClusterSenderStatistics {get;}

Specifies the interval, in minutes, between consecutive gatherings of statistics.

public int SyncpointAvailability {get;}

Indicates whether the queue manager supports units of work and sync points with the MQQueue.get and MQQueue.put methods.

public string TCPName {get;}

The name of either the only, or default, TCP/IP system to be used, depending on the value of TCPStackType.

public int TCPStackType {get;}

Specifies whether the channel initiator uses only the TCP/IP address space specified in TCPName. Alternatively, the channel initiator can bind to any TCP/IP address.

public int TraceRouteRecording {get;}

Controls the recording of route tracing information.

Methods

public MQProcess AccessProcess(string processName, int openOptions);

public MQProcess AccessProcess(string processName, int openOptions, string queueManagerName, string alternateUserId);

Throws MQException.

Access an IBM MQ process on this queue manager to inquire on process attributes.

processName

The name of the process to open.

openOptions

Options that control the opening of the process. The valid options that can be added, or combined using a bitwise OR, are:

- MQC.MQ00_FAIL_IF QUIESCING
- MQC.MQ00_INQUIRE
- MQC.MQ00_SET

- MQC.MQOO_ALTERNATE_USER_AUTHORITY

queueManagerName

The name of the queue manager on which the process is defined. You can leave a blank or null queue manager name if the queue manager is the same as the one the process is accessing.

alternateUserId

If MQC.MQOO_ALTERNATE_USER_AUTHORITY is specified in the *openOptions* parameter, *alternateUserId* specifies the alternative user ID used to check the authorization for the action. If MQOO_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be blank or null.

Default user authority is used for connection to the queue manager if MQC.MQOO_ALTERNATE_USER_AUTHORITY is not specified.

```
public MQQueue AccessQueue(string queueName, int openOptions);  
public MQQueue AccessQueue(string queueName, int openOptions, string  
queueManagerName, string dynamicQueueName, string alternateUserId);
```

Throws MQException.

Accesses a queue on this queue manager.

You can get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue. If the queue named is a model queue, a dynamic local queue is created. Query the name attribute of the resultant MQQueue object to find out the name of the dynamic queue.

queueName

Name of queue to open.

openOptions

Options that control the opening of the queue.

MQC.MQOO_ALTERNATE_USER_AUTHORITY

Validate with the specified user identifier.

MQC.MQOO_BIND_AS_QDEF

Use default binding for queue.

MQC.MQOO_BIND_NOT_FIXED

Do not bind to a specific destination.

MQC.MQOO_BIND_ON_OPEN

Bind handle to destination when queue is opened.

MQC.MQOO_BROWSE

Open to browse message.

MQC.MQOO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQOO_INPUT_AS_Q_DEF

Open to get messages using queue-defined default.

MQC.MQOO_INPUT_SHARED

Open to get messages with shared access.

MQC.MQOO_INPUT_EXCLUSIVE

Open to get messages with exclusive access.

MQC.MQOO_INQUIRE

Open for inquiry - required if you want to query properties.

MQC.MQOO_OUTPUT

Open to put messages.

MQC.MQOO_PASS_ALL_CONTEXT

Allow all context to be passed.

MQC.MQOO_PASS_IDENTITY_CONTEXT

Allow identity context to be passed.

MQC.MQOO_SAVE_ALL_CONTEXT

Save context when message retrieved.

MQC.MQOO_SET

Open to set attributes - required if you want to set properties.

MQC.MQOO_SET_ALL_CONTEXT

Allows all context to be set.

MQC.MQOO_SET_IDENTITY_CONTEXT

Allows identity context to be set.

queueManagerName

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which the MQQueueManager object is connected.

dynamicQueueName

dynamicQueueName is ignored unless *queueName* specifies the name of a model queue. If it does, *dynamicQueueName* specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last nonblank character in the name is an asterisk, *, the queue manager replaces the asterisk with a string of characters. The characters guarantee that the name generated for the queue is unique on this queue manager.

alternateUserId

If MQC.MQOO_ALTERNATE_USER_AUTHORITY is specified in the openOptions parameter, *alternateUserId* specifies the alternate user identifier that is used to check the authorization for the open. If MQC.MQOO_ALTERNATE_USER_AUTHORITY is not specified, *alternateUserId* can be left blank, or null.

```
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName);
public MQTopic AccessTopic( MQDestination destination, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);
public MQTopic AccessTopic(string topicName, string topicObject, int openAs,
int options);
public MQTopic AccessTopic(string topicName, string topicObject, int openAs,
int options, string alternateUserId);
public MQTopic AccessTopic(string topicName, string topicObject, int options,
string alternateUserId, string subscriptionName);
public MQTopic AccessTopic(string topicName, string topicObject, int options,
string alternateUserId, string subscriptionName, System.Collections.Hashtable
properties);
```

Access a topic on this queue manager.

MQTopic objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, *topicObject* points to an administrative topic object. The MQTopic constructor obtains a topic string from the topic object and combines it with *topicName* to create a topic name. Either or both *topicObject* or *topicName* can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in *topicObject*.

The topics that are associated with the MQTopic object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by *topicObject*. The second topic string is *topicString*. The resulting topic string associated with the MQTopic object can identify multiple topics by including wild cards.

Depending on whether the topic is opened for publishing or subscribing, you can use the `MQTopic.Put` methods to publish on topics, or `MQTopic.Get` methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an `MQTopic` object for subscription, without providing an `MQDestination` object, a managed subscription is assumed. If you pass a queue as an `MQDestination` object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

destination

destination is an `MQQueue` instance. By providing *destination*, `MQTopic` is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

topicName

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

topicObject

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

openAs

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- `MQC.MQTOPIC_OPEN_AS_SUBSCRIPTION`
- `MQC.MQTOPIC_OPEN_AS_PUBLICATION`

options

Combine the options that control the opening of the topic for either publication or subscription. Use `MQC.MQSO_*` constants to access a topic for subscription and `MQC.MQOO_*` constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

alternateUserId

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either `MQC.MQOO_ALTERNATE_USER_AUTHORITY` or `MQC.MQSO_ALTERNATE_USER_AUTHORITY` is set in the options parameter.

subscriptionName

subscriptionName is required if the options `MQC.MQSO_DURABLE` or `MQC.MQSO_ALTER` are provided. In both cases, `MQTopic` is implicitly opened for subscription. An exception is thrown if the `MQC.MQSO_DURABLE` is set, and the subscription exists, or if `MQC.MQSO_ALTER` is set, and the subscription does not exist.

properties

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- `MQC.MQSUB_PROP_ALTERNATE_SECURITY_ID`
- `MQC.MQSUB_PROP_SUBSCRIPTION_EXPIRY`
- `MQC.MQSUB_PROP_SUBSCRIPTION_USER_DATA`
- `MQC.MQSUB_PROP_SUBSCRIPTION_CORRELATION_ID`

- MQC.MQSUB_PROP_PUBLICATION_PRIORITY
- MQC.MQSUB_PROP_PUBLICATION_ACCOUNTING_TOKEN
- MQC.MQSUB_PROP_PUBLICATION_APPLICATIONID_DATA

public MQAsyncStatus GetAsyncStatus();

Throws MQException

Returns an MQAsyncStatus object, which represents the asynchronous activity for the queue manager connection.

public void Backout();

Throws MQException.

Backout any messages that were read or written within sync point since the last sync point.

Messages that were written with the MQC.MQPMO_SYNCPOINT flag set are removed from queues. Messages read with the MQC.MQGMO_SYNCPOINT flag are reinstated on the queues they came from. If the messages are persistent, the changes are logged.

For reconnectable clients, the MQRC_NONE reason code is returned to a client after reconnection is successful.

public void Begin();

Throws MQException.

Begin is supported only in server bindings mode. It starts a global unit of work.

public void Commit();

Throws MQException.

Commit any messages that were read or written within sync point since the last sync point.

Messages written with the MQC.MQPMO_SYNCPOINT flag set are made available to other applications. Messages retrieved with the MQC.MQGMO_SYNCPOINT flag set are deleted. If the messages are persistent, the changes are logged.

The following reason codes are returned to a reconnectable client:

- MQRC_CALL_INTERRUPTED if connection is lost while carrying out the commit call.
- MQRC_BACKED_OUT if the commit call is issued after reconnection.

Disconnect();

Throws MQException.

Close the connection to the queue manager. All objects accessed on this queue manager are not longer accessible to this application. To reaccess the objects, create a MQQueueManager object.

Generally, any work performed as part of a unit of work is committed. However, if the unit of work is managed by .NET, the unit of work might be rolled back.

```

public void Put(int type, string destinationName, MQMessage message);
public void Put(int type, string destinationName, MQMessage message
MQPutMessageOptions putMessageOptions);
public void Put(int type, string destinationName, string queueManagerName,
string topicString, MQMessage message);
public void Put(string queueName, MQMessage message);
public void Put(string queueName, MQMessage message, MQPutMessageOptions
putMessageOptions);
public void Put(string queueName, string queueManagerName, MQMessage message);
public void Put(string queueName, string queueManagerName, MQMessage message,
MQPutMessageOptions putMessageOptions);
public void Put(string queueName, string queueManagerName, MQMessage message,
MQPutMessageOptions putMessageOptions, string alternateUserId);

```

Throws MQException.

Places a single message onto a queue or topic without creating an MQQueue or MQTopic object first.

queueName

The name of the queue onto which to place the message.

destinationName

The name of a destination object. It is either a queue or a topic depending on the value of *type*.

type

The type of destination object. You must not combine the options.

MQC.MQOT_Q

Queue

MQC.MQOT_TOPIC

Topic

queueManagerName

The name of the queue manager or queue manager alias, on which the queue is defined. If type MQC.MQOT_TOPIC is specified this parameter is ignored.

If the queue is a model queue, and the resolved queue manager name is not this queue manager, an MQException is thrown.

topicString

topicString is combined with the topic name in the *destinationName* topic object.

topicString is ignored if *destinationName* is a queue.

message

The message to send. Message is an input/output object.

The following reason codes are returned to a reconnectable client:

- MQRC_CALL_INTERRUPTED if the connection is broken while performing a Put call on a persistent message.
- MQRC_NONE if the connection is successful while performing a Put call on a non-persistent message (see [Application Recovery](#)).

putMessageOptions

Options controlling the actions of the put.

If you omit *putMessageOptions*, a default instance of *putMessageOptions* is created. *putMessageOptions* is an input/output object.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

alternateUserId

Specifies an alternate user identifier used to check authorization when placing the message on a queue.

You can omit *alternateUserId* if you do not set `MQC.MQOO_ALTERNATE_USER_AUTHORITY` in *putMessageOptions*. If you set `MQC.MQOO_ALTERNATE_USER_AUTHORITY`, you must also set *alternateUserId*. *alternateUserId* has not effect unless you also set `MQC.MQOO_ALTERNATE_USER_AUTHORITY`.

Constructors

```
public MQQueueManager();  
public MQQueueManager(string queueManagerName);  
public MQQueueManager(string queueManagerName, Int options);  
public MQQueueManager(string queueManagerName, Int options, string channel,  
string connName);  
public MQQueueManager(string queueManagerName, string channel, string  
connName);  
public MQQueueManager(string queueManagerName, System.Collections.Hashtable  
properties);
```

Throws MQException.

Creates a connection to a queue manager. Select between creating a client connection or a server connection.

You must have inquire (inq) authority on the queue manager when attempting to connect to the queue manager. Without inquire authority, the connection attempt fails.

A client connection is created if one of the following conditions is true:

1. *channel* or *connName* are specified in the constructor.
2. *HostName*, *Port*, or *Channel* are specified in *properties*.
3. *MQEnvironment.HostName*, *MQEnvironment.Port*, or *MQEnvironment.Channel* are specified.

The values of the connection properties are defaulted in the order shown. The *channel* and *connName* in the constructor take precedence over the property values in the constructor. The constructor property values take precedence of the *MQEnvironment* properties.

The host name, channel name, and port are defined in the *MQEnvironment* class.

queueManagerName

Name of the queue manager, or queue manager group to connect to.

Omit the parameter, or leave it null, or blank to make a default queue manager selection. The default queue manager connection on a server is to the default queue manager on the server. The default queue manager connection on a client connection is to the queue manager the listener is connected to.

options

Specify MQCNO connection options. The values must be applicable to the type of connection being made. For example, if you specify the following server connection properties for a client connection an MQException is thrown.

- `MQC.MQCNO_FASTPATH_BINDING`
- `MQC.MQCNO_STANDARD_BINDING`

properties

The properties parameter takes a series of key/value pairs that override the properties set by *MQEnvironment*; see the example, [“Override MQEnvironment properties”](#) on page 1810. The following properties can be overridden:

- MQC.CONNECT_OPTIONS_PROPERTY
- MQC.CONNECTION_NAME_PROPERTY
- MQC.ENCRYPTION_POLICY_SUITE_B
- MQC.HOST_NAME_PROPERTY
- MQC.PORT_PROPERTY
- MQC.CHANNEL_PROPERTY
- MQC.SSL_CIPHER_SPEC_PROPERTY
- MQC.SSL_PEER_NAME_PROPERTY
- MQC.SSL_CERT_STORE_PROPERTY
- MQC.SSL_CRYPTOHARDWARE_PROPERTY
- MQC.SECURITY_EXIT_PROPERTY
- MQC.SECURITY_USERDATA_PROPERTY
- MQC.SEND_EXIT_PROPERTY
- MQC.SEND_USERDATA_PROPERTY
- MQC.RECEIVE_EXIT_PROPERTY
- MQC.RECEIVE_USERDATA_PROPERTY
- MQC.USER_ID_PROPERTY
- MQC.PASSWORD_PROPERTY
- MQC.MQAIR_ARRAY
- MQC.KEY_RESET_COUNT
- MQC.FIPS_REQUIRED
- MQC.HDR_CMP_LIST
- MQC.MSG_CMP_LIST
- MQC.TRANSPORT_PROPERTY

channel

Name of a server connection channel

connName

Connection name in the format *HostName (Port)* .

You can supply a list of *hostnames* and *ports* as an argument to the constructor `MQQueueManager (String queueManagerName, Hashtable properties)` using `CONNECTION_NAME_PROPERTY`.

For example:

```
ConnectionName = "fred.mq.com(2344),nick.mq.com(3746),tom.mq.com(4288)";
Hashtable Properties=new Hashtable();
properties.Add(MQC.CONNECTION_NAME_PROPERTY,ConnectionName);
MQQueueManager qmgr=new MQQueue Manager("qmgrname",properties);
```

When a connection attempt is made, the connection name list is processed in order. If the connection attempt to the first host name and port fails, then connection to the second pair of attributes is attempted. The client repeats this process until either a successful connection is made or the list is exhausted. If the list is exhausted, an appropriate reason code and completion code is returned to the client application.

When a port number is not provided for the connection name, the default port (configured in `mqclient.ini`) is used.

Set the Connection List

You can set the connection list by using the following methods when the automatic client reconnection options are set:

Set the connection list through MQSERVER

You can set the connection list through the command prompt.

At the command prompt, set the following command:

```
MQSERVER=SYSTEM.DEF.SVRCONN/TCP/Hostname1(Port1),Hostname2(Por2),Hostname3(Port3)
```

For example:

```
MQSERVER=SYSTEM.DEF.SVRCONN/TCP/fred.mq.com(5266),nick.mq.com(6566),jack.mq.com(8413)
```

If you set the connection in the MQSERVER, do not set it in the application.

If you set the connection list in the application, the application overwrites whatever is set in the MQSERVER environment variable.

Set the connection list through the application

You can set the connection list in the application by specifying the host name and port properties.

```
String connName = "fred.mq.com(2344), nick.mq.com(3746), chris.mq.com(4288)";  
MQQueueManager qm = new MQQueueManager("QM1", "TestChannel", connName);
```

Set the connection list through app.config

App.config is an XML file where you specify the key-value pairs.

In the connection list specify

```
<app.Settings>  
<add key="Connection1" value="Hostname1(Port1)"/>  
<add key="Connection2" value="Hostname2(Port2)"/>  
</app.Settings>
```

For example:

```
<app.Settings>  
<add key="Connection1" value="fred.mq.com(2966)"/>  
<add key="Connection2" value="alex.mq.com(6533)"/>  
</app.Settings>
```

You can directly change the connection list in the app.config file.

Set the connection list through MQEnvironment

To set the Connection list through the MQEnvironment, use the *ConnectionName* property.

```
MQEnvironment.ConnectionName = "fred.mq.com(4288),alex.mq.com(5211);
```

The *ConnectionName* property overwrites the host name and port properties set in the MQEnvironment.

Create a client connection

The following example shows you how to create a client connection to a queue manager. You can create a client connection by setting the MQEnvironment variables before creating a new MQQueueManager Object.

```

MQEnvironment.Hostname = "fred.mq.com"; // host to connect to
MQEnvironment.Port      = 1414;         // port to connect to
                                     // If not explicitly set,
                                     // defaults to 1414
                                     // (the default WebSphere MQ port)
MQEnvironment.Channel   = "channel.name"; // the case sensitive
                                     // name of the
                                     // SVR CONN channel on
                                     // the queue manager
MQQueueManager qMgr     = new MQQueueManager("MYQM");

```

Figure 43. Client connection

Override MQEnvironment properties

The following example shows you how to create a queue manager with its user ID and password defined in a hash table.

```

Hashtable properties = new Hashtable();
properties.Add( MQC.USER_ID_PROPERTY, "ExampleUserId" );
properties.Add( MQC.PASSWORD_PROPERTY, "ExamplePassword" );

try
{
    MQQueueManager qMgr = new MQQueueManager("qmgrname", properties);
}
catch (MQException mqe)
{
    System.Console.WriteLine("Connect failed with " + mqe.Message);
    return((int)mqe.Reason);
}

```

Figure 44. Overriding MQEnvironment properties

Create a reconnectable connection

The following example shows you how to automatically reconnect a client to a Queue Manager.

```

Hashtable properties = new Hashtable(); // The queue manager name and the
                                     // properties how it has to be connected

properties.Add(MQC.CONNECT_OPTIONS_PROPERTY, MQC.MQCNO_RECONNECT); // Options
                                     // through which reconnection happens

properties.Add(MQC.CONNECTION_NAME_PROPERTY, "fred.mq.com(4789),nick.mq.com(4790)"); // The list
                                     // of queue managers through which reconnection happens

MQ QueueManager qmgr = new MQQueueManager("qmgrname", properties);

```

Figure 45. Automatically reconnecting a client to a queue manager

MQSubscription.NET class

Use MQSubscription to request that retained publications are sent to the subscriber. MQSubscription is a property of an MQTopic object opened for subscription.

Class

```

System.Object
├── IBM.WMQ.MQBase
│   └── IBM.WMQ.MQBaseObject
│       └── IBM.WMQ.MQManagedObject
│           └── IBM.WMQ.MQSubscription

```

```
public class IBM.WMQ.MQSubscription extends IBM.WMQ.MQManagedObject;
```

- [“Properties” on page 1811](#)
- [“Methods” on page 1811](#)
- [“Constructors” on page 1811](#)

Properties

Access subscription properties using the `MQManagedObject` class; see [“Properties” on page 1771](#).

Methods

Access subscription Inquire, Set and Get methods using the `MQManagedObject` class; see [“Methods” on page 1771](#).

public int RequestPublicationUpdate(int options);

Throws `MQException`.

Request an updated publication for the current topic. If the queue manager has a retained publications for the topic, they are sent to the subscriber.

Before calling `RequestPublicationUpdate`, open a topic for subscription to obtain an `MQSubscription` object.

Typically, open the subscription with the `MQC.MQSO_PUBLICATIONS_ON_REQUEST` option. If no wildcards are present in the topic string, then only one publication is sent as a result of this call. If the topic string contains wildcards, many publications might be sent. The method returns the number of retained publications that are sent to the subscription queue. There is no guarantee that this many publications are received, especially if they are non-persistent messages.

options

MQC.MQSRO_FAIL_IF QUIESCING

The method fails if the queue manager is in a quiescent state. On z/OS, for a CICS or IMS application, `MQC.MQSRO_FAIL_IF QUIESCING` also forces the method to fail if the connection is in a quiescent state.

MQC.MQSRO_NONE

No options are specified.

Constructors

No Public constructor.

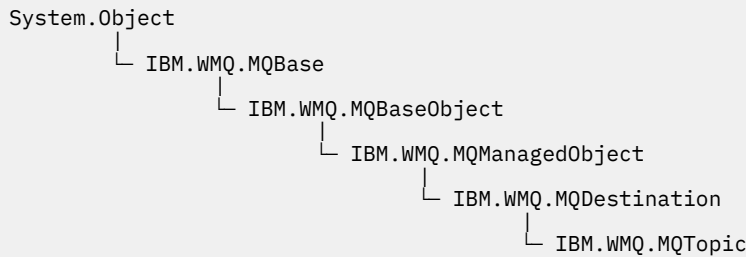

An `MQSubscription` object is returned in the `SubscriptionReference` property of an `MQTopic` object that is opened for subscription,

Call the `RequestPublicationUpdate` method. `MQSubscription` is a subclass of `MQManagedObject`. Use the reference to access the properties and methods of `MQManagedObject`.

MQTopic.NET class

Use `MQTopic` to publish or subscribe messages on a topic, or to query or set attributes of a topic. Create an `MQTopic` object for publishing or subscribing by using a constructor or the `MQQueueManager.AccessTopic` method.

Class

```
public class IBM.WMQ.MQTopic extends IBM.WMQ.MQDestination;
```

- [“Properties” on page 1812](#)
- [“Methods” on page 1812](#)
- [“Constructors” on page 1814](#)

Properties

Test for `MQException` being thrown when getting properties.

public Boolean IsDurable {get;}

Read only property that returns `True` if the subscription is durable or `False` otherwise. If the topic was opened for publication, the property is ignored and would always return `False`.

public Boolean IsManaged {get;};

Read only property that returns `True` if the subscription is managed by the queue manager, or `False` otherwise. If the topic was opened for publication, the property is ignored and would always return `False`.

public Boolean IsSubscribed {get;};

Read only property that returns `True` if the topic was opened for subscription and `False` if the topic was opened for publication.

public MQSubscription SubscriptionReference {get;};

Read only property that returns the `MQSubscription` object associated with a topic object opened for subscription. The reference is available if you want to modify the close options or start any of the objects methods.

public MQDestination UnmanagedDestinationReference {get;};

Read only property that returns the `MQQueue` associated with an unmanaged subscription. It is the destination specified when the topic object was created. The property returns null for any topic objects opened for publication or with a managed subscription.

Methods

public void Put(MQMessage message);

public void Put(MQMessage message, MQPutMessageOptions putMessageOptions);

Throws `MQException`.

Publishes a message to the topic.

Modifications to the `MQMessage` object after the `Put` call has been accomplished do not affect the actual message on the IBM MQ queue or publication topic.

`Put` updates the `MessageId` and `CorrelationId` properties of the `MQMessage` object and does not clear message data. Further `Put` or `Get` calls refer to the updated information in the `MQMessage` object. For example, in the following code snippet, the first message contains a and the second ab.

```
msg.WriteString("a");
q.Put(msg,pmo);
msg.WriteString("b");
q.Put(msg,pmo);
```

message

An MQMessage object containing the message descriptor data, and message to be sent. The message descriptor can be altered as a consequence of this method. The values in the message descriptor immediately after the completion of this method are the values that were put to the queue or published to the topic.

The following reason codes are returned to a reconnectable client:

- MQRC_CALL_INTERRUPTED if the connection is broken while running a Put call on a persistent message and the reconnection is successful.
- MQRC_NONE if the connection is successful while running a Put call on a non-persistent message (see [Application Recovery](#)).

putMessageOptions

Options controlling the action of the put.

If *putMessageOptions* is not specified the default instance of MQPutMessageOptions is used.

If you use the MQPMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

Note: For simplicity and performance, if you want to put a single message to a queue, use MQQueueManager.Put object. You should have an MQQueue object for this.

```
public void Get(MQMessage message);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions);  
public void Get(MQMessage message, MQGetMessageOptions getMessageOptions, int  
MaxMsgSize);
```

Throws MQException.

Retrieves a message from the topic.

This method uses a default instance of MQGetMessageOptions to do the get. The message option used is MQGMO_NOWAIT.

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor and message data portions of the MQMessage are replaced with the message descriptor and message data from the incoming message.

All calls to IBM MQ from a particular MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further IBM MQ calls until the Get call is accomplished. If you need multiple threads to access IBM MQ simultaneously, each thread must create its own MQQueueManager object.

message

Contains the message descriptor and the returned message data. Some of the fields in the message descriptor are input parameters. It is important to ensure that the MessageId and CorrelationId input parameters are set as required.

A reconnectable client returns the reason code MQRC_BACKED_OUT after successful reconnection, for messages received under MQGM_SYNCPOINT.

getMessageOptions

Options controlling the action of the get.

Using option MQC.MQGMO_CONVERT might result in an exception with reason code MQC.MQRC_CONVERTED_STRING_TOO_BIG when converting from single-byte character codes to double byte codes. In this case, the message is copied into the buffer without conversion.

If *getMessageOptions* is not specified, the message option used is MQGMO_NOWAIT.

If you use the MQGMO_LOGICAL_ORDER option in a reconnectable client, the MQRC_RECONNECT_INCOMPATIBLE reason code is returned.

MaxMsgSize

The largest message this message object is to receive. If the message on the queue is larger than this size, one of two things occurs:

- If the MQGMO_ACCEPT_TRUNCATED_MSG flag is set in the MQGetMessageOptions object, the message is filled with as much of the message data as possible. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_ACCEPTED reason code.
- If the MQGMO_ACCEPT_TRUNCATED_MSG flag is not set, the message remains on the queue. An exception is thrown with the MQCC_WARNING completion code and MQRC_TRUNCATED_MSG_FAILED reason code.

If *MaxMsgSize* is not specified, the whole message is retrieved.

Constructors

```
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName);
public MQTopic(MQQueueManager queueManager, MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName, System.Collections.Hashtable properties);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int openAs, int options);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int openAs, int options, string alternateUserId);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName);
public MQTopic(MQQueueManager queueManager, string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);
```

Access a topic on *queueManager*.

MQTopic objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, *topicObject* points to an administrative topic object. The MQTopic constructor obtains a topic string from the topic object and combines it with *topicName* to create a topic name. Either or both *topicObject* or *topicName* can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in *topicObject*.

The topics that are associated with the MQTopic object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by *topicObject*. The second topic string is *topicString*. The resulting topic string associated with the MQTopic object can identify multiple topics by including wild cards.

Depending on whether the topic is opened for publishing or subscribing, you can use the MQTopic.Put methods to publish on topics, or MQTopic.Get methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an MQTopic object for subscription, without providing an MQDestination object, a managed subscription is assumed. If you pass a queue as an MQDestination object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

queueManager

Queue manager to access a topic on.

destination

destination is an MQQueue instance. By providing *destination*, MQTopic is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

topicName

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

topicObject

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

openAs

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- MQC.MQTOPIC_OPEN_AS_SUBSCRIPTION
- MQC.MQTOPIC_OPEN_AS_PUBLICATION

options

Combine the options that control the opening of the topic for either publication or subscription. Use MQC.MQSO_* constants to access a topic for subscription and MQC.MQOO_* constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

alternateUserId

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either MQC.MQOO_ALTERNATE_USER_AUTHORITY or MQC.MQSO_ALTERNATE_USER_AUTHORITY is set in the options parameter.

subscriptionName

subscriptionName is required if the options MQC.MQSO_DURABLE or MQC.MQSO_ALTER are provided. In both cases, MQTopic is implicitly opened for subscription. An exception is thrown if the MQC.MQSO_DURABLE is set, and the subscription exists, or if MQC.MQSO_ALTER is set, and the subscription does not exist.

properties

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- MQC.MQSUB_PROP_ALTERNATE_SECURITY_ID
- MQC.MQSUB_PROP_SUBSCRIPTION_EXPIRY
- MQC.MQSUB_PROP_SUBSCRIPTION_USER_DATA
- MQC.MQSUB_PROP_SUBSCRIPTION_CORRELATION_ID
- MQC.MQSUB_PROP_PUBLICATION_PRIORITY
- MQC.MQSUB_PROP_PUBLICATION_ACCOUNTING_TOKEN
- MQC.MQSUB_PROP_PUBLICATION_APPLICATIONID_DATA

```

public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName);
public MQTopic MQQueueManager.AccessTopic(MQDestination destination, string
topicName, string topicObject, int options, string alternateUserId, string
subscriptionName, System.Collections.Hashtable properties);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int openAs, int options);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int openAs, int options, string alternateUserId);
public MQTopic MQQueueManager.AccessTopic(string topicName, string topicObject,
int options, string alternateUserId, string subscriptionName);
public MQTopic MQQueueManager.AccessTopic(string topicName, string
topicObject, int options, string alternateUserId, string subscriptionName,
System.Collections.Hashtable properties);

```

Access a topic on this queue manager.

MQTopic objects are closely related to administrative topic objects, which are sometimes called topic objects. On input, *topicObject* points to an administrative topic object. The MQTopic constructor obtains a topic string from the topic object and combines it with *topicName* to create a topic name. Either or both *topicObject* or *topicName* can be null. The topic name is matched to the topic tree, and the name of the closest matching administrative topic object is returned in *topicObject*.

The topics that are associated with the MQTopic object are the result of combining two topic strings. The first topic string is defined by the administrative topic object identified by *topicObject*. The second topic string is *topicString*. The resulting topic string associated with the MQTopic object can identify multiple topics by including wild cards.

Depending on whether the topic is opened for publishing or subscribing, you can use the MQTopic .Put methods to publish on topics, or MQTopic .Get methods to receive publications on topics. If you want to publish and subscribe to the same topic, you must access the topic twice, once for publish and once for subscribe.

If you create an MQTopic object for subscription, without providing an MQDestination object, a managed subscription is assumed. If you pass a queue as an MQDestination object, an unmanaged subscription is assumed. You must ensure the subscription options you set are consistent with the subscription being managed or unmanaged.

destination

destination is an MQQueue instance. By providing *destination*, MQTopic is opened as an unmanaged subscription. Publications on the topic are delivered to the queue accessed as *destination*.

topicName

A topic string that is the second part of the topic name. *topicName* is concatenated with the topic string defined in the *topicObject* administrative topic object. You can set *topicName* to null, in which case the topic name is defined by the topic string in *topicObject*.

topicObject

On input, *topicObject* is the name of the topic object that contains the topic string that forms the first part of the topic name. The topic string in *topicObject* is concatenated with *topicName*. The rules for constructing topic strings are defined in [Combining topic strings](#).

On output, *topicObject* contains the name of the administrative topic object that is the closest match in the topic tree to the topic identified by the topic string.

openAs

Access the topic to publish or subscribe. The parameter can contain only one of these options:

- MQC.MQTOPIC_OPEN_AS_SUBSCRIPTION
- MQC.MQTOPIC_OPEN_AS_PUBLICATION

options

Combine the options that control the opening of the topic for either publication or subscription. Use MQC.MQSO_* constants to access a topic for subscription and MQC.MQOO_* constants to access a topic for publication.

If more than one option is required, add the values together, or combine the option values using the bitwise OR operator.

alternateUserId

Specify the alternate user ID that is used to check for the required authorization to finish the operation. You must specify *alternateUserId*, if either MQC.MQOO_ALTERNATE_USER_AUTHORITY or MQC.MQSO_ALTERNATE_USER_AUTHORITY is set in the options parameter.

subscriptionName

subscriptionName is required if the options MQC.MQSO_DURABLE or MQC.MQSO_ALTER are provided. In both cases, MQTopic is implicitly opened for subscription. An exception is thrown if the MQC.MQSO_DURABLE is set, and the subscription exists, or if MQC.MQSO_ALTER is set, and the subscription does not exist.

properties

Set any of the special subscription properties listed using a hash table. Specified entries in the hash table are updated with output values. Entries are not added to the hash table to report output values.

- MQC.MQSUB_PROP_ALTERNATE_SECURITY_ID
- MQC.MQSUB_PROP_SUBSCRIPTION_EXPIRY
- MQC.MQSUB_PROP_SUBSCRIPTION_USER_DATA
- MQC.MQSUB_PROP_SUBSCRIPTION_CORRELATION_ID
- MQC.MQSUB_PROP_PUBLICATION_PRIORITY
- MQC.MQSUB_PROP_PUBLICATION_ACCOUNTING_TOKEN
- MQC.MQSUB_PROP_PUBLICATION_APPLICATIONID_DATA

IMQObjectTrigger.NET interface

Implement IMQObjectTrigger to process messages passed by the **runmqdmn**.NET monitor.

Interface

```
public interface IBM.WMQMonitor.IMQObjectTrigger();
```

Depending on whether sync point control is specified in the **runmqdmn** command the message is removed from the queue before or after the Execute method returns.

Methods

void Execute (MQQueueManager *queueManager*, MQQueue *queue*, MQMessage *message*, string *param*);

queueManager

Queue manager hosting the queue being monitored.

queue

Queue being monitored.

message

Message read from the queue.

param

Data passed from UserParameter.

MQC.NET interface

Refer to an MQI constant by prefixing the constant name with MQC.. MQC defines all the constants used by the MQI.

Interface

```
System.Object
└─ IBM.WMQ.MQC
```

```
public interface IBM.WMQ.MQC extends System.Object;
```

Example

```
MQQueue queue;  
queue.closeOptions = MQC.MQCO_DELETE;
```

Character set identifiers for .NET applications

Descriptions of the character sets you can select to encode .NET IBM MQ messages

Character set	Description
37	ibm037
437	ibm437 / PC Original

IBM MQ C++ classes

The IBM MQ C++ classes encapsulate the IBM MQ Message Queue Interface (MQI). There is a single C++ header file, **imqi.hpp**, which covers all of these classes.

For each class, the following information is shown:

Class hierarchy diagram

A class diagram showing the class in its inheritance relation to its immediate parent classes, if any.

Other relevant classes

Document links to other relevant classes, such as parent classes, and the classes of objects used in method signatures.

Object attributes

Attributes of the class. These are in addition to those attributes defined for any parent classes. Many attributes reflect IBM MQ data-structure members (see [“C++ and MQI cross-reference”](#) on page 1822). For detailed descriptions, see [“Attributes of objects”](#) on page 768.

Constructors

Signatures of the special methods used to create an object of the class.

Object methods (public)

Signatures of methods that require an instance of the class for their operation, and that have no usage restrictions.

Where it applies, the following information is also shown:

Class methods (public)

Signatures of methods that do not require an instance of the class for their operation, and that have no usage restrictions.

Overloaded (parent class) methods

Signatures of those virtual methods that are defined in parent classes, but exhibit different, polymorphic, behavior for this class.

Object methods (protected)

Signatures of methods that require an instance of the class for their operation, and are reserved for use by the implementations of derived classes. This section is of interest only to class writers, as opposed to class users.

Object data (protected)

Implementation details for object instance data available to the implementations of derived classes. This section is of interest only to class writers, as opposed to class users.

Reason codes

MQRC_* values (see [API completion and reason codes](#)) that can be expected from those methods that fail. For an exhaustive list of reason codes that can occur for an object of a class, consult the parent class documentation. The documented list of reason codes for a class does not include the reason codes for parent classes.

Note:

1. Objects of these classes are not thread-safe. This ensures optimal performance, but take care not to access any object from more than one thread.
2. It is recommended that, for a multithreaded program, a separate ImqQueueManager object is used for each thread. Each manager object must have its own independent collection of other objects, ensuring that objects in different threads are isolated from one another.

The classes are:

- [“ImqAuthenticationRecord C++ class”](#) on page 1837
- [“ImqBinary C++ class”](#) on page 1839
- [“ImqCache C++ class”](#) on page 1841

C++ and MQI cross-reference

This collection of topics contains information relating C++ to the MQI.

Read this information together with [“Data types used in the MQI” on page 231](#).

This table relates MQI data structures to the C++ classes and include files. The following topics show cross-reference information for each C++ class. These cross-references relate to the use of the underlying IBM MQ procedural interfaces. The classes ImqBinary, ImqDistributionList, and ImqString have no attributes that fall into this category and are excluded.

<i>Table 672. Data structure, class, and include-file cross reference</i>		
Data structure	Class	Include file
MQAIR	ImqAuthenticationRecord	imqair.hpp
	ImqBinary	imqbin.hpp
	ImqCache	imqcac.hpp
MQCD	ImqChannel	imqchl.hpp
MQCIH	ImqCICSBridgeHeader	imqcih.hpp
MQDLH	ImqDeadLetterHeader	imqdlh.hpp
MQOR	ImqDistributionList	imqdst.hpp
	ImqError	imqerr.hpp
MQGMO	ImqGetMessageOptions	imqgmo.hpp
	ImqHeader	imqhdr.hpp
MQIIH	ImqIMSBridgeHeader	imqiih.hpp
	ImqItem	imqitm.hpp
MQMD	ImqMessage	imqmsg.hpp
	ImqMessageTracker	imqmtr.hpp
	ImqNamelist	imqnml.hpp
MQOD, MQRR	ImqObject	imqobj.hpp
MQPMO, MQPMR, MQRR	ImqPutMessageOptions	imqpmo.hpp

Table 672. Data structure, class, and include-file cross reference (continued)

Data structure	Class	Include file
	ImqProcess	imqpro.hpp
	ImqQueue	imqqueue.hpp
MQBO, MQCNO, MQCSP	ImqQueueManager	imqmgr.hpp
MQRMH	ImqReferenceHeader	imqrfh.hpp
	ImqString	imqstr.hpp
MQTM	ImqTrigger	imqtrg.hpp
MQTMC		
MQTMC2	ImqTrigger	imqtrg.hpp
MQXQH		
MQWIH	ImqWorkHeader	imqwih.hpp

ImqAuthenticationRecord cross-reference

Cross-reference of attributes, data structures, fields, and calls for the ImqAuthenticationRecord C++ class.

Attribute	Data structure	Field	Call
connection name	MQAIR	AuthInfoConnName	MQCONN
password	MQAIR	LDAPPassword	MQCONN
type	MQAIR	AuthInfoType	MQCONN
user name	MQAIR	LDAPUserNamePtr	MQCONN
	MQAIR	LDAPUserNameOffset	MQCONN
	MQAIR	LDAPUserNameLength	MQCONN

ImqCache cross-reference

Cross-reference of attributes and calls for the ImqCache C++ class.

Attribute	Call
automatic buffer	MQGET
buffer length	MQGET
buffer pointer	MQGET, MQPUT
data length	MQGET
data offset	MQGET
data pointer	MQGET
message length	MQGET, MQPUT

ImqChannel cross-reference

Cross-reference of attributes, data structures, fields, and calls for the ImqChannel C++ class.

Attribute	Data structure	Field	Call
batch heart-beat	MQCD	BatchHeartbeat	MQCONN
channel name	MQCD	ChannelName	MQCONN
connection name	MQCD	ConnectionName	MQCONN
	MQCD	ShortConnectionName	MQCONN
header compression	MQCD	HdrCompList	MQCONN
heart-beat interval	MQCD	HeartbeatInterval	MQCONN
keep alive interval	MQCD	KeepAliveInterval	MQCONN
local address	MQCD	LocalAddress	MQCONN
maximum message length	MQCD	MaxMsgLength	MQCONN
message compression	MQCD	MsgCompList	MQCONN
mode name	MQCD	ModeName	MQCONN
password	MQCD	Password	MQCONN
receive exit count	MQCD		MQCONN
receive exit names	MQCD	ReceiveExit	MQCONN
	MQCD	ReceiveExitsDefined	MQCONN
	MQCD	ReceiveExitPtr	MQCONN
receive user data	MQCD	ReceiveUserData	MQCONN
	MQCD	ReceiveUserDataPtr	MQCONN
security exit name	MQCD	SecurityExit	MQCONN
security user data	MQCD	SecurityUserData	MQCONN
send exit count	MQCD		MQCONN
send exit names	MQCD	SendExit	MQCONN
	MQCD	SendExitsDefined	MQCONN
	MQCD	SendExitPtr	MQCONN
send user data	MQCD	SendUserData	MQCONN
	MQCD	SendUserDataPtr	MQCONN
SSL CipherSpec	MQCD	sslCipherSpecification	MQCONN
SSL client authentication type	MQCD	sslClientAuthentication	MQCONN
SSL peer name	MQCD	sslPeerName	MQCONN
transaction program name	MQCD	TpName	MQCONN
transport type	MQCD	TransportType	MQCONN
user id	MQCD	UserIdentifier	MQCONN

ImqCICSBridgeHeader cross-reference

Cross-reference of attributes, data structures, and fields for the ImqCICSBridgeHeader C++ class.

Attribute	Data structure	Field
bridge abend code	MQCIH	AbendCode
ADS descriptor	MQCIH	AdsDescriptor
attention identifier	MQCIH	AttentionId
authenticator	MQCIH	Authenticator
bridge completion code	MQCIH	BridgeCompletionCode
bridge error offset	MQCIH	ErrorOffset
bridge reason code	MQCIH	BridgeReason
bridge cancel code	MQCIH	CancelCode
conversational task	MQCIH	ConversationalTask
cursor position	MQCIH	CursorPosition
facility token	MQCIH	Facility
facility keep time	MQCIH	FacilityKeepTime
facility like	MQCIH	FacilityLike
function	MQCIH	Function
get wait interval	MQCIH	GetWaitInterval
link type	MQCIH	LinkType
next transaction identifier	MQCIH	NextTransactionId
output data length	MQCIH	OutputDataLength
reply-to format	MQCIH	ReplyToFormat
bridge return code	MQCIH	ReturnCode
start code	MQCIH	StartCode
task end status	MQCIH	TaskEndStatus
transaction identifier	MQCIH	TransactionId
uow control	MQCIH	UowControl
version	MQCIH	Version

ImqDeadLetterHeader cross reference

Cross-reference of attributes, data structures, and fields for the ImqDeadLetterHeader C++ class.

Attribute	Data structure	Field
dead-letter reason code	MQDLH	Reason
destination queue manager name	MQDLH	DestQMgrName
destination queue name	MQDLH	DestQName
put application name	MQDLH	PutApplName
put application type	MQDLH	PutApplType

Attribute	Data structure	Field
put date	MQDLH	PutDate
put time	MQDLH	PutTime

ImqError cross reference

Cross-reference of attributes and calls for the ImqError C++ class.

Attribute	Call
completion code	MQBACK, MQBEGIN, MQCLOSE, MQCMIT, MQCONN, MQCONNX, MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQSET
reason code	MQBACK, MQBEGIN, MQCLOSE, MQCMIT, MQCONN, MQCONNX, MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQSET

ImqGetMessageOptions cross reference

Cross-reference of attributes, data structures, and fields for the ImqGetMessageOptions C++ class.

Attribute	Data structure	Field
group status	MQGMO	GroupStatus
match options	MQGMO	MatchOptions
message token	MQGMO	MessageToken
options	MQGMO	Options
resolved queue name	MQGMO	ResolvedQName
returned length	MQGMO	ReturnedLength

Cross-reference of attributes, data structures, and fields for the ImqAuthenticationRecord C++ class.

Attribute	Data structure	Field
message token	MQWIIH	MessageToken
service name	MQWIIH	ServiceName
service step	MQWIIH	ServiceStep

ImqAuthenticationRecord C++ class

This class encapsulates an authentication information record (MQAIR) for use during execution of the `ImqQueueManager::connect` method, for custom SSL client connections.

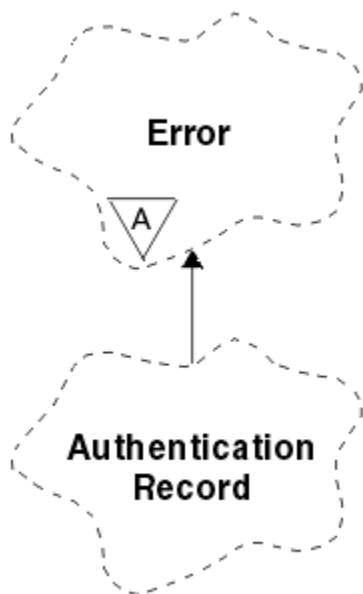

Figure 46. `ImqAuthenticationRecord` class

See the description of the `ImqQueueManager::connect` method for more details. This class is not available on the z/OS platform.

- [“Object attributes” on page 1837](#)
- [“Constructors” on page 1838](#)
- [“Object methods \(public\)” on page 1838](#)
- [“Object methods \(protected\)” on page 1838](#)

Object attributes

connection name

The name of the connection to the LDAP CRL server. This is the IP address or DNS name, followed optionally by the port number, in parentheses.

connection reference

A reference to an `ImqQueueManager` object that provides the required connection to a (local) queue manager. The initial value is zero. Do not confuse this with the queue manager name that identifies a queue manager (possibly remote) for a named queue.

next authentication record

Next object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

password

A password supplied for connection authentication to the LDAP CRL server.

previous authentication record

Previous object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

type

The type of authentication information contained in the record.

user name

A user identifier supplied for authorization to the LDAP CRL server.

Constructors

ImqAuthenticationRecord();

The default constructor.

Object methods (public)

void operator = (const ImqAuthenticationRecord & *air*);

Copies instance data from *air*, replacing the existing instance data.

const ImqString & connectionName () const ;

Returns the **connection name**.

void setConnectionName (const ImqString & *name*);

Sets the **connection name**.

void setConnectionName (const char * *name* = 0);

Sets the **connection name**.

ImqQueueManager * connectionReference () const ;

Returns the **connection reference**.

void setConnectionReference (ImqQueueManager & *manager*);

Sets the **connection reference**.

void setConnectionReference (ImqQueueManager * *manager* = 0);

Sets the **connection reference**.

void copyOut (MQAIR * *pAir*);

Copies instance data to *pAir*, replacing the existing instance data. This might involve allocating dependent storage.

void clear (MQAIR * *pAir*);

Clears the structure and releases dependent storage referenced by *pAir*.

ImqAuthenticationRecord * nextAuthenticationRecord () const ;

Returns the **next authentication record**.

const ImqString & password () const ;

Returns the **password**.

void setPassword (const ImqString & *password*);

Sets the **password**.

void setPassword (const char * *password* = 0);

Sets the **password**.

ImqAuthenticationRecord * previousAuthenticationRecord () const ;

Returns the **previous authentication record**.

MQLONG type () const ;

Returns the **type**.

void setType (const MQLONG *type*);

Sets the **type**.

const ImqString & userName () const ;

Returns the **user name**.

void setUsername (const ImqString & *name*);

Sets the **user name**.

void setUsername (const char * *name* = 0);

Sets the **user name**.

Object methods (protected)

void setNextAuthenticationRecord (ImqAuthenticationRecord * *pAir* = 0);

Sets the **next authentication record**.

Attention: Use this function only if you are sure that it will not break the authentication record list.

void setPreviousAuthenticationRecord (ImqAuthenticationRecord * pAir = 0);

Sets the **previous authentication record**.

Attention: Use this function only if you are sure that it will not break the authentication record list.

ImqBinary C++ class

This class encapsulates a binary byte array that can be used for ImqMessage **accounting token**, **correlation id**, and **message id** values. It allows easy assignment, copying, and comparison.

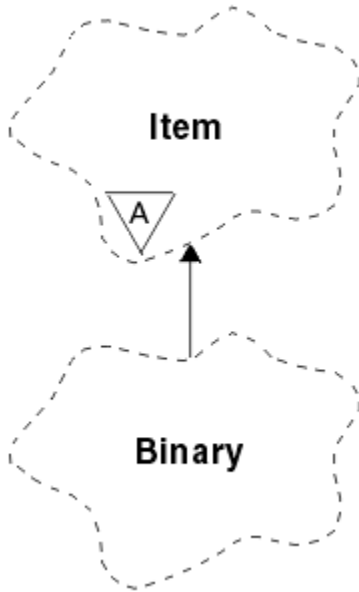

Figure 47. ImqBinary class

- [“Object attributes” on page 1839](#)
- [“Constructors” on page 1839](#)
- [“Overloaded ImqItem methods” on page 1840](#)
- [“Object methods \(public\)” on page 1840](#)
- [“Object methods \(protected\)” on page 1840](#)
- [“Reason codes” on page 1840](#)

Object attributes

data

An array of bytes of binary data. The initial value is null.

data length

The number of bytes. The initial value is zero.

data pointer

The address of the first byte of the **data**. The initial value is zero.

Constructors

ImqBinary();

The default constructor.

ImqBinary(const ImqBinary & binary);

The copy constructor.

ImqBinary(const void * data, const size_t length);

Copies *length* bytes from *data*.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & msg);

Copies the **data** to the message buffer, replacing any existing content. Sets the *msg format* to MQFMT_NONE.

See the ImqItem class method description for further details.

virtual ImqBoolean pasteIn (ImqMessage & msg);

Sets the **data** by transferring the remaining data from the message buffer, replacing the existing **data**.

To be successful, the ImqMessage **format** must be MQFMT_NONE.

See the ImqItem class method description for further details.

Object methods (public)

void operator = (const ImqBinary & binary);

Copies bytes from *binary*.

ImqBoolean operator == (const ImqBinary & binary);

Compares this object with *binary*. It returns FALSE if not equal and TRUE otherwise. The objects are equal if they have the same **data length** and the bytes match.

ImqBoolean copyOut (void * buffer, const size_t length, const char pad = 0);

Copies up to *length* bytes from the **data pointer** to *buffer*. If the **data length** is insufficient, the remaining space in *buffer* is filled with *pad* bytes. *buffer* can be zero if *length* is also zero. *length* must not be negative. It returns TRUE if successful.

size_t dataLength () const ;

Returns the **data length**.

ImqBoolean setDataLength (const size_t length);

Sets the **data length**. If the **data length** is changed as a result of this method, the data in the object is uninitialized. It returns TRUE if successful.

void * dataPointer () const ;

Returns the **data pointer**.

ImqBoolean isNull () const ;

Returns TRUE if the **data length** is zero, or if all the **data** bytes are zero. Otherwise it returns FALSE.

ImqBoolean set (const void * buffer, const size_t length);

Copies *length* bytes from *buffer*. It returns TRUE if successful.

Object methods (protected)

void clear ();

Reduces the **data length** to zero.

Reason codes

- MQRC_NO_BUFFER
- MQRC_STORAGE_NOT_AVAILABLE
- MQRC_INCONSISTENT_FORMAT

ImqCache C++ class

Use this class to hold or marshal data in memory.

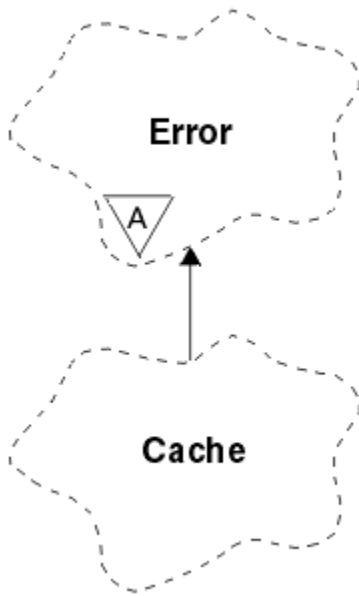

Figure 48. ImqCache class

Use this class to hold or marshal data in memory. You can nominate a buffer of memory of fixed size, or the system can provide a flexible amount of memory automatically. This class relates to the MQI calls listed in [“ImqCache cross-reference” on page 1823](#).

- [“Object attributes” on page 1841](#)
- [“Constructors” on page 1842](#)
- [“Object methods \(public\)” on page 1842](#)
- [“Reason codes” on page 1843](#)

Object attributes

automatic buffer

Indicates whether buffer memory is managed automatically by the system (TRUE) or is supplied by the user (FALSE). It is initially set to TRUE.

This attribute is not set directly. It is set indirectly using either the **useEmptyBuffer** or the **useFullBuffer** method.

If user storage is supplied, this attribute is FALSE, buffer memory cannot grow, and buffer overflow errors can occur. The address and length of the buffer remain constant.

If user storage is not supplied, this attribute is TRUE, and buffer memory can grow incrementally to accommodate an arbitrary amount of message data. However, when the buffer grows, the address of the buffer might change, so be careful when using the **buffer pointer** and **data pointer**.

buffer length

The number of bytes of memory in the buffer. The initial value is zero.

buffer pointer

The address of the buffer memory. The initial value is null.

data length

The number of bytes succeeding the **data pointer**. This must be equal to or less than the **message length**. The initial value is zero.

data offset

The number of bytes preceding the **data pointer**. This must be equal to or less than the **message length**. The initial value is zero.

data pointer

The address of the part of the buffer that is to be written to or read from next. The initial value is null.

message length

The number of bytes of significant data in the buffer. The initial value is zero.

Constructors**ImqCache();**

The default constructor.

ImqCache(const ImqCache & cache);

The copy constructor.

Object methods (public)**void operator = (const ImqCache & cache);**

Copies up to **message length** bytes of data from the *cache* object to the object. If **automatic buffer** is FALSE, the **buffer length** must already be sufficient to accommodate the copied data.

ImqBoolean automaticBuffer () const ;

Returns the **automatic buffer** value.

size_t bufferLength () const ;

Returns the **buffer length**.

char * bufferPointer () const ;

Returns the **buffer pointer**.

void clearMessage ();

Sets the **message length** and **data offset** to zero.

size_t dataLength () const ;

Returns the **data length**.

size_t dataOffset () const ;

Returns the **data offset**.

ImqBoolean setDataOffset (const size_t offset);

Sets the **data offset**. The **message length** is increased if necessary to ensure that it is no less than the **data offset**. This method returns TRUE if successful.

char * dataPointer () const ;

Returns a copy of the **data pointer**.

size_t messageLength () const ;

Returns the **message length**.

ImqBoolean setMessageLength (const size_t length);

Sets the **message length**. Increases the **buffer length** if necessary to ensure that the **message length** is no greater than the **buffer length**. Reduces the **data offset** if necessary to ensure that it is no greater than the **message length**. It returns TRUE if successful.

ImqBoolean moreBytes (const size_t bytes-required);

Assures that *bytes-required* more bytes are available (for writing) between the **data pointer** and the end of the buffer. It returns TRUE if successful.

If **automatic buffer** is TRUE, more memory is acquired as required; otherwise, the **buffer length** must already be adequate.

ImqBoolean read (const size_t length, char * & external-buffer);

Copies *length* bytes, from the buffer starting at the **data pointer** position, into the *external-buffer*.

After the data has been copied, the **data offset** is increased by *length*. This method returns TRUE if successful.

ImqBoolean resizeBuffer (const size_t length);

Varies the **buffer length**, provided that **automatic buffer** is TRUE. This is achieved by reallocating the buffer memory. Up to **message length** bytes of data from the existing buffer are copied to the new one. The maximum number copied is *length* bytes. The **buffer pointer** is changed. The **message length** and **data offset** are preserved as closely as possible within the confines of the new buffer. It returns TRUE if successful, and FALSE if **automatic buffer** is FALSE.

Note: This method can fail with MQRC_STORAGE_NOT_AVAILABLE if there is any problem with system resources.

ImqBoolean useEmptyBuffer (const char * external-buffer, const size_t length);

Identifies an empty user buffer, setting the **buffer pointer** to point to *external-buffer*, the **buffer length** to *length*, and the **message length** to zero. Performs a **clearMessage**. If the buffer is fully primed with data, use the **useFullBuffer** method instead. If the buffer is partially primed with data, use the **setMessageLength** method to indicate the correct amount. This method returns TRUE if successful.

This method can be used to identify a fixed amount of memory, as described previously (*external-buffer* is not null and *length* is nonzero), in which case **automatic buffer** is set to FALSE, or it can be used to revert to system-managed flexible memory (*external-buffer* is null and *length* is zero), in which case **automatic buffer** is set to TRUE.

ImqBoolean useFullBuffer (const char * externalBuffer, const size_t length);

As for **useEmptyBuffer**, except that the **message length** is set to *length*. It returns TRUE if successful.

ImqBoolean write (const size_t length, const char * external-buffer);

Copies *length* bytes, from the *external-buffer*, into the buffer starting at the **data pointer** position. After the data has been copied, the **data offset** is increased by *length*, and the **message length** is increased if necessary to ensure that it is no less than the new **data offset** value. This method returns TRUE if successful.

If **automatic buffer** is TRUE, an adequate amount of memory is guaranteed; otherwise, the ultimate **data offset** must not exceed the **buffer length**.

ImqChannel C++ class

This class encapsulates a channel definition (MQCD) for use during execution of the `Manager::connect` method, for custom client connections.

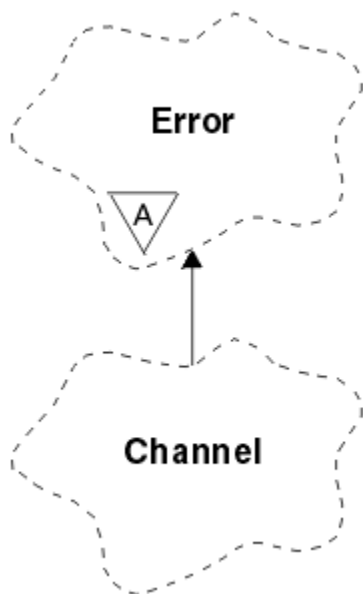

Figure 49. *ImqChannel* class

See the description of the `Manager::connect` method, and [Sample program HELLO WORLD \(imqwrlid.cpp\)](#), for more details.

Not all the listed methods are applicable to all platforms. See the descriptions of the [DEFINE CHANNEL](#) and [ALTER CHANNEL](#) commands for more information.

The `ImqChannel` class is not supported on z/OS.

- [“Object attributes” on page 1844](#)
- [“Constructors” on page 1845](#)
- [“Object methods \(public\)” on page 1846](#)
- [“Reason codes” on page 1849](#)

Object attributes

batch heart-beat

The number of milliseconds between checks that a remote channel is active. The initial value is 0.

channel name

The name of the channel. The initial value is null.

connection name

The name of the connection. For example, the IP address of a host computer. The initial value is null.

header compression

The list of header data compression techniques supported by the channel. The initial values are all set to `MQCOMPRESS_NOT_AVAILABLE`.

heart-beat interval

The number of seconds between checks that a connection is still working. The initial value is 300.

keep alive interval

The number of seconds passed to the communications stack specifying the keep alive timing for the channel. The initial value is `MQKAI_AUTO`.

local address

The local communications address for the channel.

maximum message length

The maximum length of message supported by the channel in a single communication. The initial value is 4 194 304.

message compression

The list of message data compression techniques supported by the channel. The initial values are all set to MQCOMPRESS_NOT_AVAILABLE.

mode name

The name of the mode. The initial value is null.

password

A password supplied for connection authentication. The initial value is null.

receive exit count

The number of receive exits. The initial value is zero. This attribute is read-only.

receive exit names

The names of receive exits.

receive user data

Data associated with receive exits.

security exit name

The name of a security exit to be invoked on the server side of the connection. The initial value is null.

security user data

Data to be passed to the security exit. The initial value is null.

send exit count

The number of send exits. The initial value is zero. This attribute is read-only.

send exit names

The names of send exits.

send user data

Data associated with send exits.

SSL CipherSpec

CipherSpec for use with SSL.

SSL client authentication type

Client authentication type for use with SSL.

SSL peer name

Peer name for use with SSL.

transaction program name

The name of the transaction program. The initial value is null.

transport type

The transport type of the connection. The initial value is MQXPT_LU62.

user id

A user identifier supplied for authorization. The initial value is null.

Constructors**ImqChannel() ;**

The default constructor.

ImqChannel(const ImqChannel & channel);

The copy constructor.

Object methods (public)

void operator = (const ImqChannel & *channel*);

Copies instance data from *channel*, replacing any existing instance data.

MQLONG batchHeartBeat() const ;

Returns the **batch heart-beat**.

ImqBoolean setBatchHeartBeat(const MQLONG *heartbeat* = 0L);

Sets the **batch heart-beat**. This method returns TRUE if successful.

ImqString channelName() const ;

Returns the **channel name**.

ImqBoolean setChannelName(const char * *name* = 0);

Sets the **channel name**. This method returns TRUE if successful.

ImqString connectionName() const ;

Returns the **connection name**.

ImqBoolean setConnectionName(const char * *name* = 0);

Sets the **connection name**. This method returns TRUE if successful.

size_t headerCompressionCount() const ;

Returns the supported header data compression techniques count.

ImqBoolean headerCompression(const size_t *count*, MQLONG *compress* []) const ;

Returns copies of the supported header data compression techniques in **compress**. This method returns TRUE if successful.

ImqBoolean setHeaderCompression(const size_t *count*, const MQLONG *compress* []);

Sets the supported header data compression techniques to **compress**.

Sets the supported header data compression techniques count to **count**.

This method returns TRUE if successful.

MQLONG heartBeatInterval() const ;

Returns the **heart-beat interval**.

ImqBoolean setHeartBeatInterval(const MQLONG *interval* = 300L);

Sets the **heart-beat interval**. This method returns TRUE if successful.

MQLONG keepAliveInterval() const ;

Returns the **keep alive interval**.

ImqBoolean setKeepAliveInterval(const MQLONG *interval* = MQKAI_AUTO);

Sets the **keep alive interval**. This method returns TRUE if successful.

ImqString localAddress() const ;

Returns the **local address**.

ImqBoolean setLocalAddress (const char * *address* = 0);

Sets the **local address**. This method returns TRUE if successful.

MQLONG maximumMessageLength() const ;

Returns the **maximum message length**.

ImqBoolean setMaximumMessageLength(const MQLONG *length* = 4194304L);

Sets the **maximum message length**. This method returns TRUE if successful.

size_t messageCompressionCount() const ;

Returns the supported message data compression techniques count.

ImqBoolean messageCompression(const size_t *count*, MQLONG *compress* []) const ;

Returns copies of the supported message data compression techniques in **compress**. This method returns TRUE if successful.

ImqBoolean setMessageCompression(const size_t *count*, const MQLONG *compress* []);

Sets the supported message data compression techniques to **compress**.

Sets the supported message data compression techniques count to **count**.

This method returns TRUE if successful.

ImqString modeName() const ;

Returns the **mode name**.

ImqBoolean setModeName(const char * *name* = 0);

Sets the **mode name**. This method returns TRUE if successful.

ImqString password() const ;

Returns the **password**.

ImqBoolean setPassword(const char * *password* = 0);

Sets the **password**. This method returns TRUE if successful.

size_t receiveExitCount() const ;

Returns the **receive exit count**.

ImqString receiveExitName();

Returns the first of the **receive exit names**, if any. If the **receive exit count** is zero, it returns an empty string.

ImqBoolean receiveExitNames(const size_t *count*, ImqString * *names* []);

Returns copies of the **receive exit names** in *names*. Sets any *names* in excess of **receive exit count** to null strings. This method returns TRUE if successful.

ImqBoolean setReceiveExitName(const char * *name* = 0);

Sets the **receive exit names** to the single *name*. *name* can be blank or null. Sets the **receive exit count** to either 1 or zero. Clears the **receive user data**. This method returns TRUE if successful.

ImqBoolean setReceiveExitNames(const size_t *count*, const char * *names* []);

Sets the **receive exit names** to *names*. Individual *names* values must not be blank or null. Sets the **receive exit count** to *count*. Clears the **receive user data**. This method returns TRUE if successful.

ImqBoolean setReceiveExitNames(const size_t *count*, const ImqString * *names* []);

Sets the **receive exit names** to *names*. Individual *names* values must not be blank or null. Sets the **receive exit count** to *count*. Clears the **receive user data**. This method returns TRUE if successful.

ImqString receiveUserData();

Returns the first of the **receive user data** items, if any. If the **receive exit count** is zero, returns an empty string.

ImqBoolean receiveUserData(const size_t *count*, ImqString * *data* []);

Returns copies of the **receive user data** items in *data*. Sets any *data* in excess of **receive exit count** to null strings. This method returns TRUE if successful.

ImqBoolean setReceiveUserData(const char * *data* = 0);

Sets the **receive user data** to the single item *data*. If *data* is not null, **receive exit count** must be at least 1. This method returns TRUE if successful.

ImqBoolean setReceiveUserData(const size_t *count*, const char * *data* []);

Sets the **receive user data** to *data*. *count* must be no greater than the **receive exit count**. This method returns TRUE if successful.

ImqBoolean setReceiveUserData(const size_t *count*, const ImqString * *data* []);

Sets the **receive user data** to *data*. *count* must be no greater than the **receive exit count**. This method returns TRUE if successful.

ImqString securityExitName() const ;

Returns the **security exit name**.

ImqBoolean setSecurityExitName(const char * *name* = 0);

Sets the **security exit name**. This method returns TRUE if successful.

ImqString securityUserData() const ;

Returns the **security user data**.

ImqBoolean setSecurityUserData(const char * *data* = 0);

Sets the **security user data**. This method returns TRUE if successful.

size_t sendExitCount() const ;

Returns the **send exit count**.

ImqString sendExitName();

Returns the first of the **send exit names**, if any. Returns an empty string if the **send exit count** is zero.

ImqBoolean sendExitNames(const size_t count, ImqString * names []);

Returns copies of the **send exit names** in *names*. Sets any *names* in excess of **send exit count** to null strings. This method returns TRUE if successful.

ImqBoolean setSendExitName(const char * name = 0);

Sets the **send exit names** to the single *name*. *name* can be blank or null. Sets the **send exit count** to either 1 or zero. Clears the **send user data**. This method returns TRUE if successful

ImqBoolean setSendExitNames(const size_t count, const char * names []);

Sets the **send exit names** to *names*. Individual *names* values must not be blank or null. Sets the **send exit count** to *count*. Clears the **send user data**. This method returns TRUE if successful.

ImqBoolean setSendExitNames(const size_t count, const ImqString * names []);

Sets the **send exit names** to *names*. Individual *names* values must not be blank or null. Sets the **send exit count** to *count*. Clears the **send user data**. This method returns TRUE if successful.

ImqString sendUserData();

Returns the first of the **send user data** items, if any. , Returns an empty string if the **send exit count** is zero.

ImqBoolean sendUserData(const size_t count, ImqString * data []);

Returns copies of the **send user data** items in *data*. Sets any *data* in excess of **send exit count** to null strings. This method returns TRUE if successful.

ImqBoolean setSendUserData(const char * data = 0);

Sets the **send user data** to the single item *data*. If *data* is not null, **send exit count** must be at least 1. This method returns TRUE if successful.

ImqBoolean setSendUserData(const size_t count, const char * data []);

Sets the **send user data** to *data*. *count* must be no greater than the **send exit count**. This method returns TRUE if successful.

ImqBoolean setSendUserData(const size_t count, const ImqString * data []);

Sets the **send user data** to *data*. *count* must be no greater than the **send exit count**. This method returns TRUE if successful.

ImqString sslCipherSpecification() const ;

Returns the SSL cipher specification.

ImqBoolean setSslCipherSpecification(const char * name = 0);

Sets the SSL cipher specification. This method returns TRUE if successful.

MQLONG sslClientAuthentication() const ;

Returns the SSL client authentication type.

ImqBoolean setSslClientAuthentication(const MQLONG auth = MQSCA_REQUIRED);

Sets the SSL client authentication type. This method returns TRUE if successful.

ImqString sslPeerName() const ;

Returns the SSL peer name.

ImqBoolean setSslPeerName(const char * name = 0);

Sets the SSL peer name. This method returns TRUE if successful.

ImqString transactionProgramName() const ;

Returns the **transaction program name**.

ImqBoolean setTransactionProgramName(const char * name = 0);

Sets the **transaction program name**. This method returns TRUE if successful.

MQLONG transportType() const ;

Returns the **transport type**.

ImqBoolean setTransportType(const MQLONG type = MQXPT_LU62);

Sets the **transport type**. This method returns TRUE if successful.

ImqString userId() const ;

Returns the **user id**.

ImqBoolean setId(const char * id = 0);

Sets the **user id**. This method returns TRUE if successful.

Reason codes

- MQRC_DATA_LENGTH_ERROR
- MQRC_ITEM_COUNT_ERROR
- MQRC_NULL_POINTER
- MQRC_SOURCE_BUFFER_ERROR

ImqCICSBridgeHeader C++ class

This class encapsulates specific features of the MQCIH data structure.

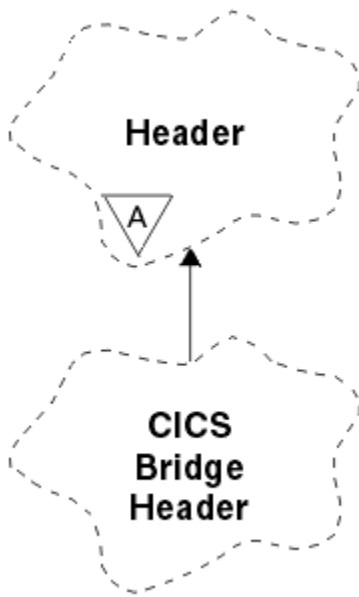

Figure 50. *ImqCICSBridgeHeader* class

Objects of this class are used by applications that send messages to the CICS bridge through IBM MQ for z/OS.

- [“Object attributes” on page 1849](#)
- [“Constructors” on page 1852](#)
- [“Overloaded ImqItem methods” on page 1852](#)
- [“Object methods \(public\)” on page 1852](#)
- [“Object data \(protected\)” on page 1854](#)
- [“Reason codes” on page 1854](#)
- [“Return codes” on page 1854](#)

Object attributes

ADS descriptor

Send/receive ADS descriptor. This is set using MQCADSD_NONE. The initial value is MQCADSD_NONE. The following additional values are possible:

- MQCADSD_NONE
- MQCADSD_SEND
- MQCADSD_RECV

- MQCADSD_MSGFORMAT

attention identifier

AID key. The field must be of length MQ_ATTENTION_ID_LENGTH.

authenticator

RACF password or passticket. The initial value contains blanks, of length MQ_AUTHENTICATOR_LENGTH.

bridge abend code

Bridge abend code, of length MQ_ABEND_CODE_LENGTH. The initial value is four blank characters. The value returned in this field is dependent on the return code. See [Table 676 on page 1854](#) for more details.

bridge cancel code

Bridge abend transaction code. The field is reserved, must contain blanks, and be of length MQ_CANCEL_CODE_LENGTH.

bridge completion code

Completion code, which can contain either the IBM MQ completion code or the CICS EIBRESP value. The field has the initial value of MQCC_OK. The value returned in this field is dependent on the return code. See [Table 676 on page 1854](#) for more details.

bridge error offset

Bridge error offset. The initial value is zero. This attribute is read-only.

bridge reason code

Reason code. This field can contain either the IBM MQ reason or the CICS EIBRESP2 value. The field has the initial value of MQRC_NONE. The value returned in this field is dependent on the return code. See [Table 676 on page 1854](#) for more details.

bridge return code

Return code from the CICS bridge. The initial value is MQCRC_OK.

conversational task

Whether the task can be conversational. The initial value is MQCCT_NO. The following additional values are possible:

- MQCCT_YES
- MQCCT_NO

cursor position

Cursor position. The initial value is zero.

facility keep time

CICS bridge facility release time.

facility like

Terminal emulated attribute. The field must be of length MQ_FACILITY_LIKE_LENGTH.

facility token

BVT token value. The field must be of length MQ_FACILITY_LENGTH. The initial value is MQCFAC_NONE.

function

Function, which can contain either the IBM MQ call name or the CICS EIBFN function. The field has the initial value of MQCFUNC_NONE, with length MQ_FUNCTION_LENGTH. The value returned in this field is dependent on the return code. See [Table 676 on page 1854](#) for more details.

The following additional values are possible when **function** contains an IBM MQ call name:

- MQCFUNC_MQCONN
- MQCFUNC_MQGET
- MQCFUNC_MQINQ
- MQCFUNC_NONE
- MQCFUNC_MQOPEN

- MQCFUNC_PUT
- MQCFUNC_MQPUT1

get wait interval

Wait interval for an MQGET call issued by the CICS bridge task. The initial value is MQCGWI_DEFAULT. The field applies only when **uow control** has the value MQCUOWC_FIRST. The following additional values are possible:

- MQCGWI_DEFAULT
- MQWI_UNLIMITED

link type

Link type. The initial value is MQCLT_PROGRAM. The following additional values are possible:

- MQCLT_PROGRAM
- MQCLT_TRANSACTION

next transaction identifier

ID of the next transaction to attach. The field must be of length MQ_TRANSACTION_ID_LENGTH.

output data length

COMMAREA data length. The initial value is MQCODL_AS_INPUT.

reply-to format

Format name of the reply message. The initial value is MQFMT_NONE with length MQ_FORMAT_LENGTH.

start code

Transaction start code. The field must be of length MQ_START_CODE_LENGTH. The initial value is MQCSC_NONE. The following additional values are possible:

- MQCSC_START
- MQCSC_STARTDATA
- MQCSC_TERMINPUT
- MQCSC_NONE

task end status

Task end status. The initial value is MQCTES_NOSYNC. The following additional values are possible:

- MQCTES_COMMIT
- MQCTES_BACKOUT
- MQCTES_ENDTASK
- MQCTES_NOSYNC

transaction identifier

ID of the transaction to attach. The initial value must contain blanks, and must be of length MQ_TRANSACTION_ID_LENGTH. The field applies only when **uow control** has the value MQCUOWC_FIRST or MQCUOWC_ONLY.

UOW control

UOW control. The initial value is MQCUOWC_ONLY. The following additional values are possible:

- MQCUOWC_FIRST
- MQCUOWC_MIDDLE
- MQCUOWC_LAST
- MQCUOWC_ONLY
- MQCUOWC_COMMIT
- MQCUOWC_BACKOUT
- MQCUOWC_CONTINUE

version

The MQCIH version number. The initial value is MQCIH_VERSION_2. The only other supported value is MQCIH_VERSION_1.

Constructors

ImqCICSBridgeHeader();

The default constructor.

ImqCICSBridgeHeader(const ImqCICSBridgeHeader & header);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut(ImqMessage & msg);

Inserts an MQCIH data structure into the message buffer at the beginning, moving existing message data further along, and sets the message format to MQFMT_CICS.

See the parent class method description for more details.

virtual ImqBoolean pasteIn(ImqMessage & msg);

Reads an MQCIH data structure from the message buffer. To be successful, the encoding of the *msg* object must be MQENC_NATIVE. Retrieve messages with MQGMO_CONVERT to MQENC_NATIVE. To be successful, the ImqMessage format must be MQFMT_CICS.

See the parent class method description for more details.

Object methods (public)

void operator = (const ImqCICSBridgeHeader & header);

Copies instance data from the *header*, replacing the existing instance data.

MQLONG ADSDescriptor() const;

Returns a copy of the **ADS descriptor**.

void setADSDescriptor(const MQLONG descriptor = MQCADSD_NONE);

Sets the **ADS descriptor**.

ImqString attentionIdentifier() const;

Returns a copy of the **attention identifier**, padded with trailing blanks to length MQ_ATTENTION_ID_LENGTH.

void setAttentionIdentifier(const char * data = 0);

Sets the **attention identifier**, padded with trailing blanks to length MQ_ATTENTION_ID_LENGTH. If no *data* is supplied, resets **attention identifier** to the initial value.

ImqString authenticator() const;

Returns a copy of the **authenticator**, padded with trailing blanks to length MQ_AUTHENTICATOR_LENGTH.

void setAuthenticator(const char * data = 0);

Sets the **authenticator**, padded with trailing blanks to length MQ_AUTHENTICATOR_LENGTH. If no *data* is supplied, resets **authenticator** to the initial value.

ImqString bridgeAbendCode() const;

Returns a copy of the **bridge abend code**, padded with trailing blanks to length MQ_ABEND_CODE_LENGTH.

ImqString bridgeCancelCode() const;

Returns a copy of the **bridge cancel code**, padded with trailing blanks to length MQ_CANCEL_CODE_LENGTH.

void setBridgeCancelCode(const char * data = 0);

Sets the **bridge cancel code**, padded with trailing blanks to length MQ_CANCEL_CODE_LENGTH. If no *data* is supplied, resets the **bridge cancel code** to the initial value.

MQLONG bridgeCompletionCode() const;
Returns a copy of the **bridge completion code**.

MQLONG bridgeErrorOffset() const ;
Returns a copy of the **bridge error offset**.

MQLONG bridgeReasonCode() const;
Returns a copy of the **bridge reason code**.

MQLONG bridgeReturnCode() const;
Returns the **bridge return code**.

MQLONG conversationalTask() const;
Returns a copy of the **conversational task**.

void setConversationalTask(const MQLONG task = MQCCT_NO);
Sets the **conversational task**.

MQLONG cursorPosition() const ;
Returns a copy of the **cursor position**.

void setCursorPosition(const MQLONG position = 0);
Sets the **cursor position**.

MQLONG facilityKeepTime() const;
Returns a copy of the **facility keep time**.

void setFacilityKeepTime(const MQLONG time = 0);
Sets the **facility keep time**.

ImqString facilityLike() const;
Returns a copy of the **facility like**, padded with trailing blanks to length MQ_FACILITY_LIKE_LENGTH.

void setFacilityLike(const char * name = 0);
Sets the **facility like**, padded with trailing blanks to length MQ_FACILITY_LIKE_LENGTH. If no *name* is supplied, resets **facility like** the initial value.

ImqBinary facilityToken() const;
Returns a copy of the **facility token**.

ImqBoolean setFacilityToken(const ImqBinary & token);
Sets the **facility token**. The **data length** of *token* must be either zero or MQ_FACILITY_LENGTH. It returns TRUE if successful.

void setFacilityToken(const MQBYTE8 token = 0);
Sets the **facility token**. *token* can be zero, which is the same as specifying MQCFAC_NONE. If *token* is nonzero it must address MQ_FACILITY_LENGTH bytes of binary data. When using predefined values such as MQCFAC_NONE, you might need to make a cast to ensure a signature match. For example, (MQBYTE *)MQCFAC_NONE.

ImqString function() const;
Returns a copy of the **function**, padded with trailing blanks to length MQ_FUNCTION_LENGTH.

MQLONG getWaitInterval() const;
Returns a copy of the **get wait interval**.

void setGetWaitInterval(const MQLONG interval = MQCGWI_DEFA
Sets the **get wait interval**.

MQLONG linkType() const;
Returns a copy of the **link type**.

void setLinkType(const MQLONG type = MQCLT_PROGRAM);
Sets the **link type**.

ImqString nextTransactionIdentifier() const ;
Returns a copy of the **next transaction identifier** data, padded with trailing blanks to length MQ_TRANSACTION_ID_LENGTH.

MQLONG outputDataLength() const;
Returns a copy of the **output data length**.

void setOutputDataLength(const MQLONG length = MQCODL_AS_INPUT);

Sets the **output data length**.

ImqString replyToFormat() const;

Returns a copy of the **reply-to format** name, padded with trailing blanks to length MQ_FORMAT_LENGTH.

void setReplyToFormat(const char * name = 0);

Sets the **reply-to format**, padded with trailing blanks to length MQ_FORMAT_LENGTH. If no *name* is supplied, resets **reply-to format** to the initial value.

ImqString startCode() const;

Returns a copy of the **start code**, padded with trailing blanks to length MQ_START_CODE_LENGTH.

void setStartCode(const char * data = 0);

Sets the **start code** data, padded with trailing blanks to length MQ_START_CODE_LENGTH. If no *data* is supplied, resets **start code** to the initial value.

MQLONG taskEndStatus() const;

Returns a copy of the **task end status**.

ImqString transactionIdentifier() const;

Returns a copy of the **transaction identifier** data, padded with trailing blanks to the length MQ_TRANSACTION_ID_LENGTH.

void setTransactionIdentifier(const char * data = 0);

Sets the **transaction identifier**, padded with trailing blanks to length MQ_TRANSACTION_ID_LENGTH. If no *data* is supplied, resets **transaction identifier** to the initial value.

MQLONG UOWControl() const;

Returns a copy of the **UOW control**.

void setUOWControl(const MQLONG control = MQCUOWC_ONLY);

Sets the **UOW control**.

MQLONG version() const;

Returns the **version** number.

ImqBoolean setVersion(const MQLONG version = MQCIH_VERSION_2);

Sets the **version** number. It returns TRUE if successful.

Object data (protected)

MQLONG olVersion

The maximum MQCIH version number that can be accommodated in the storage allocated for *opcih*.

PMQCIH opcih

The address of an MQCIH data structure. The amount of storage allocated is indicated by *olVersion*.

ImqDeadLetterHeader C++ class

This class encapsulates features of the MQDLH data structure.

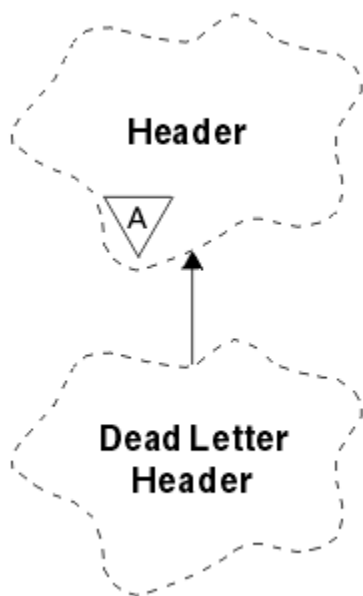

Figure 51. ImqDeadLetterHeader class

Objects of this class are typically used by an application that encounters a message that cannot be processed. A new message comprising a dead-letter header and the message content is placed on the dead-letter queue, and the message is discarded.

- [“Object attributes” on page 1856](#)
- [“Constructors” on page 1856](#)
- [“Overloaded ImqItem methods” on page 1856](#)
- [“Object methods \(public\)” on page 1856](#)
- [“Object data \(protected\)” on page 1857](#)
- [“Reason codes” on page 1857](#)

Object attributes

dead-letter reason code

The reason the message arrived on the dead-letter queue. The initial value is MQRC_NONE.

destination queue manager name

The name of the original destination queue manager. The name is a string of length MQ_Q_MGR_NAME_LENGTH. Its initial value is null.

destination queue name

The name of the original destination queue. The name is a string of length MQ_Q_NAME_LENGTH. Its initial value is null.

put application name

The name of the application that put the message on the dead-letter queue. The name is a string of length MQ_PUT_APPL_NAME_LENGTH. Its initial value is null.

put application type

The type of application that put the message on the dead-letter queue. The initial value is zero.

put date

The date when the message was put on the dead-letter queue. The date is a string of length MQ_PUT_DATE_LENGTH. Its initial value is a null string.

put time

The time when the message was put on the dead-letter queue. The time is a string of length MQ_PUT_TIME_LENGTH. Its initial value is a null string.

Constructors

ImqDeadLetterHeader();

The default constructor.

ImqDeadLetterHeader(const ImqDeadLetterHeader & header);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & msg);

Inserts an MQDLH data structure into the message buffer at the beginning, moving existing message data further along. Sets the *msg format* to MQFMT_DEAD_LETTER_HEADER.

See the ImqHeader class method description on page [“ImqHeader C++ class” on page 1864](#) for further details.

virtual ImqBoolean pasteIn (ImqMessage & msg);

Reads an MQDLH data structure from the message buffer.

To be successful, the ImqMessage *format* must be MQFMT_DEAD_LETTER_HEADER.

See the ImqHeader class method description on page [“ImqHeader C++ class” on page 1864](#) for further details.

Object methods (public)

void operator = (const ImqDeadLetterHeader & header);

Copies instance data is copied from *header*, replacing the existing instance data.

MQLONG deadLetterReasonCode () const ;

Returns the **dead-letter reason code**.

void setDeadLetterReasonCode (const MQLONG reason);

Sets the **dead-letter reason code**.

ImqString destinationQueueManagerName () const ;

Returns the **destination queue manager name**, stripped of any trailing blanks.

void setDestinationQueueManagerName (const char * *name*);

Sets the **destination queue manager name**. Truncates data longer than MQ_Q_MGR_NAME_LENGTH (48 characters).

ImqString destinationQueueName () const ;

Returns a copy of the **destination queue name**, stripped of any trailing blanks.

void setDestinationQueueName (const char * *name*);

Sets the **destination queue name**. Truncates data longer than MQ_Q_NAME_LENGTH (48 characters).

ImqString putApplicationName () const ;

Returns a copy of the **put application name**, stripped of any trailing blanks.

void setPutApplicationName (const char * *name* = 0);

Sets the **put application name**. Truncates data longer than MQ_PUT_APPL_NAME_LENGTH (28 characters).

MQLONG putApplicationType () const ;

Returns the **put application type**.

void setPutApplicationType (const MQLONG *type* = MQAT_NO_CONTEXT);

Sets the **put application type**.

ImqString putDate () const ;

Returns a copy of the **put date**, stripped of any trailing blanks.

void setPutDate (const char * *date* = 0);

Sets the **put date**. Truncates data longer than MQ_PUT_DATE_LENGTH (8 characters).

ImqString putTime () const ;

Returns a copy of the **put time**, stripped of any trailing blanks.

void setPutTime (const char * *time* = 0);

Sets the **put time**. Truncates data longer than MQ_PUT_TIME_LENGTH (8 characters).

Object data (protected)

MQDLH *omqdlh*

The MQDLH data structure.

Reason codes

- MQRC_INCONSISTENT_FORMAT
- MQRC_STRUC_ID_ERROR
- MQRC_ENCODING_ERROR

ImqDistributionList C++ class

This class encapsulates a dynamic distribution list that references one or more queues for the purpose of sending a message or messages to multiple destinations.

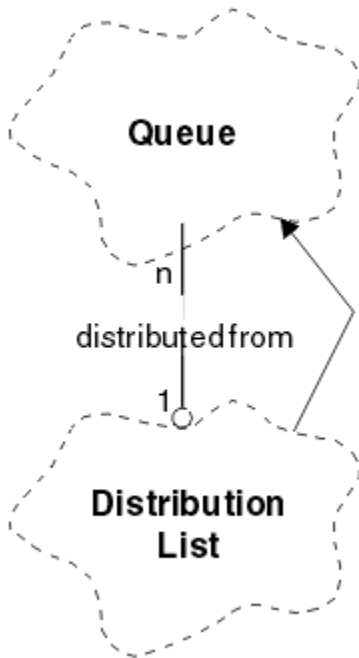

Figure 52. ImqDistributionList class

- [“Object attributes” on page 1858](#)
- [“Constructors” on page 1858](#)
- [“Object methods \(public\)” on page 1858](#)
- [“Object methods \(protected\)” on page 1859](#)

Object attributes

first distributed queue

The first of one or more objects of class , in no particular order, in which the **distribution list reference** addresses this object.

Initially there are no such objects. To open an ImqDistributionList successfully, there must be at least one such object.

Note: When an ImqDistributionList object is opened, any open objects that reference it are automatically closed.

Constructors

ImqDistributionList();

The default constructor.

ImqDistributionList(const ImqDistributionList & list);

The copy constructor.

Object methods (public)

void operator = (const ImqDistributionList & list);

All objects that reference **this** object are dereferenced before copying. No objects will reference **this** object after the invocation of this method.

*** firstDistributedQueue () const ;**
Returns the **first distributed queue**.

Object methods (protected)

void setFirstDistributedQueue (* queue = 0);
Sets the **first distributed queue**.

ImqError C++ class

This abstract class provides information on errors associated with an object.

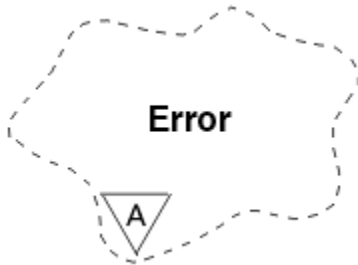

Figure 53. *ImqError* class

- [“Object attributes” on page 1859](#)
- [“Constructors” on page 1859](#)
- [“Object methods \(public\)” on page 1859](#)
- [“Object methods \(protected\)” on page 1860](#)
- [“Reason codes” on page 1860](#)

Object attributes

completion code

The most recent completion code. The initial value is zero. The following additional values are possible:

- MQCC_OK
- MQCC_WARNING
- MQCC_FAILED

reason code

The most recent reason code. The initial value is zero.

Constructors

ImqError ();

The default constructor.

ImqError (const ImqError & error);

The copy constructor.

Object methods (public)

void operator = (const ImqError & error);

Copies instance data from *error*, replacing the existing instance data.

void clearErrorCodes ();

Sets the **completion code** and **reason code** both to zero.

MQLONG completionCode () const ;

Returns the **completion code**.

MQLONG reasonCode () const ;

Returns the **reason code**.

Object methods (protected)

ImqBoolean checkReadPointer (const void * *pointer*, const size_t *length*);

Verifies that the combination of pointer and length is valid for read-only access, and returns TRUE if successful.

ImqBoolean checkWritePointer (const void * *pointer*, const size_t *length*);

Verifies that the combination of pointer and length is valid for read-write access, and returns TRUE if successful.

void setCompletionCode (const MQLONG *code* = 0);

Sets the **completion code**.

void setReasonCode (const MQLONG *code* = 0);

Sets the **reason code**.

Reason codes

- MQRC_BUFFER_ERROR

ImqGetMessageOptions C++ class

This class encapsulates the MQGMO data structure

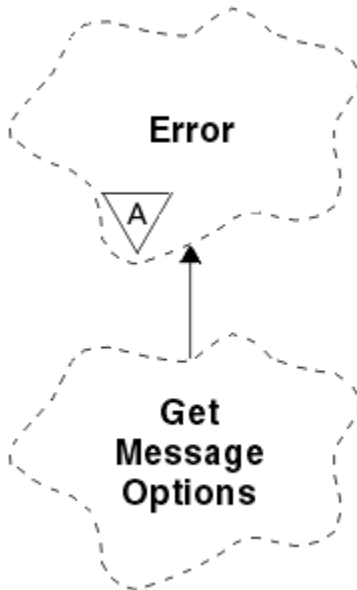

Figure 54. *ImqGetMessageOptions* class

- [“Object attributes” on page 1861](#)
- [“Constructors” on page 1862](#)
- [“Object methods \(public\)” on page 1862](#)
- [“Object methods \(protected\)” on page 1863](#)
- [“Object data \(protected\)” on page 1863](#)
- [“Reason codes” on page 1863](#)

Object attributes

group status

Status of a message for a group of messages. The initial value is MQGS_NOT_IN_GROUP. The following additional values are possible:

- MQGS_MSG_IN_GROUP
- MQGS_LAST_MSG_IN_GROUP

match options

Options for selecting incoming messages. The initial value is MQMO_MATCH_MSG_ID | MQMO_MATCH_CORREL_ID. The following additional values are possible:

- MQMO_GROUP_ID
- MQMO_MATCH_MSG_SEQ_NUMBER
- MQMO_MATCH_OFFSET
- MQMO_MSG_TOKEN
- MQMO_NONE

message token

Message token. A binary value (MQBYTE16) of length MQ_MSG_TOKEN_LENGTH. The initial value is MQMTOK_NONE.

options

Options applicable to a message. The initial value is MQGMO_NO_WAIT. The following additional values are possible:

- MQGMO_WAIT
- MQGMO_SYNCPOINT
- MQGMO_SYNCPOINT_IF_PERSISTENT
- MQGMO_NO_SYNCPOINT
- MQGMO_MARK_SKIP_BACKOUT
- MQGMO_BROWSE_FIRST
- MQGMO_BROWSE_NEXT
- MQGMO_BROWSE_MSG_UNDER_CURSOR
- MQGMO_MSG_UNDER_CURSOR
- MQGMO_LOCK
- MQGMO_UNLOCK
- MQGMO_ACCEPT_TRUNCATED_MSG
- MQGMO_SET_SIGNAL
- MQGMO_FAIL_IF QUIESCING
- MQGMO_CONVERT
- MQGMO_LOGICAL_ORDER
- MQGMO_COMPLETE_MSG
- MQGMO_ALL_MSGS_AVAILABLE
- MQGMO_ALL_SEGMENTS_AVAILABLE
- MQGMO_NONE

resolved queue name

Resolved queue name. This attribute is read-only. Names are never longer than 48 characters and can be padded to that length with nulls. The initial value is a null string.

returned length

Returned length. The initial value is MQRL_UNDEFINED. This attribute is read-only.

segmentation

The ability to segment a message. The initial value is MQSEG_INHIBITED. The additional value, MQSEG_ALLOWED, is possible.

segment status

The segmentation status of a message. The initial value is MQSS_NOT_A_SEGMENT. The following additional values are possible:

- MQSS_SEGMENT
- MQSS_LAST_SEGMENT

syncpoint participation

TRUE when messages are retrieved under syncpoint control.

wait interval

The length of time that the class **get** method pauses while waiting for a suitable message to arrive, if one is not already available. The initial value is zero, which effects an indefinite wait. The additional value, MQWI_UNLIMITED, is possible. This attribute is ignored unless the **options** include MQGMO_WAIT.

Constructors

ImqGetMessageOptions();

The default constructor.

ImqGetMessageOptions(const ImqGetMessageOptions & gmo);

The copy constructor.

Object methods (public)

void operator = (const ImqGetMessageOptions & gmo);

Copies instance data from *gmo*, replacing the existing instance data.

MQCHAR groupStatus () const ;

Returns the **group status**.

void setGroupStatus (const MQCHAR status);

Sets the **group status**.

MLONG matchOptions () const ;

Returns the **match options**.

void setMatchOptions (const MLONG options);

Sets the **match options**.

ImqBinary messageToken () const;

Returns the **message token**.

ImqBoolean setMessageToken(const ImqBinary & token);

Sets the **message token**. The **data length** of *token* must be either zero or MQ_MSG_TOKEN_LENGTH. This method returns TRUE if successful.

void setMessageToken(const MQBYTE16 token = 0);

Sets the **message token**. *token* can be zero, which is the same as specifying MQMTOK_NONE. If *token* is nonzero, then it must address MQ_MSG_TOKEN_LENGTH bytes of binary data.

When using predefined values, such as MQMTOK_NONE, you might not need to make a cast to ensure a signature match, for example (MQBYTE *)MQMTOK_NONE.

MLONG options () const ;

Returns the **options**.

void setOptions (const MLONG options);

Sets the **options**, including the **syncpoint participation** value.

ImqString resolvedQueueName () const ;

Returns a copy of the **resolved queue name**.

MQLONG returnedLength() const;

Returns the **returned length**.

MQCHAR segmentation () const ;

Returns the **segmentation**.

void setSegmentation (const MQCHAR value);

Sets the **segmentation**.

MQCHAR segmentStatus () const ;

Returns the **segment status**.

void setSegmentStatus (const MQCHAR status);

Sets the **segment status**.

ImqBoolean syncPointParticipation () const ;

Returns the **syncpoint participation** value, which is TRUE if the **options** include either MQGMO_SYNCPOINT or MQGMO_SYNCPOINT_IF_PERSISTENT.

void setSyncPointParticipation (const ImqBoolean sync);

Sets the **syncpoint participation** value. If *sync* is TRUE, alters the **options** to include MQGMO_SYNCPOINT, and to exclude both MQGMO_NO_SYNCPOINT and MQGMO_SYNCPOINT_IF_PERSISTENT. If *sync* is FALSE, alters the **options** to include MQGMO_NO_SYNCPOINT, and to exclude both MQGMO_SYNCPOINT and MQGMO_SYNCPOINT_IF_PERSISTENT.

MQLONG waitInterval () const ;

Returns the **wait interval**.

void setWaitInterval (const MQLONG interval);

Sets the **wait interval**.

Object methods (protected)

static void setVersionSupported (const MQLONG);

Sets the **MQGMO** version. Defaults to **MQGMO_VERSION_3**.

Object data (protected)

MQGMO omqgmo

An MQGMO Version 2 data structure. Access MQGMO fields supported for MQGMO_VERSION_2 only.

PMQGMO opgmo

The address of an MQGMO data structure. The version number for this address is indicated in *olVersion*. Inspect the version number before accessing MQGMO fields, to ensure that they are present.

MQLONG olVersion

The version number of the MQGMO data structure addressed by *opgmo*.

Reason codes

- MQRC_BINARY_DATA_LENGTH_ERROR

ImqHeader C++ class

This abstract class encapsulates common features of the MQDLH data structure.

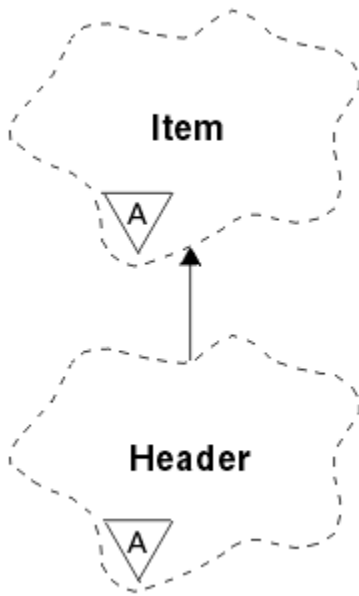

Figure 55. ImqHeader class

- [“Object attributes” on page 1864](#)
- [“Constructors” on page 1864](#)
- [“Object methods \(public\)” on page 1865](#)

Object attributes

character set

The original coded character set identifier. Initially MQCCSI_Q_MGR.

encoding

The original encoding. Initially MQENC_NATIVE.

format

The original format. Initially MQFMT_NONE.

header flags

The initial values are:

- Zero for objects of the ImqDeadLetterHeader class
- MQIIH_NONE for objects of the ImqIMSBridgeHeader class
- MQRMHF_LAST for objects of the ImqReferenceHeader class
- MQCIH_NONE for objects of the ImqCICSBridgeHeader class
- MQWIIH_NONE for objects of the ImqWorkHeader class

Constructors

ImqHeader();

The default constructor.

ImqHeader(const ImqHeader & header);

The copy constructor.

Object methods (public)

void operator = (const ImqHeader & *header*);

Copies instance data from *header*, replacing the existing instance data.

virtual MQLONG characterSet () const ;

Returns the **character set**.

virtual void setCharacterSet (const MQLONG *ccsid* = MQCCSI_Q_MGR);

Sets the **character set**.

virtual MQLONG encoding () const ;

Returns the **encoding**.

virtual void setEncoding (const MQLONG *encoding* = MQENC_NATIVE);

Sets the **encoding**.

virtual ImqString format () const ;

Returns a copy of the **format**, including trailing blanks.

virtual void setFormat (const char * *name* = 0);

Sets the **format**, padded to 8 characters with trailing blanks.

virtual MQLONG headerFlags () const ;

Returns the **header flags**.

virtual void setHeaderFlags (const MQLONG *flags* = 0);

Sets the **header flags**.

ImqIMSBridgeHeader C++ class

This class encapsulates features of the MQIIH data structure.

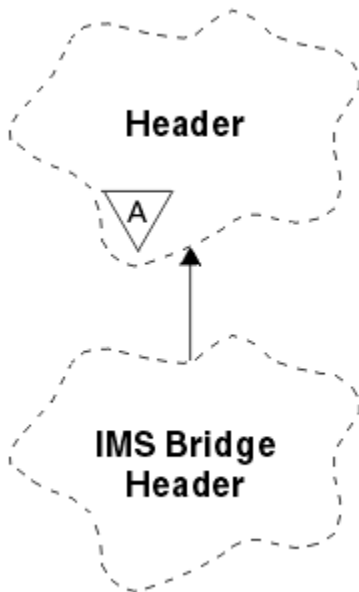

Figure 56. *ImqIMSBridgeHeader* class

Objects of this class are used by applications that send messages to the IMS bridge through IBM MQ for z/OS.

Note: The *ImqHeader* **character set** and **encoding** must have default values and must not be set to any other values.

- [“Object attributes” on page 1866](#)
- [“Constructors” on page 1866](#)
- [“Overloaded *ImqItem* methods” on page 1866](#)

- [“Object methods \(public\)” on page 1867](#)
- [“Object data \(protected\)” on page 1867](#)
- [“Reason codes” on page 1867](#)

Object attributes

authenticator

RACF password or passticket, of length MQ_AUTHENTICATOR_LENGTH. The initial value is MQIAUT_NONE.

commit mode

Commit mode. See the *OTMA User's Guide* for more information about IMS commit modes. The initial value is MQICM_COMMIT_THEN_SEND. The additional value, MQICM_SEND_THEN_COMMIT, is possible.

logical terminal override

Logical terminal override, of length MQ_LTERM_OVERRIDE_LENGTH. The initial value is a null string.

message format services map name

MFS map name, of length MQ_MFS_MAP_NAME_LENGTH. The initial value is a null string.

reply-to format

Format of any reply, of length MQ_FORMAT_LENGTH. The initial value is MQFMT_NONE.

security scope

Scope of IMS security processing. The initial value is MQISS_CHECK. The additional value, MQISS_FULL, is possible.

transaction instance id

Transaction instance identity, a binary (MQBYTE16) value of length MQ_TRAN_INSTANCE_ID_LENGTH. The initial value is MQITII_NONE.

transaction state

State of the IMS conversation. The initial value is MQITS_NOT_IN_CONVERSATION. The additional value, MQITS_IN_CONVERSATION, is possible.

Constructors

ImqIMSBridgeHeader();

The default constructor.

ImqIMSBridgeHeader(const ImqIMSBridgeHeader & header);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & msg);

Inserts an MQIIH data structure into the message buffer at the beginning, moving existing message data further along. Sets the *msg* **format** to MQFMT_IMS.

See the parent class method description for further details.

virtual ImqBoolean pasteIn (ImqMessage & msg);

Reads an MQIIH data structure from the message buffer.

To be successful, the **encoding** of the *msg* object must be MQENC_NATIVE. Retrieve messages with MQGMO_CONVERT to MQENC_NATIVE.

To be successful, the ImqMessage **format** must be MQFMT_IMS.

See the parent class method description for further details.

Object methods (public)

void operator = (const ImqIMSBridgeHeader & *header*);

Copies instance data from *header*, replacing the existing instance data.

ImqString authenticator () const ;

Returns a copy of the **authenticator**, padded with trailing blanks to length MQ_AUTHENTICATOR_LENGTH.

void setAuthenticator (const char * *name*);

Sets the **authenticator**.

MQCHAR commitMode () const ;

Returns the **commit mode**.

void setCommitMode (const MQCHAR *mode*);

Sets the **commit mode**.

ImqString logicalTerminalOverride () const ;

Returns a copy of the **logical terminal override**.

void setLogicalTerminalOverride (const char * *override*);

Sets the **logical terminal override**.

ImqString messageFormatServicesMapName () const ;

Returns a copy of the **message format services map name**.

void setMessageFormatServicesMapName (const char * *name*);

Sets the **message format services map name**.

ImqString replyToFormat () const ;

Returns a copy of the **reply-to format**, padded with trailing blanks to length MQ_FORMAT_LENGTH.

void setReplyToFormat (const char * *format*);

Sets the **reply-to format**, padded with trailing blanks to length MQ_FORMAT_LENGTH.

MQCHAR securityScope () const ;

Returns the **security scope**.

void setSecurityScope (const MQCHAR *scope*);

Sets the **security scope**.

ImqBinary transactionInstanceId () const ;

Returns a copy of the **transaction instance id**.

ImqBoolean setTransactionInstanceId (const ImqBinary & *id*);

Sets the **transaction instance id**. The **data length** of *token* must be either zero or MQ_TRAN_INSTANCE_ID_LENGTH. This method returns TRUE if successful.

void setTransactionInstanceId (const MQBYTE16 *id* = 0);

Sets the **transaction instance id**. *id* can be zero, which is the same as specifying MQITII_NONE. If *id* is nonzero, it must address MQ_TRAN_INSTANCE_ID_LENGTH bytes of binary data. When using predefined values such as MQITII_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE *)MQITII_NONE.

MQCHAR transactionState () const ;

Returns the **transaction state**.

void setTransactionState (const MQCHAR *state*);

Sets the **transaction state**.

Object data (protected)

MQIIH omqiih

The MQIIH data structure.

Reason codes

- MQRC_BINARY_DATA_LENGTH_ERROR

- MQRC_INCONSISTENT_FORMAT
- MQRC_ENCODING_ERROR
- MQRC_STRUC_ID_ERROR

ImqItem C++ class

This abstract class represents an item, perhaps one of several, within a message.

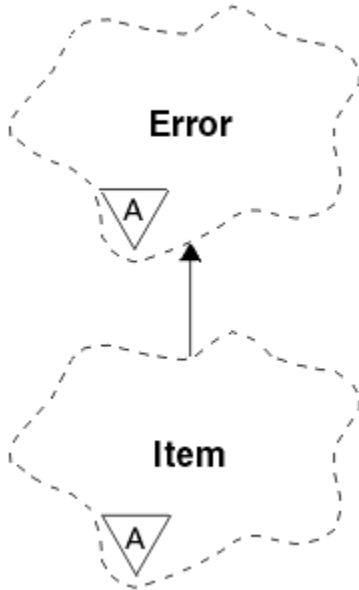

Figure 57. *ImqItem* class

Items are concatenated together in a message buffer. Each specialization is associated with a particular data structure that begins with a structure id.

Polymorphic methods in this abstract class allow items to be copied to and from messages. The `ImqMessage` class **readItem** and **writeItem** methods provide another style of invoking these polymorphic methods that is more natural for application programs.

- [“Object attributes” on page 1868](#)
- [“Constructors” on page 1868](#)
- [“Class methods \(public\)” on page 1869](#)
- [“Object methods \(public\)” on page 1869](#)
- [“Reason codes” on page 1869](#)

Object attributes

structure id

A string of four characters at the beginning of the data structure. This attribute is read-only. Consider this attribute for derived classes. It is not included automatically.

Constructors

ImqItem();

The default constructor.

ImqItem(const ImqItem & item);

The copy constructor.

Class methods (public)

static ImqBoolean structureIdIs (const char * *structure-id-to-test*, const ImqMessage & *msg*);

Returns TRUE if the **structure id** of the next ImqItem in the incoming *msg* is the same as *structure-id-to-test*. The next item is identified as that part of the message buffer currently addressed by the ImqCache **data pointer**. This method relies on the **structure id** and therefore is not guaranteed to work for all ImqItem derived classes.

Object methods (public)

void operator = (const ImqItem & *item*);

Copies instance data from *item*, replacing the existing instance data.

virtual ImqBoolean copyOut (ImqMessage & *msg*) = 0 ;

Writes this object as the next item in an outgoing message buffer, appending it to any existing items. If the write operation is successful, increases the ImqCache **data length**. This method returns TRUE if successful.

Override this method to work with a specific subclass.

virtual ImqBoolean pasteIn (ImqMessage & *msg*) = 0 ;

Reads this object *destructively* from the incoming message buffer. The read is destructive in that the ImqCache **data pointer** is moved on. However, the buffer content remains the same, so data can be re-read by resetting the ImqCache **data pointer**.

The (sub)class of this object must be consistent with the **structure id** found next in the message buffer of the *msg* object.

The **encoding** of the *msg* object should be MQENC_NATIVE. It is recommended that messages be retrieved with the ImqMessage **encoding** set to MQENC_NATIVE, and with the ImqGetMessageOptions **options** including MQGMO_CONVERT.

If the read operation is successful, the ImqCache **data length** is reduced. This method returns TRUE if successful.

Override this method to work with a specific subclass.

Reason codes

- MQRC_ENCODING_ERROR
- MQRC_STRUC_ID_ERROR
- MQRC_INCONSISTENT_FORMAT
- MQRC_INSUFFICIENT_BUFFER
- MQRC_INSUFFICIENT_DATA

ImqMessage C++ class

This class encapsulates an MQMD data structure and also handles the construction and reconstruction of message data.

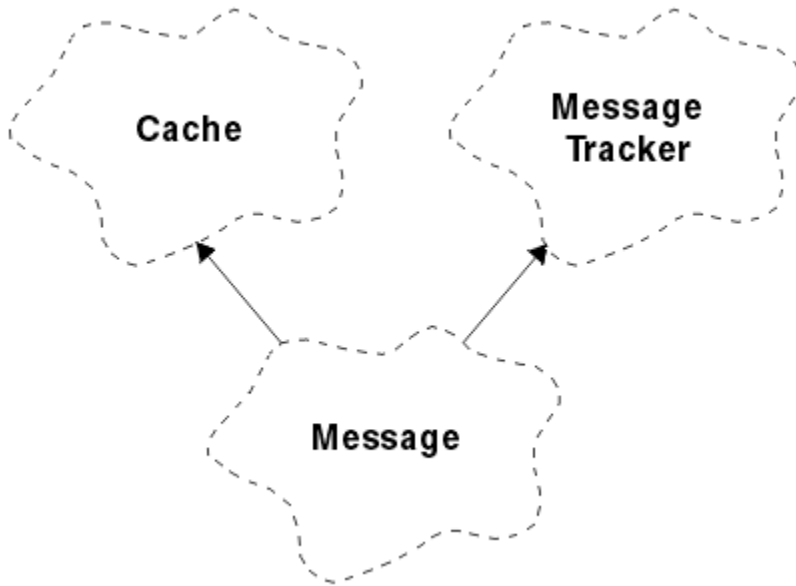

Figure 58. *ImqMessage* class

- [“Object attributes” on page 1870](#)
- [“Constructors” on page 1874](#)
- [“Object methods \(public\)” on page 1874](#)
- [“Object methods \(protected\)” on page 1876](#)
- [“Object data \(protected\)” on page 1876](#)

Object attributes

application id data

Identity information associated with a message. The initial value is a null string.

application origin data

Origin information associated with a message. The initial value is a null string.

backout count

The number of times that a message has been tentatively retrieved and subsequently backed out. The initial value is zero. This attribute is read-only.

character set

Coded Character Set Id. The initial value is MQCCSI_Q_MGR. The following additional values are possible:

- MQCCSI_INHERIT
- MQCCSI_EMBEDDED

You can also use a Coded Character Set Id of your choice. For information about this, see [“Code page conversion” on page 900](#).

encoding

The machine encoding of the message data. The initial value is MQENC_NATIVE.

expiry

A time-dependent quantity that controls how long IBM MQ retains an unretrieved message before discarding it. The initial value is MQEI_UNLIMITED.

format

The name of the format (template) that describes the layout of data in the buffer. Names longer than eight characters are truncated to eight characters. Names are always padded with blanks to eight characters. The initial constant value is MQFMT_NONE. The following additional constants are possible:

- MQFMT_ADMIN
- MQFMT_CICS
- MQFMT_COMMAND_1
- MQFMT_COMMAND_2
- MQFMT_DEAD_LETTER_HEADER
- MQFMT_DIST_HEADER
- MQFMT_EVENT
- MQFMT_IMS
- MQFMT_IMS_VAR_STRING
- MQFMT_MD_EXTENSION
- MQFMT_PCF
- MQFMT_REF_MSG_HEADER
- MQFMT_RF_HEADER
- MQFMT_STRING
- MQFMT_TRIGGER
- MQFMT_WORK_INFO_HEADER
- MQFMT_XMIT_Q_HEADER

You can also use an application-specific string of your choice. For more information about this, see the [“Format \(MQCHAR8\)”](#) on page 412 field of the message descriptor (MQMD).

message flags

Segmentation control information. The initial value is MQMF_SEGMENTATION_INHIBITED. The following additional values are possible:

- MQMF_SEGMENTATION_ALLOWED
- MQMF_MSG_IN_GROUP
- MQMF_LAST_MSG_IN_GROUP
- MQMF_SEGMENT
- MQMF_LAST_SEGMENT
- MQMF_NONE

message type

The broad categorization of a message. The initial value is MQMT_DATAGRAM. The following additional values are possible:

- MQMT_SYSTEM_FIRST
- MQMT_SYSTEM_LAST
- MQMT_DATAGRAM
- MQMT_REQUEST
- MQMT_REPLY
- MQMT_REPORT
- MQMT_APPL_FIRST
- MQMT_APPL_LAST

You can also use an application-specific value of your choice. For more information about this, see the [“MsgType \(MQLONG\)”](#) on page 423 field of the message descriptor (MQMD).

offset

Offset information. The initial value is zero.

original length

The original length of a segmented message. The initial value is MQOL_UNDEFINED.

persistence

Indicates that the message is important and must at all times be backed up using persistent storage. This option implies a performance penalty. The initial value is MQPER_PERSISTENCE_AS_Q_DEF. The following additional values are possible:

- MQPER_PERSISTENT
- MQPER_NOT_PERSISTENT

priority

The relative priority for transmission and delivery. Messages of the same priority are usually delivered in the same sequence as they were supplied (although there are several criteria that must be satisfied to guarantee this). The initial value is MQPRI_PRIORITY_AS_Q_DEF.

property validation

Specifies whether validation of properties should take place when a property of the message is set. The initial value is **MQCMHO_DEFAULT_VALIDATION**. The following additional values are possible:

- MQCMHO_VALIDATE
- MQCMHO_NO_VALIDATION

The following methods act on **property validation**:

MQLONG propertyValidation() const ;

Returns the **property validation** option.

void setPropertyValidation(const MQLONG option);

Sets the **property validation** option.

put application name

The name of the application that put a message. The initial value is a null string.

put application type

The type of application that put a message. The initial value is MQAT_NO_CONTEXT. The following additional values are possible:

- MQAT_AIX
- MQAT_CICS
- MQAT_CICS_BRIDGE
- MQAT_DOS
- MQAT_IMS
- MQAT_IMS_BRIDGE
- MQAT_MVS
- MQAT_NOTES_AGENT
- MQAT_OS2
- MQAT_OS390
- MQAT_OS400
- MQAT_QMGR
- MQAT_UNIX
- MQAT_WINDOWS
- MQAT_WINDOWS_NT

- MQAT_XCF
- MQAT_DEFAULT
- MQAT_UNKNOWN
- MQAT_USER_FIRST
- MQAT_USER_LAST

You can also use an application-specific string of your choice. For more information about this, see the [“PutApplType \(MQLONG\)”](#) on page 428 field of the message descriptor (MQMD).

put date

The date on which a message was put. The initial value is a null string.

put time

The time at which a message was put. The initial value is a null string.

reply-to queue manager name

The name of the queue manager to which any reply should be sent. The initial value is a null string.

reply-to queue name

The name of the queue to which any reply should be sent. The initial value is a null string.

report

Feedback information associated with a message. The initial value is MQRO_NONE. The following additional values are possible:

- MQRO_EXCEPTION
- MQRO_EXCEPTION_WITH_DATA
- MQRO_EXCEPTION_WITH_FULL_DATA *
- MQRO_EXPIRATION
- MQRO_EXPIRATION_WITH_DATA
- MQRO_EXPIRATION_WITH_FULL_DATA *
- MQRO_COA
- MQRO_COA_WITH_DATA
- MQRO_COA_WITH_FULL_DATA *
- MQRO_COD
- MQRO_COD_WITH_DATA
- MQRO_COD_WITH_FULL_DATA *
- MQRO_PAN
- MQRO_NAN
- MQRO_NEW_MSG_ID
- MQRO_NEW_CORREL_ID
- MQRO_COPY_MSG_ID_TO_CORREL_ID
- MQRO_PASS_CORREL_ID
- MQRO_DEAD_LETTER_Q
- MQRO_DISCARD_MSG

where * indicates values that are not supported on IBM MQ for z/OS.

sequence number

Sequence information identifying a message within a group. The initial value is one.

total message length

The number of bytes that were available during the most recent attempt to read a message. This number will be greater than the `ImqCache message length` if the last message was truncated, or if the last message was not read because truncation would have occurred. This attribute is read-only. The initial value is zero.

This attribute can be useful in any situation involving truncated messages.

user id

A user identity associated with a message. The initial value is a null string.

Constructors

ImqMessage();

The default constructor.

ImqMessage(const ImqMessage & msg);

The copy constructor. See the **operator =** method for details.

Object methods (public)

void operator = (const ImqMessage & msg);

Copies the MQMD and message data from *msg*. If a buffer has been supplied by the user for this object, the amount of data copied is restricted to the available buffer size. Otherwise, the system ensures that a buffer of adequate size is made available for the copied data.

ImqString applicationIdData () const ;

Returns a copy of the **application id data**.

void setApplicationIdData (const char * data = 0);

Sets the **application id data**.

ImqString applicationOriginData () const ;

Returns a copy of the **application origin data**.

void setApplicationOriginData (const char * data = 0);

Sets the **application origin data**.

MQLONG backoutCount () const ;

Returns the **backout count**.

MQLONG characterSet () const ;

Returns the **character set**.

void setCharacterSet (const MQLONG ccsid = MQCCSI_Q_MGR);

Sets the **character set**.

MQLONG encoding () const ;

Returns the **encoding**.

void setEncoding (const MQLONG encoding = MQENC_NATIVE);

Sets the **encoding**.

MQLONG expiry () const ;

Returns the **expiry**.

void setExpiry (const MQLONG expiry);

Sets the **expiry**.

ImqString format () const ;

Returns a copy of the **format**, including trailing blanks.

ImqBoolean formatIs (const char * format-to-test) const ;

Returns TRUE if the **format** is the same as *format-to-test*.

void setFormat (const char * name = 0);

Sets the **format**, padded to eight characters with trailing blanks.

MQLONG messageFlags () const ;

Returns the **message flags**.

void setMessageFlags (const MQLONG flags);

Sets the **message flags**.

MQLONG messageType () const ;

Returns the **message type**.

void setMessageType (const MQLONG *type*);
 Sets the **message type**.

MQLONG offset () const ;
 Returns the **offset**.

void setOffset (const MQLONG *offset*);
 Sets the **offset**.

MQLONG originalLength () const ;
 Returns the **original length**.

void setOriginalLength (const MQLONG *length*);
 Sets the **original length**.

MQLONG persistence () const ;
 Returns the **persistence**.

void setPersistence (const MQLONG *persistence*);
 Sets the **persistence**.

MQLONG priority () const ;
 Returns the **priority**.

void setPriority (const MQLONG *priority*);
 Sets the **priority**.

ImqString putApplicationName () const ;
 Returns a copy of the **put application name**.

void setPutApplicationName (const char * *name* = 0);
 Sets the **put application name**.

MQLONG putApplicationType () const ;
 Returns the **put application type**.

void setPutApplicationType (const MQLONG *type* = MQAT_NO_CONTEXT);
 Sets the **put application type**.

ImqString putDate () const ;
 Returns a copy of the **put date**.

void setPutDate (const char * *date* = 0);
 Sets the **put date**.

ImqString putTime () const ;
 Returns a copy of the **put time**.

void setPutTime (const char * *time* = 0);
 Sets the **put time**.

ImqBoolean readItem (ImqItem & *item*);
 Reads into the *item* object from the message buffer, using the ImqItem **pasteIn** method. It returns TRUE if successful.

ImqString replyToQueueManagerName () const ;
 Returns a copy of the **reply-to queue manager name**.

void setReplyToQueueManagerName (const char * *name* = 0);
 Sets the **reply-to queue manager name**.

ImqString replyToQueueName () const ;
 Returns a copy of the **reply-to queue name**.

void setReplyToQueueName (const char * *name* = 0);
 Sets the **reply-to queue name**.

MQLONG report () const ;
 Returns the **report**.

void setReport (const MQLONG *report*);
 Sets the **report**.

MQLONG **sequenceNumber () const ;**

Returns the **sequence number**.

void **setSequenceNumber (const MQLONG *number*);**

Sets the **sequence number**.

size_t **totalMessageLength () const ;**

Returns the **total message length**.

ImqString **userId () const ;**

Returns a copy of the **user id**.

void **setUserId (const char * *id* = 0);**

Sets the **user id**.

ImqBoolean **writeItem (ImqItem & *item*);**

Writes from the *item* object into the message buffer, using the ImqItem **copyOut** method. Writing can take the form of insertion, replacement, or an append: this depends on the class of the *item* object.

This method returns TRUE if successful.

Object methods (protected)

static void **setVersionSupported (const MQLONG);**

Sets the **MQMD version**. Defaults to **MQMD_VERSION_2**.

Object data (protected)

MQMD1 *omqmd*

(IBM MQ for z/OS only.) The MQMD data structure.

MQMD2 *omqmd*

(Platforms other than z/OS.) The MQMD data structure.

ImqMessageTracker C++ class

This class encapsulates those attributes of an ImqMessage or ImqQueue object that can be associated with either object.

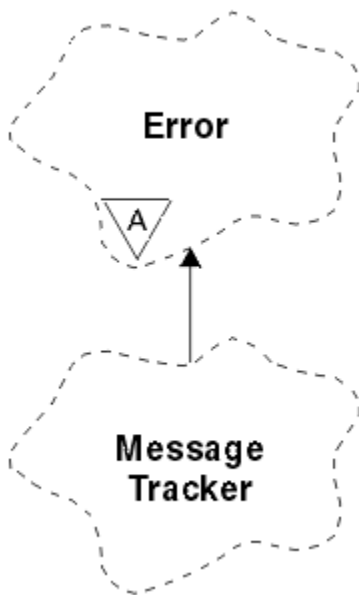

Figure 59. *ImqMessageTracker* class

This class relates to the MQI calls listed in [“ImqMessageTracker cross reference”](#) on page 1828.

- [“Object attributes”](#) on page 1877

- [“Constructors” on page 1878](#)
- [“Object methods \(public\)” on page 1878](#)
- [“Reason codes” on page 1879](#)

Object attributes

accounting token

A binary value (MQBYTE32) of length MQ_ACCOUNTING_TOKEN_LENGTH. The initial value is MQACT_NONE.

correlation id

A binary value (MQBYTE24) of length MQ_CORREL_ID_LENGTH that you assign to correlate messages. The initial value is MQCI_NONE. The additional value, MQCI_NEW_SESSION, is possible.

feedback

Feedback information to be sent with a message. The initial value is MQFB_NONE. The following additional values are possible:

- MQFB_SYSTEM_FIRST
- MQFB_SYSTEM_LAST
- MQFB_APPL_FIRST
- MQFB_APPL_LAST
- MQFB_COA
- MQFB_COD
- MQFB_EXPIRATION
- MQFB_PAN
- MQFB_NAN
- MQFB_QUIT
- MQFB_DATA_LENGTH_ZERO
- MQFB_DATA_LENGTH_NEGATIVE
- MQFB_DATA_LENGTH_TOO_BIG
- MQFB_BUFFER_OVERFLOW
- MQFB_LENGTH_OFF_BY_ONE
- MQFB_IIH_ERROR
- MQFB_NOT_AUTHORIZED_FOR_IMS
- MQFB_IMS_ERROR
- MQFB_IMS_FIRST
- MQFB_IMS_LAST
- MQFB_CICS_APPL_ABENDED
- MQFB_CICS_APPL_NOT_STARTED
- MQFB_CICS_BRIDGE_FAILURE
- MQFB_CICS_CCSID_ERROR
- MQFB_CICS_CIH_ERROR
- MQFB_CICS_COMMAREA_ERROR
- MQFB_CICS_CORREL_ID_ERROR
- MQFB_CICS_DLQ_ERROR
- MQFB_CICS_ENCODING_ERROR
- MQFB_CICS_INTERNAL_ERROR
- MQFB_CICS_NOT_AUTHORIZED

- MQFB_CICS_UOW_BACKED_OUT
- MQFB_CICS_UOW_ERROR

You can also use an application-specific string of your choice. For more information about this, see the [“Feedback \(MQLONG\)”](#) on page 409 field of the message descriptor (MQMD).

group id

A binary value (MQBYTE24) of length MQ_GROUP_ID_LENGTH unique within a queue. The initial value is MQGI_NONE.

message id

A binary value (MQBYTE24) of length MQ_MSG_ID_LENGTH unique within a queue. The initial value is MQMI_NONE.

Constructors

ImqMessageTracker();

The default constructor.

ImqMessageTracker(const ImqMessageTracker & tracker);

The copy constructor. See the **operator =** method for details.

Object methods (public)

void operator = (const ImqMessageTracker & tracker);

Copies instance data from *tracker*, replacing the existing instance data.

ImqBinary accountingToken () const ;

Returns a copy of the **accounting token**.

ImqBoolean setAccountingToken (const ImqBinary & token);

Sets the **accounting token**. The **data length** of *token* must be either zero or MQ_ACCOUNTING_TOKEN_LENGTH. This method returns TRUE if successful.

void setAccountingToken (const MQBYTE32 token = 0);

Sets the **accounting token**. *token* can be zero, which is the same as specifying MQACT_NONE. If *token* is nonzero, it must address MQ_ACCOUNTING_TOKEN_LENGTH bytes of binary data. When using predefined values such as MQACT_NONE, you might need to make a cast to ensure a signature match; for example, (MQBYTE *)MQACT_NONE.

ImqBinary correlationId () const ;

Returns a copy of the **correlation id**.

ImqBoolean setCorrelationId (const ImqBinary & token);

Sets the **correlation id**. The **data length** of *token* must be either zero or MQ_CORREL_ID_LENGTH. This method returns TRUE if successful.

void setCorrelationId (const MQBYTE24 id = 0);

Sets the **correlation id**. *id* can be zero, which is the same as specifying MQCI_NONE. If *id* is nonzero, it must address MQ_CORREL_ID_LENGTH bytes of binary data. When using predefined values such as MQCI_NONE, you might need to make a cast to ensure a signature match; for example, (MQBYTE *)MQCI_NONE.

MQLONG feedback () const ;

Returns the **feedback**.

void setFeedback (const MQLONG feedback);

Sets the **feedback**.

ImqBinary groupId () const ;

Returns a copy of the **group id**.

ImqBoolean setGroupId (const ImqBinary & token);

Sets the **group id**. The **data length** of *token* must be either zero or MQ_GROUP_ID_LENGTH. This method returns TRUE if successful.

void setGroupId (const MQBYTE24 id = 0);

Sets the **group id**. *id* can be zero, which is the same as specifying MQGI_NONE. If *id* is nonzero, it must address MQ_GROUP_ID_LENGTH bytes of binary data. When using predefined values such as MQGI_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE *)MQGI_NONE.

ImqBinary messageId () const ;

Returns a copy of the **message id**.

ImqBoolean setMessageId (const ImqBinary & token);

Sets the **message id**. The **data length** of *token* must be either zero or MQ_MSG_ID_LENGTH. This method returns TRUE if successful.

void setMessageId (const MQBYTE24 id = 0);

Sets the **message id**. *id* can be zero, which is the same as specifying MQMI_NONE. If *id* is nonzero, it must address MQ_MSG_ID_LENGTH bytes of binary data. When using predefined values such as MQMI_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE *)MQMI_NONE.

Reason codes

- MQRC_BINARY_DATA_LENGTH_ERROR

ImqNamelist C++ class

This class encapsulates a namelist.

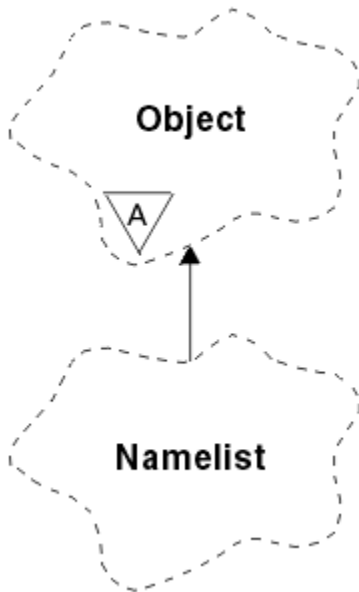

Figure 60. ImqNamelist class

This class relates to the MQI calls listed in [“ImqNamelist cross reference” on page 1828](#).

- [“Object attributes” on page 1879](#)
- [“Constructors” on page 1880](#)
- [“Object methods \(public\)” on page 1880](#)
- [“Reason codes” on page 1880](#)

Object attributes

name count

The number of object names in **namelist names**. This attribute is read-only.

namelist names

Object names, the number of which is indicated by the **name count**. This attribute is read-only.

Constructors

ImqNamelist();

The default constructor.

ImqNamelist(const ImqNamelist & list);

The copy constructor. The ImqObject **open status** is false.

ImqNamelist(const char * name);

Sets the ImqObject name to **name**.

Object methods (public)

void operator = (const ImqNamelist & list);

Copies instance data from *list*, replacing the existing instance data. The ImqObject **open status** is false.

ImqBoolean nameCount(MQLONG & count);

Provides a copy of the **name count**. It returns TRUE if successful.

MQLONG nameCount ();

Returns the **name count** without any indication of possible errors.

ImqBoolean namelistName (const MQLONG index, ImqString & name);

Provides a copy of one the **namelist names** by zero based index. It returns TRUE if successful.

ImqString namelistName (const MQLONG index);

Returns one of the **namelist names** by zero-based index without any indication of possible errors.

Reason codes

- MQRC_INDEX_ERROR
- MQRC_INDEX_NOT_PRESENT

ImqObject C++ class

This class is abstract. When an object of this class is destroyed, it is automatically closed, and its ImqQueueManager connection severed.

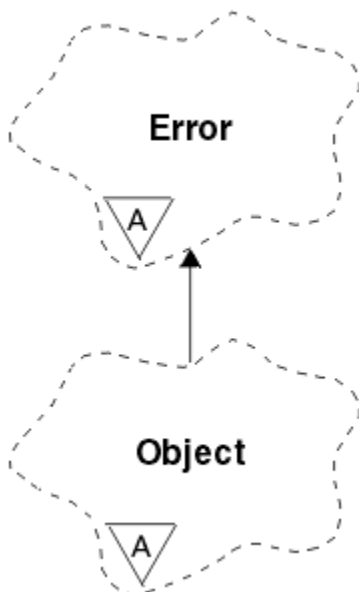

Figure 61. ImqObject class

This class relates to the MQI calls listed in [“ImqObject cross reference” on page 1828](#).

- [“Class attributes” on page 1881](#)
- [“Object attributes” on page 1881](#)

- [“Object data \(protected\)” on page 1885](#)
- [“Reason codes” on page 1885](#)
-

Class attributes

behavior

Controls the behavior of implicit opening.

IMQ_IMPL_OPEN (8L)

Implicit opening is allowed. This is the default.

Object attributes

alteration date

The alteration date. This attribute is read-only.

alteration time

The alteration time. This attribute is read-only.

alternate user id

The alternate user id, up to MQ_USER_ID_LENGTH characters. The initial value is a null string.

alternate security id

The alternate security id. A binary value (MQBYTE40) of length MQ_SECURITY_ID_LENGTH. The initial value is MQSID_NONE.

close options

Options that apply when an object is closed. The initial value is MQCO_NONE. This attribute is ignored during implicit reopen operations, where a value of MQCO_NONE is always used.

connection reference

A reference to an ImqQueueManager object that provides the required connection to a (local) queue manager. For an ImqQueueManager object, it is the object itself. The initial value is zero.

Note: Do not confuse this with the **queue manager name** that identifies a queue manager (possibly remote) for a named queue.

description

The descriptive name (up to 64 characters) of the queue manager, queue, namelist, or process. This attribute is read-only.

name

The name (up to 48 characters) of the queue manager, queue, namelist, or process. The initial value is a null string. The name of a model queue changes after an **open** to the name of the resulting dynamic queue.

Note: An ImqQueueManager can have a null name, representing the default queue manager. The name changes to the actual queue manager after a successful **open**. An ImqDistributionList is dynamic and must have a null name.

next managed object

This is the next object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

open options

Options that apply when an object is opened. The initial value is MQOO_INQUIRE. There are two ways to set appropriate values:

1. Do not set the **open options** and do not use the **open** method. IBM MQ automatically adjusts the **open options** and automatically opens, reopens, and closes objects as required. This can result in unnecessary reopen operations, because IBM MQ uses the **openFor** method, and this adds **open options** incrementally only.
2. Set the **open options** before using any methods that result in an MQI call (see [“C++ and MQI cross-reference” on page 1822](#)). This ensures that unnecessary reopen operations do not occur. Set open options explicitly if any of the potential reopen problems are likely to occur (see [Reopen](#)).

If you use the **open** method, you *must* ensure that the **open options** are appropriate first. However, using the **open** method is not mandatory; IBM MQ still exhibits the same behavior as in case 1, but in this circumstance, the behavior is efficient.

Zero is not a valid value; set the appropriate value before attempting to open the object. This can be done using either **setOpenOptions** (*IOpenOptions*) followed by **open** (), or **openFor** (*IRequiredOpenOption*).

Note:

1. MQOO_OUTPUT is substituted for MQOO_INQUIRE during the **open** method for a distribution list, as MQOO_OUTPUT is the only valid **open option** at this time. However, it is good practice always to set MQOO_OUTPUT explicitly in application programs that use the **open** method.
2. Specify MQOO_RESOLVE_NAMES if you want to use the **resolved queue manager name** and **resolved queue name** attributes of the class.

open status

Whether the object is open (TRUE) or closed (FALSE). The initial value is FALSE. This attribute is read-only.

previous managed object

The previous object of this class, in no particular order, having the same **connection reference** as this object. The initial value is zero.

queue manager identifier

The queue manager identifier. This attribute is read-only.

Constructors

ImqObject();

The default constructor.

ImqObject(const ImqObject & *object*);

The copy constructor. The **open status** will be FALSE.

Class methods (public)

static MQLONG behavior();

Returns the **behavior**.

void setBehavior(const MQLONG *behavior* = 0);

Sets the **behavior**.

Object methods (public)

void operator = (const ImqObject & *object*);

Performs a close if necessary, and copies the instance data from *object*. The **open status** will be FALSE.

ImqBoolean alterationDate(ImqString & *date*);

Provides a copy of the **alteration date**. It returns TRUE if successful.

ImqString alterationDate();

Returns the **alteration date** without any indication of possible errors.

ImqBoolean alterationTime(ImqString & time);

Provides a copy of the **alteration time**. It returns TRUE if successful.

ImqString alterationTime();

Returns the **alteration time** without any indication of possible errors.

ImqString alternateUserId () const ;

Returns a copy of the **alternate user id**.

ImqBoolean setAlternateUserId (const char * id);

Sets the **alternate user id**. The **alternate user id** can be set only while the **open status** is FALSE. This method returns TRUE if successful.

ImqBinary alternateSecurityId () const ;

Returns a copy of the **alternate security id**.

ImqBoolean setAlternateSecurityId(const ImqBinary & token);

Sets the **alternate security id**. The **alternate security id** can be set only while the **open status** is FALSE. The data length of *token* must be either zero or MQ_SECURITY_ID_LENGTH. It returns TRUE if successful.

ImqBoolean setAlternateSecurityId(const MQBYTE* token = 0);

Sets the **alternate security id**. *token* can be zero, which is the same as specifying MQSID_NONE.

If *token* is nonzero, it must address MQ_SECURITY_ID_LENGTH bytes of binary data. When using predefined values such as MQSID_NONE, you might need to make a cast to ensure signature match; for example, (MQBYTE *)MQSID_NONE.

The **alternate security id** can be set only while the **open status** is TRUE. It returns TRUE if successful.

ImqBoolean setAlternateSecurityId(const unsigned char * id = 0);

Sets the **alternate security id**.

ImqBoolean close ();

Sets the **open status** to FALSE. It returns TRUE if successful.

MQLONG closeOptions () const ;

Returns the **close options**.

void setCloseOptions (const MQLONG options);

Sets the **close options**.

ImqQueueManager * connectionReference () const ;

Returns the **connection reference**.

void setConnectionReference (ImqQueueManager & manager);

Sets the **connection reference**.

void setConnectionReference (ImqQueueManager * manager = 0);

Sets the **connection reference**.

virtual ImqBoolean description (ImqString & description) = 0 ;

Provides a copy of the **description**. It returns TRUE if successful.

ImqString description ();

Returns a copy of the **description** without any indication of possible errors.

virtual ImqBoolean name (ImqString & name);

Provides a copy of the **name**. It returns TRUE if successful.

ImqString name ();

Returns a copy of the **name** without any indication of possible errors.

ImqBoolean setName (const char * name = 0);

Sets the **name**. The **name** can only be set while the **open status** is FALSE, and, for an ImqQueueManager, while the **connection status** is FALSE. It returns TRUE if successful.

ImqObject * nextManagedObject () const ;

Returns the **next managed object**.

ImqBoolean open ();

Changes the **open status** to TRUE by opening the object as necessary, using among other attributes the **open options** and the **name**. This method uses the **connection reference** information and the ImqQueueManager **connect** method if necessary to ensure that the ImqQueueManager **connection status** is TRUE. It returns the **open status**.

ImqBoolean openFor (const MQLONG *required-options* = 0);

Attempts to ensure that the object is open with **open options**, or with **open options** that guarantee the behavior implied by the *required-options* parameter value.

If *required-options* is zero, input is required, and any input option suffices. So, if the **open options** already contain one of:

- MQOO_INPUT_AS_Q_DEF
- MQOO_INPUT_SHARED
- MQOO_INPUT_EXCLUSIVE

the **open options** are already satisfactory and are not changed; if the **open options** do not already contain any of these options, MQOO_INPUT_AS_Q_DEF is set in the **open options**.

If *required-options* is nonzero, the required options are added to the **open options** ; if *required-options* is any of these options, the others are reset.

If any of the **open options** are changed and the object is already open, the object is closed temporarily and reopened in order to adjust the **open options**.

It returns TRUE if successful. Success indicates that the object is open with appropriate options.

MQLONG openOptions () const ;

Returns the **open options**.

ImqBoolean setOpenOptions (const MQLONG *options*);

Sets the **open options**. The **open options** can be set only while the **open status** is FALSE. It returns TRUE if successful.

ImqBoolean openStatus () const ;

Returns the **open status**.

ImqObject * previousManagedObject () const ;

Returns the **previous managed object**.

ImqBoolean queueManagerIdentifier(ImqString & *id*);

Provides a copy of the **queue manager identifier**. It returns TRUE if successful.

ImqString queueManagerIdentifier();

Returns the **queue manager identifier** without any indication of possible errors.

Object methods (protected)**virtual ImqBoolean closeTemporarily ();**

Closes an object safely before reopening. It returns TRUE if successful. This method assumes that the **open status** is TRUE.

MQHCONN connectionHandle () const ;

Returns the MQHCONN associated with the **connection reference**. This value is zero if there is no **connection reference** or if the Manager is not connected.

ImqBoolean inquire (const MQLONG *int-attr*, MQLONG & *value*);

Returns an integer value, the index of which is an MQIA_* value. In case of error, the value is set to MQIAV_UNDEFINED.

ImqBoolean inquire (const MQLONG *char-attr*, char * & *buffer*, const size_t *length*);

Returns a character string, the index of which is an MQCA_* value.

Note: Both of these methods return only a single attribute value. If a *snapshot* is required of more than one value, where the values are consistent with each other for an instant, IBM MQ C++ does not provide this facility and you must use the MQINQ call with appropriate parameters.

virtual void openInformationDisperse ();

Disperses information from the variable section of the MQOD data structure immediately after an MQOPEN call.

virtual ImqBoolean openInformationPrepare ();

Prepares information for the variable section of the MQOD data structure immediately before an MQOPEN call, and returns TRUE if successful.

ImqBoolean set (const MQLONG int-attr, const MQLONG value);

Sets an IBM MQ integer attribute.

ImqBoolean set (const MQLONG char-attr, const char * buffer, const size_t required-length);

Sets an IBM MQ character attribute.

void setNextManagedObject (const ImqObject * object = 0);

Sets the **next managed object**.

Attention: Use this function only if you are sure it will not break the managed object list.

void setPreviousManagedObject (const ImqObject * object = 0);

Sets the **previous managed object**.

Attention: Use this function only if you are sure it will not break the managed object list.

Object data (protected)**MQHOBJ ohobj**

The IBM MQ object handle (valid only when **open status** is TRUE).

MQOD omqod

The embedded MQOD data structure. The amount of storage allocated for this data structure is that required for an MQOD Version 2. Inspect the version number (*omqod.Version*) and access the other fields as follows:

MQOD_VERSION_1

All other fields in *omqod* can be accessed.

MQOD_VERSION_2

All other fields in *omqod* can be accessed.

MQOD_VERSION_3

omqod.pmqod is a pointer to a dynamically allocated, larger, MQOD. No other fields in *omqod* can be accessed. All fields addressed by *omqod.pmqod* can be accessed.

Note: *omqod.pmqod.Version* can be less than *omqod.Version*, indicating that the IBM MQ MQI client has more functionality than the IBM MQ server.

Reason codes

- MQRC_ATTRIBUTE_LOCKED

ImqProcess C++ class

This class encapsulates an application process (an IBM MQ object of type MQOT_PROCESS) that can be triggered by a trigger monitor.

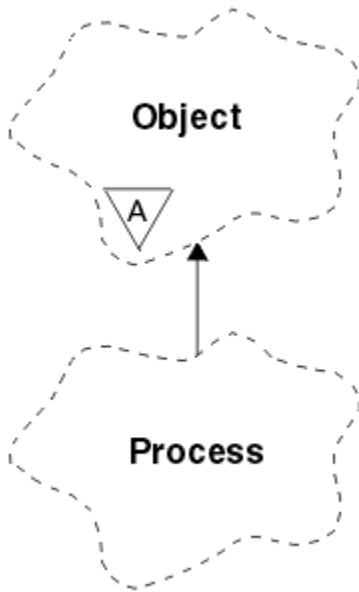

Figure 62. ImqProcess class

- [“Object attributes” on page 1886](#)
- [“Constructors” on page 1886](#)
- [“Object methods \(public\)” on page 1886](#)

Object attributes

application id

The identity of the application process. This attribute is read-only.

application type

The type of the application process. This attribute is read-only.

environment data

The environment information for the process. This attribute is read-only.

user data

User data for the process. This attribute is read-only.

Constructors

ImqProcess();

The default constructor.

ImqProcess(const ImqProcess & process);

The copy constructor. The ImqObject **open status** is FALSE.

ImqProcess(const char * name);

Sets the ImqObject **name**.

Object methods (public)

void operator = (const ImqProcess & process);

Performs a close if necessary, and then copies instance data from *process*. The ImqObject **open status** will be FALSE.

ImqBoolean applicationId (ImqString & id);

Provides a copy of the **application id**. It returns TRUE if successful.

ImqString applicationId ();

Returns the **application id** without any indication of possible errors.

ImqBoolean applicationType (MQLONG & type);

Provides a copy of the **application type**. It returns TRUE if successful.

MQLONG applicationType ();

Returns the **application type** without any indication of possible errors.

ImqBoolean environmentData (ImqString & data);

Provides a copy of the **environment data**. It returns TRUE if successful.

ImqString environmentData ();

Returns the **environment data** without any indication of possible errors.

ImqBoolean userData (ImqString & data);

Provides a copy of the **user data**. It returns TRUE if successful.

ImqString userData ();

Returns the **user data** without any indication of possible errors.

ImqPutMessageOptions C++ class

This class encapsulates the MQPMO data structure.

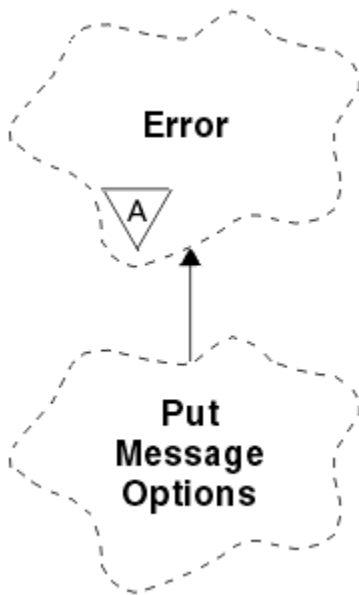

Figure 63. *ImqPutMessageOptions* class

- [“Object attributes” on page 1887](#)
- [“Constructors” on page 1888](#)
- [“Object methods \(public\)” on page 1888](#)
- [“Object data \(protected\)” on page 1889](#)
- [“Reason codes” on page 1889](#)

Object attributes

context reference

An ImqQueue that provides a context for messages. Initially there is no reference.

options

The put message options. The initial value is MQPMO_NONE. The following additional values are possible:

- MQPMO_SYNCPOINT
- MQPMO_NO_SYNCPOINT
- MQPMO_NEW_MSG_ID
- MQPMO_NEW_CORREL_ID
- MQPMO_LOGICAL_ORDER
- MQPMO_NO_CONTEXT
- MQPMO_DEFAULT_CONTEXT
- MQPMO_PASS_IDENTITY_CONTEXT
- MQPMO_PASS_ALL_CONTEXT
- MQPMO_SET_IDENTITY_CONTEXT
- MQPMO_SET_ALL_CONTEXT
- MQPMO_ALTERNATE_USER_AUTHORITY
- MQPMO_FAIL_IF QUIESCING

record fields

The flags that control the inclusion of put message records when a message is put. The initial value is MQPMRF_NONE. The following additional values are possible:

- MQPMRF_MSG_ID
- MQPMRF_CORREL_ID
- MQPMRF_GROUP_ID
- MQPMRF_FEEDBACK
- MQPMRF_ACCOUNTING_TOKEN

ImqMessageTracker attributes are taken from the object for any field that is specified.

ImqMessageTracker attributes are taken from the ImqMessage object for any field that is *not* specified.

resolved queue manager name

Name of a destination queue manager determined during a put. The initial value is null. This attribute is read-only.

resolved queue name

Name of a destination queue determined during a put. The initial value is null. This attribute is read-only.

syncpoint participation

TRUE when messages are put under syncpoint control.

Constructors

ImqPutMessageOptions();

The default constructor.

ImqPutMessageOptions(const ImqPutMessageOptions & pmo);

The copy constructor.

Object methods (public)

void operator = (const ImqPutMessageOptions & pmo);

Copies instance data from *pmo*, replacing the existing instance data.

ImqQueue * contextReference () const ;

Returns the **context reference**.

void setContextReference (const ImqQueue & *queue*);

Sets the **context reference**.

void setContextReference (const ImqQueue * *queue* = 0);

Sets the **context reference**.

MQLONG options () const ;

Returns the **options**.

void setOptions (const MQLONG *options*);

Sets the **options**, including the **syncpoint participation** value.

MQLONG recordFields () const ;

Returns the **record fields**.

void setRecordFields (const MQLONG *fields*);

Sets the **record fields**.

ImqString resolvedQueueManagerName () const ;

Returns a copy of the **resolved queue manager name**.

ImqString resolvedQueueName () const ;

Returns a copy of the **resolved queue name**.

ImqBoolean syncPointParticipation () const ;

Returns the **syncpoint participation** value, which is TRUE if the **options** include MQPMO_SYNCPOINT.

void setSyncPointParticipation (const ImqBoolean *sync*);

Sets the **syncpoint participation** value. If *sync* is TRUE, the **options** are altered to include MQPMO_SYNCPOINT, and to exclude MQPMO_NO_SYNCPOINT. If *sync* is FALSE, the **options** are altered to include MQPMO_NO_SYNCPOINT, and to exclude MQPMO_SYNCPOINT.

Object data (protected)

MQPMO *omqpmo*

The MQPMO data structure.

Reason codes

- MQRC_STORAGE_NOT_AVAILABLE

ImqQueue C++ class

This class encapsulates a message queue (an IBM MQ object of type MQOT_Q).

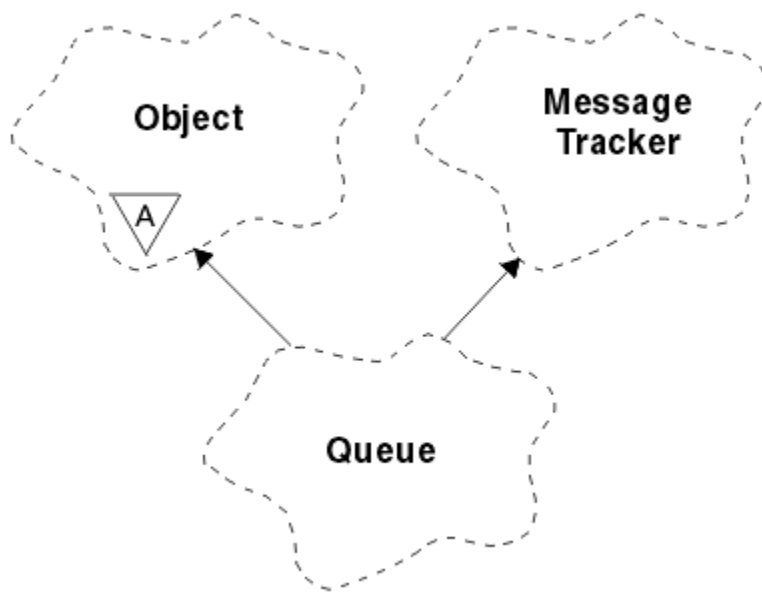

Figure 64. *ImqQueue* class

This class relates to the MQI calls listed in [Table 674 on page 1829](#).

- [“Object attributes” on page 1890](#)
- [“Constructors” on page 1893](#)
- [“Object methods \(public\)” on page 1893](#)
- [“Object methods \(protected\)” on page 1899](#)
- [“Reason codes” on page 1899](#)

Object attributes

backout requeue name

Excessive backout requeue name. This attribute is read-only.

backout threshold

Backout threshold. This attribute is read-only.

base queue name

Name of the queue that the alias resolves to. This attribute is read-only.

cluster name

Cluster name. This attribute is read-only.

cluster namelist name

Cluster namelist name. This attribute is read-only.

cluster workload rank

Cluster workload rank. This attribute is read-only.

cluster workload priority

Cluster workload priority. This attribute is read-only.

cluster workload use queue

Cluster workload use queue value. This attribute is read-only.

creation date

Queue creation data. This attribute is read-only.

creation time

Queue creation time. This attribute is read-only.

current depth

Number of messages on the queue. This attribute is read-only.

default bind

Default bind. This attribute is read-only.

default input open option

Default open-for-input option. This attribute is read-only.

default persistence

Default message persistence. This attribute is read-only.

default priority

Default message priority. This attribute is read-only.

definition type

Queue definition type. This attribute is read-only.

depth high event

Control attribute for queue depth high events. This attribute is read-only.

depth high limit

High limit for the queue depth. This attribute is read-only.

depth low event

Control attribute for queue depth low events. This attribute is read-only.

depth low limit

Low limit for the queue depth. This attribute is read-only.

depth maximum event

Control attribute for queue depth maximum events. This attribute is read-only.

distribution list reference

Optional reference to an `ImqDistributionList` that can be used to distribute messages to more than one queue, including this one. The initial value is null.

Note: When an `ImqQueue` object is opened, any open `ImqDistributionList` object that it references is automatically closed.

distribution lists

The capability of a transmission queue to support distribution lists. This attribute is read-only.

dynamic queue name

Dynamic queue name. The initial value is `AMQ.*` for all Windows, UNIX, and Linux platforms.

harden get backout

Whether to harden the backout count. This attribute is read-only.

index type

Index type. This attribute is read-only.

inhibit get

Whether get operations are allowed. The initial value is dependent on the queue definition. This attribute is valid for an alias or local queue only.

inhibit put

Whether put operations are allowed. The initial value is dependent on the queue definition.

initiation queue name

Name of the initiation queue. This attribute is read-only.

maximum depth

Maximum number of messages allowed on the queue. This attribute is read-only.

maximum message length

Maximum length for any message on this queue, which can be less than the maximum for any queue managed by the associated queue manager. This attribute is read-only.

message delivery sequence

Whether message priority is relevant. This attribute is read-only.

next distributed queue

Next object of this class, in no particular order, having the same **distribution list reference** as this object. The initial value is zero.

If an object in a chain is deleted, the previous object and next object are updated so that their distributed queue links no longer point to the deleted object.

non-persistent message class

Level of reliability for non-persistent messages put to this queue. This attribute is read-only.

open input count

Number of ImqQueue objects that are open for input. This attribute is read-only.

open output count

Number of ImqQueue objects that are open for output. This attribute is read-only.

previous distributed queue

Previous object of this class, in no particular order, having the same **distribution list reference** as this object. The initial value is zero.

If an object in a chain is deleted, the previous object and next object are updated so that their distributed queue links no longer point to the deleted object.

process name

Name of the process definition. This attribute is read-only.

queue accounting

Level of accounting information for queues. This attribute is read-only.

queue manager name

Name of the queue manager (possibly remote) where the queue resides. Do not confuse the queue manager named here with the ImqObject **connection reference**, which references the (local) queue manager providing a connection. The initial value is null.

queue monitoring

Level of monitoring data collection for the queue. This attribute is read-only.

queue statistics

Level of statistics data for the queue. This attribute is read-only.

queue type

Queue type. This attribute is read-only.

remote queue manager name

Name of the remote queue manager. This attribute is read-only.

remote queue name

Name of the remote queue as known on the remote queue manager. This attribute is read-only.

resolved queue manager name

Resolved queue manager name. This attribute is read-only.

resolved queue name

Resolved queue name. This attribute is read-only.

retention interval

Queue retention interval. This attribute is read-only.

scope

Scope of the queue definition. This attribute is read-only.

service interval

Service interval. This attribute is read-only.

service interval event

Control attribute for service interval events. This attribute is read-only.

shareability

Whether the queue can be shared. This attribute is read-only.

storage class

Storage class. This attribute is read-only.

transmission queue name

Name of the transmission queue. This attribute is read-only.

trigger control

Trigger control. The initial value depends on the queue definition. This attribute is valid for a local queue only.

trigger data

Trigger data. The initial value depends on the queue definition. This attribute is valid for a local queue only.

trigger depth

Trigger depth. The initial value depends on the queue definition. This attribute is valid for a local queue only.

trigger message priority

Threshold message priority for triggers. The initial value depends on the queue definition. This attribute is valid for a local queue only.

trigger type

Trigger type. The initial value depends on the queue definition. This attribute is valid for a local queue only.

usage

Usage. This attribute is read-only.

Constructors**ImqQueue();**

The default constructor.

ImqQueue(const ImqQueue & *queue*);

The copy constructor. The ImqObject **open status** will be FALSE.

ImqQueue(const char * *name*);

Sets the ImqObject **name**.

Object methods (public)**void operator = (const ImqQueue & *queue*);**

Performs a close if necessary, and then copies instance data from *queue*. The ImqObject **open status** will be FALSE.

ImqBoolean backoutRequeueName (ImqString & *name*);

Provides a copy of the **backout requeue name**. It returns TRUE if successful.

ImqString backoutRequeueName ();

Returns the **backout requeue name** without any indication of possible errors.

ImqBoolean backoutThreshold (MQLONG & *threshold*);

Provides a copy of the **backout threshold**. It returns TRUE if successful.

MQLONG backoutThreshold ();

Returns the **backout threshold** value without any indication of possible errors.

ImqBoolean baseQueueName (ImqString & *name*);

Provides a copy of the **base queue name**. It returns TRUE if successful.

ImqString baseQueueName ();

Returns the **base queue name** without any indication of possible errors.

ImqBoolean clusterName(ImqString & *name*);

Provides a copy of the **cluster name**. It returns TRUE if successful.

ImqString clusterName();

Returns the **cluster name** without any indication of possible errors.

ImqBoolean clusterNamelistName(ImqString & name);

Provides a copy of the **cluster namelist name**. It returns TRUE if successful.

ImqString clusterNamelistName();

Returns the **cluster namelist name** without any indication of errors.

ImqBoolean clusterWorkLoadPriority (MQLONG & priority);

Provides a copy of the cluster workload priority value. It returns TRUE if successful.

MQLONG clusterWorkLoadPriority ();

Returns the cluster workload priority value without any indication of possible errors.

ImqBoolean clusterWorkLoadRank (MQLONG & rank);

Provides a copy of the cluster workload rank value. It returns TRUE if successful.

MQLONG clusterWorkLoadRank ();

Returns the cluster workload rank value without any indication of possible errors.

ImqBoolean clusterWorkLoadUseQ (MQLONG & useq);

Provides a copy of the cluster workload use queue value. It returns TRUE if successful.

MQLONG clusterWorkLoadUseQ ();

Returns the cluster workload use queue value without any indication of possible errors.

ImqBoolean creationDate (ImqString & date);

Provides a copy of the **creation date**. It returns TRUE if successful.

ImqString creationDate ();

Returns the **creation date** without any indication of possible errors.

ImqBoolean creationTime (ImqString & time);

Provides a copy of the **creation time**. It returns TRUE if successful.

ImqString creationTime ();

Returns the **creation time** without any indication of possible errors.

ImqBoolean currentDepth (MQLONG & depth);

Provides a copy of the **current depth**. It returns TRUE if successful.

MQLONG currentDepth ();

Returns the **current depth** without any indication of possible errors.

ImqBoolean defaultInputOpenOption (MQLONG & option);

Provides a copy of the **default input open option**. It returns TRUE if successful.

MQLONG defaultInputOpenOption ();

Returns the **default input open option** without any indication of possible errors.

ImqBoolean defaultPersistence (MQLONG & persistence);

Provides a copy of the **default persistence**. It returns TRUE if successful.

MQLONG defaultPersistence ();

Returns the **default persistence** without any indication of possible errors.

ImqBoolean defaultPriority (MQLONG & priority);

Provides a copy of the **default priority**. It returns TRUE if successful.

MQLONG defaultPriority ();

Returns the **default priority** without any indication of possible errors.

ImqBoolean defaultBind (MQLONG & bind);

Provides a copy of the **default bind**. It returns TRUE if successful.

MQLONG defaultBind ();

Returns the **default bind** without any indication of possible errors.

ImqBoolean definitionType (MQLONG & type);

Provides a copy of the **definition type**. It returns TRUE if successful.

MQLONG definitionType ();

Returns the **definition type** without any indication of possible errors.

ImqBoolean depthHighEvent (MQLONG & event);

Provides a copy of the enablement state of the **depth high event**. It returns TRUE if successful.

MQLONG depthHighEvent ();

Returns the enablement state of the **depth high event** without any indication of possible errors.

ImqBoolean depthHighLimit (MQLONG & limit);

Provides a copy of the **depth high limit**. It returns TRUE if successful.

MQLONG depthHighLimit ();

Returns the **depth high limit** value without any indication of possible errors.

ImqBoolean depthLowEvent (MQLONG & event);

Provides a copy of the enablement state of the **depth low event**. It returns TRUE if successful.

MQLONG depthLowEvent ();

Returns the enablement state of the **depth low event** without any indication of possible errors.

ImqBoolean depthLowLimit (MQLONG & limit);

Provides a copy of the **depth low limit**. It returns TRUE if successful.

MQLONG depthLowLimit ();

Returns the **depth low limit** value without any indication of possible errors.

ImqBoolean depthMaximumEvent (MQLONG & event);

Provides a copy of the enablement state of the **depth maximum event**. It returns TRUE if successful.

MQLONG depthMaximumEvent ();

Returns the enablement state of the **depth maximum event** without any indication of possible errors.

ImqDistributionList * distributionListReference () const ;

Returns the **distribution list reference**.

void setDistributionListReference (ImqDistributionList & list);

Sets the **distribution list reference**.

void setDistributionListReference (ImqDistributionList * list = 0);

Sets the **distribution list reference**.

ImqBoolean distributionLists (MQLONG & support);

Provides a copy of the **distribution lists** value. It returns TRUE if successful.

MQLONG distributionLists ();

Returns the **distribution lists** value without any indication of possible errors.

ImqBoolean setDistributionLists (const MQLONG support);

Sets the **distribution lists** value. It returns TRUE if successful.

ImqString dynamicQueueName () const ;

Returns a copy of the **dynamic queue name**.

ImqBoolean setDynamicQueueName (const char * name);

Sets the **dynamic queue name**. The **dynamic queue name** can be set only while the ImqObject **open status** is FALSE. It returns TRUE if successful.

ImqBoolean get (ImqMessage & msg, ImqGetMessageOptions & options);

Retrieves a message from the queue, using the specified *options*. Invokes the ImqObject **openFor** method if necessary to ensure that the ImqObject **open options** include either one of the MQOO_INPUT_* values, or the MQOO_BROWSE value, depending on the *options*. If the *msg* object has an ImqCache **automatic buffer**, the buffer grows to accommodate any message retrieved. The **clearMessage** method is invoked against the *msg* object before retrieval.

This method returns TRUE if successful.

Note: The result of the method invocation is FALSE if the ImqObject **reason code** is MQRC_TRUNCATED_MSG_FAILED, even though this **reason code** is classified as a warning. If a truncated message is accepted, the ImqCache **message length** reflects the truncated length. In either event, the ImqMessage **total message length** indicates the number of bytes that were available.

ImqBoolean get (ImqMessage & msg);

As for the previous method, except that default get message options are used.

ImqBoolean get (ImqMessage & msg, ImqGetMessageOptions & options, const size_t buffer-size);
 As for the previous two methods, except that an overriding *buffer-size* is indicated. If the *msg* object employs an ImqCache **automatic buffer**, the **resizeBuffer** method is invoked on the *msg* object prior to message retrieval, and the buffer does not grow further to accommodate any larger message.

ImqBoolean get (ImqMessage & msg, const size_t buffer-size);
 As for the previous method, except that default get message options are used.

ImqBoolean hardenGetBackout (MQLONG & harden);
 Provides a copy of the **harden get backout** value. It returns TRUE if successful.

MQLONG hardenGetBackout ();
 Returns the **harden get backout** value without any indication of possible errors.

ImqBoolean indexType(MQLONG & type);
 Provides a copy of the **index type**. It returns TRUE if successful.

MQLONG indexType();
 Returns the **index type** without any indication of possible errors.

ImqBoolean inhibitGet (MQLONG & inhibit);
 Provides a copy of the **inhibit get** value. It returns TRUE if successful.

MQLONG inhibitGet ();
 Returns the **inhibit get** value without any indication of possible errors.

ImqBoolean setInhibitGet (const MQLONG inhibit);
 Sets the **inhibit get** value. It returns TRUE if successful.

ImqBoolean inhibitPut (MQLONG & inhibit);
 Provides a copy of the **inhibit put** value. It returns TRUE if successful.

MQLONG inhibitPut ();
 Returns the **inhibit put** value without any indication of possible errors.

ImqBoolean setInhibitPut (const MQLONG inhibit);
 Sets the **inhibit put** value. It returns TRUE if successful.

ImqBoolean initiationQueueName (ImqString & name);
 Provides a copy of the **initiation queue name**. It returns TRUE if successful.

ImqString initiationQueueName ();
 Returns the **initiation queue name** without any indication of possible errors.

ImqBoolean maximumDepth (MQLONG & depth);
 Provides a copy of the **maximum depth**. It returns TRUE if successful.

MQLONG maximumDepth ();
 Returns the **maximum depth** without any indication of possible errors.

ImqBoolean maximumMessageLength (MQLONG & length);
 Provides a copy of the **maximum message length**. It returns TRUE if successful.

MQLONG maximumMessageLength ();
 Returns the **maximum message length** without any indication of possible errors.

ImqBoolean messageDeliverySequence (MQLONG & sequence);
 Provides a copy of the **message delivery sequence**. It returns TRUE if successful.

MQLONG messageDeliverySequence ();
 Returns the **message delivery sequence** value without any indication of possible errors.

ImqQueue * nextDistributedQueue () const ;
 Returns the **next distributed queue**.

ImqBoolean nonPersistentMessageClass (MQLONG & monq);
 Provides a copy of the non persistent message class value. It returns TRUE if successful.

MQLONG nonPersistentMessageClass ();
 Returns the non persistent message class value without any indication of possible errors.

ImqBoolean openInputCount (MQLONG & count);
 Provides a copy of the **open input count**. It returns TRUE if successful.

MQLONG openInputCount ();

Returns the **open input count** without any indication of possible errors.

ImqBoolean openOutputCount (MQLONG & count);

Provides a copy of the **open output count**. It returns TRUE if successful.

MQLONG openOutputCount ();

Returns the **open output count** without any indication of possible errors.

ImqQueue * previousDistributedQueue () const ;

Returns the **previous distributed queue**.

ImqBoolean processName (ImqString & name);

Provides a copy of the **process name**. It returns TRUE if successful.

ImqString processName ();

Returns the **process name** without any indication of possible errors.

ImqBoolean put (ImqMessage & msg);

Places a message onto the queue, using default put message options. Uses the ImqObject **openFor** method if necessary to ensure that the ImqObject **open options** include MQOO_OUTPUT.

This method returns TRUE if successful.

ImqBoolean put (ImqMessage & msg, ImqPutMessageOptions & pmo);

Places a message onto the queue, using the specified *pmo*. Uses the ImqObject **openFor** method as necessary to ensure that the ImqObject **open options** include MQOO_OUTPUT, and (if the *pmo options* include any of MQPMO_PASS_IDENTITY_CONTEXT, MQPMO_PASS_ALL_CONTEXT, MQPMO_SET_IDENTITY_CONTEXT, or MQPMO_SET_ALL_CONTEXT) corresponding MQOO_*_CONTEXT values.

This method returns TRUE if successful.

Note: If the *pmo* includes a **context reference**, the referenced object is opened, if necessary, to provide a context.

ImqBoolean queueAccounting (MQLONG & acctq);

Provides a copy of the queue accounting value. It returns TRUE if successful.

MQLONG queueAccounting ();

Returns the queue accounting value without any indication of possible errors.

ImqString queueManagerName () const ;

Returns the **queue manager name**.

ImqBoolean setQueueManagerName (const char * name);

Sets the **queue manager name**. The **queue manager name** can be set only while the ImqObject **open status** is FALSE. This method returns TRUE if successful.

ImqBoolean queueMonitoring (MQLONG & monq);

Provides a copy of the queue monitoring value. It returns TRUE if successful.

MQLONG queueMonitoring ();

Returns the queue monitoring value without any indication of possible errors.

ImqBoolean queueStatistics (MQLONG & statq);

Provides a copy of the queue statistics value. It returns TRUE if successful.

MQLONG queueStatistics ();

Returns the queue statistics value without any indication of possible errors.

ImqBoolean queueType (MQLONG & type);

Provides a copy of the **queue type** value. It returns TRUE if successful.

MQLONG queueType ();

Returns the **queue type** without any indication of possible errors.

ImqBoolean remoteQueueManagerName (ImqString & name);

Provides a copy of the **remote queue manager name**. It returns TRUE if successful.

ImqString remoteQueueManagerName ();

Returns the **remote queue manager name** without any indication of possible errors.

ImqBoolean remoteQueueName (ImqString & *name*);

Provides a copy of the **remote queue name**. It returns TRUE if successful.

ImqString remoteQueueName ();

Returns the **remote queue name** without any indication of possible errors.

ImqBoolean resolvedQueueManagerName(ImqString & *name*);

Provides a copy of the **resolved queue manager name**. It returns TRUE if successful.

Note: This method fails unless MQOO_RESOLVE_NAMES is among the ImqObject **open options**.

ImqString resolvedQueueManagerName();

Returns the **resolved queue manager name**, without any indication of possible errors.

ImqBoolean resolvedQueueName(ImqString & *name*);

Provides a copy of the **resolved queue name**. It returns TRUE if successful.

Note: This method fails unless MQOO_RESOLVE_NAMES is among the ImqObject **open options**.

ImqString resolvedQueueName();

Returns the **resolved queue name**, without any indication of possible errors.

ImqBoolean retentionInterval (MQLONG & *interval*);

Provides a copy of the **retention interval**. It returns TRUE if successful.

MQLONG retentionInterval ();

Returns the **retention interval** without any indication of possible errors.

ImqBoolean scope (MQLONG & *scope*);

Provides a copy of the **scope**. It returns TRUE if successful.

MQLONG scope ();

Returns the **scope** without any indication of possible errors.

ImqBoolean serviceInterval (MQLONG & *interval*);

Provides a copy of the **service interval**. It returns TRUE if successful.

MQLONG serviceInterval ();

Returns the **service interval** without any indication of possible errors.

ImqBoolean serviceIntervalEvent (MQLONG & *event*);

Provides a copy of the enablement state of the **service interval event**. It returns TRUE if successful.

MQLONG serviceIntervalEvent ();

Returns the enablement state of the **service interval event** without any indication of possible errors.

ImqBoolean shareability (MQLONG & *shareability*);

Provides a copy of the **shareability** value. It returns TRUE if successful.

MQLONG shareability ();

Returns the **shareability** value without any indication of possible errors.

ImqBoolean storageClass(ImqString & *class*);

Provides a copy of the **storage class**. It returns TRUE if successful.

ImqString storageClass();

Returns the **storage class** without any indication of possible errors.

ImqBoolean transmissionQueueName (ImqString & *name*);

Provides a copy of the **transmission queue name**. It returns TRUE if successful.

ImqString transmissionQueueName ();

Returns the **transmission queue name** without any indication of possible errors.

ImqBoolean triggerControl (MQLONG & *control*);

Provides a copy of the **trigger control** value. It returns TRUE if successful.

MQLONG triggerControl ();

Returns the **trigger control** value without any indication of possible errors.

ImqBoolean setTriggerControl (const MQLONG *control*);

Sets the **trigger control** value. It returns TRUE if successful.

ImqBoolean triggerData (ImqString & *data*);

Provides a copy of the **trigger data**. It returns TRUE if successful.

ImqString triggerData ();

Returns a copy of the **trigger data** without any indication of possible errors.

ImqBoolean setTriggerData (const char * *data*);

Sets the **trigger data**. It returns TRUE if successful.

ImqBoolean triggerDepth (MQLONG & *depth*);

Provides a copy of the **trigger depth**. It returns TRUE if successful.

MQLONG triggerDepth ();

Returns the **trigger depth** without any indication of possible errors.

ImqBoolean setTriggerDepth (const MQLONG *depth*);

Sets the **trigger depth**. It returns TRUE if successful.

ImqBoolean triggerMessagePriority (MQLONG & *priority*);

Provides a copy of the **trigger message priority**. It returns TRUE if successful.

MQLONG triggerMessagePriority ();

Returns the **trigger message priority** without any indication of possible errors.

ImqBoolean setTriggerMessagePriority (const MQLONG *priority*);

Sets the **trigger message priority**. It returns TRUE if successful.

ImqBoolean triggerType (MQLONG & *type*);

Provides a copy of the **trigger type**. It returns TRUE if successful.

MQLONG triggerType ();

Returns the **trigger type** without any indication of possible errors.

ImqBoolean setTriggerType (const MQLONG *type*);

Sets the **trigger type**. It returns TRUE if successful.

ImqBoolean usage (MQLONG & *usage*);

Provides a copy of the **usage** value. It returns TRUE if successful.

MQLONG usage ();

Returns the **usage** value without any indication of possible errors.

Object methods (protected)

void setNextDistributedQueue (ImqQueue * *queue* = 0);

Sets the **next distributed queue**.

Attention: Use this function only if you are sure it will not break the distributed queue list.

void setPreviousDistributedQueue (ImqQueue * *queue* = 0);

Sets the **previous distributed queue**.

Attention: Use this function only if you are sure it will not break the distributed queue list.

Reason codes

ImqQueueManager C++ class

This class encapsulates a queue manager (an IBM MQ object of type MQOT_Q_MGR).

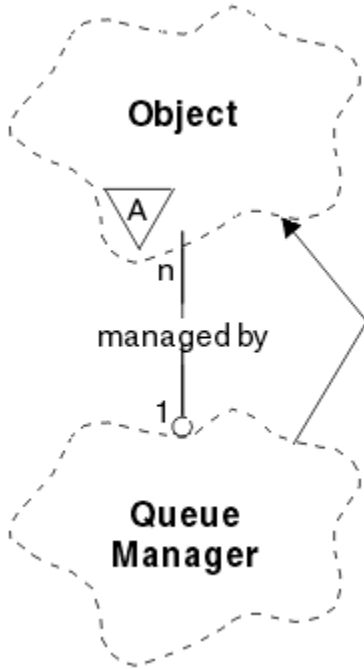

Figure 65. ImqQueueManager class

This class relates to the MQI calls listed in [“ImqQueueManager cross-reference”](#) on page 1832. Not all the listed methods are applicable to all platforms; see [ALTER QMGR](#) for more details.

- [“Class attributes”](#) on page 1900

Class attributes

behavior

Controls the behavior of implicit connection and disconnection.

IMQ_EXPL_DISC_BACKOUT (0L)

An explicit call to the **disconnect** method implies backout. This attribute is mutually exclusive with IMQ_EXPL_DISC_COMMIT.

IMQ_EXPL_DISC_COMMIT (1L)

An explicit call to the **disconnect** method implies commit (the default). This attribute is mutually exclusive with IMQ_EXPL_DISC_BACKOUT.

IMQ_IMPL_CONN (2L)

Implicit connection is allowed (the default).

IMQ_IMPL_DISC_BACKOUT (0L)

An implicit call to the **disconnect** method, which can occur during object destruction, implies backout. This attribute is mutually exclusive with the IMQ_IMPL_DISC_COMMIT.

IMQ_IMPL_DISC_COMMIT (4L)

An implicit call to the **disconnect** method, which can occur during object destruction, implies commit (the default). This attribute is mutually exclusive with IMQ_IMPL_DISC_BACKOUT.

At IBM MQ V7.0 and above, C++ applications that make use of an implicit connection, need to specify IMQ_IMPL_CONN along with any other options provided in the `setBehavior()` method on an object of class `ImqQueueManager`. If your application does not use the `setBehavior()` method to explicitly set the behavior options, for example,

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_DISC_COMMIT)
```

this change does not affect you since MQ_IMPL_CONN is enabled by default.

If your application explicitly sets the behavior options, for example,

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_DISC_COMMIT)
```

you need to include IMQ_IMPL_CONN in the `setBehavior()` method as follows, to allow your application to complete an implicit connection:

```
ImqQueueManager_object.setBehavior(IMQ_IMPL_CONN | IMQ_IMPL_DISC_COMMIT)
```

Object attributes**accounting connections override**

Allows applications to override the setting of the MQI accounting and queue accounting values. This attribute is read-only.

accounting interval

How long before intermediate accounting records are written (in seconds). This attribute is read-only.

activity recording

Controls the generation of activity reports. This attribute is read-only.

adopt new mca check

The elements checked to determine if an MCA should be adopted when a new inbound channel is detected that has the same name as an MCA that is already active. This attribute is read-only.

adopt new mca type

Whether an orphaned instance of an MCA of a particular channel type should be restarted automatically when a new inbound channel request matching the adopt new mca check parameters is detected. This attribute is read-only.

authentication type

Indicates the type of authentication which is being performed.

authority event

Controls authority events. This attribute is read-only.

begin options

Options that apply to the **begin** method. The initial value is MQBO_NONE.

bridge event

Whether IMS bridge events are generated. This attribute is read-only.

channel auto definition

Channel auto definition value. This attribute is read-only.

channel auto definition event

Channel auto definition event value. This attribute is read-only.

channel auto definition exit

Channel auto definition exit name. This attribute is read-only.

channel event

Whether channel events are generated. This attribute is read-only.

channel initiator adapters

The number of adapter subtasks to use for processing IBM MQ calls. This attribute is read-only.

channel initiator control

Whether the Channel Initiator should be started automatically when the Queue Manager is started.
This attribute is read-only.

channel initiator dispatchers

The number of dispatchers to use for the channel initiator. This attribute is read-only.

channel initiator trace autostart

Whether channel initiator trace should start automatically or not. This attribute is read-only.

channel initiator trace table size

The size of the channel initiator's trace data space (in MB). This attribute is read-only.

channel monitoring

Controls the collection of online monitoring data for channels. This attribute is read-only.

channel reference

A reference to a channel definition for use during client connection. While connected, this attribute can be set to null, but cannot be changed to any other value. The initial value is null.

channel statistics

Controls the collection of statistics data for channels. This attribute is read-only.

character set

Coded character set identifier (CCSID). This attribute is read-only.

cluster sender monitoring

Controls the collection of online monitoring data for automatically-defined cluster sender channels.
This attribute is read-only.

cluster sender statistics

Controls the collection of statistics data for automatically defined cluster sender channels. This attribute is read-only.

cluster workload data

Cluster workload exit data. This attribute is read-only.

cluster workload exit

Cluster workload exit name. This attribute is read-only.

cluster workload length

Cluster workload length. This attribute is read-only.

cluster workload mru

Cluster workload most recently used channels value. This attribute is read-only.

cluster workload use queue

Cluster workload use queue value. This attribute is read-only.

command event

Whether command events are generated. This attribute is read-only.

command input queue name

System command input queue name. This attribute is read-only.

command level

Command level supported by the queue manager. This attribute is read-only.

command server control

Whether the Command Server should be started automatically when the Queue Manager is started.
This attribute is read-only.

connect options

Options that apply to the **connect** method. The initial value is MQCNO_NONE. The following additional values may be possible, depending on platform:

- MQCNO_STANDARD_BINDING
- MQCNO_FASTPATH_BINDING
- MQCNO_HANDLE_SHARE_NONE
- MQCNO_HANDLE_SHARE_BLOCK
- MQCNO_HANDLE_SHARE_NO_BLOCK
- MQCNO_SERIALIZE_CONN_TAG_Q_MGR
- MQCNO_SERIALIZE_CONN_TAG_QSG
- MQCNO_RESTRICT_CONN_TAG_Q_MGR
- MQCNO_RESTRICT_CONN_TAG_QSG

connection id

A unique identifier that allows MQ to reliably identify an application.

connection status

TRUE when connected to the queue manager. This attribute is read-only.

connection tag

A tag to be associated with a connection. This attribute can only be set when not connected. The initial value is null.

cryptographic hardware

Configuration details for cryptographic hardware. For MQ MQI client connections.

dead-letter queue name

Name of the dead-letter queue. This attribute is read-only.

default transmission queue name

Default transmission queue name. This attribute is read-only.

distribution lists

Capability of the queue manager to support distribution lists.

dns group

The name of the group that the TCP listener that handles inbound transmissions for the queue-sharing group should join when using Workload Manager Dynamic Domain Name Services support. This attribute is read-only.

dns wlm

Whether the TCP listener that handles inbound transmissions for the queue-sharing group should register with Workload Manager for Dynamic Domain Name Services. This attribute is read-only.

first authentication record

The first of one or more objects of class ImqAuthenticationRecord, in no particular order, in which the ImqAuthenticationRecord connection reference addresses this object. For MQ MQI client connections.

first managed object

The first of one or more objects of class ImqObject, in no particular order, in which the ImqObject **connection reference** addresses this object. The initial value is zero.

inhibit event

Controls inhibit events. This attribute is read-only.

ip address version

Which IP protocol (IPv4 or IPv6) to use for a channel connection. This attribute is read-only.

key repository

Location of the key database file in which keys and certificates are stored. For IBM MQ MQI client connections.

key reset count

The number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated. This attribute applies only to client connections using MQCONN. See also [ssl key reset count](#).

listener timer

The time interval (in seconds) between attempts by IBM MQ to restart the listener if there has been an APPC or TCP/IP failure. This attribute is read-only.

local event

Controls local events. This attribute is read-only.

logger event

Controls whether recovery log events are generated. This attribute is read-only.

lu group name

The generic LU name that the LU 6.2 listener that handles inbound transmissions for the queue-sharing group should use. This attribute is read-only.

lu name

The name of the LU to use for outbound LU 6.2 transmissions. This attribute is read-only.

lu62 arm suffix

The suffix of the SYS1.PARMLIB member APPCPMxx, that nominates the LUADD for this channel initiator. This attribute is read-only.

lu62 channels

The maximum number of channels that can be current or clients that can be connected, that use the LU 6.2 transmission protocol. This attribute is read-only.

maximum active channels

The maximum number of channels that can be active at any time. This attribute is read-only.

maximum channels

The maximum number of channels that can be current (including server-connection channels with connected clients). This attribute is read-only.

maximum handles

Maximum number of handles. This attribute is read-only.

maximum message length

Maximum possible length for any message on any queue managed by this queue manager. This attribute is read-only.

maximum priority

Maximum message priority. This attribute is read-only.

maximum uncommitted messages

Maximum number of uncommitted messages within a unit of work. This attribute is read-only.

mqi accounting

Controls the collection of accounting information for MQI data. This attribute is read-only.

mqi statistics

Controls the collection of statistics monitoring information for the queue manager. This attribute is read-only.

outbound port maximum

The higher end of the range of port numbers to be used when binding outgoing channels. This attribute is read-only.

outbound port minimum

The lower end of the range of port numbers to be used when binding outgoing channels. This attribute is read-only.

password

password associated with user ID

performance event

Controls performance events. This attribute is read-only.

platform

Platform on which the queue manager resides. This attribute is read-only.

queue accounting

Controls the collection of accounting information for queues. This attribute is read-only.

queue monitoring

Controls the collection of online monitoring data for queues. This attribute is read-only.

queue statistics

Controls the collection of statistics data for queues. This attribute is read-only.

receive timeout

Approximately how long a TCP/IP message channel will wait to receive data, including heartbeats, from its partner, before returning to the inactive state. This attribute is read-only.

receive timeout minimum

The minimum time that a TCP/IP channel will wait to receive data, including heartbeats, from its partner, before returning to the inactive state. This attribute is read-only.

receive timeout type

A qualifier applied to **receive timeout**. This attribute is read-only.

remote event

Controls remote events. This attribute is read-only.

repository name

Repository name. This attribute is read-only.

repository namelist

Repository namelist name. This attribute is read-only.

shared queue manager name

Whether MQOPENS of a shared queue where the ObjectQMGrName is another queue manager in the queue-sharing group should resolve to an open of the shared queue on the local queue manager. This attribute is read-only.

ssl event

Whether SSL events are generated. This attribute is read-only.

ssl FIPS required

Whether only FIPS-certified algorithms should be used if the cryptography is executed in IBM MQ software. This attribute is read-only.

ssl key reset count

The number of unencrypted bytes sent and received within an SSL conversation before the secret key is renegotiated. This attribute is read-only.

start-stop event

Controls start-stop events. This attribute is read-only.

statistics interval

How often statistics monitoring data is written to the monitoring queue. This attribute is read-only.

syncpoint availability

Availability of syncpoint participation. This attribute is read-only.

Note: Queue manager-coordinated global units of work are not supported on the IBM i platform.

 You can program a unit of work, externally coordinated by IBM i, using the `_Rcommit` and `_Rback` native system calls. Start this type of unit of work by starting the IBM MQ application under job-level commitment control using the `STRCMTCTL` command. See [Interfaces to the IBM i external syncpoint manager](#) for further details. **Backout** and **commit** are supported on the IBM i platform for local units of work coordinated by a queue manager.

tcp channels

The maximum number of channels that can be current or clients that can be connected, that use the TCP/IP transmission protocol. This attribute is read-only.

tcp keepalive

Whether the TCP KEEPALIVE facility is to be used to check that the other end of the connection is still available. This attribute is read-only.

tcp name

The name of either the sole or default TCP/IP system to be used, depending on the value of **tcp stack type**. This attribute is read-only.

tcp stack type

Whether the channel initiator is permitted to only use the TCP/IP address space specified in **tcp name** or can bind to any selected TCP/IP address. This attribute is read-only.

trace route recording

Controls the recording of route tracing information. This attribute is read-only.

trigger interval

Trigger interval. This attribute is read-only.

user id

On UNIX and Linux platforms, the application's real user ID. On Windows platforms, the application's user ID.

Constructors**ImqQueueManager();**

The default constructor.

ImqQueueManager(const ImqQueueManager & *manager*);

The copy constructor. The **connection status** will be FALSE.

ImqQueueManager(const char * *name*);

Sets the ImqObject **name** to *name*.

Destructors

When an ImqQueueManager object is destroyed, it is automatically disconnected.

Class methods (public)**static MQLONG behavior();**

Returns the **behavior**.

void setBehavior(const MQLONG *behavior* = 0);

Sets the **behavior**.

Object methods (public)**void operator = (const ImqQueueManager & *mgr*);**

Disconnects if necessary, and copies instance data from *mgr*. The **connection status** is be FALSE.

ImqBoolean accountingConnOverride (MQLONG & *statint*);

Provides a copy of the accounting connections override value. It returns TRUE if successful.

MQLONG accountingConnOverride ();

Returns the accounting connections override value without any indication of possible errors.

ImqBoolean accountingInterval (MQLONG & *statint*);

Provides a copy of the accounting interval value. It returns TRUE if successful.

MQLONG accountingInterval ();

Returns the accounting interval value without any indication of possible errors.

ImqBoolean activityRecording (MQLONG & *rec*);

Provides a copy of the activity recording value. It returns TRUE if successful.

MQLONG activityRecording ();

Returns the activity recording value without any indication of possible errors.

ImqBoolean adoptNewMCACheck (MQLONG & check);

Provides a copy of the adopt new MCA check value. It returns TRUE if successful.

MQLONG adoptNewMCACheck ();

Returns the adopt new MCA check value without any indication of possible errors.

ImqBoolean adoptNewMCAType (MQLONG & type);

Provides a copy of the adopt new MCA type. It returns TRUE if successful.

MQLONG adoptNewMCAType ();

Returns the adopt new MCA type without any indication of possible errors.

QLONG authenticationType () const;

Returns the authentication type.

void setAuthenticationType (const MQLONG type = MQCSP_AUTH_NONE);

Sets the authentication type.

ImqBoolean authorityEvent(MQLONG & event);

Provides a copy of the enablement state of the **authority event**. It returns TRUE if successful.

MQLONG authorityEvent();

Returns the enablement state of the **authority event** without any indication of possible errors.

ImqBoolean backout();

Backs out uncommitted changes. It returns TRUE if successful.

ImqBoolean begin();

Begins a unit of work. The **begin options** affect the behavior of this method. It returns TRUE if successful, but it also returns TRUE even if the underlying MQBEGIN call returns MQRC_NO_EXTERNAL_PARTICIPANTS or MQRC_PARTICIPANT_NOT_AVAILABLE (which are both associated with MQCC_WARNING).

MQLONG beginOptions() const ;

Returns the **begin options**.

void setBeginOptions(const MQLONG options = MQBO_NONE);

Sets the **begin options**.

ImqBoolean bridgeEvent (MQLONG & event);

Provides a copy of the bridge event value. It returns TRUE if successful.

MQLONG bridgeEvent ();

Returns the bridge event value without any indication of possible errors.

ImqBoolean channelAutoDefinition(MQLONG & value);

Provides a copy of the **channel auto definition** value. It returns TRUE if successful.

MQLONG channelAutoDefinition();

Returns the **channel auto definition** value without any indication of possible errors.

ImqBoolean channelAutoDefinitionEvent(MQLONG & value);

Provides a copy of the **channel auto definition event** value. It returns TRUE if successful.

MQLONG channelAutoDefinitionEvent();

Returns the **channel auto definition event** value without any indication of possible errors.

ImqBoolean channelAutoDefinitionExit(ImqString & name);

Provides a copy of the **channel auto definition exit** name. It returns TRUE if successful.

ImqString channelAutoDefinitionExit();

Returns the **channel auto definition exit** name without any indication of possible errors.

ImqBoolean channelEvent (MQLONG & event);

Provides a copy of the channel event value. It returns TRUE if successful.

MQLONG channelEvent();

Returns the channel event value without any indication of possible errors.

MQLONG channelInitiatorAdapters ();

Returns the channel initiator adapters value without any indication of possible errors.

ImqBoolean channelInitiatorAdapters (MQLONG & adapters);
Provides a copy of the channel initiator adapters value. It returns TRUE if successful.

MQLONG channelInitiatorControl ();
Returns the channel initiator startup value without any indication of possible errors.

ImqBoolean channelInitiatorControl (MQLONG & init);
Provides a copy of the channel initiator control startup value. It returns TRUE if successful.

MQLONG channelInitiatorDispatchers ();
Returns the channel initiator dispatchers value without any indication of possible errors.

ImqBoolean channelInitiatorDispatchers (MQLONG & dispatchers);
Provides a copy of the channel initiator dispatchers value. It returns TRUE if successful.

MQLONG channelInitiatorTraceAutoStart ();
Returns the channel initiator trace auto start value without any indication of possible errors.

ImqBoolean channelInitiatorTraceAutoStart (MQLONG & auto);
Provides a copy of the channel initiator trace auto start value. It returns TRUE if successful.

MQLONG channelInitiatorTraceTableSize ();
Returns the channel initiator trace table size value without any indication of possible errors.

ImqBoolean channelInitiatorTraceTableSize (MQLONG & size);
Provides a copy of the channel initiator trace table size value. It returns TRUE if successful.

ImqBoolean channelMonitoring (MQLONG & monchl);
Provides a copy of the channel monitoring value. It returns TRUE if successful.

MQLONG channelMonitoring ();
Returns the channel monitoring value without any indication of possible errors.

ImqBoolean channelReference(ImqChannel * & pchannel);
Provides a copy of the **channel reference**. If the **channel reference** is invalid, sets *pchannel* to null. This method returns TRUE if successful.

ImqChannel * channelReference();
Returns the **channel reference** without any indication of possible errors.

ImqBoolean setChannelReference(ImqChannel & channel);
Sets the **channel reference**. This method returns TRUE if successful.

ImqBoolean setChannelReference(ImqChannel * channel = 0);
Sets or resets the **channel reference**. This method returns TRUE if successful.

ImqBoolean channelStatistics (MQLONG & statchl);
Provides a copy of the channel statistics value. It returns TRUE if successful.

MQLONG channelStatistics ();
Returns the channel statistics value without any indication of possible errors.

ImqBoolean characterSet(MQLONG & ccscid);
Provides a copy of the **character set**. It returns TRUE if successful.

MQLONG characterSet();
Returns a copy of the **character set**, without any indication of possible errors.

MQLONG clientSslKeyResetCount () const;
Returns the SSL key reset count value used on client connections.

void setClientSslKeyResetCount(const MQLONG count);
Sets the SSL key reset count used on client connections.

ImqBoolean clusterSenderMonitoring (MQLONG & monacsl);
Provides a copy of the cluster sender monitoring default value. It returns TRUE if successful.

MQLONG clusterSenderMonitoring ();
Returns the cluster sender monitoring default value without any indication of possible errors.

ImqBoolean clusterSenderStatistics (MQLONG & statacls);
Provides a copy of the cluster sender statistics value. It returns TRUE if successful.

MQLONG clusterSenderStatistics ();

Returns the cluster sender statistics value without any indication of possible errors.

ImqBoolean clusterWorkloadData(ImqString & data);

Provides a copy of the **cluster workload exit data**. It returns TRUE if successful.

ImqString clusterWorkloadData();

Returns the **cluster workload exit data** without any indication of possible errors.

ImqBoolean clusterWorkloadExit(ImqString & name);

Provides a copy of the **cluster workload exit name**. It returns TRUE if successful.

ImqString clusterWorkloadExit();

Returns the **cluster workload exit name** without any indication of possible errors.

ImqBoolean clusterWorkloadLength(MQLONG & length);

Provides a copy of the **cluster workload length**. It returns TRUE if successful.

MQLONG clusterWorkloadLength();

Returns the **cluster workload length** without any indication of possible errors.

ImqBoolean clusterWorkLoadMRU (MQLONG & mru);

Provides a copy of the cluster workload most recently used channels value. It returns TRUE if successful.

MQLONG clusterWorkLoadMRU ();

Returns the cluster workload most recently used channels value without any indication of possible errors.

ImqBoolean clusterWorkLoadUseQ (MQLONG & useq);

Provides a copy of the cluster workload use queue value. It returns TRUE if successful.

MQLONG clusterWorkLoadUseQ ();

Returns the cluster workload use queue value without any indication of possible errors.

ImqBoolean commandEvent (MQLONG & event);

Provides a copy of the command event value. It returns TRUE if successful.

MQLONG commandEvent ();

Returns the command event value without any indication of possible errors.

ImqBoolean commandInputQueueName(ImqString & name);

Provides a copy of the **command input queue name**. It returns TRUE if successful.

ImqString commandInputQueueName();

Returns the **command input queue name** without any indication of possible errors.

ImqBoolean commandLevel(MQLONG & level);

Provides a copy of the **command level**. It returns TRUE if successful.

MQLONG commandLevel();

Returns the **command level** without any indication of possible errors.

MQLONG commandServerControl ();

Returns the command server startup value without any indication of possible errors.

ImqBoolean commandServerControl (MQLONG & server);

Provides a copy of the command server control startup value. It returns TRUE if successful.

ImqBoolean commit();

Commits uncommitted changes. It returns TRUE if successful.

ImqBoolean connect();

Connects to the queue manager with the given ImqObject **name**, the default being the local queue manager. If you want to connect to a specific queue manager, use the ImqObject **setName** method before connection. If there is a **channel reference**, it is used to pass information about the channel definition to MQCONN in an MQCD. The ChannelType in the MQCD is set to MQCHT_CLNTCONN. **channel reference** information, which is only meaningful for client connections, is ignored for server connections. The **connect options** affect the behavior of this method. This method sets the **connection status** to TRUE if successful. It returns the new connection status.

If there is a first authentication record, the chain of authentication records is used to authenticate digital certificates for secure client channels.

You can connect more than one ImqQueueManager object to the same queue manager. All use the same MQHCONN connection handle and share UOW functionality for the connection associated with the thread. The first ImqQueueManager to connect obtains the MQHCONN handle. The last ImqQueueManager to disconnect performs the MQDISC.

For a multithreaded program, it is recommended that a separate ImqQueueManager object is used for each thread.

ImqBinary connectionId () const ;

Returns the **connection ID**.

ImqBinary connectionTag () const ;

Returns the **connection tag**.

ImqBoolean setConnectionTag (const MQBYTE128 tag = 0);

Sets the **connection tag**. If *tag* is zero, clears the **connection tag**. This method returns TRUE if successful.

ImqBoolean setConnectionTag (const ImqBinary & tag);

Sets the **connection tag**. The **data length** of *tag* must be either zero (to clear the **connection tag**) or MQ_CONN_TAG_LENGTH. This method returns TRUE if successful.

MQLONG connectOptions() const ;

Returns the **connect options**.

void setConnectOptions(const MQLONG options = MQCNO_NONE);

Sets the **connect options**.

ImqBoolean connectionStatus() const ;

Returns the **connection status**.

ImqString cryptographicHardware ();

Returns the **cryptographic hardware**.

ImqBoolean setCryptographicHardware (const char * hardware = 0);

Sets the **cryptographic hardware**. This method returns TRUE if successful.

ImqBoolean deadLetterQueueName(ImqString & name);

Provides a copy of the **dead-letter queue name**. It returns TRUE if successful.

ImqString deadLetterQueueName();

Returns a copy of the **dead-letter queue name**, without any indication of possible errors.

ImqBoolean defaultTransmissionQueueName(ImqString & name);

Provides a copy of the **default transmission queue name**. It returns TRUE if successful.

ImqString defaultTransmissionQueueName();

Returns the **default transmission queue name** without any indication of possible errors.

ImqBoolean disconnect();

Disconnects from the queue manager and sets the **connection status** to FALSE. Closes all ImqProcess and ImqQueue objects associated with this object, and severs their **connection reference** before disconnection. If more than one ImqQueueManager object is connected to the same queue manager, only the last to disconnect performs a physical disconnection; others perform a logical disconnection. Uncommitted changes are committed on physical disconnection only.

This method returns TRUE if successful. If it is called when there is no existing connection, the return code is also true.

ImqBoolean distributionLists(MQLONG & support);

Provides a copy of the **distribution lists** value. It returns TRUE if successful.

MQLONG distributionLists();

Returns the **distribution lists** value without any indication of possible errors.

ImqBoolean dnsGroup (ImqString & group);

Provides a copy of the DNS group name. It returns TRUE if successful.

ImqString dnsGroup ();
Returns the DNS group name without any indication of possible errors.

ImqBoolean dnsWlm (MQLONG & wlm);
Provides a copy of the DNS WLM value. It returns TRUE if successful.

MQLONG dnsWlm ();
Returns the DNS WLM value without any indication of possible errors.

ImqAuthenticationRecord * firstAuthenticationRecord () const ;
Returns the **first authentication record**.

void setFirstAuthenticationRecord (const ImqAuthenticationRecord * air = 0);
Sets the **first authentication record**.

ImqObject * firstManagedObject () const ;
Returns the **first managed object**.

ImqBoolean inhibitEvent(MQLONG & event);
Provides a copy of the enablement state of the **inhibit event**. It returns TRUE if successful.

MQLONG inhibitEvent();
Returns the enablement state of the **inhibit event** without any indication of possible errors.

ImqBoolean ipAddressVersion (MQLONG & version);
Provides a copy of the IP address version value. It returns TRUE if successful.

MQLONG ipAddressVersion ();
Returns the IP address version value without any indication of possible errors.

ImqBoolean keepAlive (MQLONG & keepalive);
Provides a copy of the keep alive value. It returns TRUE if successful.

MQLONG keepAlive ();
Returns the keep alive value without any indication of possible errors.

ImqString keyRepository ();
Returns the **key repository**.

ImqBoolean setKeyRepository (const char * repository = 0);
Sets the **key repository**. It returns TRUE if successful.

ImqBoolean listenerTimer (MQLONG & timer);
Provides a copy of the listener timer value. It returns TRUE if successful.

MQLONG listenerTimer ();
Returns the listener timer value without any indication of possible errors.

ImqBoolean localEvent(MQLONG & event);
Provides a copy of the enablement state of the **local event**. It returns TRUE if successful.

MQLONG localEvent();
Returns the enablement state of the **local event** without any indication of possible errors.

ImqBoolean loggerEvent (MQLONG & count);
Provides a copy of the logger event value. It returns TRUE if successful.

MQLONG loggerEvent ();
Returns the logger event value without any indication of possible errors.

ImqBoolean luGroupName (ImqString & name);
Provides a copy of the LU group name. It returns TRUE if successful.

ImqString luGroupName ();
Returns the LU group name without any indication of possible errors.

ImqBoolean lu62ARMSuffix (ImqString & suffix);
Provides a copy of the LU62 ARM suffix. It returns TRUE if successful.

ImqString lu62ARMSuffix ();
Returns the LU62 ARM suffix without any indication of possible errors.

ImqBoolean luName (ImqString & name);
Provides a copy of the LU name. It returns TRUE if successful.

ImqString luName ();

Returns the LU name without any indication of possible errors.

ImqBoolean maximumActiveChannels (MQLONG & channels);

Provides a copy of the maximum active channels value. It returns TRUE if successful.

MQLONG maximumActiveChannels ();

Returns the maximum active channels value without any indication of possible errors.

ImqBoolean maximumCurrentChannels (MQLONG & channels);

Provides a copy of the maximum current channels value. It returns TRUE if successful.

MQLONG maximumCurrentChannels ();

Returns the maximum current channels value without any indication of possible errors.

ImqBoolean maximumHandles(MQLONG & number);

Provides a copy of the **maximum handles**. It returns TRUE if successful.

MQLONG maximumHandles();

Returns the **maximum handles** without any indication of possible errors.

ImqBoolean maximumLu62Channels (MQLONG & channels);

Provides a copy of the maximum LU62 channels value. It returns TRUE if successful.

MQLONG maximumLu62Channels ();

Returns the maximum LU62 channels value without any indication of possible errors

ImqBoolean maximumMessageLength(MQLONG & length);

Provides a copy of the **maximum message length**. It returns TRUE if successful.

MQLONG maximumMessageLength();

Returns the **maximum message length** without any indication of possible errors.

ImqBoolean maximumPriority(MQLONG & priority);

Provides a copy of the **maximum priority**. It returns TRUE if successful.

MQLONG maximumPriority();

Returns a copy of the **maximum priority**, without any indication of possible errors.

ImqBoolean maximumTcpChannels (MQLONG & channels);

Provides a copy of the maximum TCP channels value. It returns TRUE if successful.

MQLONG maximumTcpChannels ();

Returns the maximum TCP channels value without any indication of possible errors.

ImqBoolean maximumUncommittedMessages(MQLONG & number);

Provides a copy of the **maximum uncommitted messages**. It returns TRUE if successful.

MQLONG maximumUncommittedMessages();

Returns the **maximum uncommitted messages** without any indication of possible errors.

ImqBoolean mqiAccounting (MQLONG & statint);

Provides a copy of the MQI accounting value. It returns TRUE if successful.

MQLONG mqiAccounting ();

Returns the MQI accounting value without any indication of possible errors.

ImqBoolean mqiStatistics (MQLONG & statmqi);

Provides a copy of the MQI statistics value. It returns TRUE if successful.

MQLONG mqiStatistics ();

Returns the MQI statistics value without any indication of possible errors.

ImqBoolean outboundPortMax (MQLONG & max);

Provides a copy of the maximum outbound port value. It returns TRUE if successful.

MQLONG outboundPortMax ();

Returns the maximum outbound port value without any indication of possible errors.

ImqBoolean outboundPortMin (MQLONG & min);

Provides a copy of the minimum outbound port value. It returns TRUE if successful.

MQLONG outboundPortMin ();

Returns the minimum outbound port value without any indication of possible errors.

ImqBinary password () const;

Returns the password used on client connections.

ImqBoolean setPassword (const ImqString & password);

Sets the password used on client connections.

ImqBoolean setPassword (const char * = 0 password);

Sets the password used on client connections.

ImqBoolean setPassword (const ImqBinary & password);

Sets the password used on client connections.

ImqBoolean performanceEvent(MQLONG & event);

Provides a copy of the enablement state of the **performance event**. It returns TRUE if successful.

MQLONG performanceEvent();

Returns the enablement state of the **performance event** without any indication of possible errors.

ImqBoolean platform(MQLONG & platform);

Provides a copy of the **platform**. It returns TRUE if successful.

MQLONG platform();

Returns the **platform** without any indication of possible errors.

ImqBoolean queueAccounting (MQLONG & acctq);

Provides a copy of the queue accounting value. It returns TRUE if successful.

MQLONG queueAccounting ();

Returns the queue accounting value without any indication of possible errors.

ImqBoolean queueMonitoring (MQLONG & monq);

Provides a copy of the queue monitoring value. It returns TRUE if successful.

MQLONG queueMonitoring ();

Returns the queue monitoring value without any indication of possible errors.

ImqBoolean queueStatistics (MQLONG & statq);

Provides a copy of the queue statistics value. It returns TRUE if successful.

MQLONG queueStatistics ();

Returns the queue statistics value without any indication of possible errors.

ImqBoolean receiveTimeout (MQLONG & timeout);

Provides a copy of the receive timeout value. It returns TRUE if successful.

MQLONG receiveTimeout ();

Returns the receive timeout value without any indication of possible errors.

ImqBoolean receiveTimeoutMin (MQLONG & min);

Provides a copy of the minimum receive timeout value. It returns TRUE if successful.

MQLONG receiveTimeoutMin ();

Returns the minimum receive timeout value without any indication of possible errors.

ImqBoolean receiveTimeoutType (MQLONG & type);

Provides a copy of the receive timeout type. It returns TRUE if successful.

MQLONG receiveTimeoutType ();

Returns the receive timeout type without any indication of possible errors.

ImqBoolean remoteEvent(MQLONG & event);

Provides a copy of the enablement state of the **remote event**. It returns TRUE if successful.

MQLONG remoteEvent();

Returns the enablement state of the **remote event** without any indication of possible errors.

ImqBoolean repositoryName(ImqString & name);

Provides a copy of the **repository name**. It returns TRUE if successful.

ImqString repositoryName();

Returns the **repository name** without any indication of possible errors.

ImqBoolean repositoryNameListName(ImqString & name);

Provides a copy of the **repository namelist name**. It returns TRUE if successful.

ImqString repositoryNamelistName();

Returns a copy of the **repository namelist name** without any indication of possible errors.

ImqBoolean sharedQueueQueueManagerName (MQLONG & name);

Provides a copy of the shared queue queue manager name value. It returns TRUE if successful.

MQLONG sharedQueueQueueManagerName ();

Returns the shared queue queue manager name value without any indication of possible errors.

ImqBoolean sslEvent (MQLONG & event);

Provides a copy of the SSL event value. It returns TRUE if successful.

MQLONG sslEvent ();

Returns the SSL event value without any indication of possible errors.

ImqBoolean sslFips (MQLONG & sslfips);

Provides a copy of the SSL FIPS value. It returns TRUE if successful.

MQLONG sslFips ();

Returns the SSL FIPS value without any indication of possible errors.

ImqBoolean sslKeyResetCount (MQLONG & count);

Provides a copy of the SSL key reset count value. It returns TRUE if successful.

MQLONG sslKeyResetCount ();

Returns the SSL key reset count value without any indication of possible errors.

ImqBoolean startStopEvent(MQLONG & event);

Provides a copy of the enablement state of the **start-stop event**. It returns TRUE if successful.

MQLONG startStopEvent();

Returns the enablement state of the **start-stop event** without any indication of possible errors.

ImqBoolean statisticsInterval (MQLONG & statint);

Provides a copy of the statistics interval value. It returns TRUE if successful.

MQLONG statisticsInterval ();

Returns the statistics interval value without any indication of possible errors.

ImqBoolean syncPointAvailability(MQLONG & sync);

Provides a copy of the **syncpoint availability** value. It returns TRUE if successful.

MQLONG syncPointAvailability();

Returns a copy of the **syncpoint availability** value, without any indication of possible errors.

ImqBoolean tcpName (ImqString & name);

Provides a copy of the TCP system name. It returns TRUE if successful.

ImqString tcpName ();

Returns the TCP system name without any indication of possible errors.

ImqBoolean tcpStackType (MQLONG & type);

Provides a copy of the TCP stack type. It returns TRUE if successful.

MQLONG tcpStackType ();

Returns the TCP stack type without any indication of possible errors.

ImqBoolean traceRouteRecording (MQLONG & routerec);

Provides a copy of the trace route recording value. It returns TRUE if successful.

MQLONG traceRouteRecording ();

Returns the trace route recording value without any indication of possible errors.

ImqBoolean triggerInterval(MQLONG & interval);

Provides a copy of the **trigger interval**. It returns TRUE if successful.

MQLONG triggerInterval();

Returns the **trigger interval** without any indication of possible errors.

ImqBinary userId () const;

Returns the user ID used on client connections.

ImqBoolean setUserId (const ImqString & id);

Sets the user ID used on client connections.

ImqBoolean setUserId (const char * = 0 id);

Sets the user ID used on client connections.

ImqBoolean setUserId (const ImqBinary & id);

Sets the user ID used on client connections.

Object methods (protected)

void setFirstManagedObject (const ImqObject * object = 0);

Sets the **first managed object**.

Object data (protected)

MQHCONN ohconn

The IBM MQ connection handle (meaningful only while the **connection status** is TRUE).

Reason codes

- MQRC_ATTRIBUTE_LOCKED
- MQRC_ENVIRONMENT_ERROR

ImqReferenceHeader C++ class

This class encapsulates features of the MQRMH data structure.

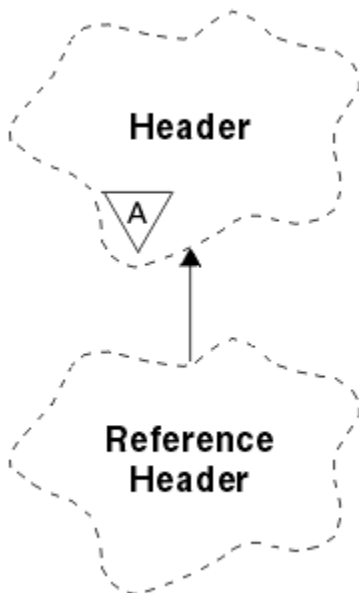

Figure 66. *ImqReferenceHeader* class

This class relates to the MQI calls listed in [“ImqReferenceHeader cross-reference”](#) on page 1836.

- [“Object attributes” on page 1916](#)
- [“Constructors” on page 1916](#)
- [“Overloaded ImqItem methods” on page 1916](#)
- [“Object methods \(public\)” on page 1917](#)
- [“Object data \(protected\)” on page 1917](#)
- [“Reason codes” on page 1918](#)

Object attributes

destination environment

Environment for the destination. The initial value is a null string.

destination name

Name of the data destination. The initial value is a null string.

instance id

Instance identifier. A binary value (MQBYTE24) of length MQ_OBJECT_INSTANCE_ID_LENGTH. The initial value is MQOII_NONE.

logical length

Logical, or intended, length of message data that follows this header. The initial value is zero.

logical offset

Logical offset for the message data that follows, to be interpreted in the context of the data as a whole, at the ultimate destination. The initial value is zero.

logical offset 2

High-order extension to the **logical offset**. The initial value is zero.

reference type

Reference type. The initial value is a null string.

source environment

Environment for the source. The initial value is a null string.

source name

Name of the data source. The initial value is a null string.

Constructors

ImqReferenceHeader();

The default constructor.

ImqReferenceHeader(const ImqReferenceHeader & header);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & msg);

Inserts an MQRMH data structure into the message buffer at the beginning, moving existing message data further along, and sets the *msg* **format** to MQFMT_REF_MSG_HEADER.

See the ImqHeader class method description on [“ImqHeader C++ class” on page 1864](#) for further details.

virtual ImqBoolean pasteIn (ImqMessage & msg);

Reads an MQRMH data structure from the message buffer.

To be successful, the ImqMessage **format** must be MQFMT_REF_MSG_HEADER.

See the ImqHeader class method description on [“ImqHeader C++ class” on page 1864](#) for further details.

Object methods (public)

void operator = (const ImqReferenceHeader & *header*);

Copies instance data from *header*, replacing the existing instance data.

ImqString destinationEnvironment () const ;

Returns a copy of the **destination environment**.

void setDestinationEnvironment (const char * *environment* = 0);

Sets the **destination environment**.

ImqString destinationName () const ;

Returns a copy of the **destination name**.

void setDestinationName (const char * *name* = 0);

Sets the **destination name**.

ImqBinary instanceId () const ;

Returns a copy of the **instance id**.

ImqBoolean setInstanceId (const ImqBinary & *id*);

Sets the **instance id**. The **data length** of *token* must be either 0 or MQ_OBJECT_INSTANCE_ID_LENGTH. This method returns TRUE if successful.

void setInstanceId (const MQBYTE24 *id* = 0);

Sets the **instance id**. *id* can be zero, which is the same as specifying MQOII_NONE. If *id* is nonzero, it must address MQ_OBJECT_INSTANCE_ID_LENGTH bytes of binary data. When using pre-defined values such as MQOII_NONE, you might need to make a cast to ensure a signature match, for example (MQBYTE *)MQOII_NONE.

MQLONG logicalLength () const ;

Returns the **logical length**.

void setLogicalLength (const MQLONG *length*);

Sets the **logical length**.

MQLONG logicalOffset () const ;

Returns the **logical offset**.

void setLogicalOffset (const MQLONG *offset*);

Sets the **logical offset**.

MQLONG logicalOffset2 () const ;

Returns the **logical offset 2**.

void setLogicalOffset2 (const MQLONG *offset*);

Sets the **logical offset 2**.

ImqString referenceType () const ;

Returns a copy of the **reference type**.

void setReferenceType (const char * *name* = 0);

Sets the **reference type**.

ImqString sourceEnvironment () const ;

Returns a copy of the **source environment**.

void setSourceEnvironment (const char * *environment* = 0);

Sets the **source environment**.

ImqString sourceName () const ;

Returns a copy of the **source name**.

void setSourceName (const char * *name* = 0);

Sets the **source name**.

Object data (protected)

MQRMH *omqrmh*

The MQRMH data structure.

ImqString C++ class

This class provides character string storage and manipulation for null-terminated strings.

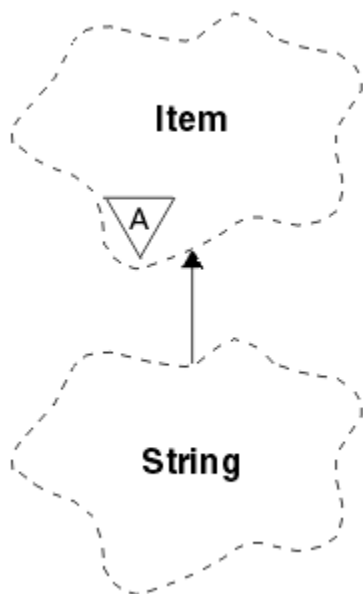

Figure 67. ImqString class

Use an ImqString in place of a **char *** in most situations where a parameter calls for a **char ***.

- [“Object attributes” on page 1918](#)

- [“Class methods \(public\)” on page 1919](#)
- [“Overloaded ImqItem methods” on page 1919](#)
- [“Object methods \(public\)” on page 1919](#)
- [“Object methods \(protected\)” on page 1922](#)
- [“Reason codes” on page 1922](#)

Object attributes

characters

Characters in the **storage** that precede a trailing null.

length

Number of bytes in the **characters**. If there is no **storage**, the **length** is zero. The initial value is zero.

storage

A volatile array of bytes of arbitrary size. A trailing null must always be present in the **storage** after the **characters**, so that the end of the **characters** can be detected. Methods ensure that this situation

is maintained, but ensure, when setting bytes in the array directly, that a trailing null exists after modification. Initially, there is no **storage** attribute.

Constructors

ImqString();

The default constructor.

ImqString(const ImqString & *string*);

The copy constructor.

ImqString(const char *c*);

The **characters** comprise *c*.

ImqString(const char * *text*);

The **characters** are copied from *text*.

ImqString(const void * *buffer*, const size_t *length*);

Copies *length* bytes starting from *buffer* and assigns them to the **characters**. Substitution is made for any null characters copied. The substitution character is a period (.). No special consideration is given to any other non-printable or non-displayable characters copied.

Class methods (public)

static ImqBoolean copy(char * *destination-buffer*, const size_t *length*, const char * *source-buffer*, const char *pad* = 0);

Copies up to *length* bytes from *source-buffer* to *destination-buffer*. If the number of characters in *source-buffer* is insufficient, fills the remaining space in *destination-buffer* with *pad* characters. *source-buffer* can be zero. *destination-buffer* can be zero if *length* is also zero. Any error codes are lost. This method returns TRUE if successful.

static ImqBoolean copy (char * *destination-buffer*, const size_t *length*, const char * *source-buffer*, ImqError & *error-object*, const char *pad* = 0);

Copies up to *length* bytes from *source-buffer* to *destination-buffer*. If the number of characters in *source-buffer* is insufficient, fills the remaining space in *destination-buffer* with *pad* characters. *source-buffer* can be zero. *destination-buffer* can be zero if *length* is also zero. Any error codes are set in *error-object*. This method returns TRUE if successful.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & *msg*);

Copies the **characters** to the message buffer, replacing any existing content. Sets the *msg* **format** to MQFMT_STRING.

See the parent class method description for further details.

virtual ImqBoolean pasteIn (ImqMessage & *msg*);

Sets the **characters** by transferring the remaining data from the message buffer, replacing the existing **characters**.

To be successful, the **encoding** of the *msg* object must be MQENC_NATIVE. Retrieve messages with MQGMO_CONVERT to MQENC_NATIVE.

To be successful, the ImqMessage **format** must be MQFMT_STRING.

See the parent class method description for further details.

Object methods (public)

char & operator [] (const size_t *offset*) const ;

References the character at offset *offset* in the **storage**. Ensure that the relevant byte exists and is addressable.

ImqString operator () (const size_t *offset*, const size_t *length* = 1) const ;

Returns a substring by copying bytes from the **characters** starting at *offset*. If *length* is zero, returns the rest of the **characters**. If the combination of *offset* and *length* does not produce a reference within the **characters**, returns an empty ImqString.

void operator = (const ImqString & *string*);

Copies instance data from *string*, replacing the existing instance data.

ImqString operator + (const char *c*) const ;

Returns the result of appending *c* to the **characters**.

ImqString operator + (const char * *text*) const ;

Returns the result of appending *text* to the **characters**. This can also be inverted. For example:

```
strOne + "string two" ;  
"string one" + strTwo ;
```

Note: Although most compilers accept **strOne + "string two"**; Microsoft Visual C++ requires **strOne + (char *)"string two"**;

ImqString operator + (const ImqString & *string1*) const ;

Returns the result of appending *string1* to the **characters**.

ImqString operator + (const double *number*) const ;

Returns the result of appending *number* to the **characters** after conversion to text.

ImqString operator + (const long *number*) const ;

Returns the result of appending *number* to the **characters** after conversion to text.

void operator += (const char *c*);

Appends *c* to the **characters**.

void operator += (const char * *text*);

Appends *text* to the **characters**.

void operator += (const ImqString & *string*);

Appends *string* to the **characters**.

void operator += (const double *number*);

Appends *number* to the **characters** after conversion to text.

void operator += (const long *number*);

Appends *number* to the **characters** after conversion to text.

operator char * () const ;

Returns the address of the first byte in the **storage**. This value can be zero, and is volatile. Use this method only for read-only purposes.

ImqBoolean operator < (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if less than and FALSE if greater than or equal to.

ImqBoolean operator > (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if greater than and FALSE if less than or equal to.

ImqBoolean operator <= (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if less than or equal to and FALSE if greater than.

ImqBoolean operator >= (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. The result is TRUE if greater than or equal to and FALSE if less than.

ImqBoolean operator == (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. It returns either TRUE or FALSE.

ImqBoolean operator != (const ImqString & *string*) const ;

Compares the **characters** with those of *string* using the **compare** method. It returns either TRUE or FALSE.

short compare(const ImqString & *string*) const ;

Compares the **characters** with those of *string*. The result is zero if the **characters** are equal, negative if less than and positive if greater than. Comparison is case sensitive. A null ImqString is regarded as less than a nonnull ImqString.

ImqBoolean copyOut(char * *buffer*, const size_t *length*, const char *pad* = 0);

Copies up to *length* bytes from the **characters** to the *buffer*. If the number of **characters** is insufficient, fills the remaining space in *buffer* with *pad* characters. *buffer* can be zero if *length* is also zero. It returns TRUE if successful.

size_t copyOut(long & *number*) const ;

Sets *number* from the **characters** after conversion from text, and returns the number of characters involved in the conversion. If this is zero, no conversion has been performed and *number* is not set. A convertible character sequence must begin with the following values:

```
<blank(s)>
<+|->
digit(s)
```

size_t copyOut(ImqString & *token*, const char *c* = ' ') const ;

If the **characters** contain one or more characters that are different from *c*, identifies a token as the first contiguous sequence of such characters. In this case *token* is set to that sequence, and the value returned is the sum of the number of leading characters *c* and the number of bytes in the sequence. Otherwise, returns zero and does not set *token*.

size_t cutOut(long & *number*);

Sets *number* as for the **copy** method, but also removes from **characters** the number of bytes indicated by the return value. For example, the string shown in the following example can be cut into three numbers by using **cutOut** (*number*) three times:

```
strNumbers = "-1 0    +55 "
```

```
while ( strNumbers.cutOut( number ) );
```

number becomes -1, then 0, then 55
leaving *strNumbers* == " "

size_t cutOut(ImqString & *token*, const char *c* = ' ')

Sets *token* as for the **copyOut** method, and removes from **characters** the *strToken* characters and also any characters *c* that precede the *token* characters. If *c* is not a blank, removes characters *c* that directly succeed the *token* characters. Returns the number of characters removed. For example, the string shown in the following example can be cut into three tokens by using **cutOut** (*token*) three times:

```
strText = " Program Version 1.1 "
```

```
while ( strText.cutOut( token ) );
```

// *token* becomes "Program", then "Version",
// then "1.1" leaving *strText* == " "

The following example shows how to parse a DOS path name:

```
strPath = "C:\OS2\BITMAP\OS2LOGO.BMP"
```

```
strPath.cutOut( strDrive, ':' );
```

```
strPath.stripLeading( ':' );
```

```
while ( strPath.cutOut( strFile, '\\' ) );
```

// *strDrive* becomes "C".
// *strFile* becomes "OS2", then "BITMAP",
// then "OS2LOGO.BMP" leaving *strPath* empty.

ImqBoolean find(const ImqString & string);

Searches for an exact match for *string* anywhere within the **characters**. If no match is found, it returns FALSE. Otherwise, it returns TRUE. If *string* is null, it returns TRUE.

ImqBoolean find(const ImqString & string, size_t & offset);

Searches for an exact match for *string* somewhere within the **characters** from offset *offset* onwards. If *string* is null, it returns TRUE without updating *offset*. If no match is found, it returns FALSE (the value of *offset* might have been increased). If a match is found, it returns TRUE and updates *offset* to the offset of *string* within the **characters**.

size_t length() const ;

Returns the **length**.

ImqBoolean pasteIn(const double number, const char * format = "%f");

Appends *number* to the **characters** after conversion to text. It returns TRUE if successful.

The specification *format* is used to format the floating point conversion. If specified, it must be one suitable for use with **printf** and floating point numbers, for example **%3f**.

ImqBoolean pasteIn(const long number);

Appends *number* to the **characters** after conversion to text. It returns TRUE if successful.

ImqBoolean pasteIn(const void * buffer, const size_t length);

Appends *length* bytes from *buffer* to the **characters**, and adds a final trailing null. Substitutes any null characters copied. The substitution character is a period (.). No special consideration is given to any other nonprintable or nondisplayable characters copied. This method returns TRUE if successful.

ImqBoolean set(const char * buffer, const size_t length);

Sets the **characters** from a fixed-length character field, which might contain a null. Appends a null to the characters from the fixed-length field if necessary. This method returns TRUE if successful.

ImqBoolean setStorage(const size_t length);

Allocates (or reallocates) the **storage**. Preserves any original **characters**, including any trailing null, if there is still room for them, but does not initialize any additional storage.

This method returns TRUE if successful.

size_t storage() const ;

Returns the number of bytes in the **storage**.

size_t stripLeading(const char c = ' ');

Strips leading characters *c* from the **characters** and returns the number removed.

size_t stripTrailing(const char c = ' ');

Strips trailing characters *c* from the **characters** and returns the number removed.

ImqString upperCase() const ;

Returns an uppercase copy of the **characters**.

Object methods (protected)**ImqBoolean assign (const ImqString & string);**

Equivalent to the equivalent **operator =** method, but non-virtual. It returns TRUE if successful.

ImqTrigger C++ class

This class encapsulates the MQTM (trigger message) data structure.

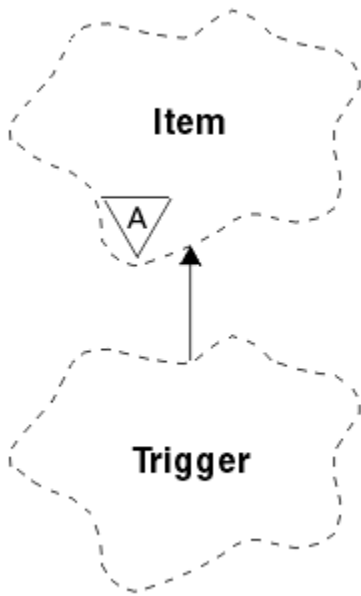

Figure 68. ImqTrigger class

Objects of this class are typically used by a trigger monitor program. The task of a trigger monitor program is to wait for these particular messages and act on them to ensure that other IBM MQ applications are started when messages are waiting for them.

See the IMQSTRG sample program for a usage example.

- [“Object attributes” on page 1923](#)
- [“Constructors” on page 1924](#)
- [“Overloaded ImqItem methods” on page 1924](#)
- [“Object methods \(public\)” on page 1924](#)
- [“Object data \(protected\)” on page 1925](#)
- [“Reason codes” on page 1925](#)

Object attributes

application id

Identity of the application that sent the message. The initial value is a null string.

application type

Type of application that sent the message. The initial value is zero. The following additional values are possible:

- MQAT_AIX
- MQAT_CICS
- MQAT_DOS
- MQAT_IMS
- MQAT_MVS
- MQAT_NOTES_AGENT
- MQAT_OS2
- MQAT_OS390
- MQAT_OS400

- MQAT_UNIX
- MQAT_WINDOWS
- MQAT_WINDOWS_NT
- MQAT_USER_FIRST
- MQAT_USER_LAST

environment data

Environment data for the process. The initial value is a null string.

process name

Process name. The initial value is a null string.

queue name

Name of the queue to be started. The initial value is a null string.

trigger data

Trigger data for the process. The initial value is a null string.

user data

User data for the process. The initial value is a null string.

Constructors

ImqTrigger();

The default constructor.

ImqTrigger(const ImqTrigger & trigger);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut (ImqMessage & msg);

Writes an MQTM data structure to the message buffer, replacing any existing content. Sets the *msg format* to MQFMT_TRIGGER.

See the ImqItem class method description at [“ImqItem C++ class” on page 1868](#) for further details.

virtual ImqBoolean pasteIn (ImqMessage & msg);

Reads an MQTM data structure from the message buffer.

To be successful, the ImqMessage **format** must be MQFMT_TRIGGER.

See the ImqItem class method description at [“ImqItem C++ class” on page 1868](#) for further details.

Object methods (public)

void operator = (const ImqTrigger & trigger);

Copies instance data from *trigger*, replacing the existing instance data.

ImqString applicationId () const ;

Returns a copy of the **application id**.

void setApplicationId (const char * id);

Sets the **application id**.

MQLONG applicationType () const ;

Returns the **application type**.

void setApplicationType (const MQLONG type);

Sets the **application type**.

ImqBoolean copyOut (MQTMC2 * ptmc2);

Encapsulates the MQTM data structure, which is the one received on initiation queues. Fills in an equivalent MQTMC2 data structure provided by the caller, and sets the QMgrName field (which is not present in the MQTM data structure) to all blanks. The MQTMC2 data structure is traditionally used as a parameter to applications started by a trigger monitor. This method returns TRUE if successful.

ImqString environmentData () const ;

Returns a copy of the **environment data**.

void setEnvironmentData (const char * data);

Sets the **environment data**.

ImqString processName () const ;

Returns a copy of the **process name**.

void setProcessName (const char * name);

Sets the **process name**, padded with blanks to 48 characters.

ImqString queueName () const ;

Returns a copy of the **queue name**.

void setQueueName (const char * name);

Sets the **queue name**, padding with blanks to 48 characters.

ImqString triggerData () const ;

Returns a copy of the **trigger data**.

void setTriggerData (const char * data);

Sets the **trigger data**.

ImqString userData () const ;

Returns a copy of the **user data**.

void setUserData (const char * data);

Sets the **user data**.

Object data (protected)

MQTM omqtm

The MQTM data structure.

Reason codes

- MQRC_NULL_POINTER
- MQRC_INCONSISTENT_FORMAT
- MQRC_ENCODING_ERROR
- MQRC_STRUC_ID_ERROR

ImqWorkHeader C++ class

This class encapsulates specific features of the MQWIH data structure.

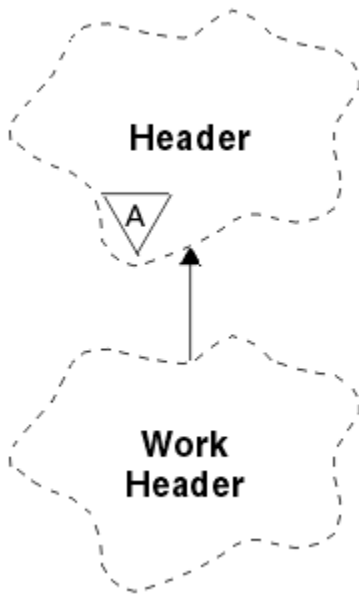

Figure 69. *ImqWorkHeader* class

Objects of this class are used by applications putting messages to the queue managed by the z/OS Workload Manager.

- [“Object attributes” on page 1926](#)
- [“Constructors” on page 1926](#)
- [“Overloaded ImqItem methods” on page 1927](#)
- [“Object methods \(public\)” on page 1927](#)
- [“Object data \(protected\)” on page 1927](#)
- [“Reason codes” on page 1927](#)

Object attributes

message token

Message token for the z/OS Workload Manager, of length MQ_MSG_TOKEN_LENGTH. The initial value is MQMTOK_NONE.

service name

The 32-character name of a process. The name is initially blanks.

service step

The 8-character name of a step within the process. The name is initially blanks.

Constructors

ImqWorkHeader();

The default constructor.

ImqWorkHeader(const ImqWorkHeader & header);

The copy constructor.

Overloaded ImqItem methods

virtual ImqBoolean copyOut(ImqMessage & msg);

Inserts an MQWIH data structure into the beginning of the message buffer, moving the existing message data further along, and sets the *msg format* to MQFMT_WORK_INFO_HEADER.

See the parent class method description for more details.

virtual ImqBoolean pasteIn(ImqMessage & msg);

Reads an MQWIH data structure from the message buffer.

To be successful, the encoding of the *msg* object must be MQENC_NATIVE. Retrieve messages with MQGMO_CONVERT to MQENC_NATIVE.

The ImqMessage format must be MQFMT_WORK_INFO_HEADER.

See the parent class method description for more details.

Object methods (public)

void operator = (const ImqWorkHeader & header);

Copies instance data from *header*, replacing the existing instance data.

ImqBinary messageToken () const;

Returns the **message token**.

ImqBoolean setMessageToken(const ImqBinary & token);

Sets the **message token**. The data length of *token* must be either zero or MQ_MSG_TOKEN_LENGTH. It returns TRUE if successful.

void setMessageToken(const MQBYTE16 token = 0);

Sets the **message token**. *token* can be zero, which is the same as specifying MQMTOK_NONE. If *token* is nonzero, it must address MQ_MSG_TOKEN_LENGTH bytes of binary data.

When using predefined values such as MQMTOK_NONE, you might need make a cast to ensure a signature match; for example, (MQBYTE *)MQMTOK_NONE.

ImqString serviceName () const;

Returns the **service name**, including trailing blanks.

void setServiceName(const char * name);

Sets the **service name**.

ImqString serviceStep () const;

Returns the **service step**, including trailing blanks.

void setServiceStep(const char * step);

Sets the **service step**.

Object data (protected)

MQWIH omqwih

The MQWIH data structure.

Reason codes

- MQRC_BINARY_DATA_LENGTH_ERROR

Properties of IBM MQ classes for JMS objects

All objects in IBM MQ classes for JMS have properties. Different properties apply to different object types. Different properties have different allowable values, and symbolic property values differ between the administration tool and program code.

IBM MQ classes for JMS provides facilities to set and query the properties of objects using the IBM MQ JMS administration tool, IBM MQ Explorer, or in an application. Many of the properties are relevant only to a specific subset of the object types.

For information on how you use the IBM MQ JMS administration tool, see [Configuring JMS objects using the administration tool](#).

Table 677 on page 1928 gives a brief description of each property and shows for each property which object types it applies to. The object types are identified using keywords; see [Configuring JMS objects using the administration tool](#) for an explanation of these objects.

Numbers refer to notes at the end of the table. See also “Dependencies between properties of IBM MQ classes for JMS objects” on page 1931.

A property consists of a name-value pair in the format:

```
PROPERTY_NAME(property_value)
```

The topics in this section list, for each property, the name of the property and a brief description, and shows the valid property values used in the administration tool. and the set method that is used to set the value of the property in an application. The topics also show the valid property values for each property and the mapping between symbolic property values used in the tool and their programmable equivalents.

Property names are not case-sensitive, and are restricted to the set of recognized names shown in these topics.

Note:

1. This property can be used with Version 7.0 of IBM MQ classes for JMS but has no effect for an application connected to a Version 7.0 queue manager unless the PROVIDERVERSION property of the connection factory is set to a version number less than 7.
2. Only the BROKERVER, CLIENTID, DESCRIPTION, DIRECTAUTH, HOSTNAME, LOCALADDRESS, MAXBUFFSIZE, MULTICAST, PORT, PROXYHOSTNAME, PROXYPORT, and TRANSPORT properties are supported for a ConnectionFactory or TopicConnectionFactory object when using a real-time connection to a broker.
3. The CCDTURL and CHANNEL properties of an object must not both be set at the same time.

Dependencies between properties of IBM MQ classes for JMS objects

The validity of some properties is dependent on the particular values of other properties.

This dependency can occur in the following groups of properties:

- Client properties
- Properties for a real-time connection to a broker
- Exit initialization strings

Client properties

For a connection to a queue manager, the following properties are relevant only if TRANSPORT has the value CLIENT:

- HOSTNAME
- PORT
- CHANNEL
- LOCALADDRESS

- CCDTURL
- CCSID
- COMPHDR
- COMPMSG
- RECEXIT
- RECEXITINIT
- SECEXIT
- SECEXITINIT
- SENDEXIT
- SENDEXITINIT
- SHARECONVALLOWED
- SSLCIPHERSUITE
- SSLCRL
- SSLFIPSREQUIRED
- SSLPEERNAME
- SSLRESETCOUNT
- APPLICATIONNAME

You cannot set values for these properties by using the administration tool if TRANSPORT has the value BIND.

If TRANSPORT has the value CLIENT, the default value of the BROKERVER property is V1 and the default value of the PORT property is 1414. If you set the value of BROKERVER or PORT explicitly, a later change to the value of TRANSPORT does not override your choices.

Properties for a real-time connection to a broker

Only the following properties are relevant if TRANSPORT has the value DIRECT or DIRECTHTTP:

- BROKERVER
- CLIENTID
- DESCRIPTION
- DIRECTAUTH
- HOSTNAME
- LOCALADDRESS
- MAXBUFFSIZE
- MULTICAST (supported only for DIRECT)
- PORT
- PROXYHOSTNAME (supported only for DIRECT)
- PROXYPORT (supported only for DIRECT)

If TRANSPORT has the value DIRECT or DIRECTHTTP, the default value of the BROKERVER property is V2, and the default value of the PORT property is 1506. If you set the value of BROKERVER or PORT explicitly, a later change to the value of TRANSPORT does not override your choices.

Exit initialization strings

Do not set any of the exit initialization strings without supplying the corresponding exit name. The exit initialization properties are:

- RECEXITINIT
- SECEXITINIT
- SENDEXITINIT

For example, specifying `RECEXITINIT(myString)` without specifying `RECEXIT(some.exit.classname)` causes an error.

Related reference

[“TRANSPORT” on page 1979](#)

The nature of a connection to a queue manager or broker.

APPLICATIONNAME

An application can set a name that identifies its connection to the queue manager. This application name is shown by the **DISPLAY CONN MQSC/PCF** command (where the field is called **APPLTAG**) or in the IBM MQ Explorer **Application Connections** display (where the field is called **App name**).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: APPLICATIONNAME

JMS administration tool short name: APPNAME

Programmatic access

Setters/getters

- `MQConnectionFactory.setAppName()`
- `MQConnectionFactory.getAppName()`

Values

Any valid string that is no longer than 28 characters. Longer names are adjusted to fit by removing leading package names, if necessary. For example, if the invoking class is `com.example.MainApp`, the full name is used, but if the invoking class is `com.example.dictionaryAndThesaurus.multilingual.mainApp`, the name `multilingual.mainApp` is used, because it is the longest combination of class name and rightmost package name that fits into the available length.

If the class name itself is more than 28 characters long, it is truncated to fit. For example, `com.example.mainApplicationForSecondTestCase` becomes `mainApplicationForSecondTest`.

ASYNCEXCEPTION

This property determines whether IBM MQ classes for JMS informs an `ExceptionListener` only when a connection is broken, or when any exception occurs asynchronously to a JMS API call. This applies to all Connections created from this `ConnectionFactory` that have an `ExceptionListener` registered.

Applicable objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: ASYNCEXCEPTION

JMS administration tool short name: AEX

Programmatic access

Setters/Getters

- `MQConnectionFactory.setAsyncExceptions()`

- `MQConnectionFactory.getAsyncExceptions()`

Values

ASYNC_EXCEPTIONS_ALL

Any exception detected asynchronously, outside the scope of a synchronous API call, and all connection broken exceptions are sent to the `ExceptionListener`.

Environment	Value
JMS Administration Tool	ALL
Programmatic	<code>WMQCONSTANTS.ASYNC_EXCEPTIONS_ALL = -1</code>
IBM MQ Explorer	All

ASYNC_EXCEPTIONS_CONNECTIONBROKEN

Only exceptions indicating a broken connection are sent to the `ExceptionListener`. Any other exceptions occurring during asynchronous processing are not reported to the `ExceptionListener`, and hence the application is not informed of these exceptions. **V 8.0.0.2** This is the default value from IBM MQ 8.0.0, Fix Pack 2 (see [JMS: Exception listener changes in Version 8.0](#)).

Environment	Value
JMS Administration Tool	CONNECTIONBROKEN
Programmatic	<code>WMQCONSTANTS.ASYNC_EXCEPTIONS_CONNECTIONBROKEN = 1</code>
MQ Explorer	Connection Broken

The following additional constant is defined:

- **V 8.0.0.2** From Version 8.0.0, Fix Pack 2: `WMQCONSTANTS.ASYNC_EXCEPTIONS_DEFAULT = ASYNC_EXCEPTIONS_CONNECTIONBROKEN`
- Before Version 8.0.0, Fix Pack 2: `WMQCONSTANTS.ASYNC_EXCEPTIONS_DEFAULT = ASYNC_EXCEPTIONS_ALL`

BROKERCCDURSUBQ

The name of the queue from which durable subscription messages are retrieved for a `ConnectionConsumer`.

Applicable objects

Topic

JMS administration tool long name: `BROKERCCDURSUBQ`

JMS administration tool short name: `CCDSUB`

Programmatic access

Setters/getters

- `MQTopic.setBrokerCCDurSubQueue()`
- `MQTopic.getBrokerCCDurSubQueue()`

Values

SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE

This is the default value.

Any valid string

BROKERCCSUBQ

The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer.

Applicable objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERCCSUBQ

JMS administration tool short name: CCSUB

Programmatic access

Setters/getters

- MQConnectionFactory.setBrokerCCSubQueue()
- MQConnectionFactory.getBrokerCCSubQueue()

Values

SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

This is the default value.

Any valid string

BROKERCONQ

The control queue name of the broker.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERCONQ

JMS administration tool short name: BCON

Programmatic access

Setters/getters

- MQConnectionFactory.setBrokerControlQueue()
- MQConnectionFactory.getBrokerControlQueue()

Values

SYSTEM.BROKER.CONTROL.QUEUE

This is the default value.

Any valid string

BROKERDURSUBQ

When the IBM MQ classes for JMS are being used in IBM MQ messaging provider migration mode, this property specifies the name of the queue from which durable subscription messages are retrieved.

Applicable objects

Topic

JMS administration tool long name: BROKERDURSUBQ

JMS administration tool short name: BDSUB

Programmatic access

Setters/getters

- `MQTopic.setBrokerDurSubQueue()`
- `MQTopic.getBrokerDurSubQueue()`

Values

SYSTEM.JMS.D.SUBSCRIBER.QUEUE

This is the default value.

Any valid string

Starting with `SYSTEM.JMS.D`

Related concepts

[Rules for selecting the IBM MQ messaging provider mode](#)

BROKERPUBQ

The name of the queue where published messages are sent (the stream queue).

Applicable Objects

ConnectionFactory, TopicConnectionFactory, Topic, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERPUBQ

JMS administration tool short name: BPUB

Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerPubQueue`
- `MQConnectionFactory.getBrokerPubQueue`

Values

SYSTEM.BROKER.DEFAULT.STREAM

This is the default value.

Any valid string

BROKERPUBQMGR

The name of the queue manager that owns the queue where messages published on the topic are sent.

Applicable Objects

Topic

JMS administration tool long name: BROKERPUBQMGR

JMS administration tool short name: BPQM

Programmatic access

Setters/getters

- `MQTopic.setBrokerPubQueueManager()`
- `MQTopic.getBrokerPubQueueManager()`

Values

null

This is the default value.

Any valid string

BROKERQMGR

The name of the queue manager on which the broker is running.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERQMGR

JMS administration tool short name: BQM

Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerQueueManager()`
- `MQConnectionFactory.getBrokerQueueManager()`

Values

null

This is the default value.

Any valid string

BROKERSUBQ

When the IBM MQ classes for JMS are being used in IBM MQ messaging provider migration mode, this property specifies the name of the queue from which non-durable subscription messages are retrieved.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: BROKERSUBQ

JMS administration tool short name: BSUB

Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerSubQueue()`
- `MQConnectionFactory.getBrokerSubQueue()`

Values

SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

This is the default value.

Any valid string

Starting with `SYSTEM.JMS.ND`

Related concepts

[Rules for selecting the IBM MQ messaging provider mode](#)

BROKERVER

The version of the broker being used.

Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`, `Topic`, `XAConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: BROKERVER

JMS administration tool short name: BVER

Programmatic access

Setters/getters

- `MQConnectionFactory.setBrokerVersion()`
- `MQConnectionFactory.getBrokerVersion()`

Values

V1

To use an IBM MQ Publish/Subscribe broker, or to use a broker of IBM MQ Integrator, WebSphere Event Broker, WebSphere Business Integration Event Broker, or WebSphere Business Integration Message Broker in compatibility mode. This is the default value if `TRANSPORT` is set to `BIND` or `CLIENT`.

V2

To use a broker of IBM MQ Integrator, WebSphere Event Broker, WebSphere Business Integration Event Broker, or WebSphere Business Integration Message Broker in native mode. This is the default value if `TRANSPORT` is set to `DIRECT` or `DIRECTHTTP`.

unspecified

After the broker has migrated from V6 to V7, set this property so that RFH2 headers are no longer used. After migration this property is no longer relevant.

CCDTURL

A Uniform Resource Locator (URL) that identifies the name and location of the file containing the client channel definition table and specifies how the file can be accessed.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CCDTURL

JMS administration tool short name: CCDT

Programmatic access

Setters/getters

- MQConnectionFactory.setCCDTURL()
- MQConnectionFactory.getCCDTURL()

Values

null

This is the default value.

A Uniform Resource Locator (URL)

CCSID

The coded character set ID to be used for a connection or destination.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CCSID

JMS administration tool short name: CCS

Programmatic access

Setters/getters

- MQConnectionFactory.setCCSID()
- MQConnectionFactory.getCCSID()

Values

819

This is the default value for a connection factory.

1208

This is the default value for a destination.

Any positive integer

CHANNEL

The name of the client connection channel being used.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CHANNEL

JMS administration tool short name: CHAN

Programmatic access

Setters/getters

- MQConnectionFactory.setChannel()
- MQConnectionFactory.getChannel()

Values

SYSTEM.DEF.SVRCONN

This is the default value.

Any valid string

CLEANUP

Cleanup Level for BROKER or MIGRATE Subscription Stores.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLEANUP

JMS administration tool short name: CL

Programmatic access

Setters/getters

- MQConnectionFactory.setCleanupLevel()
- MQConnectionFactory.getCleanupLevel()

Values

SAFE

Use safe cleanup. This is the default value.

ASPROP

Use safe, strong, or no cleanup according to a property set on the Java command line.

NONE

Use no cleanup.

STRONG

Use strong cleanup.

CLEANUPINT

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLEANUPINT

JMS administration tool short name: CLINT

Programmatic access

Setters/getters

- MQConnectionFactory.setCleanupInterval()
- MQConnectionFactory.getCleanupInterval()

Values

3600000

This is the default value.

Any positive integer

CONNECTIONNAMELIST

List of TCP/IP connection names. The list is tried in order, once per each reconnection retry attempt.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory

JMS administration tool long name: CONNECTIONNAMELIST

JMS administration tool short name: CNLIST

Programmatic access

Setters/getters

- MQConnectionFactory.setconnectionNameList()
- MQConnectionFactory.getconnectionNameList()

Values

Comma separated list of HOSTNAME(PORT). HOSTNAME can be either a DNS name or IP address.

PORT defaults to 1414.

CLIENTRECONNECTOPTIONS

Options governing reconnection.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory

JMS administration tool long name: CLIENTRECONNECTOPTIONS

JMS administration tool short name: CROPT

Programmatic access

Setters/getters

- `MQConnectionFactory.setClientReconnectOptions()`
- `MQConnectionFactory.getClientReconnectOptions()`

Values

QMGR

The application can reconnect, but only to the queue manager to which it originally connected.

Use this value if an application can be reconnected, but there is an affinity between the IBM MQ classes for JMS application, and the queue manager to which it first established a connection.

Choose this value if you want an application to automatically reconnect to the standby instance of a highly available queue manager.

To use this value programmatically, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_Q_MGR`.

ANY

The application can reconnect to any queue manager.

Use the reconnect option only if there is no affinity between the IBM MQ classes for JMS application and the queue manager with which it initially established a connection.

To use this value from a program, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT`.

DISABLED

The application will not be reconnected.

To use this value programmatically, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_DISABLED`.

ASDEF

Whether the application will reconnect automatically depends on the value of the IBM MQ channel attribute `DefReconnect`.

To use this value from a program, use the constant `WMQConstants.WMQ_CLIENT_RECONNECT_AS_DEF`.

CLIENTRECONNECTTIMEOUT

Time before reconnection retries cease.

Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: `CLIENTRECONNECTTIMEOUT`

JMS administration tool short name: `CRT`

Programmatic access

Setters/getters

- `MQConnectionFactory.setClientReconnectTimeout()`
- `MQConnectionFactory.getClientReconnectTimeout()`

Values

Interval in seconds. Default 1800 (30 minutes).

CLIENTID

The client identifier is used to uniquely identify the application connection for durable subscriptions.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLIENTID

JMS administration tool short name: CID

Programmatic access

Setters/getters

- MQConnectionFactory.setClientId()
- MQConnectionFactory.getClientId()

Values

null

This is the default value.

Any valid string

CLONESUPP

Whether two or more instances of the same durable topic subscriber can run simultaneously.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CLONESUPP

JMS administration tool short name: CLS

Programmatic access

Setters/getters

- MQConnectionFactory.setCloneSupport()
- MQConnectionFactory.getCloneSupport()

Values

DISABLED

Only one instance of a durable topic subscriber can run at a time. This is the default value.

ENABLED

Two or more instances of the same durable topic subscriber can run simultaneously, but each instance must run in a separate Java virtual machine (JVM).

COMPHDR

A list of the techniques that can be used for compressing header data on a connection.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: COMPHDR

JMS administration tool short name: HC

Programmatic access

Setters/getters

- MQConnectionFactory.setHdrCompList()
- MQConnectionFactory.getHdrCompList()

Values

NONE

This is the default value.

SYSTEM

RLE message header compression is performed.

COMPMSG

A list of the techniques that can be used for compressing message data on a connection.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: COMPMSG

JMS administration tool short name: MC

Programmatic access

Setters/getters

- MQConnectionFactory.setMsgCompList()
- MQConnectionFactory.getMsgCompList()

Values

NONE

This is the default value.

A list of one or more of the following values separated by blank characters:

RLE ZLIBFAST ZLIBHIGH

CONNOPT

Controls how IBM MQ classes for JMS applications that use the bindings transport connect to the queue manager.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory.

JMS administration tool long name: CONNOPT

JMS administration tool short name: CNOPT

Programmatic access

Setters/getters

- `MQConnectionFactory.setMQConnectionOptions()`
- `MQConnectionFactory.getMQConnectionOptions()`

Values

STANDARD

The nature of the binding between the application and the queue manager depends on the value of the *DefaultBindType* attribute of the queue manager. The STANDARD value maps to the IBM MQ *ConnectOption* MQCNO_STANDARD_BINDING.

SHARED

The application and the local queue manager agent run in separate units of execution but share some resources. This value maps to the IBM MQ *ConnectOption* MQCNO_SHARED_BINDING.

ISOLATED

The application and the local queue manager agent run in separate units of execution and share no resources. The ISOLATED value maps to the IBM MQ *ConnectOption* MQCNO_ISOLATED_BINDING.

FASTPATH

The application and the local queue manager agent run in the same unit of execution. This value maps to the IBM MQ *ConnectOption* MQCNO_FASTPATH_BINDING.

SERIALQM

The application requests exclusive use of the connection tag within the scope of the queue manager. This value maps to the IBM MQ *ConnectOption* MQCNO_SERIALIZE_CONN_TAG_Q_MGR.

SERIALQSG

The application requests exclusive use of the connection tag within the scope of the queue sharing group to which the queue manager belongs. The SERIALQSG value maps to the IBM MQ *ConnectOption* MQCNO_SERIALIZE_CONN_TAG_QSG.

RESTRICTQM

The application requests shared use of the connection tag, but there are restrictions on the shared use of the connection tag within the scope of the queue manager. This value maps to the IBM MQ *ConnectOption* MQCNO_RESTRICT_CONN_TAG_Q_MGR.

RESTRICTQSG

The application requests shared use of the connection tag, but there are restrictions on the shared use of the connection tag within the scope of the queue sharing group to which the queue manager belongs. This value maps to the IBM MQ *ConnectOption* MQCNO_RESTRICT_CONN_TAG_QSG.

For further information on IBM MQ connection options, see [Connecting to a queue manager using the MQCONN call](#).

CONNTAG

A tag that the queue manager associates with the resources updated by the application within a unit of work while the application is connected to the queue manager.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: CONNTAG

JMS administration tool short name: CNTAG

Programmatic access

Setters/getters

- MQConnectionFactory.setConnTag()
- MQConnectionFactory.getConnTag()

Values

A byte array of 128 elements, where each element is 0

This is the default value.

Any string

The value is truncated if it is longer than 128 bytes.

DESCRIPTION

A description of the stored object.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: DESCRIPTION

JMS administration tool short name: DESC

Programmatic access

Setters/getters

- MQConnectionFactory.setDescription()
- MQConnectionFactory.getDescription()

Values

null

This is the default value.

Any valid string

DIRECTAUTH

Whether SSL authentication is used on a real-time connection to a broker.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: DIRECTAUTH

JMS administration tool short name: DAUTH

Programmatic access

Setters/getters

- MQConnectionFactory.setDirectAuth()
- MQConnectionFactory.getDirectAuth()

Values

BASIC

No authentication, username authentication, or password authentication. This is the default value.

CERTIFICATE

Public key certificate authentication.

ENCODING

How numeric data in the body of a message is represented when the message is sent to this destination. The property specifies the representation of binary integers, packed decimal integers, and floating point numbers.

Applicable Objects

Queue, Topic

JMS administration tool long name: ENCODING

JMS administration tool short name: ENC

Programmatic access

Setters/getters

- MQDestination.setEncoding()
- MQDestination.getEncoding()

Values

ENCODING property

The valid values that the ENCODING property can take are constructed from the three sub-properties:

integer encoding

Either normal or reversed

decimal encoding

Either normal or reversed

floating-point encoding

IEEE normal, IEEE reversed, or z/OS

The ENCODING property is expressed as a three-character string with the following syntax:

```
{N|R}{N|R}{N|R|3}
```

In this string:

- N denotes normal
- R denotes reversed
- 3 denotes z/OS
- The first character represents *integer encoding*
- The second character represents *decimal encoding*
- The third character represents *floating-point encoding*

This provides a set of twelve possible values for the ENCODING property.

There is an additional value, the string NATIVE, which sets appropriate encoding values for the Java platform.

The following examples show valid combinations for ENCODING:

```
ENCODING (NNR)  
ENCODING (NATIVE)  
ENCODING (RR3)
```

EXPIRY

The time after which messages at a destination expire.

Applicable Objects

Queue, Topic

JMS administration tool long name: EXPIRY

JMS administration tool short name: EXP

Programmatic access

Setters/getters

- MQDestination.setExpiry()
- MQDestination.getExpiry()

Values

APP

Expiry can be defined by the JMS application. This is the default value.

UNLIM

No expiry occurs.

0

No expiry occurs.

Any positive integer representing expiry in milliseconds.

FAILIFQUIESCE

This property determines whether calls to certain methods fail if either the queue manager is in a quiescing state, or an application is connecting to a queue manager using the CLIENT transport and the

channel that the application is using has been put into a quiescing state, for example, by using the **STOP CHANNEL** or **STOP CHANNEL MODE(QUIESCE)** MQSC command.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, Topic, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: FAILIFQUIESCE

JMS administration tool short name: FIQ

Programmatic access

Setters/getters

- MQConnectionFactory.setFailIfQuiesce()
- MQConnectionFactory.getFailIfQuiesce()

Values

YES

Calls to certain methods fail if either the queue manager is in a quiescing state, or the channel being used to connect to a queue manager is quiescing. If an application detects either of these conditions, the application can complete its immediate task and close the connection, allowing the queue manager or channel instance to stop. This is the default value.

NO

No method call fails because either the queue manager, or the channel being used to connect to a queue manager, is in a quiescing state. If you specify this value, an application cannot detect that the queue manager or channel is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

HOSTNAME

For a connection to a queue manager, the host name or IP address of the system on which the queue manager is running or, for a real-time connection to a broker, the host name or IP address of the system on which the broker is running.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: HOSTNAME

JMS administration tool short name: HOST

Programmatic access

Setters/getters

- MQConnectionFactory.setHostName()
- MQConnectionFactory.getHostName()

Values

localhost

This is the default value.

Any valid string

LOCALADDRESS

For a connection to a queue manager, this property specifies either the local network interface to be used, or the local port, or range of local ports, to be used.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: LOCALADDRESS

JMS administration tool short name: LA

Programmatic access

Setters/getters

- MQConnectionFactory.setLocalAddress()
- MQConnectionFactory.getLocalAddress()

Values

"" (empty string)

This is the default value.

A string in the format [ip-addr]([low-port[,high-port]])

Here are some examples:

192.0.2.0

The channel binds to address 192.0.2.0 locally.

192.0.2.0(1000)

The channel binds to address 192.0.2.0 locally and uses port 1000.

192.0.2.0(1000,2000)

The channel binds to address 192.0.2.0 locally and uses a port in the range 1000 to 2000.

(1000)

The channel binds to port 1000 locally.

(1000,2000)

The channel binds to a port in the range 1000 to 2000 locally.

You can specify a host name instead of an IP address. For a real-time connection to a broker, this property is relevant only when multicast is used, and the value of the property must not contain a port number, or a range of port numbers. The only valid values of the property in this case are null, an IP address, or a host name.

MAPNAMESTYLE

Allows compatibility style to be used for MapMessage element names.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: MAPNAMESTYLE

JMS administration tool short name: MNST

Programmatic access

Setters/getters

- `MQConnectionFactory.setMapNameStyle()`
- `MQConnectionFactory.getMapNameStyle()`

Values

STANDARD

The standard `com.ibm.jms.JMSMapMessage` element naming format is to be used. This is the default value and allows non-legal Java identifiers to be used as the element name.

COMPATIBLE

The older `com.ibm.jms.JMSMapMessage` element naming format is to be used. Only legal Java identifiers can be used as the element name. This is needed only if map messages are being sent to an application that is using a version of IBM MQ classes for JMS earlier than Version 5.3.

MAXBUFFSIZE

The maximum number of received messages that can be stored in an internal message buffer while waiting to be processed by the application. This property applies only when `TRANSPORT` has the value `DIRECT` or `DIRECTHTTP`.

Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: `MAXBUFFSIZE`

JMS administration tool short name: `MBSZ`

Programmatic access

Setters/getters

- `MQConnectionFactory.setMaxBufferSize()`
- `MQConnectionFactory.getMaxBufferSize()`

Values

1000

This is the default value.

Any positive integer

MDREAD

This property determines whether a JMS application can extract the values of MQMD fields.

Applicable Objects

JMS administration tool long name: `MDREAD`

JMS administration tool short name: `MDR`

Programmatic access

Setters/getters

- `MQDestination.setMQMDReadEnabled()`
- `MQDestination.getMQMDReadEnabled()`

Values

NO

When sending messages, the JMS_IBM_MQMD* properties on a sent message are not updated to reflect the updated field values in the MQMD. When receiving messages, none of the JMS_IBM_MQMD* properties are available on a received message, even if the sender had set some or all of them. This is the default value for administrative tools.

For programs, use False.

Yes

When sending messages, all of the JMS_IBM_MQMD* properties on a sent message are updated to reflect the updated field values in the MQMD, including the properties that the sender did not set explicitly. When receiving messages, all of the JMS_IBM_MQMD* properties are available on a received message, including the properties that the sender did not set explicitly.

For programs, use True.

MDWRITE

This property determines whether a JMS application can set the values of MQMD fields.

Applicable Objects

Queue, Topic

JMS administration tool long name: MDWRITE

JMS administration tool short name: MDR

Programmatic access

Setters/getters

- MQDestination.setMQMDWriteEnabled()
- MQDestination.getMQMDWriteEnabled()

Values

NO

All JMS_IBM_MQMD* properties are ignored and their values are not copied into the underlying MQMD structure. This is the default value for administrative tools.

For programs, use False.

YES

JMS_IBM_MQMD* properties are processed. Their values are copied into the underlying MQMD structure.

For programs, use True.

MDMSGCTX

What level of message context is to be set by the JMS application. The application must be running with appropriate context authority for this property to take effect.

Applicable Objects

JMS administration tool long name: MDMSGCTX

JMS administration tool short name: MDCTX

Programmatic access

Setters/getters

- `MQDestination.setMQMDMessageContext()`
- `MQDestination.getMQMDMessageContext()`

Values

DEFAULT

The MQOPEN API call and the MQPMO structure specify no explicit message context options. This is the default value for administrative tools.

For programs, use `WMQ_MDCTX_DEFAULT`.

SET_IDENTITY_CONTEXT

The MQOPEN API call specifies the message context option `MQOO_SET_IDENTITY_CONTEXT` and the MQPMO structure specifies `MQPMO_SET_IDENTITY_CONTEXT`.

For programs, use `WMQ_MDCTX_SET_IDENTITY_CONTEXT`.

SET_ALL_CONTEXT

The MQOPEN API call specifies the message context option `MQOO_SET_ALL_CONTEXT` and the MQPMO structure specifies `MQPMO_SET_ALL_CONTEXT`.

For programs, use `WMQ_MDCTX_SET_ALL_CONTEXT`.

MSGBATCHSZ

The maximum number of messages to be taken from a queue in one packet when using asynchronous message delivery.

Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: `MAXBUFFSIZE`

JMS administration tool short name: `MBSZ`

Programmatic access

Setters/getters

- `MQConnectionFactory.setMsgBatchSize()`
- `MQConnectionFactory.getMsgBatchSize()`

Values

10

This is the default value.

Any positive integer

MSGBODY

Determines whether a JMS application accesses the `MQRFH2` of an IBM MQ message as part of the message payload.

Applicable Objects

`Queue`, `Topic`

JMS administration tool long name: WMQ_MESSAGE_BODY

JMS administration tool short name: MBODY

Programmatic access

Setters/getters

- MQConnectionFactory.setMessageBodyStyle()
- MQConnectionFactory.getMessageBodyStyle()

Values

UNSPECIFIED

When sending, IBM MQ classes for JMS does or does not generate and include an MQRFH2 header, depending on the value of WMQ_TARGET_CLIENT. When receiving, acts as value JMS.

JMS

When sending, IBM MQ classes for JMS automatically generates an MQRFH2 header and includes it in the IBM MQ message.

When receiving, IBM MQ classes for JMS set the JMS message properties according to values in the MQRFH2 (if present); it does not present the MQRFH2 as part of the JMS message body.

MQ

When sending, IBM MQ classes for JMS does not generate an MQRFH2.

When receiving, IBM MQ classes for JMS presents the MQRFH2 as part of the JMS message body.

MSGRETENTION

Whether the connection consumer keeps undelivered messages on the input queue.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory,

JMS administration tool long name: MSGRETENTION

JMS administration tool short name: MRET

Programmatic access

Setters/getters

- MQConnectionFactory.setMessageRetention()
- MQConnectionFactory.getMessageRetention()

Values

Yes

Undelivered messages remain on the input queue. This is the default value.

No

Undelivered messages are dealt with according to their disposition options.

MSGSELECTION

Determines whether message selection is done by the IBM MQ classes for JMS or by the broker. If TRANSPORT has the value DIRECT, message selection is always done by the broker and the value of

MSGSELECTION is ignored. Message selection by the broker is not supported when BROKERVER has the value V1.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: MSGSELECTION

JMS administration tool short name: MSEL

Programmatic access

Setters/getters

- MQConnectionFactory.setMessageSelection()
- MQConnectionFactory.getMessageSelection()

Values

CLIENT

Message selection is done by IBM MQ classes for JMS. This is the default value.

BROKER

Message selection is done by the broker.

MULTICAST

To enable multicast on a real-time connection to a broker and, if enabled, to specify the precise way in which multicast is used to deliver messages from the broker to a message consumer. The property has no effect on how a message producer sends messages to a broker.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, Topic

JMS administration tool long name: MULTICAST

JMS administration tool short name: MCAST

Programmatic access

Setters/getters

- MQConnectionFactory.setMulticast()
- MQConnectionFactory.getMulticast()

Values

DISABLED

Messages are not delivered to a message consumer using multicast transport. This is the default value for ConnectionFactory and TopicConnectionFactory objects.

ASCF

Messages are delivered to a message consumer according to the multicast setting for the connection factory associated with the message consumer. The multicast setting for the connection factory is noted at the time that the message consumer is created. This value is valid only for Topic objects, and is the default value for Topic objects.

ENABLED

If the topic is configured for multicast in the broker, messages are delivered to a message consumer using multicast transport. A reliable quality of service is used if the topic is configured for reliable multicast.

RELIABLE

If the topic is configured for reliable multicast in the broker, messages are delivered to the message consumer using multicast transport with a reliable quality of service. If the topic is not configured for reliable multicast, you cannot create a message consumer for the topic.

NOTR

If the topic is configured for multicast in the broker, messages are delivered to the message consumer using multicast transport. A reliable quality of service is not used even if the topic is configured for reliable multicast.

OPTIMISTICPUBLICATION

This property determines whether IBM MQ classes for JMS returns control immediately to a publisher that has published a message, or whether it returns control only after it has completed all the processing associated with the call and can report the outcome to the publisher.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: OPTIMISTICPUBLICATION

JMS administration tool short name: OPTPUB

Programmatic access

Setters/getters

- MQConnectionFactory.setOptimisticPublication()
- MQConnectionFactory.getOptimisticPublication()

Values

NO

When a publisher publishes a message, IBM MQ classes for JMS do not return control to the publisher until it has completed all the processing associated with the call and can report the outcome to the publisher. This is the default value.

YES

When a publisher publishes a message, IBM MQ classes for JMS returns control to the publisher immediately, before it has completed all the processing associated with the call and can report the outcome to the publisher. IBM MQ classes for JMS reports the outcome only when the publisher commits the message.

OUTCOMENOTIFICATION

This property determines whether IBM MQ classes for JMS return control immediately to a subscriber that has just acknowledged or committed a message, or whether it returns control only after it has completed all the processing associated with the call and can report the outcome to the subscriber.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: OUTCOMENOTIFICATION

JMS administration tool short name: NOTIFY

Programmatic access

Setters/getters

- `MQConnectionFactory.setOutcomeNotification()`
- `MQConnectionFactory.getOutcomeNotification()`

Values

YES

When a subscriber acknowledges or commits a message, IBM MQ classes for JMS do not return control to the subscriber until it has completed all the processing associated with the call and can report the outcome to the subscriber. This is the default value.

NO

When a subscriber acknowledges or commits a message, IBM MQ classes for JMS returns control to the subscriber immediately, before it has completed all the processing associated with the call and can report the outcome to the subscriber.

PERSISTENCE

The persistence of messages sent to a destination.

Applicable Objects

Queue, Topic

JMS administration tool long name: PERSISTENCE

JMS administration tool short name: PER

Programmatic access

Setters/getters

- `MQDestination.setPersistence()`
- `MQDestination.getPersistence()`

Values

APP

Persistence is defined by the JMS application. This is the default value.

QDEF

Persistence takes the value of the queue default.

PERS

Messages are persistent.

NON

Messages are nonpersistent.

HIGH

See [JMS persistent messages](#) for further information on the use of this value.

POLLINGINT

If each message listener within a session has no suitable message on its queue, this is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue. If it frequently happens that no suitable message is available for any of the message listeners in a session, consider increasing the value of this property. This property is relevant only if `TRANSPORT` has the value `BIND` or `CLIENT`.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: POLLINGINT

JMS administration tool short name: PINT

Programmatic access

Setters/getters

- MQConnectionFactory.setPollingInterval()
- MQConnectionFactory.getPollingInterval()

Values

5000

This is the default value.

Any positive integer

PORT

For a connection to a queue manager, the number of the port on which the queue manager is listening or, for a real-time connection to a broker, the number of the port on which the broker is listening for real-time connections.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: PORT

JMS administration tool short name: PORT

Programmatic access

Setters/getters

- MQConnectionFactory.setPort()
- MQConnectionFactory.getPort()

Values

1414

This is the default value if TRANSPORT is set to CLIENT.

1506

This is the default value if TRANSPORT is set to DIRECT or DIRECTHTTP.

Any positive integer

PRIORITY

The priority for messages sent to a destination.

Applicable Objects

Queue, Topic

JMS administration tool long name: PRIORITY

JMS administration tool short name: PRI

Programmatic access

Setters/getters

- `MQDestination.setPriority()`
- `MQDestination.getPriority()`

Values

APP

Priority is defined by the JMS application. This is the default value.

QDEF

Priority takes the value of the queue default.

Any integer in the range 0-9

Lowest to highest.

PROCESSDURATION

This property determines whether a subscriber guarantees to process quickly any message it receives before returning control to IBM MQ classes for JMS.

Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`

JMS administration tool long name: PROCESSDURATION

JMS administration tool short name: PROCDUR

Programmatic access

Setters/getters

- `MQConnectionFactory.setProcessDuration()`
- `MQConnectionFactory.getProcessDuration()`

Values

UNKNOWN

A subscriber can give no guarantee about how quickly it can process any message it receives. This is the default value.

SHORT

A subscriber guarantees to process quickly any message it receives before returning control to IBM MQ classes for JMS.

PROVIDERVERSION

This property differentiates between the three IBM MQ messaging modes of operation: IBM MQ messaging provider normal mode, IBM MQ messaging provider normal mode with restrictions, and IBM MQ messaging provider migration mode.

The IBM MQ messaging provider normal mode uses all the features of an IBM MQ queue manager to implement JMS. This mode is optimized to use the JMS 2.0 API and functionality. The IBM MQ messaging provider normal mode with restrictions uses the JMS 2.0 API, but not the new features such as shared subscriptions, delayed delivery, or asynchronous send.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: PROVIDERVERSION

JMS administration tool short name: PVER

Programmatic access

Setters/getters

- MQConnectionFactory.setProviderVersion()
- MQConnectionFactory.getProviderVersion()

Values

You can set the **PROVIDERVERSION** property to any of the values 8 (normal mode), 7 (normal mode with restrictions), 6 (migration mode), or unspecified (the default value). The value that you specify for the **PROVIDERVERSION** property must be a string. If you are specifying an option of 8, 7 or 6, you can do this in any of the following formats:

- V.R.M.F
- V.R.M
- V.R
- V

where V, R, M and F are integer values greater than or equal to zero. The extra R, M and F values are optional and are available for you to use in case fine grained control is needed. For example, if you wanted to use a **PROVIDERVERSION** level of 7, you could set **PROVIDERVERSION=7**, **7.0**, **7.0.0** or **7.0.0.0**.

8 - Normal mode

The JMS application uses the IBM MQ messaging provider normal mode. Normal mode uses all the features of a IBM MQ queue manager to implement JMS. This mode is optimized to use the JMS 2.0 API and functionality.

If you are connecting to a queue manager with a command level of 800, then all of the JMS 2.0 API and features, such as asynchronous send, delayed delivery, or shared subscription, can be used.

If the queue manager specified in the connection factory settings is not a Version 8.0.0 queue manager, the `createConnection` method fails with an exception JMSFMQ0003.

The IBM MQ messaging provider normal mode uses the sharing conversations feature and the number of conversations that can be shared is controlled by the **SHARECNV()** property on the server connection channel. If this property is set to 0, you cannot use IBM MQ messaging provider normal mode and the `createConnection` method fails with an exception JM5CC5007.

7 - Normal mode with restrictions

The JMS application uses the IBM MQ messaging provider normal mode with restrictions. This mode uses the JMS 2.0 API, but not the new features such as shared subscriptions, delayed delivery, or asynchronous send.

If you set **PROVIDERVERSION** to 7 only the IBM MQ messaging provider normal with restrictions mode of operation is available. If the queue manager specified in the connection factory settings is not a Version 7.0.1, or later, queue manager, the `createConnection` method fails with exception JM5FCC5008.

If you are connecting using normal mode with restrictions, to a queue manager with a command level between 700 and 800 then you can use the JMS 2.0 API, but not the asynchronous send, delayed delivery, or shared subscription features.

The IBM MQ messaging provider normal mode with restrictions uses the sharing conversations feature and the number of conversations that can be shared is controlled by the **SHARECNV()** property on the server connection channel. If this property is set to 0, you cannot use IBM MQ messaging provider normal mode with restrictions and the `createConnection` method fails with an exception JMSCC5007.

6 - Migration mode

The JMS application uses the IBM MQ messaging provider migration mode.

The IBM MQ classes for JMS use the features and algorithms supplied with IBM WebSphere MQ 6.0. If you want to connect to WebSphere Message Broker Version 6.0 or 6.1 using IBM WebSphere MQ Enterprise Transport Version 6.0, you must use this mode. You can connect to a IBM MQ 8.0 queue manager using this mode, but none of the new features of a IBM MQ classes for JMS queue manager are used, for example, read ahead or streaming.

If you have a IBM MQ 8.0 client connecting to a IBM MQ 8.0 queue manager, then the message selection is done by the queue manager rather than on the client system.

If IBM MQ messaging provider migration mode is specified and you attempt to use any of the JMS 2.0 API, the API method call fails with the exception JMSCC5007.

unspecified (default)

The **PROVIDERVERSION** property is set to *unspecified* by default.

A connection factory that was created with a previous version of IBM MQ classes for JMS in JNDI takes this value when the connection factory is used with the new version of IBM MQ classes for JMS. The following algorithm is used to determine which mode of operation is used. This algorithm is used when the `createConnection` method is called and uses other aspects of the connection factory to determine if IBM MQ messaging provider normal mode, normal mode with restrictions, or IBM MQ messaging provider migration mode is required.

1. First, an attempt to use IBM MQ messaging provider normal mode is made.
2. If the queue manager connected is not IBM MQ 8.0, or later, an attempt to use IBM MQ messaging provider normal mode with restrictions is made.
3. If the queue manager connected is not IBM WebSphere MQ 7.0.1, or later, the connection is closed and IBM MQ messaging provider migration mode is used instead.
4. If the **SHARECNV** property on the server connection channel is set to 0, the connection is closed and IBM MQ messaging provider migration mode is used instead.
5. If **BROKERVER** is set to V1 or the default *unspecified* value, IBM MQ messaging provider normal mode continues to be used, and therefore any publish/subscribe operations use the new IBM WebSphere MQ 7.0.1, or later, features.

See [ALTER QMGR](#) for information about the **PSMODE** parameter of the **ALTER QMGR** command for further information on compatibility.

6. If **BROKERVER** is set to V2 the action taken depends on the value of **BROKERQMGR** :

- If the **BROKERQMGR** is blank:

If the queue specified by the **BROKERCONQ** property can be opened for output (that is, **MQOPEN** for output succeeds) and **PSMODE** on the queue manager is set to **COMPAT** or **DISABLED**, then IBM MQ messaging provider migration mode is used.

- If the queue specified by the **BROKERCONQ** property cannot be opened for output, or the **PSMODE** attribute is set to **ENABLED**:

IBM MQ messaging provider normal mode is used.

- If **BROKERQMGR** is non-blank :

IBM MQ messaging provider migration mode is used.

If you cannot change the connection factory that you are using, you can use the `com.ibm.msg.client.wmq.overrideProviderVersion` property to override any setting on the

connection factory. This override applies to all connection factories in the JVM but the actual connection factory objects are not modified.

Related concepts

[Rules for selecting the IBM MQ messaging provider mode](#)

Related tasks

[Configuring the JMS **PROVIDERVERSION** property](#)

PROXYHOSTNAME

The host name or IP address of the system on which the proxy server is running when using a real-time connection to a broker through a proxy server.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: PROXYHOSTNAME

JMS administration tool short name: PHOST

Programmatic access

Setters/getters

- MQConnectionFactory.setProxyHostName()
- MQConnectionFactory.getProxyHostName()

Values

null

The host name of the proxy server. This is the default value.

PROXYPORT

The number of the port on which the proxy server is listening when using a real-time connection to a broker through a proxy server.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: PROXYPORT

JMS administration tool short name: PPORT

Programmatic access

Setters/getters

MQConnectionFactory.setProxyPort()

MQConnectionFactory.getProxyPort()

Values

443

The port number of the proxy server. This is the default value.

PUBACKINT

The number of messages published by a publisher before IBM MQ classes for JMS requests an acknowledgment from the broker.

When you lower the value of this property, IBM MQ classes for JMS requests acknowledgments more often, therefore the performance of the publisher decreases. When you raise the value, IBM MQ classes for JMS take a longer time to throw an exception if the broker fails. This property is relevant only if TRANSPORT has the value BIND or CLIENT.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: PROXYPORT

JMS administration tool short name: PPORT

Programmatic access

Setters/getters

MQConnectionFactory.setPubAckInterval()

MQConnectionFactory.getPubAckInterval()

Values

25

Any positive integer may be the default value.

PUTASYNCALLOWED

This property determines whether message producers are allowed to use asynchronous puts to send messages to this destination.

Applicable Objects

Queue, Topic

JMS administration tool long name: PUTASYNCALLOWED

JMS administration tool short name: PAALD

Programmatic access

Setters/getters

MQDestination.setPutAsyncAllowed()

MQDestination.getPutAsyncAllowed()

Values

AS_DEST

Determine whether asynchronous puts are allowed by referring to the queue or topic definition. This is the default value.

AS_Q_DEF

Determine whether asynchronous puts are allowed by referring to the queue definition.

AS_TOPIC_DEF

Determine whether asynchronous puts are allowed by referring to the topic definition.

NO

Asynchronous puts are not allowed.

YES

Asynchronous puts are allowed.

QMANAGER

The name of the queue manager to connect to.

However, if your application uses a client channel definition table to connect to a queue manager, see [Using a client channel definition table with IBM MQ classes for JMS](#).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, Queue, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: QMANAGER

JMS administration tool short name: QMGR

Programmatic access

Setters/getters

- MQConnectionFactory.setQueueManager()
- MQConnectionFactory.getQueueManager()

Values

" " (empty string)

Any string can be the default value.

QUEUE

The name of the JMS queue destination. This matches the name of the queue used by the queue manager.

Applicable Objects

Queue

JMS administration tool long name: QUEUE

JMS administration tool short name: QU

Values

Any string

Any valid IBM MQ queue name.

Related concepts

[Rules for naming IBM MQ objects](#)>

READAHEADALLOWED

This property determines whether message consumers and queue browsers are allowed to use read ahead to get nonpersistent messages from this destination into an internal buffer before receiving them.

Applicable Objects

Queue, Topic

JMS administration tool long name: READAHEADALLOWED

JMS administration tool short name: RAALD

Programmatic access

Setters/getters

- `MQDestination.setReadAheadAllowed()`
- `MQDestination.getReadAheadAllowed()`

Values

AS_DEST

Determine whether read ahead is allowed by referring to the queue or topic definition. This is the default value in administrative tools.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_DEST` in programs.

AS_Q_DEF

Determine whether read ahead is allowed by referring to the queue definition.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_Q_DEF` in programs.

AS_TOPIC_DEF

Determine whether read ahead is allowed by referring to the topic definition.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_AS_TOPIC_DEF` in programs.

NO

Read ahead is not allowed.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_DISABLED` in programs.

YES

Read ahead is allowed.

Use `WMQConstants.WMQ_READ_AHEAD_ALLOWED_ENABLED` in programs.

READAHEADCLOSEPOLICY

For messages being delivered to an asynchronous message listener, what happens to messages in the internal read ahead buffer when the message consumer is closed.

Applicable Objects

Queue, Topic

JMS administration tool long name: READAHEADCLOSEPOLICY

JMS administration tool short name: RACP

Programmatic access

Setters/getters

- `MQDestination.setReadAheadClosePolicy()`

- `MQDestination.getReadAheadClosePolicy()`

Values

DELIVER_ALL

All messages in the internal read ahead buffer are delivered to the message listener of the application before returning. This is the default value in administrative tools.

Use `WMQConstants.WMQ_READ_AHEAD_DELIVERALL` in programs.

DELIVER_CURRENT

Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

Use `WMQConstants.WMQ_READ_AHEAD_DELIVERCURRENT` in programs.

RECEIVECCSID

Destination property that sets the target CCSID for queue manager message conversion. The value is ignored unless `RECEIVECONVERSION` is set to `WMQ_RECEIVE_CONVERSION_QMGR`

Applicable Objects

Queue, Topic

JMS administration tool long name: `RECEIVECCSID`

JMS administration tool short name: `RCCS`

Programmatic access

Setters/Getters

- `MQDestination.setReceiveCCSID`
- `MQDestination.getReceiveCCSID`

Values

WMQConstants.WMQ_RECEIVE_CCSID_JVM_DEFAULT

0 - Use `JVM Charset.defaultCharset`

1208

UTF-8

CCSID

Supported coded character set identifier.

RECEIVECONVERSION

Destination property that determines if data conversion is going to be performed by the queue manager.

Applicable Objects

Queue, Topic

JMS administration tool long name: `RECEIVECONVERSION`

JMS administration tool short name: `RCNV`

Programmatic access

Setters/Getters

- `MQDestination.setReceiveConversion`

- `MQDestination.getReceiveConversion`

Values

WMQConstants.WMQ_RECEIVE_CONVERSION_CLIENT_MSG

1 - Only perform data conversion on the JMS client. The default value from up to V7.0, and from, and including, 7.0.1.5.

WMQConstants.WMQ_RECEIVE_CONVERSION_QMGR

2 - Perform data conversion on the queue manager before sending a message to the client. The default (and only) value from V7.0 to V7.0.1.4 inclusive, except if APAR IC72897 is applied.

RECEIVEISOLATION

This property determines whether a subscriber might receive messages that have not been committed on the subscriber queue.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: RECEIVEISOLATION

JMS administration tool short name: RCVISOL

Values

COMMITTED

A subscriber receives only those messages on the subscriber queue that have been committed. This is the default value in administrative tools.

Use `WMQConstants.WMQ_RCVISOL_COMMITTED` in programs.

UNCOMMITTED

A subscriber can receive messages that have not been committed on the subscriber queue.

Use `WMQConstants.WMQ_RCVISOL_UNCOMMITTED` in programs.

RECEXIT

Identifies a channel receive exit, or a sequence of receive exits to be run in succession.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate receive exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: RECEXIT

JMS administration tool short name: RCX

Programmatic access

Setters/getters

- `MQConnectionFactory.setReceiveExit()`
- `MQConnectionFactory.getReceiveExit()`

Values

null

A string comprising one or more items separated by commas, where each item is either:

- The name of a class that implements the WMQReceiveExit interface (for a channel receive exit written in Java).
- A string in the format *libraryName(entryPointName)* (for a channel receive exit not written in Java).

This is the default value.

RECEXITINIT

The user data that is passed to channel receive exits when they are called.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: RECEXITINIT

JMS administration tool short name: RCXI

Programmatic access

Setters/getters

- MQConnectionFactory.setReceiveExitInit()
- MQConnectionFactory.getReceiveExitInit()

Values

null

A string comprising one or more items of user data separated by commas. This is the default value.

REPLYTOSTYLE

Determines how the JMSReplyTo field in a received message is constructed.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: REPLYTOSTYLE

JMS administration tool short name: RTOST

Programmatic access

Setters/getters

- MQConnectionFactory.setReplyToStyle()
- MQConnectionFactory.getReplyToStyle()

Values

DEFAULT

Equivalent to MQMD.

RFH2

Use the value supplied in the RFH2 header. If a JMSReplyTo value has been set in the sending application, use that value.

MQMD

Use the MQMD supplied value. This behavior is equivalent to the default behavior of IBM WebSphere MQ 6.0.2.4 and 6.0.2.5.

If the JMSReplyTo value set by the sending application does not contain a queue manager name, the receiving queue manager inserts its own name in the MQMD. If you set this parameter to MQMD, the reply-to queue you use is on the receiving queue manager. If you set this parameter to RFH2, the reply-to queue you use is on the queue manager specified in the RFH2 of the sent message as originally set by the sending application.

If the JMSReplyTo value set by the sending application contains a queue manager name, the value of this parameter is unimportant because both the MQMD and RFH2 contain the same value.

RESCANINT

When a message consumer in the point-to-point domain uses a message selector to select which messages it wants to receive, IBM MQ classes for JMS search the IBM MQ queue for suitable messages in the sequence determined by the `MsgDeliverySequence` attribute of the queue.

After IBM MQ classes for JMS find a suitable message and deliver it to the consumer, IBM MQ classes for JMS resume the search for the next suitable message from its current position in the queue. IBM MQ classes for JMS continue to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this property, has expired. In each case, IBM MQ classes for JMS return to the beginning of the queue to continue the search, and a new time interval commences.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: RESCANINT

JMS administration tool short name: RINT

Programmatic access

Setters/getters

- `MQConnectionFactory.setRescanInterval()`
- `MQConnectionFactory.getRescanInterval()`

Values**5000**

Any positive integer can be the default value.

SECEXIT

Identifies a channel security exit.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate security exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SECEXIT

JMS administration tool short name: SXC

Programmatic access

Setters/getters

- MQConnectionFactory.setSecurityExit()
- MQConnectionFactory.getSecurityExit()

Values

null

The name of a class that implements the WMQSecurityExit interface (for a channel security exit written in Java).

A string in the format *libraryName(entryPointName)* (for a channel security exit not written in Java).

SECEXITINIT

The user data that is passed to a channel security exit when it is called.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SECEXITINIT

JMS administration tool short name: SCXI

Programmatic access

Setters/getters

- MQConnectionFactory.setSecurityExitInit()
- MQConnectionFactory.getSecurityExitInit()

Values

null

Any string can be the default value.

SENDCHECKCOUNT

The number of send calls to allow between checking for asynchronous put errors, within a single non-transacted JMS session.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SENDCHECKCOUNT

JMS administration tool short name: SCC

Programmatic access

Setters/getters

- MQConnectionFactory.setSendCheckCount()
- MQConnectionFactory.getSendCheckCount()

Values

null

Any string can be the default value.

SENDEXIT

Identifies a channel send exit, or a sequence of send exits to be run in succession.

Additional configuration might be required in order for the IBM MQ classes for JMS to locate send exits. For more information, see [Configuring the IBM MQ classes for JMS to use channel exits](#).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SENDEXIT

JMS administration tool short name: SDX

Programmatic access

Setters/getters

- MQConnectionFactory.setSendExit()
- MQConnectionFactory.getSendExit()

Values

null

Any string comprising one or more items separated by commas, where each item is either:

- The name of a class that implements the WMQSendExit interface (for a channel send exit written in Java).
- A string in the format *libraryName(entryPointName)* (for a channel send exit not written in Java).
-

This is the default value.

SENDEXITINIT

The user data that is passed to channel send exits when they are called.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SENDEXITINIT

JMS administration tool short name: SDXI

Programmatic access

Setters/getters

- MQConnectionFactory.setSendExitInit()

- MQConnectionFactory.getSendExitInit()

Values

null

Any string comprising one or more items of user data separated by commas can be the default value.

SHARECONVALLOWED

This property determines whether a client connection can share its socket with other top-level JMS connections from the same process to the same queue manager, if the channel definitions match.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SHARECONVALLOWED

JMS administration tool short name: SCALD

Programmatic access

Setters/getters

- MQConnectionFactory.setShareConvAllowed()
- MQConnectionFactory.getShareConvAllowed()

Values

YES

This is the default value for administrative tools.

For programs, use WMQConstants.WMQ_SHARE_CONV_ALLOWED_YES.

NO

This value is for administrative tools.

For programs, use WMQConstants.WMQ_SHARE_CONV_ALLOWED_NO.

SPARSESUBS

Controls the message retrieval policy of a TopicSubscriber object.

Applicable Objects

ConnectionFactory, TopicConnectionFactory

JMS administration tool long name: SPARSESUBS

JMS administration tool short name: SSUBS

Programmatic access

Setters/getters

- MQConnectionFactory.setSparseSubscriptions()
- MQConnectionFactory.getSparseSubscriptions()

Values

NO

Subscriptions receive frequent matching messages. This is the default value for administrative tools.

For programs, use false.

YES

Subscriptions receive infrequent matching messages. This value requires that the subscription queue can be opened for browse.

For programs, use true.

SSLCIPHERSUITE

The CipherSuite to use for an SSL connection.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLCIPHERSUITE

JMS administration tool short name: SCPHS

Programmatic access

Setters/getters

- MQConnectionFactory.setSSLCipherSuite()
- MQConnectionFactory.getSSLCipherSuite()

Values

null

This is the default value. For more information, see [SSL properties of JMS objects](#).

SSLCRL

CRL servers to check for SSL certificate revocation.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLCRL

JMS administration tool short name: SCRL

Programmatic access

Setters/getters

- MQConnectionFactory.setSSLCertStores()
- MQConnectionFactory.getSSLCertStores()

Values

null

Space-separated list of LDAP URLs. This is the default value. For more information, see [SSL properties of JMS objects](#).

SSLFIPSREQUIRED

This property determines whether an SSL connection must use a CipherSuite that is supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS).

Note: On UNIX, Linux, and Windows, IBM MQ provides FIPS 140-2 compliance through the IBM Crypto for C (ICC) cryptographic module. The certificate for this module has been moved to the Historical status. Customers should view the [IBM Crypto for C \(ICC\) certificate](#) and be aware of any advice provided by NIST. A replacement FIPS 140-3 module is currently in progress and its status can be viewed by searching for it in the [NIST CMVP modules in process list](#).

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLFIPSREQUIRED

JMS administration tool short name: SFIPS

Programmatic access

Setters/getters

- MQConnectionFactory.setSSLFipsRequired()
- MQConnectionFactory.getSSLFipsRequired()

Values

NO

An SSL connection can use any CipherSuite that is not supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS).

This is the default value. In programs, use false.

YES

An SSL connection must use a CipherSuite that is supported by IBMJSSEFIPS.

In programs, use true.

SSLPEERNAME

For SSL, a *distinguished name* skeleton that must match that provided by the queue manager.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLPEERNAME

JMS administration tool short name: SPEER

Programmatic access

Setters/getters

- MQConnectionFactory.setSSLPeerName()
- MQConnectionFactory.getSSLPeerName()

Values

null

This is the default value. For more information, see [SSL properties of JMS objects](#).

SSLRESETCOUNT

For SSL, the total number of bytes sent and received by a connection before the secret key that is used for encryption is renegotiated.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SSLRESETCOUNT

JMS administration tool short name: SRC

Programmatic access

Setters/getters

- MQConnectionFactory.setSSLResetCount()
- MQConnectionFactory.getSSLResetCount()

Values

0

Zero, or any positive integer less than or equal to 999, 999, 999. This is the default value. For more information, see [SSL properties of JMS objects](#).

STATREFRESHINT

The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager.

This property is relevant only if SUBSTORE has the value QUEUE.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: STATREFRESHINT

JMS administration tool short name: SRI

Programmatic access

Setters/getters

- MQConnectionFactory.setStatusRefreshInterval()
- MQConnectionFactory.getStatusRefreshInterval()

Values

60000

Any positive integer can be the default value. For more information, see [SSL properties of JMS objects](#).

SUBSTORE

Where IBM MQ classes for JMS stores persistent data relating to active subscriptions.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SUBSTORE

JMS administration tool short name: SS

Programmatic access

Setters/getters

- MQConnectionFactory.setSubscriptionStore()
- MQConnectionFactory.getSubscriptionStore()

Values

BROKER

Use the broker-based subscription store to hold details of subscriptions. This is the default value for administrative tools.

For programs, use WMQConstants.WMQ_SUBSTORE_BROKER.

MIGRATE

Transfer subscription information from the queue-based subscription store to the broker-based subscription store.

For programs, use WMQConstants.WMQ_SUBSTORE_MIGRATE.

QUEUE

Use the queue-based subscription store to hold details of subscriptions.

For programs, use WMQConstants.WMQ_SUBSTORE_QUEUE.

SYNCPOINTALLGETS

This property determines whether all gets are to be performed under syncpoint.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: SYNCPOINTALLGETS

JMS administration tool short name: SPAG

Programmatic access

Setters/getters

- MQConnectionFactory.setSyncpointAllGets()
- MQConnectionFactory.getSyncpointAllGets()

Values

No

This is the default value.

Yes

TARGCLIENT

This property determines whether the IBM MQ RFH2 format is used to exchange information with target applications.

Applicable Objects

Queue, Topic

JMS administration tool long name: TARGCLIENT

JMS administration tool short name: TC

Programmatic access

Setters/getters

- `MQDestination.setTargetClient()`
- `MQDestination.getTargetClient()`

Values

JMS

The target of the message is a JMS application. This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_CLIENT_JMS_COMPLIANT`.

MQ

The target of the message is a non-JMS IBM MQ application.

For programs, use `WMQConstants.WMQ_CLIENT_NONJMS_MQ`.

TARGCLIENTMATCHING

This property determines whether a reply message, sent to the queue identified by the `JMSReplyTo` header field of an incoming message, has an `MQRFH2` header only if the incoming message has an `MQRFH2` header.

Applicable Objects

`ConnectionFactory`, `QueueConnectionFactory`, `XAConnectionFactory`, `XAQueueConnectionFactory`

JMS administration tool long name: TARGCLIENTMATCHING

JMS administration tool short name: TCM

Programmatic access

Setters/getters

- `MQConnectionFactory.setTargetClientMatching()`
- `MQConnectionFactory.getTargetClientMatching()`

Values

YES

If an incoming message does not have an `MQRFH2` header, the `TARGCLIENT` property of the `Queue` object derived from the `JMSReplyTo` header field of the message is sent to MQ. If the message does have an `MQRFH2` header, the `TARGCLIENT` property is set to `JMS` instead. This is the default value for administrative tools.

For programs, use `true`.

NO

The TARGCLIENT property of the Queue object derived from the JMSReplyTo header field of an incoming message is always set to JMS.

For programs, use false.

TEMPMODEL

The name of the model queue from which JMS temporary queues are created.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: TEMPMODEL

JMS administration tool short name: TM

Programmatic access

Setters/getters

- MQConnectionFactory.setTemporaryModel()
- MQConnectionFactory.getTemporaryModel()

Values

SYSTEM.DEFAULT.MODEL.QUEUE

Any string can be the default value.

TEMPQPREFIX

The prefix that is used to form the name of an IBM MQ dynamic queue.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory

JMS administration tool long name: TEMPQPREFIX

JMS administration tool short name: TQP

Programmatic access

Setters/getters

- MQConnectionFactory.setTempQPrefix()
- MQConnectionFactory.getTempQPrefix()

Values

" " (empty string)

The prefix used is CSQ.* on z/OS and AMQ.* on all other platforms. These are the default values.

queue prefix

The queue prefix is any string that conforms to the rules for forming contents of the *DynamicQName* field in an IBM MQ object descriptor (structure MQOD), but the last non-blank character must be an asterisk.

TEMPTOPICPREFIX

When creating temporary topics, JMS generates a topic string of the form "TEMP /*TEMPTOPICPREFIX*/*unique_id*", or if this property is left with the default value, just "TEMP /*unique_id*". Specifying a non-empty TEMPTOPICPREFIX allows specific model queues to be defined for creating the managed queues for subscribers to temporary topics created under this connection.

Applicable Objects

ConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: TEMPTOPICPREFIX

JMS administration tool short name: TTP

Programmatic access

Setters/getters

- MQConnectionFactory.setTempTopicPrefix()
- MQConnectionFactory.getTempTopicPrefix()

Values

Any non-null string consisting only of valid characters for an IBM MQ topic string. The default value is "" (empty string).

TOPIC

The name of the JMS topic destination, this value is used by the queue manager as the topic string of a publication or subscription.

Applicable Objects

Topic

JMS administration tool long name: TOPIC

JMS administration tool short name: TOP

Values

Any string

A string that forms a valid IBM MQ topic string. When using IBM MQ as a messaging provider with WebSphere Application Server, specify a value that matches the name by which the topic is known for administrative purposes within WebSphere Application Server.

Related concepts

[Topic strings](#)

TRANSPORT

The nature of a connection to a queue manager or broker.

Applicable Objects

ConnectionFactory, QueueConnectionFactory, TopicConnectionFactory, XAConnectionFactory, XAQueueConnectionFactory, XATopicConnectionFactory

JMS administration tool long name: TRANSPORT

JMS administration tool short name: TRAN

Programmatic access

Setters/getters

- `MQConnectionFactory.setTransportType()`
- `MQConnectionFactory.getTransportType()`

Values

BIND

For a connection to a queue manager in bindings mode. This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_CM_BINDINGS`.

CLIENT

For a connection to a queue manager in client mode.

For programs, use `WMQConstants.WMQ_CM_CLIENT`.

DIRECT

For a real-time connection to a broker not using HTTP tunnelling.

For programs, use `WMQConstants.WMQ_CM_DIRECT_TCPIP`.

DIRECTHTTP

For a real-time connection to a broker using HTTP tunnelling. Only HTTP 1.0 is supported.

For programs, use `WMQConstants.WMQ_CM_DIRECT_HTTP`.

Related concepts

[“Dependencies between properties of IBM MQ classes for JMS objects” on page 1931](#)

The validity of some properties is dependent on the particular values of other properties.

WILDCARDFORMAT

This property determines which version of wildcard syntax is to be used.

Applicable Objects

`ConnectionFactory`, `TopicConnectionFactory`, `XAConnectionFactory`, `XATopicConnectionFactory`

JMS administration tool long name: `WILDCARDFORMAT`

JMS administration tool short name: `WCFMT`

Programmatic access

Setters/getters

- `MQConnectionFactory.setWildCardFormat()`
- `MQConnectionFactory.getWildCardFormat()`

Values

TOPIC_ONLY

Recognizes topic level wildcards only, as used in broker version 2. This is the default value for administrative tools.

For programs, use `WMQConstants.WMQ_WILDCARD_TOPIC_ONLY`.

CHAR_ONLY

Recognizes character wildcards only, as used in broker version 1.

For programs, use `WMQConstants.WMQ_WILDCARD_CHAR_ONLY`.

The ENCODING property

The ENCODING property comprises three sub-properties, in twelve possible combinations.

The valid values that the ENCODING property can take are constructed from the three sub-properties:

integer encoding

Either normal or reversed

decimal encoding

Either normal or reversed

floating-point encoding

IEEE normal, IEEE reversed, or z/OS

The ENCODING property is expressed as a three-character string with the following syntax:

```
{N|R}{N|R}{N|R|3}
```

In this string:

- N denotes normal
- R denotes reversed
- 3 denotes z/OS
- The first character represents *integer encoding*
- The second character represents *decimal encoding*
- The third character represents *floating-point encoding*

This provides a set of twelve possible values for the ENCODING property.

There is an additional value, the string NATIVE, which sets appropriate encoding values for the Java platform.

The following examples show valid combinations for ENCODING:

```
ENCODING(NNR)  
ENCODING(NATIVE)  
ENCODING(RR3)
```

SSL properties of JMS objects

Enable Secure Sockets Layer (SSL) encryption using the SSLCIPHERSUITE property. You can then change the characteristics of the SSL encryption using several other properties.

When you specify TRANSPORT(CLIENT), you can enable Secure Sockets Layer (SSL) encrypted communication using the SSLCIPHERSUITE property. Set this property to a valid CipherSuite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the CHANNEL property.

However, CipherSpecs (as specified on the SVRCONN channel) and CipherSuites (as specified on ConnectionFactory objects) use different naming schemes to represent the same SSL encryption algorithms. If a recognized CipherSpec name is specified on the SSLCIPHERSUITE property, JMSAdmin issues a warning and maps the CipherSpec to its equivalent CipherSuite. See [SSL/TLS CipherSpecs and CipherSuites in IBM MQ classes for JMS](#) for a list of CipherSpecs recognized by IBM MQ and JMSAdmin.

If you require a connection to use a CipherSuite that is supported by the IBM Java JSSE FIPS provider (IBMJSSEFIPS), set the SSLFIPSREQUIRED property of the connection factory to YES. The default value of this property is NO, which means that a connection can use any supported CipherSuite. The property is ignored if SSLCIPHERSUITE is not set.

The SSLPEERNAME matches the format of the SSLPEER parameter, which can be set on channel definitions. It is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
SSLPEERNAME(CN=QMGR.*, OU=IBM, OU=WEBSphere)
```

The set of names and values makes up a *distinguished name*. For more details about distinguished names and their use with IBM MQ, see [Security](#).

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

If SSLPEERNAME is not set, no such checking is performed. SSLPEERNAME is ignored if SSLCIPHERSUITE is not set.

The SSLCRL property specifies zero or more CRL (Certificate Revocation List) servers. Use of this property requires a JVM at Java 2 v1.4. This is a space-delimited list of entries of the form:

```
ldap:// hostname:[ port ]
```

optionally followed by a single /. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. See [Security](#) for more about CRL security.

If SSLCRL is not set, no such checking is performed. SSLCRL is ignored if SSLCIPHERSUITE is not set.

The SSLRESETCOUNT property represents the total number of bytes sent and received by a connection before the secret key that is used for encryption is renegotiated. The number of bytes sent is the number before encryption, and the number of bytes received is the number after decryption. The number of bytes also includes control information sent and received by IBM MQ classes for JMS.

For example, to configure a ConnectionFactory object that can be used to create a connection over an SSL enabled MQI channel with a secret key that is renegotiated after 4 MB of data have flowed, issue the following command to JMSAdmin:

```
ALTER CF(my.cf) SSLRESETCOUNT(4194304)
```

If the value of SSLRESETCOUNT is zero, which is the default value, the secret key is never renegotiated. The SSLRESETCOUNT property is ignored if SSLCIPHERSUITE is not set.

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area.
